Abstract— **Phishing attacks continue to be a notable threat to network and information security. They plan to expose user information and privacy, such as login credentials, passwords, credit card numbers, and other details, by tricking internet users into thinking they are the real deal. For the detection of phishing websites, Machine learning (ML) techniques have been progressively used, because of their abilities like to learn from and adapt to complex designs and features. A new approach for detecting phishing websites using ML techniques is proposed that incorporates the URL structure. The Horse Herd Optimisation Algorithm is used to determine the features, and the suggested method is tested on a dataset of websites with phishing threats. In the context of network and information security, these techniques are employed to identify websites with phishing threats. The objectives include collecting a new dataset, extracting pertinent features, and addressing the challenges of imbalanced data and adversarial attacks in phishing detection. The findings can assist security professionals and researchers in identifying the techniques that are best suitable for improving phishing detection and prevention.**

Keywords— Phishing, Ransomware, Horse Herd Algorithm, Detection, Cybersecurity, Random Forest.

I.INTRODUCTION

Machine learning is a branch of artificial intelligence (AI) that uses data and algorithms to mimic human learning and increase the ability of systems in prediction tasks. It enables software programmers to create more accurate predictive models. Machine learning can be classified into three types: supervised, unsupervised learning, and reinforcement learning.

Horse Herd Optimization (HHO) is an algorithm that mimics the natural herding behavior of horses. HHO algorithm utilizes the hierarchical structure and the collective motion of a horse herd to perform feature selection, which is a crucial step for machine learning problems.

In HHO, the features of a dataset are considered as potential solutions, and the algorithm aims to find the most optimal subset of features that contribute significantly to the problem at hand. The algorithm iteratively explores the solution space by dividing the features into leaders and followers.

Initially, a set of randomly selected features are assigned as leaders, and the rest of the features become followers. The leaders guide the search process by influencing the followers through a combination of exploration and exploitation strategies. This allows for a balanced exploration of the feature space while exploiting the potential of promising features.

During each iteration, the leaders compete for dominance based on their fitness. The fitness of each leader feature is evaluated using a fitness function for feature selection that measures the quality of the selected features. The leaders update their positions based on their fitness, while the followers adapt their positions to the leaders' movements.

Through the interaction and coordination among the leaders and followers, HHO algorithm gradually converges towards an optimal subset of features that best represents the data and contributes to accurate classification or regression models.

The HHO algorithm offers a nature-inspired approach to efficiently identify relevant features and reduce the dimensionality of the dataset. By leveraging the collective intelligence of a horse herd, this algorithm shows promise in enhancing the performance and interpretability of machine learning models.

To produce accurate predictions or classifications, Random Forest, a powerful machine learning technique, combines the advantages of using several decision trees. First, Random Forest constructs multiple decision trees. Next, each of these decision trees are trained using a diverse range of characteristics and data.

During training, Random Forest generates a collection of decision trees through a process called bagging, which involves sampling the dataset with replacement. This sampling ensures diversity in the trees, allowing them to capture different aspects of the data.

The algorithm develops predictions through integrating every prediction of all the ensemble's decision trees. The final class label for classification tasks is determined by voting or averaging, but for regression tasks, the predicted values from each tree are summed.

Random Forest offers several advantages. It is robust against overfitting and noise in the data, thanks to the ensemble approach and the random feature selection. It can handle large datasets with high dimensionality, as well as categorical and numerical features. Additionally, it provides estimates of feature importance, allowing for interpretability and insight into the data.

SCOPE: The project's limited scope is focused on feature selection and testing utilizing the present algorithms to increase the precision in phishing website identification.

OBJECTIVES:

1. To collect a data set that best suits for the project.

2. To extract features that help in detection of phishing websites.

3. To use Horse Herd Optimization Algorithm to select the features.

4. To use Random Forest Algorithm to find the precision and accuracy in classification of websites.

5. To overcome the challenges encountered by recent techniques in the detection of the phishing URL.

The rest of this article is as follows: section 2 - a literature review of related work, section 3 - a methodology of the proposed approach, section 4 - an evaluation and discussion of the approach, section 5 - a summary and future directions, and section 6 - a list of references.

II. RELATED WORKS

This section presents a review of the literature that informs the references used in this study.

In this research, [1] introduced a machine learning (ML) model for the identification of websites with phishing threats. The features used to train this model included statistical reports, IP addresses, Google, subdomains, web traffic, domain pages, prefixes and suffixes, domain registrations, URL lengths, DNS records, and CPR rankings. These articles developed a model using a variety of algorithms, including support vector machines, black trees, logistic regression, linear discriminant analysis, K- nearest neighbors, and random forests, and they ultimately achieved a random forest algorithm accuracy of 98.90%.

Advantages: Higher accuracy in detection of phishing websites when compared to other algorithms.

Disadvantages: Inadequate detection techniques

In this research, [2] introduced a GAN (generative adversarial networks) model for identifying phishing websites. In order to make a distinction between legal and phishing URLs, this model employs CNN (Convolutional neural network) as a discriminator. LSTM (long short-term memory network) is used to create fake phishing URLs with characteristics that resemble real phishing URLs. The results of the research show that, the PDGAN model is able to detect objects with an accuracy of 97.58% and a precision of 98.02% without the aid of other services.

Advantages: This mentioned model is independent of o any third-party services. It detects the websites used for phishing by evaluating the various characteristics of the URL of the website. This model does not require manual extraction of the features.

Disadvantages: One of the main disadvantages of GAN model is that it is very difficult to train. This model categorizes the websites as used for phishing or not, purely basing its reasoning on the characteristics of the URLs.

In this research [3] a ML model on phishing website detection is presented. They made advantage of characteristics that includes URL length, the presence of HTTP, suspicious characters in the URL, prefixes and suffixes, the number of dots and slashes, the phishing terms, the length of the subdomain, and the IP address in the URL to train their models. They used two algorithms named 1) random forest algorithm 2) decision tree algorithm in which the RF model gave a accuracy of 97.25% for legitimate URL and 97.29% for phishing URL and DT model gave a accuracy of 95.90% for legitimate URL and 95.91% for phishing URL.

Advantages: Higher accuracy in detection of phishing websites.

Disadvantages: Addition of the redundant and useless features can degrade the model performance. The data set taken in this model is outdated.

In this research [4], different machine learning techniques were contrasted, and a model that produced the best results was recommended. In order to pick features for this project, they detailed about 21 characteristics and used feature selection approaches like the gain ratio attribute evaluator (GainRatioAttributeEval), one R attribute evaluator (using the one R classifier), relief attribute evaluator, and symmetric uncertainty attribute evaluator. Utilizing the random forest technique after feature selection, they achieved a very high accuracy.

Advantages: Features are selected based on the feature selection algorithms.

Disadvantages: Inadequate data collection since it is not possible to produce a model with 100 percent accuracy.

In this research [5], a multilayered stacked ensemble learning model was presented for the detection and identification of websites with phishing intent. This model has three levels - which are stacked in the order - layer-i, layer-ii, and meta. Classifiers like XGBoost (XGB), Logistic Regression (LR), Random Forest classifier (RF), MLP, and the k- Nearest Neighbour (KNN) classifier are present in the top layer. The second layer, which include classifiers like XGB, RF, and MLP, receives the output of the first layer. The second layer's output is then transferred into the meta layer, which contains the XGB algorithm. The trained model is assessed using the datasets listed in datasets, and the trained model attained a detection rate with an accuracy range from 96.79% to 98.90%.

Advantages: The outputs of several learning algorithms can be combined, varied features can be extracted, and greater predicted performance is the end result.

Disadvantages: It is very difficult to create a model with ensemble techniques

In this research [6] tells us about the model in which the feature selection is done by a feature selection method known as PSO (particle swarm optimization). At first, they extract some of the features which they think are important in detection of phishing website. After that, they use PSO

algorithm to weigh the selected features. The features with most weight are used in the model training, whereas the features with less weight are ignored. At last, the machine learning techniques' performance before applying the PSO and after applying the PSO are compared. From the observation, we can conclude that the accuracy of the models when applied with PSO algorithms are better when compared to models without PSO algorithm.
Advantages: Useless features are eliminated with the help of PSO algorithm that can degrade the performance.
Disadvantages: Due to its simplicity in establishing local optimums in high-dimensional space and its sluggish rate of convergence during repetitive procedures, the particle swarm optimization (PSO) algorithm has some disadvantages.

The authors of this study [7] proposed a parameter-free similarity measure called the Normalized Compression distance (NCD), that compresses two webpages to ascertain how similar they are to one another. This allows a approach for identifying websites without features created with the purpose of phishing from the original ones. The extraction of any features is not necessary for this procedure. With this method, websites are categorized based on how much their HTML resembles well-known phishing websites. They used the farthest point first technique to extract phishing prototypes and select those instances that are normal of a group of phishing web sites. This paper received an AUC of 98.68.
Advantages: The main benefit of these model is that they do not need feature extraction to be developed. Rather than creating new features in the presence of idea or concept drift, this approach employs an incremental learning method as the framework that enables persistent and flexible detection.
Disadvantages: It is unable to recognize new phishing website variations or zero-day attacks.

The writers of this research [8] conducted a poll and had a discussion on the methods that can be used to identify phishing websites. The methods they discussed are Random Forest, XGBoost (XGB), Support Vector machines, K-Nearest Neighbors (KNN), Decision Tree, Gradient Boosting, Logistic Regression. Additionally, they talked about the feature selection techniques of filtering and wrapping. They also mentioned about the evaluation metrics of these models before concluding.
Advantages: The main advantage of these paper is that it discusses about all the available solutions present for the detection of the phishing websites.
Disadvantages: The main disadvantage of these paper is that it does not provide a new solution to the existing problem rather it only provides the existing solutions.

III. PROPOSED METHOD

This section describes the architecture of the model, methodology of the model, algorithm of the model discussed in this paper.

A. Architecture:

For developing this model, First, we collect a data set that best suits the project. The data set is collected in such a way that the features are already extracted in the data set. After data collection, we preprocess the data set. Preprocessing including removing duplicate values, converting categorical values into numerical values, removing the uniform resource locators for which uniform resource locator length is less than 8. After preprocessing the data, we extract the important features using optimization algorithm. After feature selection, we divide the data set into two sets -training and testing data set and train the model using training model. After training, we test the model using testing dataset and evaluate the performance various using performance metrics. Figure 1 shows the proposed system

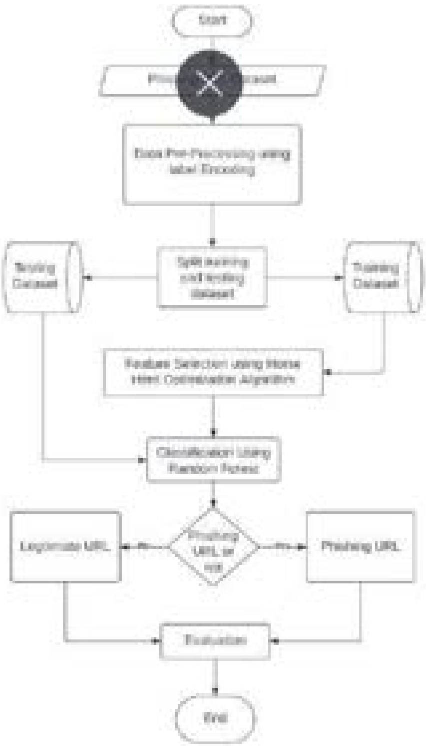

Figure 1: Proposed System

B. Methodology:

In this research paper, the methodology section consists of the following modules: Data collection, Data pre-processing, Feature selection, Model development and Evaluation and performance metrics. Each module is described in detail below:

1. Data Collection:

The dataset was retrieved from the Kaggle dataset, which has 87 features and 11430 URLs. This dataset is used to test and compare how well the machine learning methods can find phishing websites. The features are broken down into three categories: seven of the features are retrieved through contacting external services. The 56 remaining features taken based on the structure and syntax of URLs. 50% dataset is made up of both authentic and phishing URLs, hence ensuring it is evenly dispersed.

2. Pre-processing Module:

The crucial stage for any machine learning model is pre-processing. In this stage, the data that is present in the dataset is converted so that can be used to train and test machine learning models.

The pre-processing steps include: Converting categorial data into numerical data using One Hot Encode. Removing duplicate values and the records that contain the content of email and page's information. Removing URL's that of the size less than or equal to 8. Feature selection from the dataset is done with the help of Horse Herd Optimization Algorithm

3. Model Selection and Development.

In this study, we adopted Random Forest algorithm for the detection of phishing websites. After feature selection using Horse Herd Optimization Algorithm, the training of the model is done with training dataset which is 80% of the original dataset and tested with testing dataset which is 20% of the original dataset. Both training and testing datasets contains class labels in the form of numerical data i.e.: 1's(phishing) and 0's(legitimate). The results of the testing is illustrated below.

4. Evaluation metrics

The performance of the ML-based model is assessed using different metrics, such as confusion matrix, classification report, accuracy, precision, recall, f1 score, roc-auc curve etc. This model takes approximately 5 to 10 minutes to train, depending on the selected features. The model achieves an accuracy of 97% in predicting the class labels for the test data.

4.1 Confusion Matrix:

Confusion matrix can be considered as a 3×3 table that summarizes the performance of a ML model on a set of test data. It shows the number of correct and incorrect predictions for each class, and helps to measure the accuracy, precision, recall and other metrics of the model. A confusion matrix shows in figure 2 reveal the weaknesses and strengths of the model, and identify the classes that are most confused by the model.

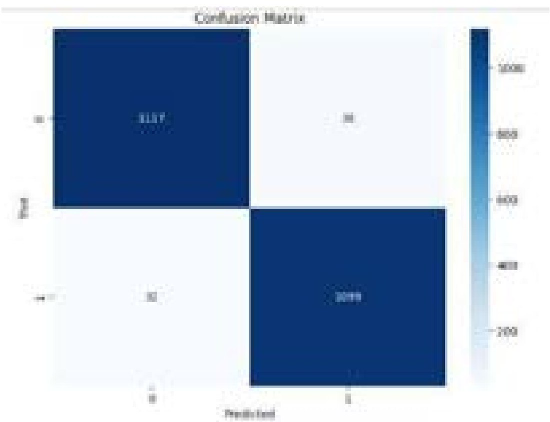

Figure 2: The Confusion Matrix obtained for this model

4.2 Classification Report:

A classification report is a summary of the classification quality of a ML model. It displays the number of true and false predictions for each class and the whole model. It also computes some metrics to assess the model performance such as precision, f1-score, recall, support, etc

classification report	precision	recall	f1-score	support
0.0	0.97	0.97	0.97	1149
1.0	0.97	0.97	0.97	1137
accuracy			0.97	2286
macro avg	0.97	0.97	0.97	2286
weighted avg	0.97	0.97	0.97	2286

Figure 3: Classification Report

The classification report for this model is represented in Figure 3, which displays the precision, recall, F1 score, and support for each class label.

4.2.1 Precision:

Precision is a metric that quantifies the ratio of correctly classified positive samples among all classified positive samples made by a machine learning model. It is calculated as the ratio of true positives to the sum of true positives samples and false positives samples. A high precision implies a low rate of false positives or type I errors for the model. The precision value of this model is around 0.97 which suggests that it is very good at correctly identifying positive instances without mistakenly labelling negative instances as positive

4.2.2 Recall:

Recall is a metric that evaluate the proportion of true positive samples out of the total number of actual positive samples. It is calculated as the ratio of true positives samples to the sum of true positives samples and false negatives samples. A high recall implies a low rate of false negatives or type II errors for the model. The recall value of this model is around 0.97, which implies that the model identifies 97% of all the positive instances.

4.2.3 F1 score:

F1 score can be considered as the combination of precision and recall to measure the accuracy and performance of a machine learning model. It is especially useful for imbalanced datasets, where accuracy alone might not be a reliable indicator of the model's quality. The F1 score is also around 0.97 which implies the model is robust and reliable.

4.3 ROC-AUC Curve:

The ROC-AUC curve is a graphical measure of the performance of a binary classification model across different decision thresholds. It plots the true positive rate against the false positive rate for various values of the threshold. It also quantifies the overall quality of the model by computing the area under the curve, which represents the probability that the model ranks a positive instance higher than a negative one.

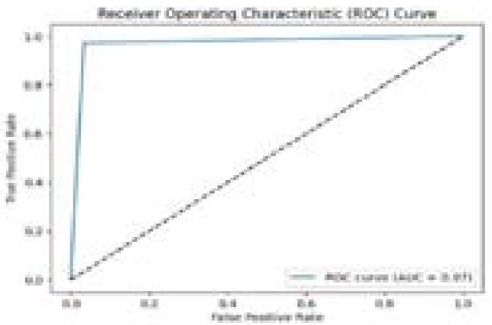

Figure 4: ROC_AUC curve

Figure 4 shows ROC curve for the trained model. The curve shows high TPR and a low FPR, indicating an good model performance. The AUC value is 0.97, which means the model can accurately distinguish between the classes. This suggests that the model has a high distinguishing power as the AUC value is closer to 1.

C. Algorithm:

<u>*Horse Herd Optimization Algorithm:*</u>

<u>*Input*</u>*:* Dataset X with N samples and D features, Maximum number of generations G, Number of horses NH, Number of selected features K.

<u>*Output*</u>*:* Selected features for best horse H_{best}.

<u>*Steps:*</u>

1*:* Initialize horse herd: H_{herd} = {H1, H2, ..., HNH}.

2: Initialize best horse: H_{best} = None, best fitness = ∞.

3: for generation = 1 to G do

4: for i = 1 to NH do

5: Randomly initialize horse Hi with K features.

6: Evaluate fitness for horse Hi using a feature evaluation metric.

7: if the fitness of Hi is better than best fitness then

8: Update best fitness with the fitness of Hi.

9: Update H_{best} with the features of Hi.

10: end if

11: end for

12: Select top p horses from H_{herd} based on fitness.

13: Perform crossover and mutation on the selected horses to create offspring.

14: Replace the worst p horses in H_{herd} with the offspring.

15: end for

16: Return selected features of the best horse H_{best}.

The Horse Herd Optimization Algorithm was chosen for efficient feature selection, leveraging its collective intelligence to identify relevant URL structure characteristics.

<u>*Random Forest Algorithm:*</u>

<u>*Input*</u>: Training dataset D with legitimate and phishing URLs, Number of trees T, Number of features F, Number of instances per tree N.

<u>*Output*</u>: Collection of decision trees RF.

<u>*Steps:*</u>

1: Input the training dataset D, containing both phishing and legitimate URLs.

2: Define T which is the number of trees to create in the random forest model.

3: Define the number of features F to consider at each split in the decision trees.

4: Define the number of instances per tree N to randomly sample from D with replacement.

5: Initialize an empty collection of decision trees RF.

6: for each tree t in the range 1 to T do

7: Randomly sample N instances from D with replacement.

8: Randomly select F features from the total set of features.

9: Train a decision tree using the sampled instances and features.

10: Add the decision tree to the collection RF.

11: end for

12: Return the collection of decision trees RF.

13: To classify a new URL u as legitimate or phishing, do the following:

14: Pass u through each decision tree in RF, and get the decision of each tree.

15: Aggregate the decisions of all trees by taking the majority vote.

16: if the majority vote is legitimate then

17: Classify u as legitimate.

18: else

19: Classify u as phishing.

20: end if

IV. RESULT ANALYSIS

This research paper consists of four modules: preprocessing, feature selection, classification and performance evaluation. The preprocessing module converts the categorical values in the 'status' column into numerical values using encoding techniques, and updates the Data Frame accordingly. The feature selection module applies the Horse Herd Optimization algorithm to select different subsets of features from the original features set as herds. Three subsets are then used to train the classification model. The classification module employs the Random Forest algorithm to predict the class of a given URL, either legitimate or phishing. The model achieves an accuracy of 97.1%, with a training time of approximately 12 minutes and a prediction time of around 0.5 seconds. The precision, recall, and f1-score metrics for the model are also reported using a classification report which are around the value of 0.97. The performance evaluation module plots the ROC curve for the model, which shows and AUC of 0.97. These values imply that the model is robust in nature and is reliable.

V. CONCLUSION AND FUTURE WORK

The Primary focus has been on the selection of optimized features using the innovative Horse Herd Algorithm. The primary scope of the project is to improve the efficiency and accuracy of feature selection processes in complex datasets, with a particular emphasis on applications related to phishing website detection. The project employs the Horse Herd Algorithm, an optimization technique inspired by the behaviour of horse herds, to tackle the feature selection challenge. This approach capitalizes on the collective intelligence and dynamic interactions observed in horse herds, translating them into a computational framework. By simulating the herding behaviour, the algorithm is adept at exploring the solution space and identifying the most useful and relevant features that contribute to accurate phishing detection. This innovative approach showcases the potential for nature-inspired algorithms to revolutionize the field of feature selection. We got an accuracy of 97.1 percent with respect to different sets of features. The accuracy may be increased upon continuous working on different set of features. The effectiveness of the detection model was validated through rigorous testing using internal and external datasets. Performance metrics were evaluated under various scenarios Optimizing algorithm parameters and exploring ensemble methods can enhance detection accuracy. Additionally, incorporating additional features for improved discrimination between phishing and legitimate URLs may further boost performance. Continuous refinement and validation against real-world data are crucial for ongoing performance enhancement. To ensure security, rigorous data handling protocols were followed, including anonymization of sensitive information and validation checks. During model training, measures were taken to prevent overfitting, and performance was evaluated against benchmarks, enhancing the reliability of our phishing URL detection system.

By highlighting the complexities inherent in evolving URL structures and phishing tactics, objectives aim to overcome these challenges. Through the utilization of the Horse Herd Optimization Algorithm and Random Forest Algorithm, the study endeavors to enhance detection accuracy. By emphasizing the collection of a tailored dataset, feature extraction, and tackling challenges like data imbalance and adversarial attacks, the approach aims to advance phishing URL detection systems' efficacy against malicious threats.

Further in future our project can be extended in trying to detect whether the emails sent to users are phishing or legitimate based on the links, contents, data present in the emails. The phishing websites can be detected with the comparison of the content of the web page with the original contents by analysing the patterns and characteristics of known phishing emails and legitimate correspondence, the system can develop a more sophisticated understanding of potential threats.

***Abstract*- The demand for electrical energy continues to rise steadily, particularly in developing countries like India. This surge in demand is attributed to the country's ongoing development, leading to a significant annual increase in power requirements. However, there exists a substantial disparity between electricity generation and this escalating demand. While increasing generation capacity seems like a plausible solution, it is hindered by formidable challenges such as high capital investments and logistical complexities. In light of these constraints, a promising alternative emerges: the adoption of energy-saving measures at the individual level, coupled with the utilization of non-conventional energy sources such as wind, solar, and tidal power. This approach not only helps bridge the demand-supply gap but also holds the potential for significant economic benefits, particularly for developing nations like India. Voltage control can be achieved by electronic control above a minimum set limit. Noise is because of chain & sprocket. It could be reduced by timer belt transmission by incorporating the gear mechanism and hence increasing the RPM of the prime mover**

Keywords —Low Rotations Per Minute Alternator, Green Energy, Cost Effective

1 INTRODUCTION

IMPORTANCE OF LOW RPM ALTERNATOR

An alternator serves as an electromechanical apparatus that transforms mechanical energy into electrical energy, specifically in the form of alternating current. The fundamental principle behind alternators involves the induction of electromotive force (EMF) in a onductor when there is a change in the surrounding magnetic field. Typically, a rotor, which is a rotating magnet, turns within a stationary set of conductors wound in coils on an iron core known as the stator. As the rotor turns due to a mechanical input, the magnetic magnet, turns within a stationary set of conductors wound in coils on an iron core known as the stator. As the rotor turns due to a mechanical input, the magnetic field intersects with the conductors, creating an induced EMF. Low-speed alternators can easily connect to small power sources like wind turbines, tidal turbines, micro-hydropower plants, and exercise cycles. Additionally, they can be installed atop [8] micro-turbines along water canals.

2 LITERATURE REVIEW

[1] Due to the escalating demand for power in India, there is a pressing need to generate power economically using non-conventional energy resources. This objective can be effectively realized through the utilization of [2] small generators operating within low and controllable speed ranges. The employment of low RPM alternators proves to be particularly beneficial at both [3] household and small commercial levels.

The alternator offers a [4] high degree of design flexibility, allowing for easy adaptation to varying output requirements without significant parameter adjustments.[5] Furthermore, their operation at low speeds translates to minimal maintenance requirements. Additionally, [12] their cost-effectiveness is enhanced by the utilization of non-conventional prime movers. The necessary raw materials [11] for constructing such alternators, including mild steel, magnets, copper conductors, [6] paper insulators, and bearings, are readily available in the market. Moreover, their assembly is straightforward.

The project can be broadly divided into two main components: the alternator and the prime mover assembly. The alternator comprises [7] two basic parts: the stator and the rotor. For demonstration purposes, a bicycle [9] has been chosen as the prime mover.

The prime mover assembly includes the bicycle itself, alternator stands, cycle stands, chain and sprocket arrangements, [10]and a base plate with a tension adjustment system.

TABLE 1. COMPARATIVE STUDY

Paper Title	**Method Used**	**Advantages of Method Used**	**Limitations**
Bicycle-Powered AC Generator	Bicycle connected to AC generator	Sustainable, portable energy source	Limited power output, requires physical effort
Generation of Electricity through Bicycle and Solar Energy	Bicycle connected to generator powered by solar panels	Renewable energy sources combined	Dependency on sunlight for solar energy generation
Bicycle Power Generator	Bicycle connected to DC generator	Simple mechanism, potentially low cost	Limited power output, requires physical effort
Pedal Power Generation	Pedals connected to generator	Exercise benefits, potential for off-grid power generation	Limited power output, requires continuous pedaling
Experimental study on the effect of alternator speed to the car charging system	Alternator speed variation for car charging	Optimization of car charging system	Specific to car charging system, limited applicability
Low Speed Alternator Design	Design optimization for low-speed alternator	Efficient power generation at low speeds	May not be suitable for high-speed applications
Generation of Electrical Power using Bicycle Pedal	Pedals connected to generator	Human-powered energy generation	Limited power output, requires continuous pedaling
Back-up Power Generation using Bicycle	Bicycle connected to backup generator	Emergency power supply	Requires physical effort, limited power output
Power Generation Using Bicycle Mechanism as an Alternative Energy Source	Bicycle connected to generator	Sustainable energy source	Limited power output, requires physical effort
Power Generation through Pedaling	Pedals connected to generator	Exercise benefits, potential for off-grid power generation	Limited power output, requires continuous pedaling
Pedal power generation: An implementation of stationary bike generator	Stationary bike connected to generator	Fitness benefits, potential for off-grid power generation	Limited power output, requires continuous pedaling
Bike powered electricity generator	Bicycle connected to generator	Portable energy source, potentially low cost	Limited power output, requires physical effort

3 PROBLEM STATEMENT

The basic aim of this project is to produce electrical energy by harnessing sustainable energy resources. This brings about saving in terms of usage of conventional sources on a personalized and domestic level.This project involves building up of a low RPM alternator by using materials such as magnets, M.S.(Mild steel) ,C.I.(Carbon Iron), copper wires etc.

4 METHODOLOGY

An alternator converts mechanical energy into electrical energy, producing alternating current (AC). It operates on the principle that changing magnetic fields induce electromotive force (EMF) in conductors. A rotor rotates within a fixed set of conductors (the stator), generating EMF as the magnetic field intersects with the conductors. Low rpm alternators are easily coupled with small prime movers like wind turbines and can be mounted over micro-turbines in water canals. They can generate AC voltage at frequencies above 40 Hz with minimal ripple, making them suitable for battery charging without affecting battery health. These alternators are primarily used for charging batteries, which can then power various appliances, ensuring safety due to low voltage output. A general representation is shown in figure 1

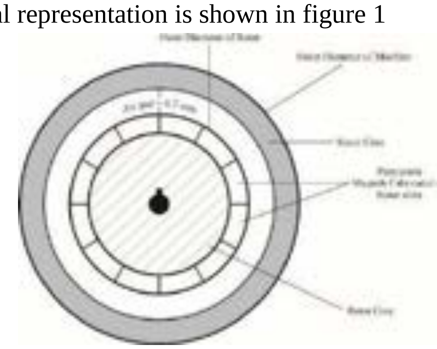

Figure 1. Alternator

a) Stator- The stator is stationary part of the alternator. It is a cylindrical structure, built up of dynamo grade laminations. The laminations are 0.5 mm thick. The laminated segments are held together by axial key bar or bright bar. Fitting into parallel sided slots in the outer ring of the core.

b) Stator Frame- They fulfill several functions, including:

- Providing containment for the core and windings
- Serving as a ventilating enclosure
- Acting as a protective barrier, shielding live and moving parts from human contact"

c) Rotor-

The rotor, made of a hollow Mild Steel (M.S.) cylinder, holds the magnets. Thin M.S. plates at both ends support the shaft, with keyholes for locking. Cooling is by natural air convection.

d) Magnets- High gauss strength permanent rare earth magnets are used for field excitation, placed on the rotor cylinder with alternating polarities, ensuring strong surface polarity.

e) Air Gap- The air gap, a critical factor in electrical machine design, affects performance. It must be minimized to reduce flux reluctance but large enough to prevent stator-rotor rubbing during operation or bearing failure.

f) Windings- This is a Single Phase - single Layer winding, where conductors in stator slots produce EMF. They can be arranged in series to increase voltage or in parallel to double current and halve voltage.

g) Bearings-

Horizontal shaft machines use deep groove ball bearings for anti-friction, while vertical shaft machines use thrust bearings. Bearings can be ball or roller type. In horizontal shaft machines, forces mainly act radially.

5. DESIGN

C.1 Sator Design- Stator laminations of low rpm alternator are made up of silicon steel with thickness of around 0.5 mm. The stator has 36 slots which accommodates 18 coils. The coils are connected in series.

Slots Dimensions of the Stator:

No. Of slots	:	36
Slot Depth	:	21.6 mm
Maximum Slot width	:	10 mm
Minimum Slot width	:	3.6 mm
Pole Width	:	12 mm
Slot Area	:	136 mm^2

Stator Dimensions:

Inner Diameter of stator	:	179.8 mm
Outer Diameter of Stator	:	258.0 mm

C.2 Rotor Assembly

a)Rotor Cylinder- The rotor is the rotating part of the machine on which the magnets are placed.

The cooling is provided to the rotor shown in figure 2 by natural convection of air.

Rotor Specifications:

Rotor Outer Diameter	:	170.16 mm
Rotor Inner Diameter	:	152.00 mm
Rotor Thickness	:	9.8 mm
Rotor Material	:	M.S.

FIGURE 2. OUTPUT DESIGN

b) End Shields- End shields, composed of mild steel (M.S.), are secured by four studs, firmly clamping the stator stack in place between them.

C.3 Bearings- Bearings reduce friction between the generator shaft and end ring. Spherical roller ball bearings are utilized for this purpose, shielded to prevent dust contamination. Bearing selection considers various factors:

1. Basic static load (C_0)

Basic static load (C0) represents the load causing permanent deformation at the bearing contact point, reaching 0.01% of the ball's diameter

2. Basic dynamic load (C)

This load is the point at which the bearing's nominal lifetime will achieve one million revolutions.

3. Life time

The life time of bearing is the number of revolutions that the bearing can accomplish before the first sign of fatigue begin to appear on ring or rolling component.

C.4 Mounting- A low RPM alternator typically follows the IM 1001 (IM B3) standard, featuring a horizontal shaft and floor-mounted feet. In certain instances, it can be vertically mounted with a vertical shaft.

C.5 Terminal Box- Made of pressed steel, it houses the alternator's terminals, located on the right-hand side when viewed from the non-drive end as shown in figure 3. Featuring

IP55 protection, it offers cable entry provisions and includes a terminal bar made of molded epoxy resin.

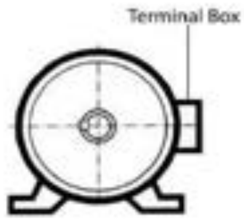

Figure 3. Terminal Box

C.6 Shaft design-
It is made up of carbon steel. The shaft is provided with a keyway to ensure locking of shaft with rotor. The keyway in the shaft is designed to fit the key perfectly.
Shaft length: 220 mm
Shaft diameter: 25 mm

C.7 Magnet- The average gauss value measured is 155 kGauss. As the machine is designed for 18 poles, 18 magnets are employed on the rotor.

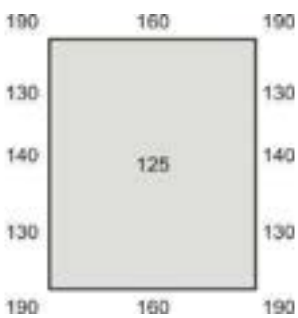

Figure 4

C.8 Cooling- IC 01 signifies 'Free Convection', utilizing temperature variations for coolant flow, with negligible rotor-induced fanning.
'Self Circulation' (denoted by '1') relies on the main machine's rotational speed, facilitated by rotor action or specialized component design, such as direct mounting or mechanical drive by the main rotor.

1) Design Parameters and Construction Data

A) Basic Assumptions

1)Rating of Prime mover: Trials & measurements were taken on exercise bicycle, measurements are as below;

- Torque developed in Kgm = 16 kg X 0.15 m at 120 rpm
  Torque developed = 2.4 Kgm
- Power developed in KW= T X rpm = 0.295 Kw (approx 300 w)

2) Efficiency for Prime mover & alternator were assumed as 80 % & 70% respectively.
Thus output power of the alternator = 300 X 0.8 X 0.7 = 170 watts
= 170 VA
3)Availability of stator stampings is 36 slots/ 48 slots. Hence 36 slots stamping is selected considering 2 slots per pole. Therefore no. of poles are 18.

B) Stator Design

The design parameters are as follows-

1. Outer diameter : 258 mm
2. Internal diameter : 179.8 mm
3. Slot no. : 36 slots
4. Slot area : 136 mm^2
5. Slot depth : 21.6 mm
6. Slot width bottom : 10mm
7. Slot width face : 8 mm
8. Core length : 40mm
9. Tooth top distance : 3.6 mm
10. Tooth top length : 12mm
11. Tooth width (parallel) : 8.4 mm
12. Stamping width : 39mm

C) ROTOR DESIGN

The design parameters are as follows-

1. Outer diameter of ring : 169 mm
2. Internal diameter of ring : 152 mm
3. Width of ring : 43 mm
4. Width of end plates : 2.5 mm
5. Outer diameter of end plates : 179 mm
6. Inner diameter of end plates : 25mm
7. Key slot size on end plates : 8*8 mm

D) Shaft Design

The design parameters are as follows-

1. Material : M. S.
2. Shaft diameter : 25mm
3. Shaft steps : 6 No.
4. Key way length : 46mm
5. Key way width : 8 mm

E) Winding

Winding used for this alternator is series, single phase, single layer winding with SWG = 18. The connection diagram is shown below. In this scheme 2 slots constitute 1 pole.

2) CALCULATIONS

Table 1 shows the preliminary estimation of conductor

SWG of Copper Wire	Diameter (mm)	Area (mm^2)	No. of slots
20	0.914	0.6567	150
18	1.220	1.1680	90
16	1.630	2.0760	45
14	2.030	3.2430	30

A) *Symbols Used*

Ø: Magnetic flux (possibly peak flux)
kG: Kilogauss (unit of magnetic flux density)
wb/m^2: Weber per square meter (alternative unit of magnetic flux density)
Q: Reactive power (in kVA)
C0: Constant
D: Wire diameter
L: Length
Ns: Number of turns
Bav: Average magnetic flux density
p: Number of poles
Iz: Current in winding
Z: Impedance
V: Voltage (RMS)
W: Power (W)
cos Ø: Power factor

B) *Calculations for Winding*

i) Length of mean turn= (200 mm) * (No. of turns) * (No. of coils) **Total length**= 108 m
= 0.108 km

ii) Resistance of total winding= 1.5174 Ω at 20^{O} C.

iii) Current density: 4 Amp/mm3 **(As per electrical design datasheet)**

iv) Total weight of winding = (10.379 kg/km) * (0.108 km)
= 1.12 kg

v) $Ø = 154$ kG=15.4 wb/m^2

$Q = C_0D^2LN_s$
= 0.3 kVA

Q= 0.3/0.7= 0.428

Therefore,

$0.428 = C_0 * (0.18)^2 * 0.04 * 5.555$

$C_0 = 41.7083 * 10^3$

But $C_0 = 11B_{av}*ac*K_w*10^{-3}$

B_{av}=(p Ø)/(pi D L)

ac= (I_z Z)/(pi D)

Z =30

C_0=11 * (p Ø)/(pi D L) * (I_z Z)/(pi D)

$41.7083 * 10^3 = (11*18*15.4* Iz*30 *10^{-3})/(3.141^2*.180^2*0.04)$

I_z= 5.83 A

W=VI cos Ø

200= V * 5.83 * 0.7

Therefore,

V= 49 V

Hence the output voltage is **49 v**olts.

3) *TESTING*

A) *Testing Alternator:*

- Voltage Output:

Sr. No.	Speed of rotor(rpm)	Voltage (Volts)
1	150	21
2	200	30
3	250	35
4	300	49
5	350	55
6	400	67

- ***Coil Resistance:***

Sr. No.	Coil No.	Resistance(Ω)
1	1-18	0.09 PER COIL

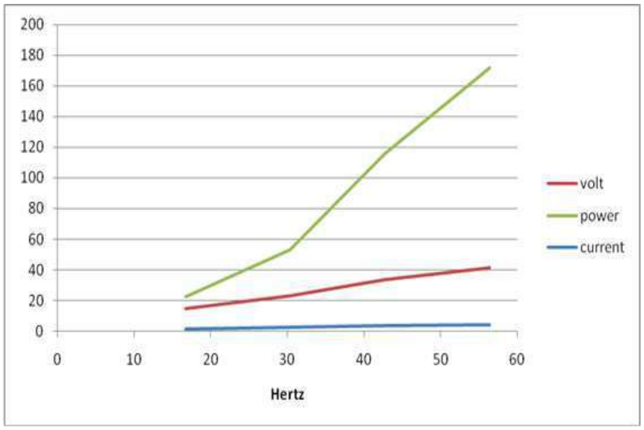
Total Resistance of stator winding: 1.65 Ω

Winding Impedance: 9.863 Ω

B) *Load Testing:*

Load: Resistive
Total Resistance: 10 Ohms

Load	Voltage	Hz	Power	Current
Ohm	V (V)	F (Hz)	$W = V^2 / R$	I = V / R
10	14.91	16.7	22.23	1.49
10	22.99	30.3	52.85	2.30
10	33.97	42.7	115.40	3.40
10	41.44	56.4	171.73	4.14



`

Figure 4 Performance Analysis

4) *Advantages:*

1. Energy can be harnessed at low speeds.
2. Output can be increased i.e. rating be increased by replacing magnets with higher flux densities.
3. Design is done with assumption of least speed of prime mover.
4. Increased voltage can be controlled by using electronic devices e.g. SMPS (Switched Mode Power Supplies).
5. Rectification can be done at any frequency.
6. The noise level is low due to low rpm.

5) *Limitations*

1. Frequency control depends on prime mover.
2. Field excitation cannot be controlled.
3. Voltage regulation depends only on design parameters.

6) Energy saving calculations:

200 watt * 24 hrs * 365 days = 1752 kWhrs generated per year

1752 kWhr * 5.10 Rs. / kWhrs = Rs. 8917 Saving of electricity

Charges by conventional energy sources

Cost of Generator = Rs. 8000

Consider wind turbine as a prime mover for 24 hrs * 365 days.

Cost of wind turbine is approximately Rs. 10000

Therefore,

Cost of prime mover = Rs. 10000

Cost of Alternator = Rs. 8000

Total = Rs. 18000

Payback period = Cost of installation / saving per year

= 18000 / 8917

Payback period = 2.01 years.

Estimated life of low rpm alternator = 10 years

Total gain from this alternator in its life cycle is = 8 years * Rs. 8917

= Rs. 71,336 (as per prevailing rate)

Payback period for this alternator is 11 months only.

CONCLUSION & FUTURE SCOPE

This study has highlighted the issue of increasing demand for electrical energy in countries like India, amidst challenges in meeting this demand due to constraints in traditional generation methods. This approach not only addresses the demand-supply gap but also holds potential economic benefits, especially for developing nations. Furthermore, technical solutions are proposed for voltage control and noise reduction in energy systems, emphasizing the importance of innovative technologies in addressing energy challenges. Overall, the findings highlight the significance of a multifaceted approach encompassing both policy interventions and technological innovations to meet the escalating energy demands sustainably.

In the near future, sustainable energy is poised to become the most cost-effective electricity source, possibly already holding this status. As fossil fuel reserves dwindle, their prices are likely to sharply rise, making them economically unsustainable. Key technological advancements needed for the commercialization of sustainable power have been made, with ongoing improvements expected. A rising trend is the development of small-scale sustainable energy systems for personal use, gaining traction due to their economic and environmental benefits.

***Abstract*— Computer vision is leveraged to tackle the challenge of recognizing micro-expressions with brief facial movements for the revealing of genuine emotions. As micro-expressions are brief and have low intensity, they are hard to capture and frequently go unnoticed. Current techniques for micro-expression recognition (MER) suffer from low classification accuracy due to the limited dataset. This study addresses the challenge of Micro-expression recognition (MER) by proposing a novel approach that combines Generative Adversarial Networks (GANs) and Convolutional Neural Networks (CNNs). Leveraging the CASME II dataset, GANs are first employed to synthesize realistic micro-expressions, effectively augmenting the dataset with diverse samples. Subsequently, a CNN model is trained on this augmented dataset to classify micro-expressions into seven predefined categories. Evaluation metrics including accuracy, precision, f1-score, support, and recall are used to assess model performance. Our proposed GAN-CNN approach outperforms existing CNN models for MER and achieves competitive performance compared to state-of-the-art methods. The integration of GANs with CNNs demonstrates promising potential for accurately recognizing micro-expressions, overcoming the limitations of dataset scarcity, and improving classification accuracy.**

Keywords*—*Convolutional Neural Networks, Micro-expression Recognition, Facial Movements, Generative Adversarial Networks, Data Augmentation.

I. Introduction

Micro-expressions are momentary and involuntary facial expressions that offer brief insights into a person's authentic emotions, even when they are consciously attempting to hide or suppress them. These subtle movements, lasting for a fraction of a second, typically ranging from 1/25th to 1/2nd of a second, can serve as crucial indicators of an individual's genuine feelings. The motivation behind the proposed work stems from its diverse applications, which encompass criminal interrogation, assessing the credibility of an interviewee, and determining the true emotional state of a patient. [1]. Because of the spontaneously induced nature of micro-expressions, only a limited number of well-established datasets have been introduced. One widely utilized dataset in this context is the CASME II[2] dataset. Researchers have recently become interested in the computational automatic analysis of micro-expressions. CNNs stand out in image recognition due to their specialized architecture, which automatically learns features from raw pixel data, reducing the need for manual feature engineering. Leveraging parameter sharing and local connectivity, CNNs efficiently extract features from images, resulting in improved performance and reduced computational complexity compared to other deep learning methods. This makes CNNs the preferred choice for many computer vision applications.

CNNs are replacing the manual feature engineering process by automatically identifying the best feature representations for images. However, CNNs often yield lower accuracies due to the limited sizes of available micro-expression datasets. In order to overcome this limitation, we incorporated a deep learning model called Generative Adversarial Network (GAN) that consists of a generator and a discriminator that has been trained adversarially. The generator creates realistic data, while the discriminator evaluates and distinguishes between generated and real data, fostering a continuous improvement loop to augment the dataset size. GANs enhance the dataset by creating new micro-expression samples. Subsequently, The classification of facial micro-expressions into seven broad classes—happiness, sadness, disgust, suppression, fear, surprise, and other was done using CNNs. Utilizing GANs to enhance the dataset would, in turn, improve the classification performance by overcoming the limited dataset problem.

The proposed model outperforms other state-of-the- art CNN models. In the comprehensive framework for micro-expression MER, this study initiates the procedure by preprocessing the apex frames of the micro-expression. Subsequently, we employ GAN to augment these apex frames, we train and test the CNN model using the augmented dataset.

The structure of the paper is as follows: Section II provides a review of literature, Section III outlines the methods employed, Section IV details the experiments conducted, Section V presents the results and discussion, and Section VI concludes the study and suggests future research directions.

II. LITERATURE REVIEW

Researchers have proposed a method that use conditional GAN and an optimized compact CNN model [3]. The authors presented an enhanced continuous labelling method for identifying a video's apex frame. Conditional GAN are used to augment the training data. The network is optimized for mobile based micro-expression analysis using techniques like weight pruning, architecture search etc. They achieved an accuracy of 78.53%, 78.53% on CASME II and SMIC datasets. The OC-Net is designed to be compact and optimized for mobile based micro-expression analysis with fewer parameters and faster computation time compared to other deep learning models. There is a decrease in the accuracy for SAMM dataset.

The methodology they proposed in this [4] is for synthesizing long video datasets of micro-expressions using reference-guided style transfer. The authors first detected the Action Units (AUs) in the original dataset, which are then used as reference points for the style transfer process. They used GANs to generate synthetic videos that mimic the facial expressions of the original dataset. After comparing the AUs obtained in the original and synthetic datasets, they performed a correlation study and discovered strong correlation on two AUs, AU12 and AU6, with Pearson's correlation values of
0.74 and 0.72, respectively. The primary benefit of the suggested approach is its ability to produce lengthy video sequences of facial expressions, including both macro- and micro-expressions, an accomplishment that is difficult to do with current techniques. In addition, the technique generates new data without altering the identification of the original film, which can be advantageous for maintaining anonymity.

Researchers have introduced an approach called ICE-GAN (Identity-aware and Capsule-Enhanced Generative Adversarial Network) for expression recognition and synthesis [5]. ICE-GAN uses graph-based reasoning to capture long-ranged dependencies, i.e., the relationships between different parts of a facial expression that are not immediately adjacent to each other. The ICE-GAN methodology is evaluated using the Leave-One-Subject-Out (LOSO) validation method. They achieved an F1-score of 87.4%. Graph-based reasoning allows for more comprehensive understanding of the relationships between different facial regions. ICE-GAN is an identity- aware approach, which means that it can produce synthetic faces with controllable micro-expressions and identity-aware features. The ICE-GAN's reliance on graph-based reasoning may introduce computational complexity.

In this paper, they examined the impact of dense and sparse optical flow methods and their effect on MER. The data sample size is increased by using GAN to generate "fake" optical flow images [6]. Finally, they implemented a state-of- the-art CNN architecture and modify it for feature enhancement and classification operations. On the SMIC, CASME II, and SAMM datasets, the accuracy attained is 71.43%, 84.85%, and 68.75%, respectively. The use of GAN-based data augmentation can increase the diversity and sample size of the dataset, which can increase the generalization ability of the model.

In this paper, they proposed an approach is a discriminatively deep fusion approach with an improved conditional generative adversarial network (im-cGAN) for facial expression recognition (FER) [7]. To produce additional labelled expression examples for training, the im-cGAN is employed. The method extracts discriminative features from training data by combining global and local characteristics. The obtained accuracy on JAFFE, CK+, Oulu-CASIA, and KDEF datasets is 98.37%, 98.20%, 93.34%, and 98.30%, respectively. The performance of im-cGAN is dependent on choice of hyperparameters and architecture. Depending on the dataset and application, there may be a risk of overfitting if the im- cGAN-generated samples do not accurately represent the diversity of real-world facial expressions.

The two main strategies used in the methodology suggested in this paper are Décalcomanie data augmentation and N-step pre-training [8]. Multiple transfers of learning from action recognition datasets to facial recognition datasets are carried out throughout the N-step pre-training. A deep neural network is trained on a sizable dataset as part of the pre-training process, and it is then fine-tuned using the target micro- expression dataset. Using décalcomanie data augmentation, which is predicated on facial symmetry, a composite image is produced by circling the centre lines of both faces. They achieved the Weighted Average Recall (WAR) as 0.7927. The multiple transfers of learning and fine-tuning enhance the model's ability to generalize across datasets.
performance.

Some researchers have recently proposed a dual-stream approach that combines dynamic image convolutional neural networks with optical flow. Histogram equilization is used for image enhancement [9]. In order to categorise micro-expressions, the algorithm first creates a number of attributes. Then OF-Block module is proposed to extract flow features from video data, which can capture the motion and movement of facial muscles over time. Then hierarchical fusion strategy that fuses face motion features and spatio-temporal features several times to protect diversity of features. Accuracy of 61.20%, 73.09% and 58.07% is achieved in the CASME and CASME II and SAMM datasets, respectively. The proposed algorithm uses two streams of information, optical flow and dynamic images to capture both the motion and appearance of facial expressions. Despite its feature-rich approach, the algorithm achieves accuracy levels that might be considered relatively modest.

They suggested Deep3DCANN, an end-to-end framework for detecting face micro-expressions, in this [10]. Deep 3D CNN, the initial element, learns practical spatiotemporal features from a series of facial photos. A deep artificial neural network is the second element, and it tracks the beneficial visual connections between various facial subregions. To forecast the micro-expressions, a fusion technique combines learnt facial traits with semantic links between the areas. Regarding the SAMM, CASME, and CASME II datasets, the 3DCANN framework achieves accuracy of 87, 86, and 93 percent, respectively. Deep 3D CNNs and deep ANNs increases computational complexity that result in longer training times and extra resources like GPU.

III METHODOLOGY

The suggested system's architecture and the used methodology are covered in this section.

3.1 Architecture:

The overview of the proposed framework is described in Figure 1, outlining both the data augmentation module and the classification module.

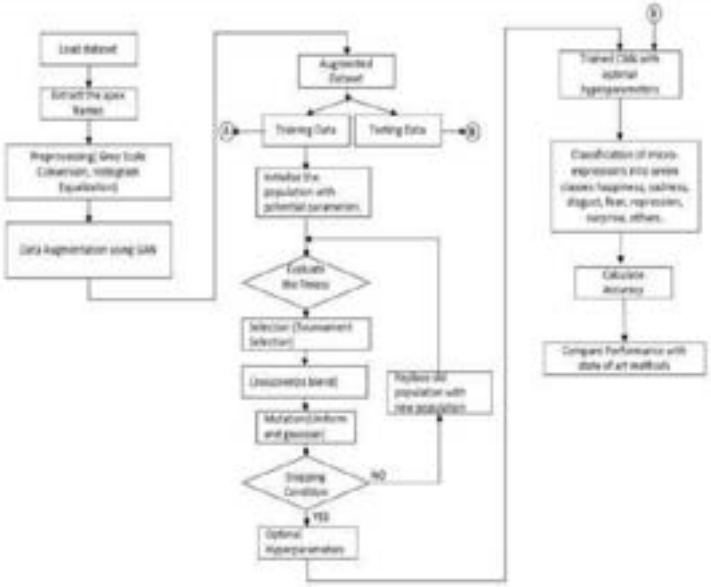

Fig. 1. Proposed System for GAN-CNN model

3.2 Methodology:

An all-encompassing framework for micro-expression recognition, with CNN and GAN as its main building blocks is presented in this research study. The micro-expression (ME) sequences' apex frames are first recognized and preprocessed by the framework. Subsequently, the dataset is augmented through GAN, and CNN is employed for classification.

3.2.1 Preprocessing

In the study of facial micro-expressions and emotions, the identification of apex frames is crucial for analyzing and comprehending micro-expressions. Apex frames are representative of the highest point of intensity in a facial expression, while onset frames indicate the initial stages of an expression where it becomes apparent. The CASME II dataset, which is a prevalent database of spontaneous micro-expressions, provides annotations of apex frame for each micro-expression sequence. This allows to extract corresponding apex frame from each expression sequence of each subject, thereby facilitating accurate analysis of micro-expressions.

Following this, the apex frames undergo grayscale processing, a procedure that transforms a colored image into a grayscale image. It allows for simpler and more efficient processing of the images, as grayscale images have only one channel of information per pixel, as opposed to the three channels (red, green, and blue) found in color images. By calculating the weighted average of the red, green, and blue values of each pixel, it transforms the input color image into grayscale, Equation 1 represents grayscale value calculation.

$$Grayscale\ value = 0.299 * R + 0.587 * G + 0.114 * B \quad (1)$$

The red, green, and blue values of the pixel are denoted as R, G, and B, correspondingly. The coefficients 0.299, 0.587, and 0.114 are the weights that are used to compute the weighted average.

The images are next subjected to histogram equalisation, which is the process of converting the original image's histogram into a uniformly distributed histogram. By redistributing the pixel intensity values, this technique reduces the effect of illumination and improves the image's overall contrast.

3.2.2 Generative Adversarial Networks

GANs play a role in generating novel micro-expression samples [11]. The data augmentation is achieved using GANs. Among the essential elements are the Discriminator (D) and Generator (G) functions. P_{data} is the training dataset's probability distribution, and P_z is the latent space's probability distribution, which is usually a random Gaussian distribution. The adversarial dynamics of GANs revolve around the interaction between these two functions.

When a sample (x) is drawn from P_{data}, the Discriminator's goal is to classify it as a real micro-expression sample, effectively distinguishing between real micro-expressions and those generated by the model. Conversely, the Generator aims to produce micro-expression samples (G(z)) from the latent space in a manner that, when presented to the Discriminator, they are perceived as real. The Generator continuously refines its process to create samples that increasingly resemble the real micro-expression samples, as the Discriminator's capacity to distinguish between produced and genuine samples increases.

For generated samples, the generator minimizes the log likelihood that the discriminator makes correct classifications. This loss incentivizes the generator to create samples that the discriminator is likely to categorize as real (logD(G(zi)) close to 1). The process is shown in figure 2.

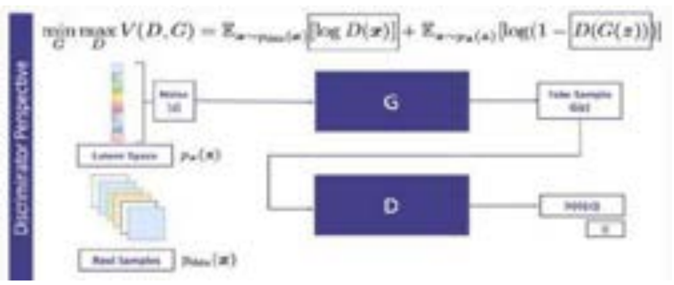

Fig. 2. Objective function in GAN formulation [12]

Generator: The generator network takes random noise or a latent representation as input and attempts to generate realistic data samples, such as images, audio, or text. It learns to map the input noise to the data distribution of the training set, effectively generating new data instances that are indistinguishable from real examples. The goal of the generator is to produce outputs that are convincing enough to fool the discriminator into believing they are real.

Discriminator: The discriminator network acts as a binary classifier, distinguishing between real and generated data samples. It is trained to differentiate between authentic data from the training set and synthetic data produced by the generator. The discriminator learns to assign high probabilities to real data and low probabilities to generated data. Its objective is to accurately classify the origin of the input samples, thereby providing feedback to the generator on how to improve its outputs.

3.2.3 Convolutional Neural Networks

In Figure 3, the proposed CNN architecture incorporates three pairs of convolutional and MaxPooling layers is illustrated. Convolutional layers are particularly effective in detecting patterns and features within images, while max pooling layers contribute to reducing the spatial dimensionality of the output from the convolutional layers, introducing translation invariance.

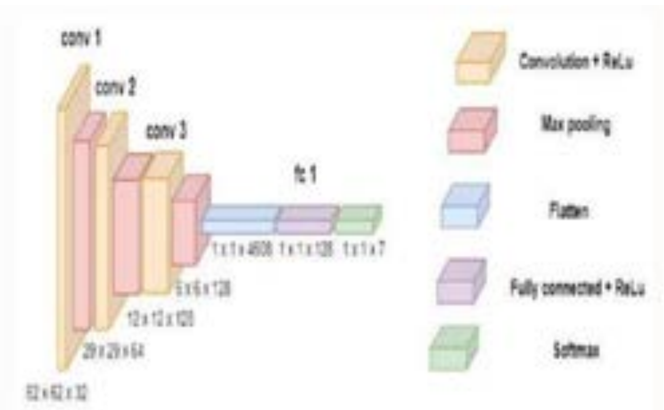

Fig. 3. Architecture of proposed CNN

The first convolutional layer uses the ReLU activation function and consists of 32 filters with a 3x3 kernel size. The input images have the shape (64, 64, 1), where the height and breadth (64 pixels each) of the input images are represented by the first two dimensions, and the number of channels is indicated by the final dimension. A MaxPooling layer with a pool size of 2x2 follows this layer. The subsequent convolutional layer features 64 filters with a 3x3 size and employs the ReLU activation function. Another MaxPooling layer with a pool size of 2x2 succeeds this layer. Following this, a third convolutional layer is introduced, incorporating 128 filters with a 3x3 size, along with a MaxPooling layer with a pool size of 2x2.

To mitigate overfitting, dropout regularization is applied after the flatten layer. Following the convolutional and pooling layers, the flattened feature maps are connected to fully connected (Dense) layers. These layers integrate the extracted features and learn complex relationships between them. In this architecture, a fully connected layer with 128 units and ReLU activation is employed. This layer acts as a bridge between the convolutional layers and the output layer, facilitating high-level feature representation and abstraction. The output layer utilizes a SoftMax activation function to produce probability distributions over the designated classes for each input image. This enables the model to make predictions by assigning probabilities to each class, indicating the likelihood of the input image belonging to a particular category.

IV EXPERIMENTAL ANALYSIS

4.1 Experimental Setup:

In the proposed architecture, the GAN model augments the dataset by generating images of size [64, 64, 1]. The enhanced dataset is then employed to train the CNN model using an 80:20 stratified split and tested accordingly to evaluate the model's performance. We used the Adam optimizer with a learning rate of 0.0006 during the optimisation process. The model was trained for 52 epochs with a batch size of 17 and a dropout ratio of 0.29. These hyperparameters were fine-tuned using a genetic algorithm. Google colab was utilized to run the model.

4.2 Datasets:

The experiments utilized the CASME II dataset provided by the Fu Xiaolan research group of the Chinese Academy of Sciences with permission. It is a comprehensive repository of spontaneous micro-expression that comprises 247 video samples drawn from 26 Asian participants, with an average age of 22.03 years. The videos depict participants evoked by one of five micro-expression categories: Happiness, Disgust, Repression, Surprise, and Others. Recorded at a high frame rate of 200 fps, this dataset offers a diverse and dynamic collection of micro-expressions. Table 1 illustrates the counts of original samples, GAN-augmented samples, and the total number of samples post-augmentation.

Table 1. displays the count of original and augmented frames in the CASME II dataset.

Type	Original	GAN augmented	Total
Happiness	32	64	96
Sadness	7	63	70
Repression	27	64	91
Disgust	63	-	63
Surprise	25	50	75
Fear	2	60	62
Others	99	-	99
Total	255	301	556

The below images in figure 4 show the generated images of GAN.

Fig. 4. Generated images using GAN

4.3 Evaluation Metrics:

Using a variety of metrics, including accuracy, precision, recall, f1-score, and UAR, the performance of the GAN-CNN model was evaluated on the CASME II dataset.

V RESULTS AND DISCUSSION

In conducting the facial micro-expression classification project using Google Colab, minimal system requirements include a stable internet connection and a compatible web browser such as Google Chrome or Mozilla Firefox. Software requirements entail access to a Google Colab account, freely available, and the installation of essential Python libraries, including TensorFlow, Keras, OpenCV, NumPy, and Matplotlib. Additional libraries may be necessary for tasks such as data preprocessing, model training, and evaluation. This section provides a thorough analysis of the experimental results derived from the benchmark CASME II dataset. We delve into a detailed discussion of these results, conducting a comparative study that assesses the performance of the proposed GAN-CNN model against baseline models such as VGG16, ResNet50, and InceptionV3. These baseline models are considered as reference points. Additionally, we compare our work with state-of-the-art methods in the realm of micro- expression classification. Table 2 illustrates the comparative performance analysis between the GAN-CNN model and the baseline models.

Table 2. Comparison of classification performance of GAN-CNN with baseline models.

Metrics	**Resnet50**	**VGG16**	**Inception V3**	**GAN-CNN**
Accuracy	0.8986	0.7707	0.8295	0.9222
Recall	0.8986	0.7707	0.8295	0.9222
F1-Score	0.9015	0.7732	0.8314	0.9229
Precision	0.9154	0.8076	0.8464	0.9260
UAR	0.9091	0.7721	0.8277	0.9399

The assessment revealed significant enhancements in the performance of the GAN-CNN model. Specifically, it demonstrated a 2.36% increase in classification accuracy compared to ResNet50, a 15.15% improvement compared to VGG16, and a 9.27% higher accuracy compared to the InceptionV3 baseline model. The proposed framework achieved the highest Unweighted Average Recall (UAR) at 93.99%, surpassing the performance of the other models under evaluation. Consistent trends were observed across various metrics, underscoring the superior performance of the proposed framework. Figure 5 illustrates the variation in training and validation accuracies for the proposed GAN-CNN employed in the experiments.

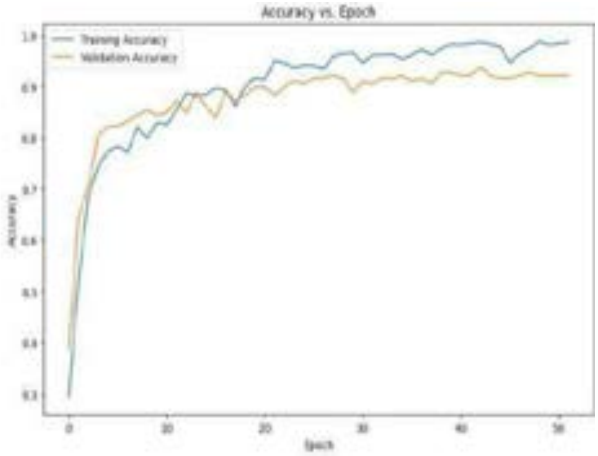

Fig. 5. Accuracy vs Epoch graph

Figure 6 present the confusion matrix of our proposed model. Upon analyzing the provided confusion matrix, it becomes apparent that the GAN-CNN model exhibits superior class- wise micro-expression recognition performance.

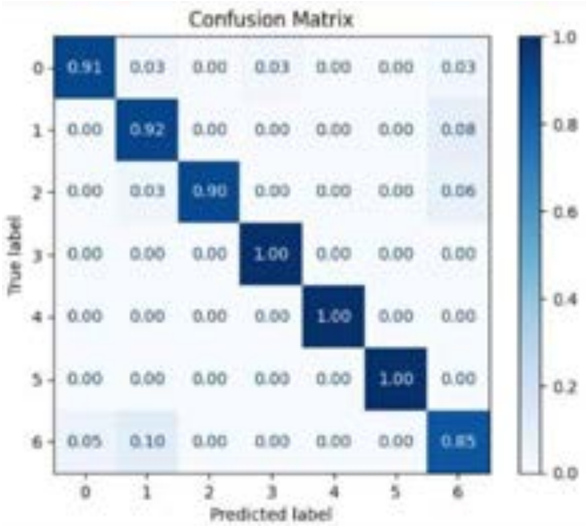

Fig.6: Confusion matrix

We extensively compared the GAN-CNN model with existing micro-expression recognition baselines using CNN architectures and deep features. Table 3 summarizes the evaluation findings, highlighting the overall performance of the proposed model.

Table 3: Comparison table of GAN-CNN with the state-of-art methods

VI CONCLUSION

In conclusion, this study presents a promising approach to addressing the challenge of recognizing micro-expressions, which are often elusive yet significant indicators of genuine emotions. By leveraging Generative Adversarial Networks (GANs) in conjunction with Convolutional Neural Networks (CNNs), our proposed method offers a novel solution to the limitations posed by the scarcity of micro-expression datasets. Through the synthesis of realistic micro-expressions using GANs and subsequent training of a CNN model on an augmented dataset, the proposed approach has achieved notable improvements in classification accuracy compared to existing techniques. The evaluation results demonstrate the efficacy of our approach, as evidenced by superior performance metrics such as accuracy, precision, f1-score, support, and recall. Overall, the integration of GANs with CNNs showcases promising potential for advancing micro-expression recognition, thereby contributing to the broader field of computer vision and emotion analysis.

***Abstract*— Credit card fraud remains a persistent challenge, undermining financial security and trust. Traditional fraud detection systems struggle with the dynamic nature of fraudulent transactions, necessitating innovative approaches. Recent advancements introduce promising methodologies but face hurdles like data imbalance and evolving fraud patterns. This research study aims to elevate credit card fraud detection by integrating ensemble and deep learning models. Leveraging techniques like Voting, Stacking, CNN, and LSTM on the IEEE-CIS Fraud Detection dataset, we address challenges such as data imbalance and feature selection inefficiencies. The proposed approach, Fraud Shield, aims to fortify detection capabilities, acknowledging evolving fraud activities. By combining advanced techniques and a comprehensive dataset, our project provides a powerful tool for combating fraud in the financial sector. This study highlights the need for continual innovation in fraud detection and highlights the importance of collaboration between academia, industry, and regulatory bodies. Through comprehensive analysis and collaboration, this study paves way for a safer financial ecosystem resilient to emerging threats.**

Keywords—Long short-term memory, Convolutional neural network, Synthetic minority oversampling, Voting, Stacking, deep learning, ensemble.

I. Introduction

Credit card fraud poses a significant threat to financial institutions and consumers alike, with increasingly sophisticated tactics emerging in the digital age. In response to this challenge, Fraud Shield emerges as a comprehensive fraud detection system leveraging ensemble learning and deep learning techniques. This study introduces Fraud Shield, highlighting its key features and benefits in the realm of credit card fraud detection.

FraudShield integrates ensemble learning, a machine learning paradigm known for its ability to combine multiple models to enhance predictive performance. By aggregating diverse fraud detection algorithms, Fraud Shield creates a robust system capable of identifying and mitigating fraudulent activities associated with credit card transactions. This approach ensures higher accuracy and generalization compared to individual models, addressing the evolving landscape of financial fraud.

Additionally, the proposed model leverages the power of deep learning, a subset of machine learning inspired by the human brain's neural networks. Deep learning models, including convolutional neural networks (CNNs) and long short-term memory (LSTMs), excel at learning intricate patterns and features from complex data. By leveraging deep learning, Fraud Shield can effectively discern fraudulent patterns within credit card transaction data, even amidst challenging scenarios where traditional methods may falter.

The synergy between ensemble learning and deep learning within Fraud Shield enables it to adapt and evolve in response to emerging fraud tactics and evolving transaction patterns. Through continuous analysis and learning from new data, Fraud Shield remains at the forefront of fraud detection, providing financial institutions and merchants with the confidence to transact securely in the digital landscape.

Key features and benefits of Fraud Shield include enhanced accuracy, real-time detection capabilities, adaptability to evolving fraud patterns, scalability to handle large volumes of transaction data, and comprehensive protection against various types of credit card fraud. These attributes position Fraud Shield as a vital tool for safeguarding financial transactions and preserving trust in the digital ecosystem.

II. Literature Review

Ibomoiye Domor Mienye et al. [1] propose a deep learning ensemble for credit card fraud detection, merging LSTM and GRU neural networks with an MLP meta-learner. Through SMOTE-ENN for class distribution balancing, the approach achieves superior sensitivity (1.000) and specificity (0.997) compared to traditional ML methods. While effective in capturing intricate transactional patterns, the ensemble's complexity and computational demands may hinder practical deployment. Nevertheless, it underscores the potential of ensemble techniques in enhancing fraud detection, necessitating further research to optimize efficiency for real-world implementation.

Khushi Goyal et al. [2] propose a real-time scam recognition system for e-commerce credit card fraud using an ensemble of machine learning and deep learning models. Leveraging technologies like NumPy and Scikit-learn, the study aims for robust fraud detection. The dataset comprises 492 fraud cases out of 283,806 transactions, with testing conducted using Random Forest Classifier and Decision Tree algorithms on European cardholder data. While promising for real-time fraud detection, the approach's efficacy may vary based on dataset representativeness and algorithm adaptability to evolving fraud patterns.

Harshit Muhal et al. [3] tackle credit card fraud employing a champion-challenger approach with three ensemble models. Champion Challenger 1, comprising Random Forest, Ada-boost, and LSTM, achieves notable Accuracy, Precision, Recall, and F1-Score of 99.86, 99.73, 99.99, and 99.86, respectively. While offering robust fraud mitigation, this approach may face challenges in real-time adaptability and scalability. However, its superior performance indicates potential for significant financial risk reduction in global fraud scenarios.

Damanpreet Kaur et al. [4], credit card companies must ensure top-notch security against fraudulent transactions. This study explores fraud detection using machine learning, deep learning, and their ensemble on imbalanced data. The goal is to achieve high recall without sacrificing precision, critical for maintaining customer trust. Various techniques, including resampling and metric selection, are demonstrated to address data imbalance and enhance model accuracy.

Wei Luo [5], utilizing various deep learning techniques, this research focuses on quantifying uncertainty for credit card fraud detection, crucial for reliable decision-making in dynamic fraud scenarios. Methods like Monte Carlo dropout and ensemble modelling are employed to assess uncertainty, enhancing fraud detection accuracy. Ensemble methods prove superior in capturing prediction uncertainty, thereby improving fraud detection outcomes, and providing valuable information for decision-making.

PFawaz Khaled Alarfaj et al. [6] detecting credit card fraud is imperative due to its financial implications. This study explores state-of-the-art machine learning and deep learning algorithms to address the challenges posed by fraud, including data imbalance and evolving fraud tactics. Empirical analysis on a benchmark dataset showcases significant improvements in accuracy, f1-score, precision, and AUC curves, surpassing existing methods and offering effective real-world fraud detection solutions.

Xiong Kewei et al. [7], Addressing the surge in credit card fraud, this research introduces a hybrid deep learning model enhanced by feature engineering, memory compression, mixed precision, and ensemble loss techniques. Evaluated on the IEEE-CIS fraud dataset, the model exhibits superior performance compared to traditional machine learning methods such as Bayes and SVM, offering a promising solution to combat online fraud.

Vejalla et al. [8] explore "Credit Card Fraud Detection Using Machine Learning Techniques," focusing on traditional machine learning methods. While effective in initial fraud detection, reliance on these techniques may limit the model's ability to detect complex fraud patterns. The absence of deep learning and ensemble methods could hinder performance in identifying sophisticated fraud, potentially constraining the model's effectiveness in combating online fraud.

Bayhan et al. [9] investigate "The Effect of Feature Selection on Credit Card Fraud Detection Success," highlighting the importance of feature selection in fraud detection models. While feature selection enhances model interpretability and efficiency, it may inadvertently discard crucial information relevant to fraud patterns. Consequently, reliance solely on feature selection methods without incorporating ensemble or deep learning techniques could limit the model's ability to detect intricate fraud schemes, potentially compromising its overall effectiveness in fraud detection.
Parekh et al. [10] explore "Credit Card Fraud Detection with Resampling Techniques," focusing on the application of resampling methods like SMOTE and ENN to address class imbalance. However, the study suggests the necessity of integrating ensemble and deep learning techniques for more comprehensive fraud detection solutions.

Al Smadi and Min [11] conduct a "Critical review of Credit Card Fraud Detection Techniques," presenting an exhaustive analysis of existing methods. They evaluate the effectiveness of various techniques, shedding light on their strengths and limitations in addressing the evolving challenges posed by fraudulent activities. Their comprehensive review offers valuable insights into the landscape of credit card fraud detection, aiding researchers, and practitioners in developing more robust and efficient detection systems.\

Boutaher et al. [12] provide a comprehensive "Review of Credit Card Fraud Detection Using Machine Learning Techniques," offering insights into the application of various machine learning algorithms for fraud detection. Their analysis encompasses the strengths and weaknesses of different techniques, providing researchers and practitioners with valuable guidance in selecting the most appropriate approach for combating fraudulent activities. This review serves as a valuable resource for advancing the field of credit card fraud detection, facilitating the development of more effective and efficient detection models.

III. Methodology

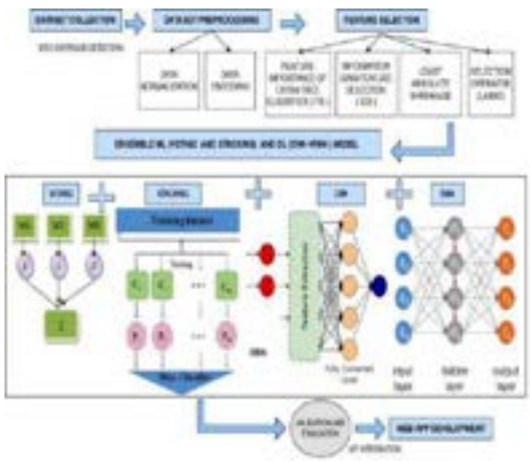

Fig 1: Architecture Diagram

Fig 1 illustrates the flow of data and processing steps within the proposed Credit Card Fraud detection, from data collection to preprocessing to implementation of algorithms.

1. Principal Component Analysis (PCA) is first used to process our modified dataset. This includes cleaning up any redundant features from the dataset, normalizing attributes with large fluctuation, and locating and fixing any missing data entries.

2.We address class imbalance using the Synthetic Minority Over-sampling Technique (SMOTE). Initially, the dataset exhibited severe class imbalance with over 25,000 instances of non-fraudulent transactions and only around 1,000 instances of Fraudulent transactions. After the SMOTE application, the classes were balanced, resulting in approximately 25,000 instances for both Fraudulent and Non-Fraudulent transactions, enhancing model robustness.

3.In the third crucial step of our methodology, we implement normalization using the scikit-learn library. This crucial process ensures that every feature derived after PCA transformation, spanning from v1 to v28, is appropriately scaled within the range of 0 to 1. This normalization procedure enhances the consistency and effectiveness of model training and evaluation by harmonizing the data distribution across all features.

4. Post-normalization, feature selection is conducted using Extra Tree Classifier and information gain score, alongside LASSO regression. This process aims to identify the most influential features for predicting fraudulent transactions. Following evaluation, a common set comprising 11 top-ranking features is selected, enhancing the model's efficiency and interpretability in credit card fraud detection.

5.Subsequently, the selected important features are inputted into a Voting Classifier, comprising Random Forest Classifier, Gradient Boost Classifier, and Logistic Regression. This ensemble method combines the predictions of multiple classifiers to enhance fraud detection accuracy. By leveraging the strengths of each classifier, the Voting Classifier provides a robust and effective solution for identifying fraudulent credit card transactions.

6. Following the Voting Classifier, a Stacking Classifier is implemented, with a Decision Tree Classifier as the final estimator. This ensemble technique combines the predictions of multiple classifiers, providing further improvements in fraud detection accuracy. Comparative analysis of the output accuracies from each ML algorithm, along with those from the Voting and Stacking Classifiers, highlights the superior efficiency of the Stacking Classifier in identifying fraudulent transactions.

7. Following, Convolutional Neural Network (CNN) and Long Short-Term Memory (LSTM) algorithms are trained for 10 epochs. Additionally, a hybrid model combining LSTM and CNN is employed. Subsequently, the accuracies and results of all models are compared. Once more, the Stacking Classifier proves to be the most effective algorithm for credit card fraud detection, outperforming both individual DL algorithms and their hybrid combination.

IV. Implementation

A. Data Collection

A key tool in this study is the Kaggle Credit Card Fraud Detection dataset, which is well-known in several academic and scientific fields. This dataset is an extensive collection of transactional data from Europe and was assembled over the course of two days in September 2013. The dataset contains essential identity information linked to the people who are carrying out these transactions in addition to transactional facts. With a total of 284,807 cases, it offers a detailed look into the nuances of financial transactions throughout this time. Remarkably, even with its large size, the dataset exhibits a stark disparity in class, with only 492 cases of fraudulent transactions—that is, 0.17% of the entire dataset.

This glaring disparity highlights the inherent difficulties in effectively assessing and forecasting fraudulent activity. To derive valuable insights from the dataset, it is imperative to ensure that rigorous techniques are in place to rectify this imbalance. Furthermore, the combination of transactional and identity-related features in the dataset provides researchers with a wealth of information, enabling a comprehensive investigation of credit card fraud detection techniques.

B. Data Preprocessing

An extensive investigation of credit card fraud detection was made possible in this study by the merging of company’s identity and transaction databases. These datasets were carefully combined to create a coherent dataset that is suitable for additional research. The datasets contained crucial identifying attributes and transactional information. Following the merger, Principal Component Analysis (PCA) became apparent as a potent dimensionality reduction method that made it possible to extract crucial elements required for fraud detection. The condensed collection of features, designated as V1 through V20, was created via PCA from the combined dataset, encapsulating the most important elements of the original data.

Preprocessing such large datasets required several careful processes to guarantee data dependability and integrity. Notably, PCA was essential for managing null and empty values in addition to feature extraction. Null and empty values were effectively reduced by utilizing PCA's innate ability to identify and keep the most informative features while eliminating unnecessary ones. Furthermore, pretreatment methods including scaling and data normalization were used to improve the dataset's resilience and readability. This rigorous preprocessing routine made sure the information was ready for further analysis and provided a strong framework for investigating credit card fraud detection techniques.

C. Oversampling Using SMOTE

We use the Synthetic Minority Over-sampling Technique (SMOTE) to address the extreme class imbalance in our dataset. At the beginning of the collection, there was a notable discrepancy: more than 25,000 examples of transactions that were not fraudulent were significantly more than the around 1,000 examples of fraudulent transactions. We rebalance the classes by using SMOTE, yielding around 25,000 instances for both fraudulent and non-fraudulent transactions. By improving the resilience of our models, this augmentation reduces the possibility of biased predictions and guarantees a more equal representation of both classes.

Although SMOTE is a commonly used oversampling technique, there are other solutions available to alleviate class imbalance, including Random Over-sampling, Near Miss and Tomek Links under-sampling techniques, and ensemble methods like Balanced Random Forest and Easy Ensemble. SMOTE, however, is a better option due to its ease of use, efficiency, and capacity to produce artificial instances that closely resemble actual minority class samples. Its application in our study greatly enhances model performance, leading to increased accuracy and dependability in fraud detection.

D. Normalization and Feature Selection

We deal with the normalization of our dataset in the next step of our process. This crucial step makes sure that all features, which after PCA transformation range from v1 to v28, are scaled correctly between 0 and 1. Normalization is essential for improving the uniformity and effectiveness of model training and assessment since it uniformizes the distribution of data for all characteristics, reducing the impact of different scales on model performance.

After normalization, feature selection is the next important step, which is to find the features that have the greatest impact on predicting fraudulent transactions. We use LASSO regression together with two different techniques: Information Gain Score (IGS) and Extra Tree Classifier. The Extra Tree Classifier, which is well-known for its resilience and capacity to process high-dimensional data, assesses each feature's relative value by considering random splits at each decision tree node. In addition, the information gain score offers important insights into feature importance by quantifying the decrease in entropy or uncertainty attained when a specific feature is chosen for node splitting. Furthermore, by applying a penalty to the absolute magnitude of the regression coefficients, LASSO regression successfully promotes feature selection and sparsity. Through the amalgamation of these techniques, we establish a shared collection of 11 highest-ranking attributes, augmenting the effectiveness and comprehensibility of our model within the credit card fraud identification field.

E. Training with Ensemble ML (Voting and Stacking)

After going through the feature selection procedure, the major features that were found are combined with the Random Forest, Gradient Boost, and Logistic Regression classifiers to create a Voting Classifier. The objective of this ensemble strategy is to increase the accuracy of fraud detection by combining the predictive powers of several classifiers. The Voting Classifier offers a robust and effective way to identify fraudulent credit card transactions by utilizing the distinct advantages of each classifier.

Accurate predictions are produced by the Random Forest Classifier, which is known for its robustness and versatility when processing high-dimensional data. It does this by combining the output of several decision trees. By concentrating on cases with high error rates, the Gradient Boost Classifier, on the other hand, uses a sequential boosting strategy to enhance model performance iteratively and increase predicted accuracy. Furthermore, Logistic Regression functions as a basic yet potent linear model that provides interpretability and effectiveness in identifying the underlying associations between the target variable and the features.
The Voting Classifier's remarkable precision result of 98.289% is attained by the ensemble of several classifiers, highlighting its effectiveness in fraud detection. But to improve even more, we apply a Stacking Classifier, which raises precision to a remarkable 99%. The Stacking Classifier combines predictions from several base classifiers to obtain higher fraud detection accuracy. It uses a Decision Tree Classifier as the final estimator. This combination of classifiers, designed to handle the subtleties of credit card fraud identification, highlights the effectiveness of ensemble approaches for handling difficult classification problems.

F. Training with DL (CNN and LSTM)

We implement Long Short-Term Memory (LSTM) and Convolutional Neural Network (CNN) models to detect credit card fraud. Following three Conv1D layers with filter widths of 32, 64, and 128 respectively, the CNN design comprises MaxPooling1D layers for feature extraction. It employs the Adam optimizer with a learning rate of 0.001 and the categorical cross-entropy loss function for model compilation.

Fig 2. LSTM accuracy

The best-performing model weights are saved via the Model Checkpoint callback. On the other hand, dropout regularization prevents overfitting in the LSTM model by combining two LSTM layers for sequential data processing and Conv1D layers for feature extraction. Both models are trained for ten epochs, and the LSTM model achieves an impressive test accuracy of about 99.8% as shown in fig. 2.

These models use different but complementary techniques to address the difficulties associated with credit card fraud detection. While the LSTM model is better at identifying temporal patterns and long-term relationships, the CNN model is better at capturing spatial connections found in transactional data as shown in fig 3.

Fig 3. CNN Accuracy

The fraud detection system gains from a thorough examination of transactional data by utilizing the advantages of both models, which improves its accuracy and effectiveness in spotting fraudulent activity.

Fig 4. Hybrid model Accuracy

We have also developed a hybrid Convolutional Neural Network (CNN) and Long Short-Term Memory (LSTM) model. The model's capacity to identify both spatial and temporal patterns in transactional data is improved by this architecture, which combines CNN for spatial feature extraction and LSTM for sequential data processing. The hybrid model undergoes training, assessment, and comparison with separate CNN and LSTM models as shown in fig 4.

The hybrid approach's efficacy in fraud detection is demonstrated by the results, which show that it produces performance that is either comparable to or better than that of the separate CNN and LSTM models.

VI. Results And Observations

The model's performance over the dataset is displayed in the tables 1 to 5, which also illustrate the model's training level using several metrics like F1-score, precision, and recall. The model's performance is balanced by the F1-score, which is the average of precision and recall. Precision denotes the accuracy of positive predictions, recall indicates the percentage of accurately predicted true positives.

TABLE 1. LSTM Results

	precision	recall	f1-score	support
Not Fraud	99%	100%	100%	5014
Fraud	100%	99%	100%	4986
accuracy			97%	10000
Macro average	97%	97%	97%	10000
Weighted average	97%	97%	97%	10000

Table 2. CNN Results

	precision	recall	f1-score	support
Not Fraud	99%	99%	99%	5014
Fraud	99%	99%	99%	4986
accuracy			99%	10000
Macro average	99%	99%	99%	10000
Weighted average	99%	99%	99%	10000

The results from both LSTM and CNN models demonstrate high precision, recall, and F1-score values for both the "Not Fraud" and "Fraud" classes, indicating robust performance in credit card fraud detection. Both models achieved an overall accuracy of 99%, showcasing their effectiveness in correctly classifying transactions. Additionally, the macro and weighted average scores further confirm the models' balanced performance across all classes and their ability to generalize well on the dataset.

Table 3. Hybrid (CNN+LSTM) Results

	precision	recall	f1-score	support
Not Fraud	97%	98%	97%	5014
Fraud	98%	97%	97%	4986
accuracy			97%	10000
Macro average	97%	97%	97%	10000
Weighted average	97%	97%	97%	10000

Table 4. Voting Observations

	precision	recall	f1-score	support
Not Fraud	97%	99%	98%	5014
Fraud	99%	97%	98%	4986
accuracy			98%	10000
Macro average	98%	98%	98%	10000
Weighted average	98%	98%	98%	10000

Table 5. Stacking Results

	precision	recall	f1-score	support
Not Fraud	99%	100%	100%	5014
Fraud	100%	99%	100%	4986
accuracy			100%	10000
Macro average	100%	100%	100%	10000
Weighted average	100%	100%	100%	10000

The results from the ensemble methods, Voting and Stacking, highlight the efficacy of combining multiple classifiers for credit card fraud detection. While both methods exhibit impressive precision, recall, and F1-score values, Stacking outperforms Voting across all metrics, achieving perfect accuracy scores. This suggests that Stacking, which leverages the predictions from various classifiers, offers superior performance in accurately identifying both fraudulent and non-fraudulent transactions.

VII. CONCLUSION

The obtained results highlight the potential of ensemble learning techniques, particularly Stacking, in enhancing existing fraud detection systems. By integrating diverse classifiers and leveraging their collective predictive power, Stacking can provide more robust and reliable fraud detection capabilities. Overall, these results emphasize the value of ensemble methods as a promising approach for increasing the effectiveness of credit card fraud detection systems.

***Abstract*— This research study presents an innovative Android application for a Temporary Driver Booking System, which aims to revolutionize the temporary driver industry by providing a streamlined, efficient, and safe solution for connecting customers with qualified drivers. The platform offers a seamless user experience, allowing customers to specify their transportation needs and choose from a pool of verified drivers based on availability, experience, and ratings within the stipulated range by calculating shortest distance between User and Drivers using Haversine and Dijkstra's algorithms on the other hand, driver can manage their availability, and accept service requests. Safety and reliability are ensured through rigorous driver verification processes, including background checks and license verification. In case of emergencies, an emergency assistance feature allows users to quickly alert the support team and share ride details for prompt assistance. The platform incorporates advanced features such as real-time driver tracking, and notifications to enhance transparency and communication. Multiple payment modes, including card and cash, cater to diverse user preferences. The utilization of analytics for driver bookings offers valuable insights for optimization and service enhancement. By leveraging technology, this Android application redefines industry accessibility reliability, promising convenience, efficiency, and safety for all stakeholders involved.**

Keywords*— *Temporary Drivers, Android application, Haversine algorithm, Dijkstra's algorithm, Emergency Assistances, Real-time tracking.

I. Introduction

The traditional methods of accessing temporary driver services present several challenges, including fragmented experiences, inefficiencies, and safety concerns. These methods lack a centralized platform to connect customers with qualified drivers seamlessly. Furthermore, there is a lack of transparency and security in the hiring process, with minimal options for customers to verify driver credentials and track their journey progress.

This Android application revolutionizes the industry by providing a seamless, efficient, and secure platform that connects customers with skilled drivers, eliminating the fragmentation and inconvenience previously experienced. Through a detailed analysis of its core features, the research paper underscores the system's commitment to enhancing safety and security, evident in its stringent verification processes and emergency protocols. Furthermore, the paper explores how advanced functionalities such as real-time tracking and automated payments contribute to an improved user experience, while also highlighting the broader benefits for both customers and drivers, including transparency, fair wages, and flexible work opportunities.

Moreover, the research paper emphasizes the positive societal impact of the Temporary Driver Booking System revolutionizes the industry by providing a seamless platform connecting customers with skilled drivers, prioritizing safety [8], efficiency, and transparency. Through stringent verification processes, real-time tracking, and automated payments, it enhances user experience while fostering a more inclusive and sustainable transportation ecosystem, setting new standards for convenience and reliability.

II. Literature Survey

The traditional temporary driver booking system faces several challenges. Firstly, the market is fragmented, lacking centralized platforms, which makes it difficult for users to find reliable drivers and compare rates efficiently. The booking process is often inefficient, relying on manual methods that are time-consuming and prone to errors. Safety concerns arise due to unverified drivers and inadequate tracking mechanisms, raising questions about the safety. Moreover, limited payment options, primarily cash-based transactions, can be inconvenient and insecure for both users and drivers. Addressing these challenges requires innovative solutions that streamline the booking process, enhance safety measures, and offer more flexible payment options.

Self-owned System: If a fleet is planned with the help of temporary drivers, an auto-booking system streamlines the process for users. Instead call or email directly, users can book drivers directly through the app. This system facilitates direct booking for users, reducing the need for manual intervention. The project proposes a centralized platform connecting individuals seeking transportation with car rental services, enhancing their retention and simplifying the booking process.

It addresses common challenges in drivers hiring, such as added costs, driver cancellations, and long journeys. The project leverages SMS technology to provide notifications and integrates online frameworks to streamline the rental process, including vehicle information retrieval, reservation, and immediate leasing. Overall, this application aims to offers a practical and efficient method for hiring drivers, benefiting both users and drivers.

R. Sathya., et al. [1], Car Hiring System using Web Technology, have done a web application that utilizing recent technologies, the project simplifies car rental, addressing risks like added costs and driver cancellations. Instead, this application used to hire drivers for fulfilling customers' requirements if they have cars.

Furqan Talha., et al. [2], Emergency Vehicles Assistance System, have done the Road Vehicle Breakdown Assistance Finder web application utilizes GPS tracking and real-time communication to swiftly connect to distressed vehicle owners, with licensed mechanics, ensuring fair pricing and service quality. Additionally, proposed application provides emergency assistance which is a pre-composed text can directly send to get support.

Md Rayhan Hasnat., et al. [3] Development of an online based Driver Recruitment system, proposes the process of hiring drivers through interviews, providing an in-depth analysis of crucial elements such as job advertisement, application data management, interview coordination and scheduling, documentation of interview results, and the final candidate selection for employment. Furthermore, our paper proposes an extension of this process to facilitate the temporary availability of drivers.

Athira Krishnan T R ., et al. [4], Android-Based Transport Tracking and Monitoring System, have done the paper proposes a GPS-tracking application for buses, offering real-time location updates, route information, and estimated arrival times. It includes a comprehensive monitoring system for safety, engine fault detection, and efficient time management, suitable for deployment in both urban and rural transportation systems.

Harshada Shinde., et al. [5], Online Car and Driver Hiring System, paper introduces a novel system that grants the freedom to select both cars and drivers based on their preferences. In contrast to existing applications where users are unable to confirm prices in advance and must negotiate with drivers after making a booking, Proposed system enables to choose drivers based on their specific prices. Moreover, proposed application provides seamless payment options to enhance overall user experience.

V. Hemanth Kumar, K. Sentamilselvan, [6], Customer Satisfaction towards Call Taxi Services A study with reference to Chennai, this study investigates customer satisfaction with different call taxi service providers in Chennai, a major hub in the southern region. It delves into perceptions regarding the utilization of call taxi services, taking into account factors such as comfort, accessibility, pricing models, promotional strategies, safety precautions, convenience, and overall satisfaction with the quality of service offered by these companies. Building upon the findings of this research, proposed application gathers users feedback after the completion of a ride to improve safety and convenience further.

Uttam Pandey., et al. [7], Online Driver Booking Service, this paper introduces a system where users can easily book drivers from their homes by providing a few details through an online application. Once the booking is confirmed, users can begin their journey, and upon completion, the payment process is initiated. Driver searches are customized to align with the language preferences specified by customers. Proposed system enhances driver searches by utilizing both the shortest path and multi-conditional search algorithms to deliver the best available list of drivers.

Vijay Kumar A.G., Kumar U, [8], Profile of Fatal Road Traffic Accidents Due to Drunken Driving, this paper says that findings from the Alcohol & Drug Information Centre (AIDC) in India highlight a troubling pattern: around 40% of road accidents are linked to alcohol consumption. This risk is notably higher among young male drivers. The research emphasizes the substantial impact of alcohol use on fatal road accidents, especially in cases involving single vehicles and young male drivers. Proposed application aims to provide a solution for intoxicated individuals by enabling them to book a driver to safely operate their vehicle.

III. Methodology

The system architecture for a temporary driver booking platform comprises tailored components aimed at streamlining user interaction and service provision. Through a mobile application, users - both customers and drivers - engage with various functionalities such as registration, specifying transportation needs, driver selection, ride tracking, payments, and feedback provision. Behind the scenes, a robust database serves as a central repository for storing user, driver, vehicle, booking, and transaction data, ensuring seamless operation and data integrity.

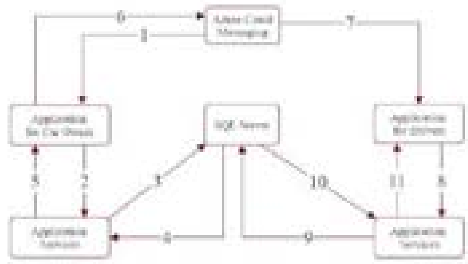

Fig. 1. Application Architecture

Additional modules include secure login/registration, driver profiles for informed decision-making, and transaction handling for financial operations. The Android application further enhances temporary driver bookings by allowing users and drivers to register with personal details and licenses. Users input ride details, and an algorithm matches them with available drivers based on various criteria, presenting a curated list of drivers ranked with the best match on top. Real-time journey tracking via GPS ensures transparency and safety, with emergency assistance features for quick contact with authorities if needed. Transparent fare calculation based on distance travelled is facilitated at the end of the journey, with options to store user preferences for future bookings and rate drivers to improve the ranking system. Additional communication features may enable interaction between users and drivers before the ride, optimizing overall efficiency and effectiveness of the temporary driver booking services.

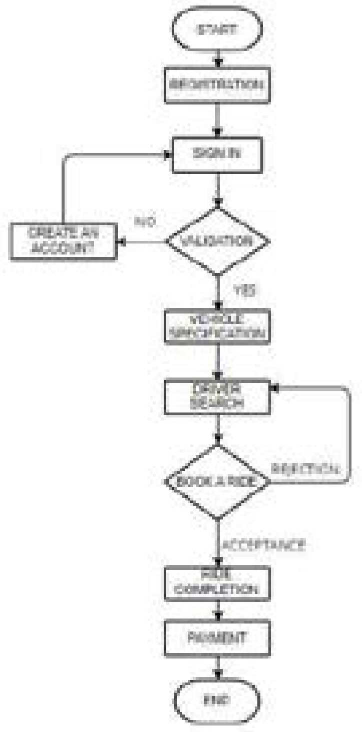

Fig. 2. Flow Chart

Driver.com is an android application for a temporary driver booking system that has two modules: driver and user. Driver registration can be done using personal details and a license. The driver needs to login with valid credentials for access.

User Module

A. Registration and Login Screen

Users will initiate their journey with our Android application by either logging in or signing up to create a new account. Upon successful registration, they gain access to our application's features. During the registration process, users are prompted to provide all necessary details, Users will be directed to the login screen shown in Figure 3.

B. Driver Availability Screen

On this screen, users can easily browse and access the list of drivers based on various criteria such as ratings, number of days available for rides, car models, and more. Users have the flexibility to select from a diverse range of options, as illustrated in Figure 4. Once users find a driver of interest, they can view the fare associated with that particular driver. The user can hire a driver by entering details of the ride. The user will get a list of available drivers with their details

Algorithms

i) *Driver Selection by the User*

- Enter the User's vehicle details.
- Select the driver based on driver's experience, route, source, destination and rating using multi-conditional search.
- Nearest drivers list is obtained by calculating distance between user and drivers using Dijkstra's algorithm, which finds the shortest distance. The input for Dijkstra's algorithm is obtained from Haversine algorithm.
- Drive cost is calculated based on the distance and time.

ii) *Haversine algorithm*

- Retrieve driver and user locations from google maps.
- Convert the latitude and longitude values from degrees to radians.

$$rad\_lat = latitude \times \frac{\Pi}{180} \quad --\rightarrow \quad eq(1)$$

- Calculate the differences in latitude and longitude.
- Haversine formula to calculate the distance between the two points.

$$a = sin^2\left(\frac{\Delta lat}{2}\right) + cos(latA) \times cos(latB) \times sin^2\left(\frac{\Delta \mathrm{lon}}{2}\right) \quad --\rightarrow \quad eq(2)$$

$$c = 2 \times atan2\left(\sqrt{a}, \sqrt{1-a}\right) \quad --\rightarrow eq(3)$$

$$d = R \times c \quad --\rightarrow eq(4)$$

- Where
  - Δlat is the difference in latitude (delta_ latitude),
  - Δlon is the difference in longitude (delta_ longitude),
  - R is the radius of the Earth (approximately 6,371 kilometres or 3,959 miles),
  - a is the intermediate result,
  - c is the great-circle distance in radians, and
  - d is the distance between the two points in the same units as the Earth's radius.

Let

latA = 12.965835163156859,

lonA = 77.57453865017378

latB = 13.626971577753114

lonB = 79.41860086877251

By using eq(1) convert latA, lonA, latB, lonB values from degrees to radians values after converting:

latA = 0.226296513739

latB = 0.237835520971

lonA = 1.353931114389

lonB = 1.386116071697

Then by substituting the values in eq(2) value

a = 0.00027852683

by substituting the values in eq(3) value

c= 0.03892638518

by substituting the values in eq(4) value

d=248 KM

iii) *Dijkstra's Algorithm*

Step 1: Start by selecting the user's location as the source node in the graph.

Step 2: Set the distance of all other nodes (drivers' locations) to infinity with respect to the user's location.

Step 3: Create an empty set called 'N' to store nodes for which the shortest path has been found

Step 4: Assign a distance of zero to the user's location. Add it to set 'N' and designate it as the 'active node'

Step 5: Look at the neighbouring nodes of the active node, i.e., the drivers' locations, which are connected by weighted edges (distances between geographical coordinates). Calculate the total distance from the user to each neighbouring driver by using Haversine's algorithm.

Step 6: If a neighbouring node already has a distance assigned, compare the newly obtained distance (from step 5) with the current value. Update the distance if the new distance is shorter.

Step 7: Select the driver's location with the minimum distance assigned to it. Insert this node into set 'N', making it the new 'active node'.

Step 8: Repeat steps 5 to 7 until either the destination node (the nearest driver) is included in set 'N', indicating that the shortest distance has been found, or if there are no more labelled nodes (unvisited drivers' locations) in set 'N'.

The process begins by treating the geographical locations of both the driver and the user as nodes within a graph, where each node is uniquely identified and stores its respective latitude and longitude coordinates. Utilizing the Haversine formula, distances between every pair of nodes are meticulously calculated, thereby establishing the weights of the edges in the graph. Armed with this information, a comprehensive graph structure is constructed, interconnecting each node with its adjacent nodes based on the derived distances. Subsequently, Dijkstra's algorithm is employed to effectively determine the shortest path between the starting and destination nodes. Upon completion of the algorithm's execution, the shortest path, comprising a sequential arrangement of nodes, is extracted from its output. Finally, the cumulative distance along this optimal path is computed by aggregating the distances between consecutive nodes. This meticulous process culminates in the determination of the shortest distance between the driver and the user, facilitating efficient navigation.

C. *Booking screen*

On the Booking Screen, users have the opportunity to select their preferred driver from the list. They can proceed by filling out a form with details such as the date, time, location, and duration of the driver's hire, as depicted in Figure 5. The best match will come on top in decreasing order. The user can select one of them from the list of drivers. An emergency assistance is embedded in the application. The distance travelled is calculated with the help of integrated Google Maps API into the application. This process allows users to finalize their booking seamlessly and efficiently.

D. *Payment screen*

In the Payment Module, once users or customers have provided all the required details, they can proceed to make their payment. This module supports various payment methods such as Phone Pe, Google Pay, credit/debit cards, and more. Users have the flexibility to choose the payment method that best suits their preferences, ensuring a convenient and hassle-free transaction process. After the payment is completed, the ride will be confirmed.

Driver Module

A. *Registration and Login screen*

Drivers will initiate their interaction with our Android application by either logging in or signing up to establish a new account. Once registered, they gain access to our application's functionalities. During the registration phase, drivers are prompted to furnish all necessary details to complete the process.

B. *Ride details screen*

The ride details screen provides comprehensive information about the upcoming trip, including pick-up and drop-off locations, passenger details, and any special instructions. It serves as a central hub for drivers to access essential ride information and manage their schedules efficiently.

IV. RESULTS & DISCUSSION

These are the screens that are provided in the application which help the user and driver to interact with the application.

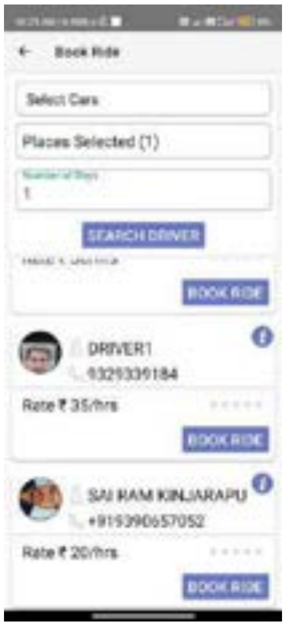

Fig. 3. Driver selection screen of the application

The user registration screen enables new users to create an account within the application. Its components consist of input fields and a submit button. Input fields typically include username, email address, password, and possibly additional details such as name, date of birth, etc. The submit button allows users to submit their registration details.

The login screen allows registered users to access their accounts by providing their credentials. Its components consist of input fields, a "forgot password" link, and a submit button. Input fields usually include fields for username/email and password. The "forgot password" link is an option for users who have forgotten their password to reset it. The sign-in button allows users to submit their login credentials.

The ride booking feature in the Android application for the temporary driver booking system enables users to easily book a driver for their transportation needs. Here's a brief description of the process:

Select Type of Place or Route: Users can specify the type of route they intend to travel. Options such as High Pass Roads, Mountain Ranges, Hill Station custom routes may be available for selection.

Fig. 4. Ride confirmation screen of the application

Select Driver from Available Drivers: Users can choose a driver based on preferences such as rating, vehicle type, or availability. List of available drivers with details such as name, rating, vehicle model, and possibly distance from the user's location. Pickup Location: Users provide the location from where they want the driver to pick them up. Input field or map interface allowing users to specify their current location accurately. Destination: Users specify the destination where they wish to be dropped off. Input field or map interface for users to input the destination address.

Users select the preferred payment method and confirm the booking. Options for payment methods such as credit/debit card, mobile wallet, or cash on delivery. Users may also see the estimated fare before confirming the booking.

Once all the necessary details are provided and the booking is confirmed, the system assigns the selected driver to the ride, and both the user and the driver receive confirmation notifications. The driver then proceeds to the pickup location, and the user can track the driver's location in real-time. After reaching the destination, the payment is processed, and the ride concludes.

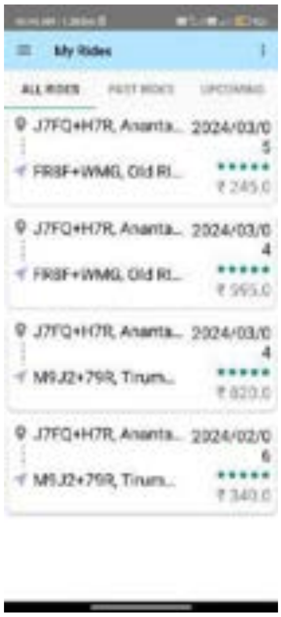

Fig. 5. Ride history screen of the application

The "My Rides" section within the Android application of the temporary driver booking system provides users with a comprehensive history of their past rides, offering convenience and transparency. Here's a brief description:

Fig. 6. Transaction history screen of the application

"My Rides" serves as a centralized location for users to review their entire ride history, facilitating easy access to past bookings and relevant details. Its components consist of a list of past rides and a list of upcoming rides. The list of past rides displays a chronological list of all previous bookings made by the user, while the list of upcoming rides displays a chronological list of all upcoming bookings made by the user.

This ride booking feature simplifies the process of hiring a temporary driver, providing users with a convenient and efficient means of transportation within the temporary driver booking system application.

The "My Transactions" feature provides users with a comprehensive view of their financial activities related to the booking services. Here's a brief description:

"My Transactions": This section serves as a ledger for users to track their financial interactions within the temporary driver booking system. Its components consist of transaction history and details. Transaction History presents a chronological list of all financial transactions associated with the user's account, including payments for bookings and any refunds or credits. Each transaction entry typically includes details such as the date and time of the transaction, the amount paid or received, and any relevant notes.

The user transactions and ride history will be maintained in the database for further analysis and reference. After completion of the ride, the user will be asked for feedback on the ride experience. The data collected from the user feedback will be used to rate the driver using a Moving Average.

To ensure security of the both user and driver an emergency assistance feature included in the application. It is a pre-composed text requesting for the assistance which can be directly send through platforms like WhatsApp, Gmail, and messenger.

The ability to store user preferences for future bookings and transaction history add convenience and personalized the user experience. Additionally, the rating system facilitated user-driver interactions, allowing users to provide feedback and improve the overall quality of service.

Through Dijkstra’s algorithm distance is calculated accurately. As driver booking is done based on driver’s authentication through driving licence and choosing a driver based on availability, experience, and price, which proves the efficiency.

The App is validated by choosing few rides and distance calculations are matching with physical distances in real-time.

V. CONCLUSION & FUTURE WORK

This research investigates the development and potential implications of an Android application designed for temporary driver bookings. The application sought to overcome the shortcomings of current solutions by providing a seamless, safe, and user-oriented experience for both users and drivers. The key objectives included enhancing the efficiency of the booking process, ensuring platform security, and prioritizing user satisfaction. Through a comprehensive analysis, the study aimed to elucidate the innovative features and potential impact of the proposed application on the transportation service industry. The Android application for temporary driver booking aims to consistently enhance its features to remain competitive in the industry and provide the best user experience. This application provides emergency assistance for both driver and user to enhance security. Developing functionalities specifically for the admin role, allowing for better management and oversight of the platform. Enhancing the user interface and user experience design to make the application more visually appealing, intuitive, and user-friendly, ultimately increasing its significance and appeal to users.

***Abstract*— This research study describes the integration of big data analytics to develop a novel and robust e-commerce recommendation system. Acknowledging the challenges associated with providing accurate and timely suggestions, advanced recommendation algorithms, and the utilization of big data analytics tools. This study employs a comprehensive methodology, beginning with the characterization of the e-commerce dataset. As a first step, this study explains the data pre-processing steps undertaken to ensure the quality and relevance of information. The proposed recommendation system design incorporates state-of-the-art algorithms. Implementation details describe the practical aspects of deploying the recommendation system in an e-commerce environment, including the challenges encountered and their resolutions. The results section presents key findings, supported by visual representations and performance metrics that gauge the effectiveness of the proposed system. Through a thoughtful discussion, this study contextualizes the results within the broader landscape of e-commerce recommendation systems and big data analytics. Drawing comparisons with existing literature, this study highlights the significance of various research contributions and identify opportunities for future research. In conclusion, this research not only provides insights into optimizing e-commerce recommendations but also contributes to the ongoing research on leveraging big data analytics in enhancing user engagement and satisfaction.**

***Keywords*— Diabetes Prediction, Machine learning, Healthcare analytics, Decision trees, Support Vector Machines.**

I. Introduction

In the dynamic world of online commerce, where choices are abundant and time is limited, the role of recommendation systems has become increasingly crucial. These systems serve virtual shopping assistants, helping users discover products tailored to their preferences and needs. In the vast sea of available options, customers often find themselves overwhelmed, and this is where recommendation systems step in, offering personalized suggestions.

Understanding the importance of these systems involves recognizing their ability to bridge the gap between consumers and a myriad of available products. As e-commerce platforms continue to grow, the challenge lies not only in providing an extensive array of choices but also in helping users navigate through this abundance.

Despite the undeniable benefits of recommendation systems in e-commerce, several challenges persist in delivering recommendations that are truly effective and resonate with users. One major hurdle lies in the complexity of user preferences, which can be dynamic, diverse, and often challenging to accurately predict. The ever-evolving nature of consumer tastes and trends adds an additional layer of complexity, making it difficult for traditional recommendation approaches to keep pace [1].

The "cold start" issue presents another difficulty, especially for new users or objects for which there is insufficient previous data to enable the system to produce pertinent recommendations. In certain situations, the algorithm has trouble anticipating and comprehending human preferences, which results in recommendations that are less precise. Furthermore, problems with data sparsity, in which there is little to no data available for certain items or user preferences, might make it more difficult for the system to make thorough and trustworthy suggestions.

The environment is made more difficult by privacy issues, as people are growing increasingly hesitant to provide personal information. A difficult problem for e-commerce recommendation systems is to strike a balance between the requirement for individualized recommendations and the obligation to preserve user privacy. Furthermore, there is also worry about how recommendation algorithms can scale to handle enormous datasets effectively, especially in light of the rapid expansion of e-commerce platforms and user interactions [2].

Scope and Limitations:

1) Scope:

The objective of our study is to enhance the accuracy and efficacy of tailored product recommendations in e-commerce by integrating big data analytics into recommendation systems [5]. The scope of this project involves creating and using sophisticated recommendation algorithms to tackle issues like the "cold start" problem, data sparsity, and finding the right balance between personalization and user privacy. The study also investigates the scalability of recommendation algorithms, assuring their effectiveness in managing the increasing amounts of data created by the ongoing expansion of e-commerce platforms.

2) Limitations:

Despite our comprehensive approach, certain limitations exist within the scope of this study. The generalization of findings may be constrained by the specific characteristics of the dataset utilized, and the effectiveness of the proposed solutions could vary based on the nature and scale of different e-commerce platforms. Additionally, while our research aims to address the "cold start" problem, complete mitigation may not be achievable in all circumstances, especially in cases where minimal historical data is available [6].

II. LITERATURE REVIEW

A. E-commerce Recommendation Systems:

The literature on e-commerce recommendation systems demonstrates a diverse range of studies, highlighting the crucial impact these systems have in the online retail environment. Preliminary research frequently concentrated on collaborative filtering and content-based recommendation methods. Collaborative filtering utilizes user behavior and preferences, whereas content-based techniques examine item properties. Over time, there have been the emergence of hybrid models that try to combine both techniques in order to use the advantages of each.

Recent progress has shown the use of sophisticated deep learning methods, such as neural networks, to accurately detect complex patterns in user behavior. Furthermore, there has been a growing interest in context-aware recommendation systems, which take into account several parameters such as user location, device, and time in order to improve the accuracy and appropriateness of suggestions. These studies highlight the ongoing development of recommendation algorithms to adapt to the ever-changing nature of e-commerce platforms.

B. Big Data in E-commerce:

Existing research works have analysed the difficulties and advantages presented by large amounts of data in online commerce, such as preparing the data, analyzing it in real-time, and ensuring it can handle increasing amounts of data. The utilization of cloud computing and distributed computing architectures has been investigated to address the computational requirements of extensive e-commerce activities. The literature highlights the significance of big data in revealing concealed patterns, forecasting user behavior, and enhancing many areas of e-commerce. This lays the foundation for our investigation into its incorporation with recommendation systems [7].

C. Integration of Big Data into E-commerce Recommendation Systems:

The intersection of e-commerce recommendation systems and big data analytics is a relatively new but quickly growing field of study. Recent studies acknowledge that recommendation algorithms may be significantly enhanced by using the potential of big data. The integration facilitates a more sophisticated comprehension of user preferences, surmounting obstacles such as the "cold start" issue and data scarcity.

D. Algorithms, Techniques, and Methodologies in E-commerce Recommendation Systems:

Collaborative filtering continues to be a fundamental aspect in the work on recommendation systems. User-based collaborative filtering utilizes the preferences and actions of comparable users to provide suggestions. Item-based collaborative filtering, however, determines commonalities between objects by analyzing user interactions [8]. These algorithms encounter difficulties when dealing with sparse datasets and the "cold start" problem, which refers to the absence of adequate data for reliable suggestions for new users or objects.

Content-based filtering is a method that examines the characteristics of things and the preferences of users in order to provide suggestions. This strategy employs elements such as item descriptions, user profiles, and past interactions to provide tailored recommendations. Nevertheless, it may encounter difficulties in comprehending intricate user preferences and has a tendency to suggest goods that are like to those previously chosen by the user.

Hybrid models leverage the capabilities of both collaborative filtering and content-based filtering. Weighted hybrid models provide distinct weights to collaborative and content-based components, determined by their respective performance. Hybrid models seek to alleviate the constraints of separate methods, offering more resilient and precise suggestions.

Matrix factorization methods, such as Singular Value Decomposition (SVD) and Alternating Least Squares (ALS), break down the matrix representing the interactions between users and items into hidden elements. The latent variables in question capture the hidden patterns in user preferences and item features, resulting in more precise suggestions. Matrix factorization has demonstrated efficacy, particularly in managing datasets with low density and enhancing the precision of recommendations.

In recent years, deep learning techniques, specifically neural networks have become increasingly prominent. Collaborative and content-based neural networks can detect complex patterns in user behavior and item attributes, enabling more advanced and context-aware suggestions. Deep learning models frequently surpass standard approaches in effectively managing intricate connections throughout extensive datasets.

Context-aware recommendation systems include further contextual information, such as user location, time, and device, in order to customize suggestions with more precision. These systems optimize customization by tailoring suggestions to the user's unique context, enhancing the pertinence of recommendations in dynamic situations.

E. Integration of Advanced Algorithms with Big Data Analytics:

Although previous research acknowledges the importance of big data in e-commerce recommendation systems, there is a noticeable lack of integration between cutting-edge recommendation algorithms and advanced big data analytics methodologies. Our study aims to close this divide by investigating how the combination of advanced algorithms and the analytical capabilities of large datasets might enhance the precision and efficacy of tailored product recommendations [9].

F. Scalability of Recommendation Algorithms in Real-Time Environments:

The scalability of recommendation algorithms, especially in real-time situations with dynamic user interactions, is an area that current literature may further improve upon. Our research aims to fill this void by assessing the effectiveness of recommendation algorithms using big data technologies, assuring their capacity to manage the constantly expanding amounts of data produced by the ongoing expansion of e-commerce platforms [10].

G. Comprehensive User Understanding through Big Data Analytics:

Although current research delves into user behavior and preferences, there is still an opportunity to gain a more thorough knowledge of people by utilizing big data analytics. This study focuses on analysing user interactions, transactional data, and contextual information to gain a better understanding of recommendation systems. By extracting more profound insights, we strive to improve and enhance these systems over time. A graphical comparison of the identified research gaps and the research contribution areas is depicted in figure 1.

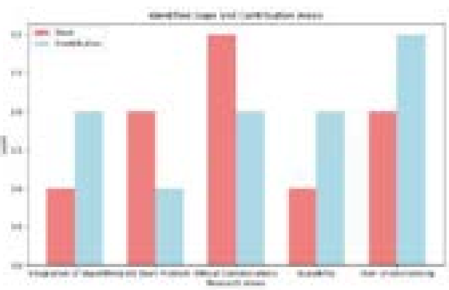

Fig.1 Gaps in the Areas

III. METHODOLOGY

A. Describing the Dataset:

To improve e-commerce recommendation systems using big data analytics, it is crucial to provide a detailed description of the dataset. This ensures transparency, repeatability, and a thorough knowledge of the study's basis [11].

B. Source of the Dataset:

The e-commerce dataset under scrutiny for this research has been meticulously curated from a diverse range of online retail platforms, encompassing various product categories and user demographics. The dataset amalgamates transactional data, user profiles, and contextual information to construct a holistic representation of the intricate dynamics inherent to e-commerce interactions.

C. Characteristics of the Dataset:

1) Transactional Data:

The dataset encapsulates a vast array of transactions, each entry detailing the purchase history of users. This includes information such as product IDs, quantities purchased, and timestamps, providing a temporal dimension to user interactions.

2) User Profiles:

User-centric details are a crucial part, encompassing information such as user IDs, demographic characteristics, and past preferences. These specific facts enhance the customization part of the recommendation system by aiding in the comprehension of unique user actions.

3) Contextual Information:

Recognizing the significance of context in e-commerce interactions, the dataset encompasses contextual elements. These may include user locations, device types, and time stamps, offering valuable insights into the circumstances surrounding each transaction.

4) Data Volume and Scalability:

The dataset is sufficiently large to emulate the scale of real-world e-commerce platforms, ensuring that the recommendation system's performance and scalability can be rigorously evaluated. It accommodates the intricate interplay of variables while simulating the challenges posed by substantial user bases and transaction volumes.

5) Data Preprocessing:

Prior to the implementation of recommendation algorithms, extensive data preprocessing measures are applied. This encompasses cleaning procedures to handle missing or erroneous entries, normalization to ensure consistency in data formats, and the anonymization of sensitive information to align with privacy considerations.

6) Dataset Splitting:

In order to ensure a thorough assessment of the recommendation system's effectiveness, the dataset is divided into training, validation, and testing sets using a stratification method. This guarantees that the model is trained using a wide range of user behaviors, validated to find the best hyperparameters, and thoroughly tested to evaluate its ability to generalize [12].

D. Recommendation System Design:

The design of our e-commerce recommendation system incorporates the strategic integration of innovative algorithms and techniques, as well as the utilization of big data analytics for the purpose of improving accuracy and personalization [13]. The implementation of our recommendation system involved an integration of algorithms and big data analytics tools.

IV. RESULTS & DISCUSSION

The findings show that the recommendation algorithms can be successfully integrated with big data analytics in e-commerce. The development and assessment of the recommendation system produced informative data, allowing for a more nuanced knowledge of user preferences and system performance.

A. Recommendation Accuracy:

The recommendation system exhibited a commendable level of accuracy, as indicated by the Root Mean Squared Error (RMSE) metric. The accuracy comparison of the three experiments carried out is given below in figure 2:

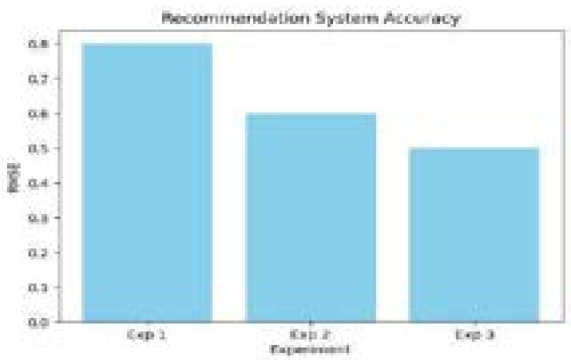

Fig.2 Performance Metrices

Collaborative filtering, content-based filtering, and hybrid models demonstrated robust performance in capturing user preferences. The integration of matrix factorization and deep learning techniques contributed to a more comprehensive understanding of intricate patterns within the dataset [15]. The hybrid method effectively solved the "cold start" issue by making relevant suggestions even for new users or goods with insufficient previous data. Content-based suggestions proved useful in several circumstances, offering a tailored experience from the start.

The addition of contextual information, such as user location and time, dramatically increased the relevancy of suggestions [16]. Users received more personalized suggestions based on their individual situations, resulting in a more interesting and tailored buying experience.

Leveraging big data technologies, including Apache Spark, ensured the scalability and efficient processing of recommendation algorithms. The system demonstrated the capability to handle large-scale e-commerce datasets, meeting the demands of real-time recommendation generation.

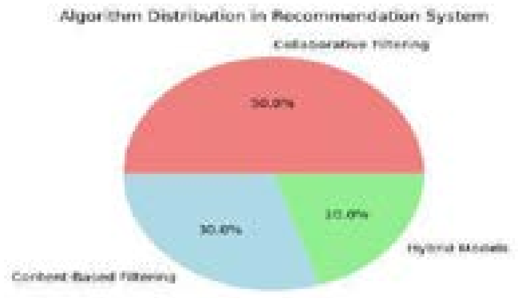

Fig.3 Distribution of different algorithms used in recommendation system.

Figure 3 depicts the distribution of different algorithms used in recommendation system. The implementation of differential privacy techniques and transparent disclosure practices addressed user privacy concerns. The recommendation system prioritized the ethical handling of user data, establishing a foundation for trust and transparency [17].

These results collectively highlight the effectiveness of our recommendation system, highlighting its potential to elevate the e-commerce user experience. The successful integration of advanced algorithms with big data analytics not only improves recommendation accuracy but also establishes a foundation for responsible and user-centric data practices in the evolving landscape of online commerce.

V. CONCLUSION

The successful management of the "cold start" problem, as well as the inclusion of contextual information, helped to provide a customized and engaging user experience. Furthermore, ethical issues, such as user privacy measures, guaranteed appropriate data practices. The generalizability of the findings may be constrained by the specific characteristics of the dataset used. The effectiveness of the recommendation system is contingent on the quality and representativeness of the data, and variations in user behavior across different e-commerce domains may impact the system's performance. Moreover, while the integration of big data analytics enhances scalability, real-time processing efficiency, and context-aware recommendations, there may be challenges in optimizing these aspects for diverse e-commerce platforms.

In conclusion, our research marks a significant step toward advancing recommendation systems in e-commerce. While celebrating the achievements, recognizing limitations, and charting pathways for future exploration are crucial for the continued evolution of personalized and effective e-commerce experiences.

***Abstract*—In modern image acquisition and transmission, a crucial task is image denoising, particularly in fields like medical imaging (e.g., MRIs, CT scans, and ultrasounds) and surveillance (e.g., CCTV and video surveillance). The challenge lies in effectively locating and removing noise from images while preserving essential signal properties. To address this, a VLSI architecture is proposed, aiming to minimize noise in images while prioritizing speed. Unlike previous methods that relied on multipliers, the proposed approach utilizes distance matrix techniques for both bilateral and median filters. This technique not only reduces noise but also enhances processing speed, making the VLSI architecture more efficient. The proposed hardware design is implemented on a Spartan 6 FPGA kit to measure parameters such as power consumption, processing speed, and area usage, ensuring its practical viability and effectiveness.**

Keywords—FPGA, Image processing, Median filter, VLSI architecture

I. Introduction

Image denoising is a crucial task aimed at estimating the original image by suppressing noise, particularly challenging in image processing and computer vision. Among various denoising techniques, median filters stand out for their effectiveness in reducing noise without sacrificing image details. These filters are widely employed due to their remarkable performance in eliminating noise from images. However, to enhance efficiency further, a highly efficient VLSI architecture for median filters is proposed for denoising purposes. This advanced architecture aims to improve the performance of median filters, allowing for more effective noise reduction while preserving image quality. The proposed VLSI architecture enables the evaluation of performance metrics such as speed, power consumption, and area usage, facilitating a comprehensive analysis of denoising effectiveness compared to conventional methods. By leveraging this advanced approach, the challenge of image denoising can be addressed more efficiently, leading to improved results in various applications.

II. Literature Review

F. Spagnolo et al.(2023) emphasized the contemporary significance of streamlining computing complexity and minimizing power consumption. This research marks a significant stride in addressing computational challenges while preserving data fidelity, especially In image processing and filtering techniques, the Peak Signal-to-Noise Ratio (PSNR) serve as crucial metrics for assessing the quality of processed or filtered images [1].

G. D.-G. Kim et al.:(2021)suggested eliminating the impulse noise (IN) and gaussian (AWGN) in order to solve the image resortation issues.The AWGN and SPIN values are then measured to generate the AMNLRA [2].

Changmeng Peng, Maohan Xia, Zhizhong Fu, Jin Xu, and Xiaofeng Li: (2021) Considering deep learning has caused an enormous evolution in society, the author suggests improving the bit depth and quality of the images.It comprises three key modules: adaptive iteration number selection based on content, iterative false contour eliminationthen comparing the output of several algorithms, such as ZP, BR, MRC, and ACDC, whose goal is to calculate the PSNR and SSIM[3].

Qingyu Xu, Longguang Wang, Yingqian Wang, Weidong Sheng, and Xinpu Deng:(2021) Restoring an image's original information is a major processing challenge.The suggestion made by the author entails creating high-resolution (HR) images by reconstructing from a pair of low-resolution images.The Nvidia GTV 3090 GPU can be used to execute the notion in Pytorch[4].

Qiubo Hu, Wenxiang Xu, Xiaobo Liu, Zhihua Cai,and Junjie Cai :(2022) There are three steps in the suggested process. Firstly, the original HSI is subjected to principal component analysis (PCA) to yield multiple components that contain nearly all of the information. F Particularly when contrasted with our major reference object, BF, the suggested technique worked admirably and was successful in categorizing HSIs with the maximum accuracy [5].

Chih-Yuan Lien, Chi-Huan Tang, Pei-Yin Chen, Yao-Tsung Kuo, Yue-Ling Deng The techniques employed reduce the number of multipliers and memory space needed is accomplished by applying LUT reduction, resource sharing, and distance-oriented grouping. The findings demonstrate that the suggested architecture is more economical and requires less memory and multipliers [6].

Satyajit Bora, Roy Paily(2021) The Baugh Wooley, Booth, veddic multiplier, and 32-bit Radix-16 Divider are methodologies used in the architecture. While using the ULVt variant can result in greater frequency performance, power losses are also increased [7].

M. Monajati and E. Kabir (2020) The algorithm employed inexact median filtering. A MATLAB comparison was conducted on Peak Signal-to-Noise Ratio (PSNR) using various inexact filters for images. The mean PSNR of the test images was determined based on the MF values.The output image quality is slightly inferior to that of the exact filter, the disparity is minimal and hardly discernible to the human eye [8].

K. Mishiba(2023) The proposal introduces an innovative weighted median filter designed to address challenges related to histogram construction, ensuring real-time processing capabilities for higher resolution images and complex multidimensional, multichannel. Moreover, the proposed method is adaptable for both CPU and GPU implementations, enabling faster computation speeds than traditional weighted median filters [9].

III.METHODOLOGY

Different types of filters are considered in this research study, they are linear and non-linear filters. This study mainly focuses on non-linear filters because they are preferred in VLSI image processing due to their robustness to outliers, edge preservation, and adaptability to local variations in images.

a) LINEAR FILTER

A linear filter is an instance of image processing filter in which the local neighborhood's weighted sum of the input pixel values is the output pixel value.

b) NON-LINEARFILTER

A non-linear filter is an image processing filter that considers the local arrangement and values of pixels in a neighbourhood, and the output pixel value is determined by a non-linear function of these values.

BLOCK DIAGRAM

This section will provide an overview of the system depicted in Fig 1.1.The main objective of this system is to remove noise from input images and enhance image quality in both videos and images. The proposed system is composed of several elements, including the input image and its resizing to optimize computational efficiency, image processing procedures aimed at enhancing image quality, and segmentation techniques utilized to extract useful objects while removing unwanted background.

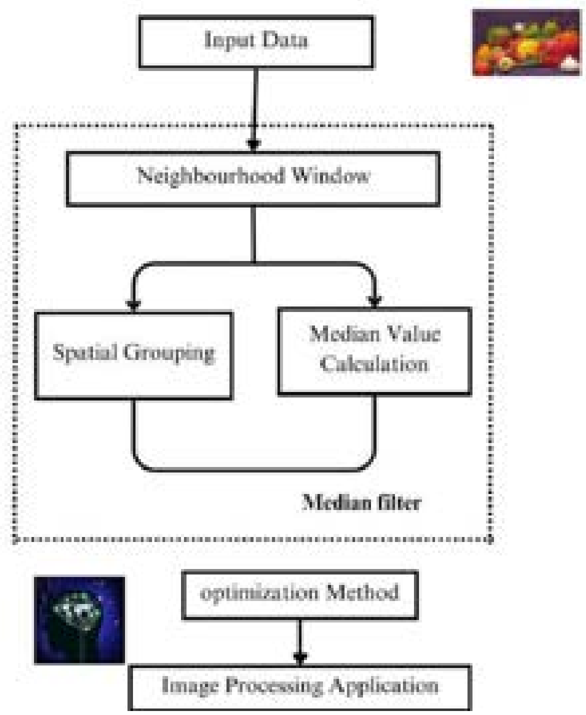

Fig.1.1Block Diagram for Proposed Filter Architecture

The image data is first transformed into binary format using MATLAB, employing a technique based on neighborhood window analysis. This involves configuring a window size and establishing spatial grouping within it. Subsequently, the median value is computed using a specified equation. The resulting data is then utilized in a VLSI architecture, where metrics such as power consumption, area coverage, and processing speed are evaluated.

a) EXISTING METHOD

All digits in the current system have the same weight and are processed using a stochastic technique based on uniformly distributed unknown bit streams. Numbers are encoded based on the likelihood of producing a one in the stream as opposed to a zero, and are limited to the [0, 1] interval. The CAS Network is shown in a conventional manner.

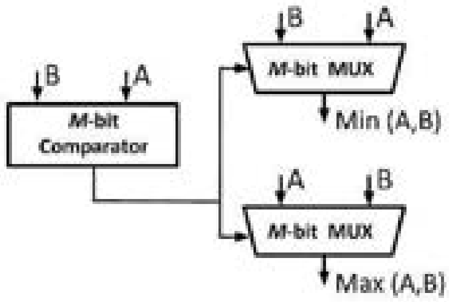

Fig 1.2 Existing Method of CAS Network

As shown in fig 1.2, in this existing method, a conventional binary design is used. The existing system drawbacks are less compact, high cost, less accuracy.

b) PROPOSED METHOD

The center pixel of each window is recommended to be passed through predefined threshold values of "0" and "255," which are predetermined before the procedure starts, in order to identify noisy pixels. The center pixel value is regarded as noise-free and is not altered if it lies between these criteria. If not, the threshold is set based on the window's median value. The fourth or sixth pixel in the sorted list is used to replace the center pixel if the median is noise-free. A decision-based strategy is used if the median is noisy. In this instance, if both the fourth and sixth pixels are noisy, the center pixel of the sorted list is substituted with the mean of the first three pixels.

The median filter replaces noisy pixel values with the adjacent window's median value. It is an essential non-linear filter for eliminating impulse noise. When calculating the median for odd-sized windows, all pixels are sorted in ascending order, and the middle value is used to determine the window's median.

c) PROPOSED ALGORITHM

i) From a noisy image, select a 3x3 window.

ii) Set starting threshold values of "0" and "255," which are fixed threshold values. Next, determine the noisy image's pixel value.

iii) Hold onto the pixel as noise-free and unaltered if its value is between larger than 0 and less than 255.

iv) Replace the center pixel with the related window's median value if it is noise-free if the pixel value is equal to "0" or "255."

v) If the median is determined to be noisy, swap out the central pixel for the median's nearby pixel values. The fourth and sixth pixels in the sorting list are referred to as the surrounding pixels.

vi) Substitute the mean value of the first, second, and third pixel values in the sorted list for the center pixel if the surrounding pixels are also thought to be noisy.

$$\text{Median}(M_{x)}= \left\{ \frac{n+1}{2}, \text{if n is odd} \right. \quad (4)$$

IV. FILTER EVALUATION

This segment assesses the filter using a variety of commonly employed grayscale images. The performance of the newly introduced filter with a 3x3 window size is depicted in Fig 1.5

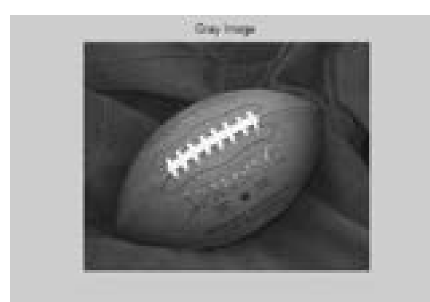

Fig 1.5 Input image

IMLEMENTATION AND RESULTS

The suggested filter undergoes simulation in the MATLAB and is subsequently converted into binary format via ModelSim. The hardware realization is executed on a Spartan 6 FPGA board employing Xilinx 9.1 design software. The performance of median and bilateral filters was compared based on PSNR and SNR values. In parallel, Xilinx software was employed to gauge the speed, area, and power efficiency of the median filter, leveraging a sorting algorithm. This methodology provides a comprehensive assessment of the filters efficiency and computational characteristics.

MATLAB OUTPUT

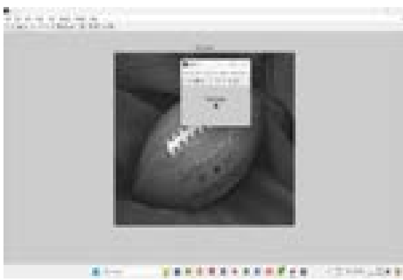

Fig 1.6 Adding of noise with Denoised image

The MATLAB procedure begins by accepting image data in its original format, which is then converted into binary form for processing. The code includes functionality to compute the Signal-to-Noise Ratio (SNR) and Peak Signal-to-Noise Ratio (PSNR) values based on the input image. Additionally, the algorithm incorporates a logic for removing salt and pepper noise from the image, employing a median filter for denoising purposes. The resulting image, termed as the "denoised image," is produced through the implementation of Algorithm.

MODELISM OUTPUT

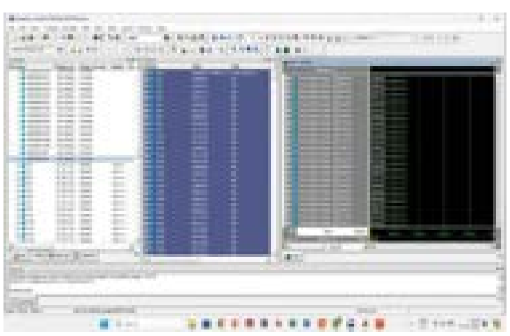

Fig 1.7 3x3 Conventional Output for median filter

In this software, the input text file that is in the form of binary an input is kept and the matlab code is converted into verilog code in the fig 1.5 and the graph must be taken in the area by using modelism can calculate the 3x3 conventional method. Again, the data must be stored in the output file in respect to the spatial grouping algorithm and sorting methods.

V CONCLUSION

This research illustrates superior performance of the filter compared to a basic median filter across various noise ratios, effectively preserving signal content. Particularly in scenarios with higher noise ratios, the filter achieves improved Peak Signal-to-Noise Ratio (PSNR) values. Moreover, the research proposes a more efficient approach for implementing sorting networks using unary processing. Traditional sorting networks often incur high hardware costs and power consumption, thus limiting their practicality. Proposed hardware filter design is implemented on a Spartan6 FPGA Kit, demonstrating significant area and power compared to conventional weighted binary implementations.

VI FUTURE WORKS

Future research in this field should prioritize the enhancement and extension of the proposed hybrid denoising method. This can be achieved by delving into advanced deep learning architectures, utilizing larger and more diverse datasets for model training, and refining VLSI implementations to ensure scalability and adaptability. It's worth noting that as input data resolution increases, the VLSI cost rises considerably. Therefore, a user-centric approach would also involve exploring real-time feedback mechanisms and integrating user preferences to customize denoising results. Additionally, future endeavors may focus on implementing a modified threshold-based median filter to improve signal-to-noise ratio while minimizing hardware resource consumption.

***Abstract*— The efficient functioning of public transportation systems is pivotal for societal connectivity and economic progress, as they serve as lifelines for commuting and mobility. However, the dependency on manual ticketing processes often leads to bottlenecks and inefficiencies, hindering smooth operations and customer satisfaction. This research work focuses on developing an Automated Ticketing System for public transportation, utilizing Computer Vision and Neural Networks. Through the incorporation of Neural Architecture Search and the integration of Deep Sort, a Deep Learning-based object tracking model, with aim to enhance system efficiency. The study demonstrates promising results, indicating the potential for streamlined ticketing processes in public transportation.**

Keywords—Computer Vision, Neural Networks, Neural Architecture Search, Deep Sort, Deep Learning, Object Tracking, Public Transportation Ticketing.

I. Introduction

Transportation systems, being vital to the global economy, serve as its lifeblood by facilitating the movement of people and goods. A country's development hinges on the efficiency and connectivity offered by public transport. Unfortunately, obsolete ticketing processes often limit the performance of these services. Currently, passengers must navigate cumbersome booking procedures, which involve queuing at physical ticketing counters or vending machines to purchase tickets. This process not only consumes valuable time but also requires passengers to carry and keep track of physical tickets throughout their journey. Moreover, once onboard, passengers must present their tickets to conductors for verification, leading to potential delays and inefficiencies, particularly during peak travel times. These outdated practices not only inconvenience passengers but also impose operational burdens on transportation providers, contributing to decreased service reliability and customer satisfaction.

Ineffective ticketing systems in public transportation cause long queues, transport delays, and substantial revenue losses due to fare evasion and inefficiencies in revenue collection processes. Traditional ticketing methods, cumbersome and manual in nature, not only inconvenience passengers but also pose security vulnerabilities and lack integration with modern payment technologies. This leads to increased labor costs for operators and diverts funds from essential maintenance and expansion activities. Moreover, manual processes increase the risk of errors in fare calculations, impacting revenue reconciliation and financial reporting. Beyond immediate functionality issues, inefficient ticketing has broader economic implications, including reduced patronage, income levels, and economic productivity, alongside environmental degradation from increased congestion and emissions. To address these challenges, modernizing ticketing systems with advanced technologies like contactless payments and automated fare collection is imperative. Such upgrades enhance efficiency, revenue accuracy, and environmental sustainability while ensuring the long-term viability of public transportation networks globally.

II. Literature Review

The necessity for modernized ticketing systems in public transportation networks has been extensively recognized, as highlighted by Noor (2008) [1]. Recent studies have investigated the potential of emerging technologies like computer vision and neural networks to enhance ticketing efficiency, as demonstrated by Olivková (2017) [2]. Notably, Nasir et al. (2018) showcased the feasibility and effectiveness of utilizing these technologies to automate ticketing and improve passenger experience [3]. Drawing inspiration from these pioneering works, this study proposes the utilization of YOLO-NAS and DeepSORT algorithms, identified as the most efficient and accurate methods for automated ticketing in public transportation.

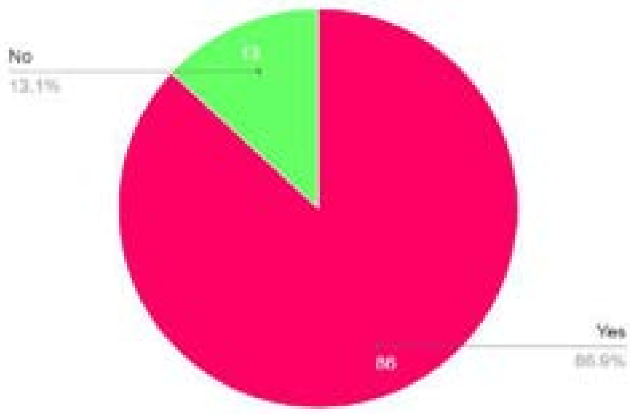

Fig. 1. Survey result with over 200 responses responding to whether the present ticketing system hinders the growth and consumption of public transport.

Furthermore, several studies have offered valuable insights into leveraging deep learning and computer vision for automated fare collection and passenger management within public transport. Sun et al. (2020) proposed a system using these techniques for passenger detection and fare calculation in buses, thereby emphasizing the feasibility of the chosen approach; however, their focus is primarily on buses and may not readily apply to other modes of public transport [4]. Chen et al. (2020) explored deep learning for passenger counting, demonstrating its potential for optimizing resource allocation and enhancing the overall public transport experience; however, their study does not directly address automated fare collection [5]. Shafiq et al. (2021) introduced a smart ticketing system using image processing and deep learning [6], while Ibrahim et al. (2022) investigated deep learning for real-time passenger counting and fare collection [7]. Together, these studies provide collective support for the potential of the proposed solution to streamline the ticketing process and enhance operational efficiency in public transportation.

III. PROPOSED WORK

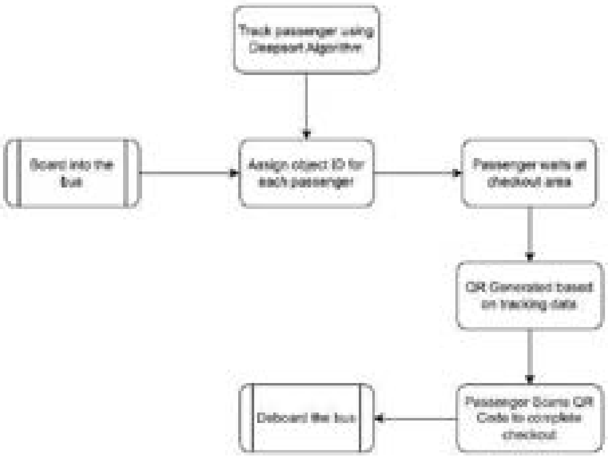

Fig. 2. Workflow of the Proposed Work

A. Data Description

To evaluate the model's performance, several snapshots from the real world to assess its functionality under varying conditions, including different lighting conditions, camera angles, and vehicle types. Fig.3 and Fig.4 shows the sample of the data set used.

Fig. 3. Good quality image with sufficient lighting and correct camera angle capturing.

Fig. 4. Average quality image with poor lighting and incorrect camera angle capturing.

B. Object Detection:

YOLO-NAS model has been employed for object detection [13], a system that has demonstrated superior efficiency compared to its predecessors in the YOLO series. Unlike previous YOLO models, which relied on manually designed architectures, YOLO-NAS operates on the principle of Neural Architecture Search (NAS) [8]. NAS involves automatically discovering optimal neural network architectures tailored to the specific task at hand. By leveraging NAS, YOLO-NAS can systematically explore the design space of neural networks, identifying architectures that maximize performance while minimizing computational costs. This approach enables YOLO-NAS to achieve higher levels of accuracy and speed in real-time object detection tasks compared to earlier YOLO models [9]. This made YOLO-NAS the preferred choice for the work.

1. Using the pre-trained YOLO-NAS model:

Utilizing the YOLO NAS pre-trained model has significantly expedited the implementation process, bypassing the need for extensive training while still achieving high accuracy rates. In addition, the analysis underscores the superiority of the YOLO NAS pre-trained model, especially in detecting people. This model's exceptional performance in this domain is attributed to its thorough training with a vast dataset, empowering it to accurately identify individuals amid the complexities of diverse environments. Particularly, the YOLO NAS S version stands out among other pre-trained models, exhibiting superior accuracy-to-latency ratios. This attribute is crucial for real-time applications, where swift detection is paramount. In our comparative analysis with other pre-trained models such as YOLO NAS-S, YOLO NAS-M, and YOLO NAS-L, on meticulously evaluating various parameters, as illustrated in Fig.5, confirming the efficacy of our chosen model. Its robust performance across diverse settings underscores its suitability for our specific task, offering both accuracy and efficiency in equal measure.

Feature	YOLO-NAS S	YOLO-NAS M	YOLO-NAS L
mAP (Accuracy)	47.5	51.55	52.22
Latency (ms)	3.21	5.85	7.87
Size	Smaller	Medium	Larger
Computational Cost	Lower	Medium	Higher

Fig. 5. Comparison of the results obtained by testing between various pre-trained YOLO-NAS models.

Fig. 6. Object Detection is performed on a high-quality image where higher confidence prediction is observed.

Fig. 7. Object detection performed on a low-quality image with a very poor confidence of prediction is observed.

2. Neural Architecture Search and its working:

Neural Architecture Search (NAS) revolutionizes the process of designing neural networks by automating the search for optimal architectures tailored to specific tasks like object detection and tracking in public transportation systems. The working principle of NAS involves the use of algorithmic search strategies, such as reinforcement learning or evolutionary algorithms, to explore a vast space of possible network architectures. These strategies iteratively propose, evaluate, and refine architectures based on their performance on a given dataset. In the context of object detection and tracking, NAS algorithms focus on discovering architectures that excel at extracting meaningful features from input data, reasoning about spatial relationships between objects, and maintaining temporal continuity to track objects over time. This entails exploring a range of design choices, including network depth, width, convolutional kernel sizes, and connectivity patterns, to find architectures that strike a balance between accuracy, speed, and resource efficiency. One key advantage of NAS is its ability to reduce the reliance on manual experimentation and domain expertise traditionally required for neural network design. By automating the search process, NAS algorithms can uncover novel architectures that surpass handcrafted designs, leading to significant performance improvements. Moreover, NAS can adapt architectures to specific deployment scenarios and hardware constraints, optimizing them for real-time processing on edge devices commonly found in public transportation systems.

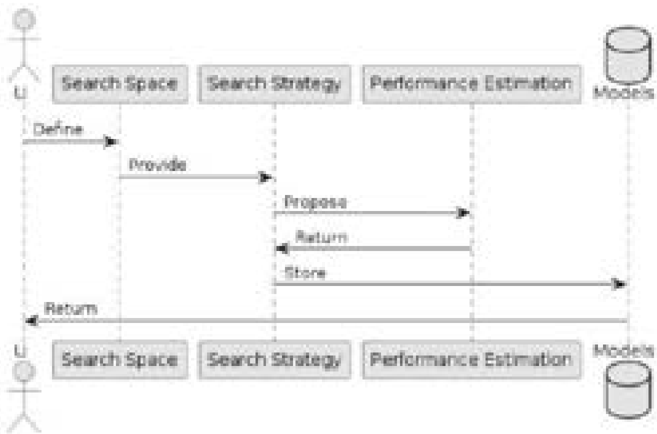

Fig. 8. Top level working of Neural Architecture Search

C. Object Tracking:

Given the specific conditions and requirements of our work and on comparison with other object tracking [10] libraries- it is DeepSORT that is the optimal choice for our needs. By leveraging deep learning techniques [14], DeepSORT is capable of reliably tracking objects over time while simultaneously handling occlusions and other challenging scenarios. Its ability to maintain object identities across frames makes it well-suited for our application, where precise and reliable tracking of objects, such as vehicles or passengers in a transportation setting, is paramount. Furthermore, the scalability and adaptability of DeepSORT ensures that it can effectively handle varying conditions and environments, making it the ideal solution for our use case. We could reduce the latency in object detection by changing the IOU distance metric in the matching process and integrating Feature Pyramid Network (FPN) and multi-layer pedestrian appearance features based on the conditions.

1. DeepSORT Working:

DeepSORT, optimized for person tracking in public transportation systems, employs a sophisticated blend of deep learning and classical tracking techniques [15]. Initially, it utilizes a convolutional neural network (CNN) to extract deep features from detected individuals, capturing detailed appearance information crucial for accurate tracking. These features are then associated with existing track objects using a combination of the Kalman filter [14] and a data association algorithm like the Hungarian algorithm, which considers both appearance features and predicted states. DeepSORT further enhances tracking precision by refining object locations through bounding box regression and managing tracks by updating states, initiating new tracks, and eliminating inactive ones. Its incorporation of deep learning models aids in overcoming challenges related to person re-identification, ensuring consistent and reliable tracking performance even in dynamic and crowded environments commonly encountered in public transportation settings. Moreover, DeepSORT incorporates advanced techniques such as non-maximum suppression to refine detections, ensuring that only the most relevant information contributes to the tracking process. Additionally, it leverages recurrent neural networks (RNNs) or long short-term memory (LSTM) networks to model temporal dependencies, allowing for smoother trajectory predictions and handling occlusions more effectively. Furthermore, DeepSORT's modular architecture enables seamless integration with existing surveillance systems, facilitating rapid deployment and scalability across diverse transportation infrastructures.

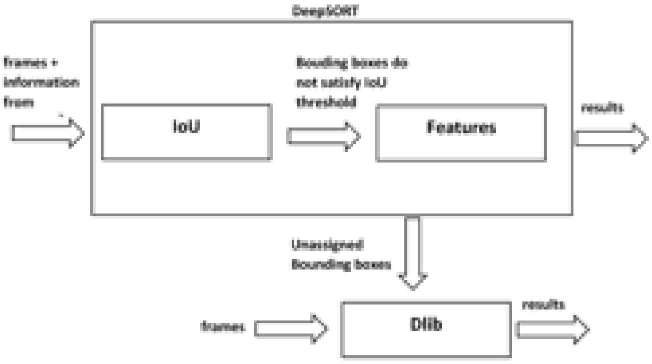

Fig. 9. DeepSORT Woking

2. Using DeepSORT over other object tracking libraries

Upon continuous testing of the footage using various tracking algorithms including SORT, DeepSORT, FairMOT, TransMOT, and BYTETrack, obtaining derived insightful results indicating DeepSORT as the most efficient solution for our tracking needs [12]. Across multiple metrics such as accuracy, efficiency, scalability, robustness, and ease of implementation, DeepSORT consistently outperformed the other algorithms. Its high accuracy in maintaining precise object identities, even in crowded and dynamic environments, stood out prominently during testing. Additionally, DeepSORT exhibited remarkable efficiency, processing video streams in real-time without compromising on tracking quality [16] . Its robust performance in handling challenging scenarios such as occlusions and varying lighting conditions further solidified its superiority. The scalability of DeepSORT was also noteworthy, as it effortlessly handled large-scale tracking tasks with a significant number of objects. Lastly, while the implementation of DeepSORT required some expertise in deep learning techniques, its wide availability of pre-trained models and libraries facilitated its integration into our tracking system seamlessly.

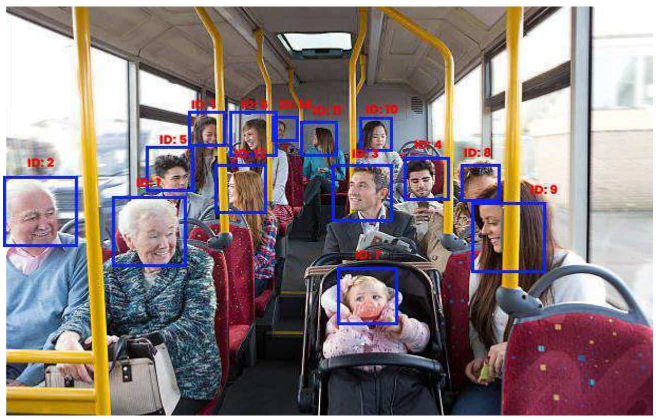

Fig. 10. DeepSORT performed in well-lit conditions performs well with high accuracy and delivers optimal output.

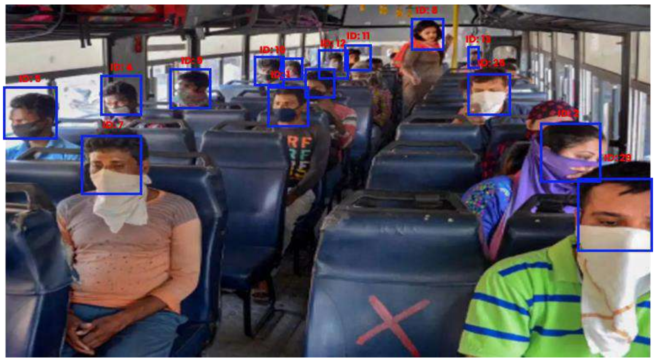

Fig. 11. DeepSORT, performed in bad conditions, performs not as expected delivering average results.

D. Internal System Logic:

The system operates based on the output derived from the DeepSORT algorithm, which assigns unique identifiers to individual objects, representing passengers in this context. Upon passenger boarding, the system initiates constant monitoring, tracking the movement and progression of each passenger until they reach the designated deboarding point. Throughout the journey, the system captures the boarding location and timestamps to maintain a record of the passenger's travel itinerary. Once a passenger arrives at the deboarding point, the system triggers the display of a QR code containing essential information, such as the passenger's identity and total fare for the journey. This QR code serves as a digital ticket, providing a convenient and efficient means for fare payment and verification.

Algorithm 1 Passenger Tracking and QR Code Generation

```
Initialize passenger_record
Initialize fare_rates
while journey_in_progress do
    for each detected_object in frame do
        if detected_object not in passenger_record then
            Add detected_object to passenger_record with initial values:
              "boarding_location" = current_location
              "boarding_time" = current_time
              "current_location" = current_location
              "current_time" = current_time
              "fare" = 0
        else
            Update passenger_record[detected_object]["current_location"]
            Update passenger_record[detected_object]["current_time"]
            Calculate distance_traveled
            Calculate time_elapsed
            Update passenger_record[detected_object]["fare"] += distance_traveled × fare_rates[vehicle_type]
        end if
    end for
    for each passenger in passenger_record do
        if passenger reaches deboarding_point then
            Generate QR code containing passenger information and total fare
            Display QR code
        end if
    end for
end while
```

1. Deboarding Area

The deboarding area serves as a designated space within the transportation system where passengers disembark from their journey. It plays a crucial role in the efficient processing of exiting passengers' details. Upon reaching the deboarding area, the system employs a sophisticated detection mechanism to identify passengers who are in the process of deboarding. Specifically, if a passenger remains within the deboarding area for more than 30 seconds, the system automatically initiates the processing of their QR code, facilitating swift fare calculation and verification. Additionally, to expedite the process further, passengers have the option to manually trigger the QR code processing by activating a switch. This approach ensures that passengers can seamlessly complete their journey while allowing the system to capture essential information for record-keeping and fare management purposes. The deboarding area thus acts as a pivotal point in the passenger transit experience, streamlining exit procedures and enhancing overall system efficiency.

E. Operator/ Driver Interface.

In order to ensure seamless operation without the need for a ticket collector or conductor, the system provides the driver or operator with essential monitoring capabilities. Through integration with a dedicated monitor installed within the bus, the driver gains real-time visibility into passenger-related data and operational statistics. This monitor displays comprehensive information, including the current number of passengers onboard, individual passenger details such as boarding and deboarding locations, fare payment status, and total revenue collected. Additionally, the monitor provides alerts or notifications regarding critical events, such as passenger deboarding or fare processing requests. By centralizing this information on a single display, the driver can efficiently manage passenger flow, track fare transactions, and ensure compliance with operational requirements, all while maintaining focus on safe and reliable driving. This monitoring system enhances operational transparency, facilitates decision-making, and empowers the driver to effectively oversee bus operations without the need for additional assistance.

IV. Challenges Involved

There are several challenges involved, which pose significant hurdles in the implementation of the project. Poor camera quality or the absence of CCTV systems in all vehicles can severely impede the accuracy and reliability of object tracking, as low-quality footage may result in insufficient data for effective analysis. Moreover, the high cost involved in deploying and maintaining the necessary hardware and software infrastructure presents a substantial financial barrier, particularly for transportation agencies with limited budgets. Furthermore, instances of bus overloading, where the number of passengers exceeds specified guidelines, can significantly complicate object tracking and fare calculation, leading to inaccuracies and potential revenue losses. Another critical challenge lies in ensuring the successful adaptation and training of passengers and transportation staff to the new system, which may require considerable time and effort to achieve widespread acceptance and proficiency. Additionally, addressing privacy concerns and complying with data protection regulations present additional complexities that must be carefully navigated during project implementation. Overcoming these challenges demands a comprehensive approach that encompasses technological innovation, stakeholder engagement, and robust implementation strategies to ensure the successful deployment and operation of the passenger tracking and fare calculation system in public transportation.

V. Conclusion and Future Works

In conclusion, our pursuit of an Automated Ticketing System represents a significant leap forward in revolutionizing public transportation efficiency. The integration of cutting-edge technologies, such as Computer Vision and Neural Networks with YOLO-NAS and DeepSORT algorithms, underscores a promising solution for real-time object detection and tracking. The proposed system logic, featuring QR code-based digital ticketing and an operator-friendly interface, embodies a modernized, user-centric approach. While challenges like budget constraints and user adaptation demand attention, with commitment to a people-centric strategy aims to overcome these obstacles for successful deployment. Looking ahead, focus will be on refining system resilience in adverse conditions, optimizing Neural Architecture Search integration, addressing privacy concerns, and ensuring scalability and efficiency improvements. To increase transparency in our system we need to clearly communicate the system’s lifecycle, grant users access to the data and algorithms used, and establish regular feedback loops with human experts to ensure the system’s outputs are understood and validated. Collaborative efforts with transportation agencies will be pivotal for large-scale implementations, user feedback, and seamless integration into existing public transit systems. Additionally, ongoing research will explore emerging technologies like edge computing and blockchain to bolster data security and processing efficiency, while continuous monitoring and analysis of system performance metrics will drive proactive adjustments for optimal functionality and user satisfaction. Fostering partnerships with academic institutions and industry leaders will further facilitate knowledge exchange, driving innovation and propelling the evolution of public transportation systems towards greater sustainability and inclusivity.

***Abstract*—In light of many reports generated in recent years, fraud insurance claims have caused havoc in the medical and insurance sectors. 100's of crores of rupees are stolen by fraudsters who claim insurance money by showing fake certificates of hospital bills, medical invoices, prescription lists, etc. This practice can be stopped by checking the legitimacy of the certificate. With artificial intelligence evolving daily, using this technology to our advantage is the best thing to do. The solution to the fraud document detection problem can be found by implementing machine learning algorithms. The primary idea of the solution is that the algorithm will check for a few parameters on a certificate and then determine if the certificate is genuine. For the solution to be in the scope of usage by the public, an IoT element has been introduced. People appointed to check the authenticity of the submitted documents can conveniently scan the document, and the retrieved scanned copy can be uploaded to a database on our mobile application. After uploading, the application is built in a way that contacts the main server, substantiates the certificate, and features its accessibility to the user.**

I. Introduction

Recent discoveries using technologies such as blockchain and cryptography in document authentication have proven promising despite difficulties. Applying blockchain has resulted in various confusion and isn't very scalable. At the same time, bio-metrics have their odds, such as privacy concerns, which make the system prone to deception attacks. Problems, including data biases, reliability, and system integrity, haven't been validated yet. Over the years, inventions such as the Telephone, Computer, Big data analytics, Artificial intelligence, and the Internet of Things have elevated proficiency, precision, and anti-fraud measures. From the instantaneous communication enabled by the telephone in 1876 to intelligent automation in the 2010s, every progress marks an inclination towards improved methods aligned with developing technologies [1]. Scams in the insurance sector are widely divided into two categories: hard and soft. While the former consists of calculated forgeries or misleading claims, such as organizing accidents or injuries to deceive the insurer, the latter is comparatively more sophisticated and mainly involves exaggerating legitimate claims, like overestimating the damages in a genuine accident. However, both types of fraud have quite detrimental impacts on the insurance industry, leading to intensified premiums and resource exhaustion. Solely in India, insurers incur losses that amount to almost 10% of their total premiums, which would be about USD 6 billion [13]. As per the National Health Care Anti-Fraud Association (NHCAA), monetary damages resulting from healthcare fraud amount to approximately $68 billion; collectively, it goes as high as $300 billion[15]. A few models do exist that predict fraudulent documents, but identifying minute negligible attributes and resilient detection remains challenging. For instance, This paper [1] doesn't discuss its shortcomings, which makes it difficult to conduct a transparent analysis. [2] indicates the lack of tools for thoroughly investigating the document. [3] acknowledges that eliminating false claims isn't entirely possible. [4] and [5] face issues with dataset inconsistencies. Currently, existing approaches have several drawbacks, such as inadequate tools for thoroughly checking the document [2], completely nullifying false claims [3], and irregular data [5]. Hence, by including an element of IoT, quick scanning of documents and synchronous verification are enabled. Moreover, the problem of dependency on fixed data is also resolved. Subsequently, this proposed method may aid in several document-related frauds, especially in financially dependent industries.

Section II manages a literature review on template matching

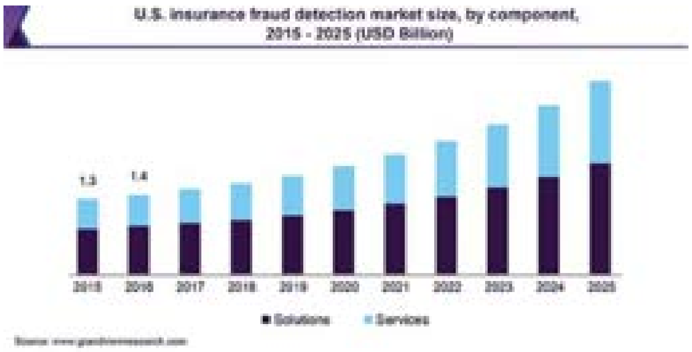

Fig. 1: Market size of fraud detection[14].

algorithms, data analytics, and machine learning techniques in the area of fraud detection, subsequently determining the limitations of the current research. Section III outlines the method sequentially. Section IV depicts the algorithm used to develop the technique in a structured manner. Section V presents the system's efficacy in detecting fraud, and it also includes discussions on the consequences of the results found. Section VI recaps the research and emphasizes the system's likelihood of improving the methods used to combat fraud.

II. Literature Review

This solution proposed in a particular research paper uses template matching techniques to identify fraudulent documents submitted when claiming insurance. A method involves using advanced computer vision algorithms that analyze and compare visual elements in a document with a template of known original documents. This method increases the accuracy of detecting any anomalies in the document. This method requires the usage of a valid and sufficient dataset. The performance metrics after evaluation are decent.[7]

Another paper proposes to use a convolutional neural network(CNN) to detect tumors from an MRI scan, a common concept used in medical imaging. The method proposed in [8] includes feature extraction, selection, and combination phases. The algorithm used in this method consists of a separate class named 'I do not know' to mark images that couldn't be classified, hence letting users know the model's reliability. This provides an insight into the evolution of the classification process.[8] There are various applications of image compression, and the authors have especially used deep learning techniques like multi-layer perceptrons (MLPs), convolutional neural networks (CNNs), and generative adversarial networks (GANs). The paper discusses AI-based tools for image compression (openCV, Tensorflow, MATLAB, High-Fidelity Generative Image Compression, and CompressAI). [9] In another paper, the Yelp dataset of restaurant reviews fed into a machine-learning model to identify fake reviews. The method described in the paper begins with data preprocessing, and feature extraction is performed. Among the classifier evaluations, KNN(k=7) yielded the best results. [10] A problem can be approached in multiple ways, and one such algorithm uses deep-learning, a two-step PCA-based feature extraction, to perform point cloud classification. This method extends the PointNet framework for high-scale aerial LiDar data. The paper emphasizes the importance of feature extraction in pattern recognition and standardized results for real-world ALS point cloud datasets.[11] The paper also highlights supervised and unsupervised learning methods when facing insurance fraud challenges.[11] A study elaborates on the effectiveness of strategies such as Multi-Layer Perceptrons, Convolutional Neural Networks, and Generative Adversarial Networks in image compression. The paper includes insights into other AI platforms that perform image compression and a summary of the functions/methods they provide. One paper proposes understanding and then optimizing existing practices in fraud detection. The dataset consists of an ethnographic study that explored the nature of motor insurance fraud-detection methods in two major insurance companies. The results shown in [12] conclude that a professional concentration on the practices of fraud

TABLE I: Summarized Research Findings

Title	**Methodology**	**Metrics Used**	**Key Findings**
IoT Based Fraud Documentation Detection	Template Matching, SSIM tools, Logistic Regression, Histgradient boost classifier, Unique identifier checks	Accuracy, Precision, Confusion Matrix	Accuracy: >98%. Precision: 0.98, Recall: 0.98, F1-score: 0.98
Insurance Fraud Detection [7]	SVM, RF, DT Adaboost, KNN, LR, NB, MLP	Precision, Recall, F1-Score	DT: 79%, Adaboost: 78%
Tumor Disease Categorization [8]	CNN with Feature Extraction and Selection	Accuracy	Accuracy: >99.76%, Improvement: 2%
Copy Move Image Forgery Detection [10]	Fridrich et al.'s Method	Precision, Recall, F-Score, Execution Time	Precision: 0.96, Recall: 0.8, F-Score: 0.87
ALS Point Cloud Classification [11]	PointNet, PCA	F1, mF1, IoU, mIoU, OA	Best OA: 75.65% with LiFs and 10PCs
Fake Reviews Detection [12]	KNN, NB, SVM, Logistic Regression, Random Forest	F-Score	KNN (K=7): 82.40%

Detection combined with forensic and data-mining approaches to fraud claim detection produces enhanced outcomes. The literature survey results are compared in Table I.

There have been several studies regarding fraud document detection. Some of them have been listed in the table. Initially, insurance fraud detection employed machine learning algorithms such as SVM, Random Forest (RF), Decision Trees(DT), Adaboost KNN, etc., to identify fraud. To calculate accuracy and precision, recall and f1-score have been used. DT showed the highest accuracy of 79%, which Adaboost followed at 78%. Then comes tumor disease categorization. A convolutional neural network (CNN) is commonly used for medical imaging to detect tumors from an MRI scan. The accuracy achieved was above 99.76%, which provides a 2% improvement over the original method. Copy-move image forgery detection mostly uses the Fridrich et al. method. To calculate accuracy, precision, recall, f-score, and execution time are used. This method had a high precision of 0.96, recall of 0.8, and f-score of 0.87. Another method used was ALS Point Cloud Classification and the methodology used in this scenario is PointNet and Principal Component Analysis (PCA) to calculate F1, mF1, lou, mloU, and OA. OA depicted the highest accuracy of 75.65%, including LiFs and 10PCs. And the last was fake review detection, which again used several machine learning models like KNN, SVM, RF, logistic regression, and NB and used the F-score to calculate accuracy. KNN showed the best result of all the algorithms with an F-score of 82.4%.

Whereas in this research paper, diverse concepts from previous papers have been seamlessly integrated to provide maximum accuracy. Techniques such as template matching, SSIM tools, a logistic regression model, a histogram boost classifier, and unique identifier checks were used. This model also uses advanced techniques like CNN GAN to incorporate feature extraction and selection. Precision and accuracy were employed to achieve maximum accuracy, and a confusion matrix depicts how many predictions are correct or incorrect per class. The model presented a high precision of 0.98, recall of 0.98, and f1-score of 0.98, concluding that the accuracy exceeds 98% as shown.

III. Methodology

This project follows the following steps and produces results:

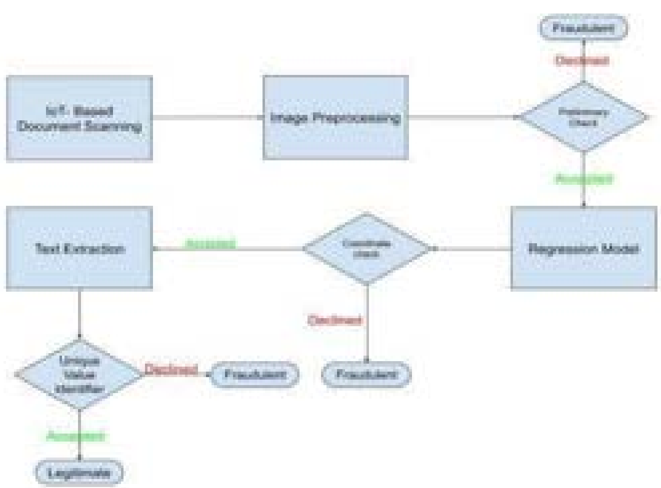

Fig. 2: Workflow diagram of the system.

A. Dataset

The dataset used in this paper is limited to Coursera-certificates as a case study since we do not have access to medical records and other documents that are put forth as documents for claiming insurance policies. According to The Medical Council of India's Code of Ethics Regulations[15], no one can access medical records unless the patient approves. For the amount of data that needs to be generated, 100s of medical records would be required, and not many would authorize sharing their data. Instead, the dataset for this project was generated from accessible sources. Using certificates and documents related to students, peers, and others who approved of their documents being used, the model used in this project was fed legitimate documents. The testing set was created by making changes to the original documents. The changes range from as big as missing features to as minute as a mistake in the recipient's name. Through the generation of fraudulent documents concerning the testing of various parameters, there was enough variety to counter different possibilities of fraud.

B. IoT-based Document Scanning

The Internet of Things ensures different technologies are streamlined and easily accessible. The feature of scanning documents through an app aims to solve a major problem i.e. the documents are classified as fake or not **instantly**. A normal verifying routine has several moving parts, such as physical identification, template matching, ID verification, etc. The inclusion of scanning facilitates document verification by enabling remote scanning and real-time uploading for analysis, making the process accessible from anywhere. The prerequisites of using such a technology are reduced to minimal skills like smartphone operating and scanning steadily. This efficiency is crucial for scenarios requiring timely verification, streamlining the entire process.

C. Image Pre-processing

This step prepares the image to pass through the model to accommodate specific requirements by adjusting image brightness and contrast, noise reduction(especially in scanned images), and removing unwanted variations. This step also ensures that high-resolution scans capture minute details, crucial for authentic document differentiation. This is done by using Open CV and scikit-image libraries in Python. After pre-processing, the images are of the required resolution(1650x1275) for the next steps.

D. Document Template Matching

This step segregates the necessary and common elements, like logos, watermarks, and specific text areas, from the document. For instance, extracting text from the document involves recognizing font styles, sizes, and alignments, whereas removing a logo focuses on identifying its shape, color, and position. It compares them to an extensive authentic database, detecting minor alterations or inconsistencies.

E. Logistic Regression Model

This model evaluates the graphical elements and textual contents with the same precision. Moreover, the model can not only determine the probability of fraudulence and give a binary solution of 'fraud or no-fraud' outcome but also provide detailed, informative results. This permits the system to mark the documents as ‘likely fraudulent,’ requiring further human review. The logistic function is defined as:

$$P(Y=1) = \frac{1}{1 + e^{(b_0 + b_1 x_1 + b_2 x_2 + \ldots + b_n x_n)}}$$

Where (Y=1) is the probability that the dependent variable where Y is equal to 1. e is the base of the natural algorithm

$$b_0, b_1, b_2, ..., b_n$$

are the coefficients of the model and

$$x_0, x_1, x_2, ..., x_n$$

are the independent variables.

Algorithm 1 Image Fraud Detection Algorithm

        return No Match
    end if
end procedure

procedure UNIQUE TEXT VERIFICATION(D, D_{db})
    $V \leftarrow f_{\text{verify}}(D, D_{\text{db}})$
    if $V < \mu$ **then**
        return Verification Passed
    else
        return Verification Failed
    end if
end procedure

F. Unique Identifier Extraction

This step identifies and segregates any unique identifier or barcode through which a document is distinctly identified and verifies its authenticity within the organization’s record-keeping system. The barcode or URL can be extracted from the scanned document using Regular Expressions, text processing libraries, or barcode scanning software. Once extracted, the dataset needs to be queried like a database or a data repository using the extracted value. Then, a search is performed between the extracted identifier and the corresponding entry. If the match is found, the user’s information or any related information linked to the identifier is retrieved, verifying the user’s identity or checking the information against the scanned document. Finally, the results can be displayed to the user, which may validate the patient’s identity or the information provided in the document.

IV. RESULTS AND DISCUSSION

Since insurance and other medical certificates are private and cannot be accessed publicly as large datasets, the template matching algorithms have been provided with our certifications in different courses. This simulates a similar result to the insurance certificates as the algorithm constantly tries to identify the standard features and then compares them with every input certificate.

- The preliminary check for the genuineness of the certificates begins with comparing the differences in the templates and basic structure of the documents. SSIM tools are deployed to figure out differences between two documents. The difference is shown using black and white marking imposed on the document to be verified.

Fig. 3: Input of preliminary check (case 1)

- In figures 5 and 6, it is seen that the differences shown are more with a higher concentration of block shade. This is because the certificate tested in case 2 is a fraudulent certificate. The program returns an output (fig.6) with a high difference of 34.28%, unlike a difference of 15-18% when tested with an original certificate, like in case 1, as shown in figures 3 and 4.
- The document, after passing the preliminary check and verifying if it can be of the same template, is passed to the next stage: regression model. Here are the coordinates of various features in the document, such as coordinates of where the signature is, the educator’s logo,

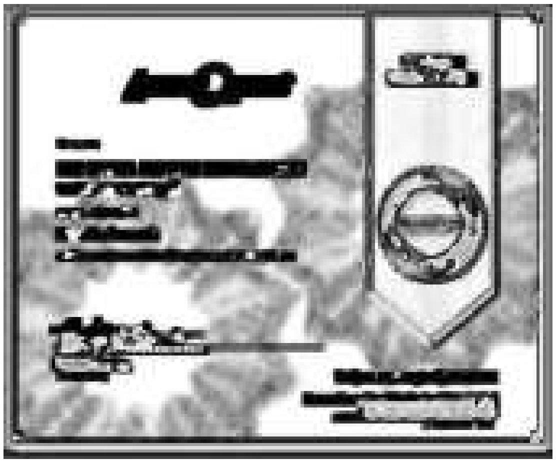

Fig. 4: Output of preliminary check (case 1)

Fig. 5: Input of preliminary check (case 2)

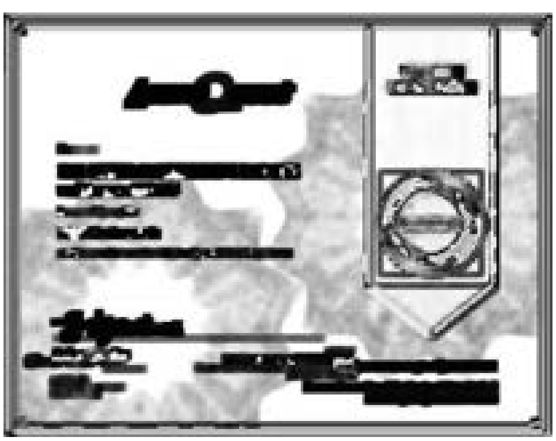

Fig. 6: Output of preliminary check (case 2)

the verification link is provided, etc. Once extracted, these coordinates are saved in a CSV file and ready to be fed to a model.

- In the third step of execution, the certificates pass the second flag, i.e., coordinate check. Logistic regression models are used to check the genuineness of the documents. The following results were observed upon passing some documents to verify their originality: the accuracy was marked over 98%, and the model showed high precision(0.98), recall(0.98), and f1-score(0.98).

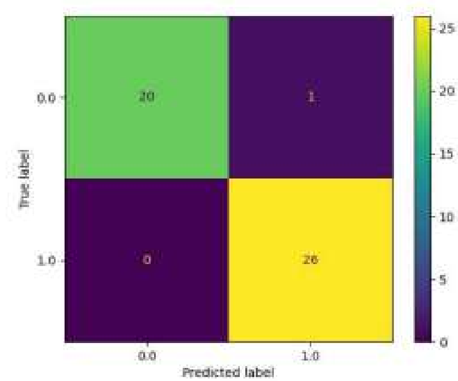

Fig. 7: The confusion matrix shows the comparison of accurate and inaccurate predictions per class

- After passing through the ML model, the proposed system uses another check to compare unique identifiers. In the example case, the unique identifier is linked to the URL below the Coursera badge to the bottom right. Upon text extraction, the documents pass through a unique identifier check.

Fig. 8: Original certificate with the unique identifier value as document title

- After checking the three flags, results show the verdict of whether the certificate is fraudulent. Users can check the authenticity directly on their mobile apps.

Fig. 9: Name, ID, and course name comparison with the corresponding fields from the document

V. Conclusion

This paper proposes an innovative approach to tackle the widespread fraud issue in medical insurance claims with the help of Artificial Intelligence and IoT. The suggested system, integrating advanced machine learning algorithms and the ImCT method for implicit certificates with Certificate Transparency, aims to revolutionize the document verification process. This system is designed to counteract the significant financial losses caused by document fraud in the medical insurance field. At the heart of the solution is a user-friendly mobile app that lets individuals scan and upload documents for validation. These documents are then authenticated through a powerful server setup employing state-of-the-art machine-learning techniques. The integration of ImCT bolsters document verification security within IoT frameworks, effectively overcoming the shortcomings of existing certificate transparency practices.

***Abstract* —The advent of the digital age has brought about previously unheard levels of connectedness and information availability, as well as an increase in cyber threats. Unauthorized Uniform Resource Locators (URLs) are now a common threat and a preferred avenue for cyberattacks. Because of the inadequacy of traditional blacklist-based solutions to counteract shifting strategies, machine learning (ML) is being investigated for proactive and predictive cybersecurity measures. The goal of this research work is to improve cybersecurity defenses against URL-based vulnerabilities by utilizing ML and ensemble learning. Several machine learning methods are used, such as Random Forest, Decision Tree, Logistic Regression, XGBoost, SVM, and Naive Bayes. The intricacy of the digital threat landscape is addressed by combining the strengths of different models through the use of ensemble approaches like Weighted Voting and Soft Voting. This study highlights the significance of Weighted Voting and shows how well ensemble techniques may combine different machine learning model and emphasizes how important it is to keep improving cybersecurity defenses in line with changing threats. The results enable the possibilities for further advancements in the sector and offer workable answers to the emerging cybersecurity issues.**

Keywords — Malware Detection, Uniform Resource Locator (URL) Classification, Ensemble Learning, Majority Voting, Soft Voting, Weighted Voting, Cybersecurity, Phishing Detection.

I. INTRODUCTION

With the fast-paced advancement of technology and online platforms, vulnerabilities and cyber threats have increased and is characterized by unparalleled accuracy and knowledge accessibility. Malicious URLs have become a major risk in the vast digital ecosystem, endangering the security of people, businesses, and organizations. Unfortunately, Uniform Resource Locators (URLs), which are the main means of navigation for API and website endpoints, which have turned into a route of distribution that hackers choose to use. When users click on Traditional blacklist-based remedies have proven inadequate in tackling the complexity of these threats, as cyber adversaries consistently create new strategies to hide their bad intentions. The cybersecurity community has responded by concentrating on more advanced, proactive, and predictive solutions.

The motivation for this study is the growing difficulties presented by URL-based attacks in the online environment, as well as the acknowledged shortcomings of conventional cybersecurity strategies. This era of unmatched convenience and connectedness has been brought about by the widespread use of Internet platforms and the explosive expansion of digital resources. But this ease is tainted by a concomitant rise in cyber threats and vulnerabilities, endangering the security of people, companies, and institutions. Within the extensive digital environment, malicious URLs have become an especially pernicious hazard. Given that URLs are the main means of navigation for both website and API endpoints, hackers have learned to embrace them as a means of distribution when looking to take advantage of gullible consumers. Interacting with malicious URLs can result in a variety of negative outcomes, such as inadvertent virus downloads, phishing attacks, the input of personal information, and vulnerability to defacement attacks. These dangers have the potential to undermine networks or systems, putting people's safety at serious risk.

II. LITERATURE REVIEW

The digital landscape has seen a surge in the prevalence and complexity of malware, posing significant challenges to traditional signature-based detection methods. Researchers have turned to machine learning (ML) and deep learning (DL) techniques as promising alternatives to address this growing threat.

Several studies have focused on leveraging static features extracted from applications for malware detection. B. Urooj et al. [1] proposed a unique approach that involved reverse engineering of Android applications to derive a distinctive static feature set, including permissions, intents, and API calls. The researchers then incorporated this data into a model trained on a vast collection of malware samples, employing ensemble learning techniques such as AdaBoost and Support Vector Machine (SVM), achieving an impressive accuracy rate of 96.24% for malware detection. Similarly, Kai Lu et al. [2] presented a solution that optimizes computational resources by identifying and removing unnecessary features using a feature selection procedure, and a malware detection model for capsule networks that maintains local information, leading to improved model robustness.

Complementing the static feature-based approaches, researchers have also explored dynamic behavior-based malware detection. Vinayakumar et al. [3] evaluated deep learning architectures and classical ML algorithms using various public and private datasets, showcasing the potential of their innovative combination of visualization and deep learning in a scalable and hybrid framework for robust and intelligent zero-day malware detection. Şahin et al. [4] introduced an attribute selection method driven by machine learning, highlighting the significance of attribute selection techniques in the domain of Android malware detection, and achieving a noteworthy high F-measure metric of 0.961. The growing threat of polymorphic malware, which evades traditional detection methods by constantly changing its signature traits, has prompted researchers to explore ML-based solutions. P. Singh et al. [5] examined the use of supervised ML classifiers, including Decision Trees (DT), Convolutional Neural Networks (CNN), and Support Vector Machines (SVM), for malware detection and classification, with DT achieving the highest accuracy of 99%. S. Agarkar et al. [6] focused on behavior-based detection techniques using ML algorithms, including Decision Tree, Random Forest, and Light Gradient Boosting Machine, with Light Gradient Boosting Machine exhibiting the highest accuracy at approximately 99.50%.

With a focus on polymorphic malware, S. Agarkar et al. suggested behavior-based detection techniques that make use of machine learning models. [6] Focusing on polymorphic malware highlights the evolving threats in the internet landscape. The study successfully applied machine learning algorithms, including Decision Tree, Random Forest, and Light Gradient Boosting Machine, to static features extracted from legitimate and malicious executable files. Results revealed the efficacy of behavior-based detection, with Light Gradient Boosting Machine showcasing the highest accuracy at approximately 99.50%, surpassing both Decision Tree and Random Forest. Despite its slower training time, the Light Gradient Boosting Machine demonstrated efficiency in both accuracy and False Negative rates, making it a viable option for classification, especially in heavy-load scenarios. The study concludes by emphasizing the

ongoing need for research in tackling new malware developments and suggests further exploration of techniques to enhance the robustness of behavior-based detection methods.

In *[11]* an effort has been made to create practical malware detection algorithms based on machine learning that are straightforward but dependable. The features retrieved by Byte and ASM are combined with the detection functions of k-NN, RF, and LR in the suggested techniques. The proposed schemes' simulation analysis yielded performance metrics such as recall, specificity, sensitivity, and F1-score. The comparison of the different outcomes shows unequivocally that the malware detection strategy based on RF works better than the model based on k-NN and LR. The suggested machine learning models' detection efficiency is either the same as or similar to that of deep learning-based techniques. Effective feature selection and extraction are crucial for enhancing the performance of ML-based malware detection models. R. Patil, W. Deng et al. [7] examined multiple algorithms, including LightGBM, XGBoost, Random Forest, and others, and found that LightGBM demonstrated superior performance with an impressive accuracy rate of 96.5% during cross-validation. M. Al-Janabi et al. [8] presented a comparative analysis of various ML-based malware detection techniques, highlighting the effectiveness of the J48 algorithm combined with Hybrid analysis for Windows-based malware detection and the Decision Tree algorithm with Dynamic analysis for Android malware detection. Researchers have also explored the use of opcode frequency as a feature vector for malware detection. Rathore, Hemant et al. [9] found that when opcode frequency is employed as a feature, the Random Forest algorithm performs better than Deep Neural Networks, suggesting that simpler ML models and feature reduction techniques can be more effective in detecting and analyzing malware.

Recognizing the inherent limitations of individual ML models, researchers have explored ensemble learning techniques to enhance malware detection capabilities. S. A. Roseline et al. [12] proposed a visual method that represents malware as two-dimensional graphics and a layered ensemble approach, outperforming deep learning techniques. B. Kapekar et al. [15] advocate for future research on hybrid techniques, combining the Random Forest algorithm and blacklist methods, to further improve phishing website detection accuracy.

A comprehensive review by A. F. Agarap et al. [13] examined the use of deep learning techniques for malware and intrusion detection, highlighting the widespread adoption of Convolutional Neural Networks (CNN), Autoencoders (AE), Recurrent Neural Networks (RNN), and Long Short-Term Memory (LSTM) models, achieving accuracy rates up to 99.9%. P. Priyadarshan et al. [11] explored practical malware detection algorithms based on machine learning (k-NN, RF, LR), with the Random Forest algorithm exhibiting better performance than k-NN and LR. *R. A. Desai et al [14]* proposes the development of a Google A Chrome addon that serves as a go-between for unsuspecting consumers and potentially dangerous websites. The authors emphasize the need for such a tool as traditional methods of maintaining a list of malicious websites are not exhaustive and cannot keep up with the continuous development of new attack techniques. The paper provides a comprehensive literature survey, presenting related work on detecting malicious web pages, including various machine learning approaches. The findings of the paper demonstrate the effectiveness of the proposed approach in identifying malicious websites and protecting users from potential harm. Using machine learning, particularly the Random Forest algorithm, provides accurate results in classifying websites, enabling safe browsing even for users who are unaware of potential threats.

Key Motivations include growing difficulties with URL-based Attacks which is due to the widespread nature of URL-based threats, which include a variety of cyber-attacks, detection and mitigation strategies must become more sophisticated and complex. Limitations of traditional approaches makes it difficult for traditional cybersecurity measures, especially those that depend on blacklists, to stay up to date with the constantly changing strategies used by cyber adversaries. Through the investigation of novel strategies, this study seeks to circumvent these constraints. The research is driven by the idea that adding machine learning methods can greatly improve cybersecurity systems' capabilities. This entails making use of machine learning's capacity to examine big datasets, spot trends, and adjust to new dangers. The research adopts ensemble learning as a tactic to integrate the advantages of several models, realizing that no one machine learning model can fully represent the intricacy of the digital threat landscape. The research's main objective is to aid in the creation of a stronger defense system. The goal of the project is to increase the accuracy and dependability of threat identification in real-world scenarios by adopting ensemble learning and overcoming the inherent limitations of individual models.

III. OBJECTIVES

To develop and put into practice a cutting-edge system specifically suited for URL detection and classification, Advanced Detection & Classification is used to classify them into phishing, benign, defacement, and malware. We seek to investigate and utilize the power of ensemble approaches, with a specific focus on Majority Voting, including both Soft Voting and Weighted Voting, realizing that no single algorithm provides comprehensive solutions. While individual models have advantages, their collective intelligence is where their true power rests. By utilizing each algorithm's unique capabilities through ensemble learning, we hope to minimize any potential biases and inaccuracies inherent in any single model. To carefully assess and contrast various machine learning models and ensemble strategies, pinpointing their unique benefits, drawbacks, and applicability to our problem domain. This study addresses the difficulties related to dynamic and polymorphic malware detection, suggests a unique ensemble approach, and synthesizes and expands upon the results of other investigations. The goal is to enhance threat detection mechanisms through the creation of an advanced URL-specific malware detection system and the investigation of ensemble approaches.

IV. SYSTEM OVERVIEW

The main goal of proposed system is to sort URLs into four different danger categories malware, phishing, defacement, and benign. The necessity of creating a sophisticated detection method is critical given the increasing number of harmful URLs in the modern digital environment. The proposed system is the result of the integration of numerous cutting-edge machine learning algorithms, further strengthened by ensemble techniques, rather than being the only output of a single methodology. The design of the system, its parts, and the dynamics of their interactions are all covered in detail in this section.

1. Architecture & Framework

The first process includes data gathering & preprocessing. A sizable, well-balanced dataset derived from reputable cybersecurity organizations serves as the cornerstone of our system. Preprocessing of this dataset is careful to ensure that all anomalies, missing values, and redundancy are eliminated. The processed dataset is used to produce the training and testing subsets, which allow the model to be trained and tested.

The dataset includes instances of different types or classes, such as:

Malware: Malicious software with the intention of damaging or abusing computer systems. This group includes ransomware, worms, trojan horses, viruses, and other harmful software.

Phishing: Attempts to pose as a reliable organization in order to fool people into disclosing private information, including credit card numbers or passwords. Phishing often involves deceptive emails, websites, or other communication channels.

Benign: Non-malicious or harmless activities. In the context of cybersecurity, this class represents normal, safe, and expected behavior.

Defacement: Unauthorized alteration of a website's appearance, typically to convey a message or vandalize the site. This can include changes to the visual elements or content of a webpage.

b. Individual Model Training: A number of machine learning algorithms, including Random Forest, SVM, XGBoost, Naive Bayes, Logistic Regression, LightGBM, and Decision Tree among others,
are independently trained on the dataset. Every one of these algorithms learns and internalizes the patterns found in the data with the goal of predicting the category of an upcoming URL.

c. Individual Model Evaluation: The testing subset of the dataset is used to construct each model's post-training performance metrics, including recall, accuracy, precision, and F-score. The results of this examination paint a clear picture of the advantages and shortcomings of each method.
d. Integration of ensemble models: We use ensemble approaches because we understand that no one model can fully represent the issue space. The various models are synergized, their combined intelligence harnessed, and forecasts are produced by methods including hard voting, soft voting, and weighted voting.

2. Operational Dynamics

The operational dynamics of a malware detection system involve a series of intricate steps aimed at accurately categorizing URLs as malicious, phishing, defacement, or benign. The process begins with the input mechanism, where a URL is fed into the program, and the algorithm extracts the necessary information, aligning it with the format used during model training Following the input mechanism, the system utilizes parallel processing, enabling each trained model to independently examine the URL and predict its category based on its unique algorithmic biases. This step ensures that multiple perspectives are considered, increasing the overall accuracy of the system. Once the individual models have made their predictions, the ensemble layer combines these predictions using a predefined ensemble voting method, such as hard, soft, or weighted voting.

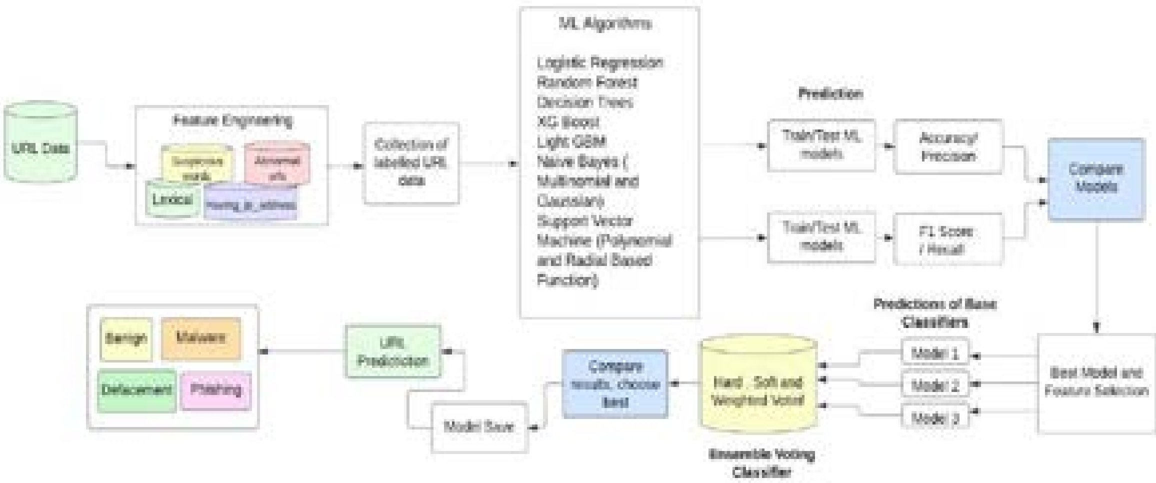

Fig. 1 Architectural flow of the proposed system

This layer helps to consolidate the predictions from all models, making the final decision on the URL's category. The system then outputs the categorization of the URL, along with a confidence score that reflects the models' overall assurance in the prediction, depending on the ensemble technique employed. This score can be useful in determining the level of risk associated with the URL, allowing users to make informed decisions about their online activities. The entire process is depicted clearly in Figure 1.

V. METHODOLOGY

2.1. Requirement Analysis & Data Collection

The first stage in our study was understanding the criteria for a reliable malware detection and classification system. Given the wide variety of malicious URLs, it was crucial to collect a diversified and thorough dataset that appropriately reflected the different threat categories. In order to guarantee a fair representation of different URL categories, we gathered an extensive dataset from reputable cybersecurity groups for this investigation. Ten thousand URLs in all, 2,500 samples from each of the following categories (malware, phishing, defacement, and benign) make up the collection.

We retrieved 215 elements, comprising different properties like the length of the URL, the age and popularity of the domain, the use of suspicious keywords, the existence of redirects, and other significant characteristics, for every URL. We preprocessed the dataset by fixing duplicate URLs, guaranteeing data fidelity, and normalizing and scaling the data before training the machine learning models. This procedure ensures consistency and quality of data, which makes it appropriate for machine learning algorithms.

We employed an 80-20 split for the data splitting approach, meaning that 80% of the dataset was used for training and 20% for testing. To further guarantee the models' robustness and generalizability, we also used 5-fold cross-validation.

Due to the diversity and good representation of our dataset, we did not use any data augmentation techniques in this investigation. To improve the model's performance even more, future research could investigate data augmentation methods like generative modeling, introducing noise, or changing URL properties. Having learned this, we started the process of gathering data. The extensive database that was assembled contained URLs from the following categories: malware, benign, defacement, and phishing. Since the URLs were gathered from several trustworthy sources, their authenticity and diversity were guaranteed. Reputable cybersecurity firms, open-source threat intelligence platforms, and scholarly databases served as the information's primary sources.

To train, validate, and test our machine-learning models, this database was created to be a mirror of real-world circumstances. It offers a wide range of samples. The dataset's diversity was meant to test the models and make sure they were good at spotting the finer details and patterns that were specific to the various danger categories. Basically, this sizable database served as the foundation for our research and also helped to make sure that the conclusions and solutions we came up with were applicable, timely, and efficient in tackling today's cybersecurity concerns.

2.2. Data Preprocessing

The quality of the data has a direct impact on how well the model performs in any machine-learning project. As a result, we meticulously preprocessed our dataset to guarantee its top quality before starting model training. The problem of duplicate URLs was first addressed. Repetitive entries might skew the training process and cause overfitting. The database's duplicate URLs were so quickly found and eliminated.

In order to assure data quality and consistency and prepare the dataset for machine learning algorithms, we scale, normalize, and ensure data dependability at this phase. We employ the following methodical approach to data cleaning Removal of Duplicate URLs: In order to avoid bias during the model training process, we eliminate duplicate URLs. This guarantees the uniqueness of every URL and aids in the model's learning process.

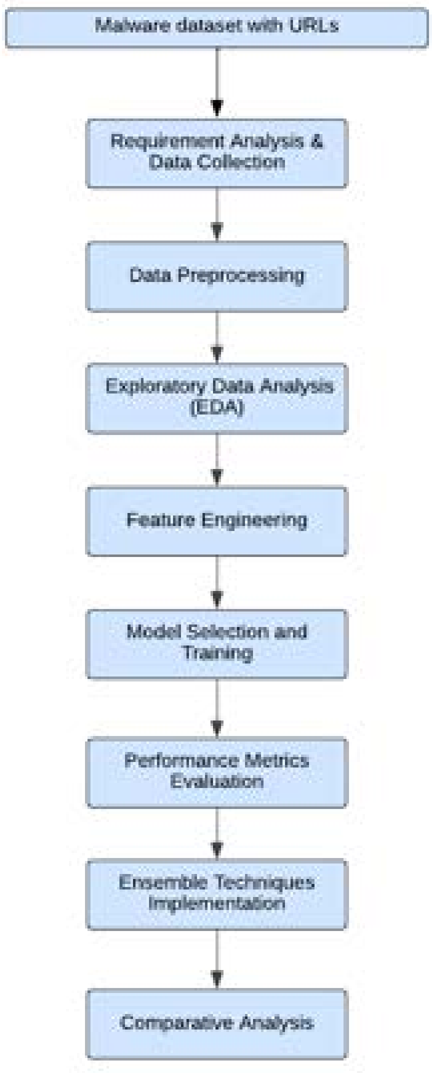

Fig. 2 Flowchart outlining the general steps involved in machine learning-based virus prediction

Data Reliability: We make sure that the data is reliable by eliminating inaccurate or partial entries. In order to prevent any detrimental effects on the model's learning process, this step is essential.
Normalization and Scaling: To guarantee that every data point has a uniform format and scale, we normalize and scale the collection. This stage is crucial since various machine learning algorithms require particular data.

The reliability of the data was the subject of our next inquiry. If left unchecked, incomplete or corrupt data entries might affect the model's learning process, which in turn affects how accurately it predicts outcomes. Only complete and accurate data samples were kept by meticulously filtering out such entries. Finally, the dataset underwent normalization and scaling operations due to the variety of machine learning methods utilized in this work, each with its own specific data requirements. This stage made sure that every data point had a consistent format and scale, which allowed the various algorithms to process and learn from them efficiently. In conclusion, by doing these preprocessing processes, we made sure that our dataset was both free of irregularities and consistency issues and that it was also suited to meet the specific needs of the machine learning algorithms we had chosen.

2.3. Exploratory Data Analysis (EDA)

An essential phase in the research process is exploratory data analysis (EDA), which offers insightful knowledge about the underlying patterns and structure of the data. In order to comprehend the dataset's distribution, spot outliers, and choose pertinent characteristics for malware identification and classification, we used EDA in our investigation.

Data Visualization: We employed a variety of plots, such as pie charts, bar plots, and histograms, to display the data distribution. The distribution of several URL types, including malware, phishing, benign, and defacement, was clearly understood thanks to these graphics.

Correlation Analysis: We computed correlation coefficients and plotted correlation matrices to visualize the links between various features. Through the use of this research, we were able to pinpoint highly correlated characteristics that should be eliminated in order to reduce redundancy and enhance model performance.

Feature Selection: We chose pertinent features for malware identification and classification based on the EDA results. The length of the URL, the use of special characters, the inclusion of particular keywords, and domain information were some of these criteria. Additionally, we developed specialized characteristics for each category of URL, such as phishing URLs that resemble genuine domain names and malware URLs that are identified by looking for scripts or files connected to malware.

2.4. Feature Engineering

Opcode frequency served as a feature vector that we employed to classify malware. Using this method, the frequency of opcode basic machine language instructions is extracted from the malware samples. Through the use of opcode frequency to represent the malware samples, a feature vector is included that encapsulates the distinct attributes of every sample. For the purpose of classification, machine learning algorithms get this feature vector as input.

Moreover, we discovered that the Random Forest approach performed better in malware classification than Deep Neural Networks when opcode frequency was used as a feature. Based on opcode frequency, Random Forest which is renowned for its capacity to manage high-dimensional data and intricate relationships performed remarkably well in the accurate classification of malware samples. This highlights the effectiveness of utilizing opcode frequency as a feature vector in conjunction with the Random Forest algorithm for robust malware classification.

Any machine learning pipeline would not be complete without feature engineering, which turns unstructured data into useful inputs that algorithms can handle quickly. In order to fully understand each URL and determine its potential intent for us, it was essential to extract the appropriate elements for our URL categorization task.

Fig.3 Overall description of URL

URL length: The length of a URL in and of itself can be a sign. Malicious URLs frequently contain malicious sites, routes, or query parameters, making them lengthier. As a result, the URL's length was calculated and employed as a distinctive attribute. Presence of Specific Keywords: Malicious URLs frequently include specific keywords that hint at their intentions, such as "secure-login" and "account-verify," among others. Such terms were searched for in the URL using a feature extraction algorithm, which then noted their presence. Domain Information: A URL's domain portion contains a wealth of information regarding its reliability. It is possible to determine whether a URL is coming from a reliable source or one that could be dangerous by extracting the main domain, any sub-domains, and even the domain registration information. Use of Special Characters: URL anomalies can raise a red warning if they use too many special characters. The "@" symbol or several consecutive hyphens, for instance, may allude to misleading user behavior. The number of special characters and their order were therefore retrieved as characteristics. Tailored Features for Specific URL Categories: Custom features were created in recognition of the distinctive traits that each URL category possesses. For instance, the resemblance of phishing URLs to real domain names was computed, whereas malware URLs were examined for the existence of scripts or files that are known to be associated with malware.

In summary, we turned unstructured URLs into a richly informational format through deliberate feature engineering. These attributes set the framework for later modeling by capturing the various aspects of the URLs, enabling our algorithms to effectively learn and predict the nature of each URL.

2.5. Model Selection and Training

Model Selection Process: Early on, we realized that depending on a single model would be too reductionist of an approach given the complexity of the digital environment and the multiple nature of URL threats. As a result, we tended to favor a number of algorithms that are well-known for being skilled in solving classification-related problems. We favored algorithms like Random Forest, SVM, XGBoost, Decision Tree, Logistic Regression, LightBGM, and Naive Bayes after consulting recent academic literature, industry best practices, and previous practical investigations. These models each have a successful track record in pattern recognition and provide distinctive viewpoints, therefore encompassing a wide range of analytical options.

In this study phase, we investigated deep learning, feature engineering, and transfer learning as advanced machine learning techniques to improve the system's malware detection and classification capabilities. In order to extract subtler and meaningful properties from the URLs and improve the models' ability to distinguish minute changes between different danger categories, feature engineering was further developed. This procedure attempted to improve the system's capacity for prediction and flexibility in response to changing cyber threats.

Robust performance assessments were carried out to guarantee the system's robustness and dependability across various datasets and attack scenarios. The efficacy of the system was evaluated using a variety of datasets, including as the Mailing, BIG 2015, and MaleVis malware datasets, in order to determine its accuracy and detection rates in a range of scenarios. The system's performance was rigorously evaluated under simulated attack scenarios to gauge its resilience and effectiveness in identifying sophisticated and novel malware threats. By subjecting the system to diverse attack simulations, we aimed to validate its ability to detect and classify malicious URLs accurately in real-world cybersecurity environments.

Once our algorithmic arsenal was chosen, the focus shifted toward model training. Training is the process by which these algorithms 'learn' from data. Each algorithm was independently fed the training subset of our dataset. As these models processed the data, they began adjusting their internal parameters to best map the input features to the desired output - the URL categories in this instance. This iterative learning process ensures that the model can discern and remember patterns and nuances inherent in URLs that determine their category. Validation and Fine-tuning, In parallel with the training cycle, we set aside a certain subset of our dataset exclusively for validation purposes. A litmus test is used to evaluate the model's performance using this dataset, which was unaltered during the training process. By assessing the models on this validation set, we may adjust their parameters and make sure they generalize properly to new, unknown data rather than simply repeating back learned data (a problem known as overfitting).

2.6. Performance Metrics Evaluation

After training, it became critical to comprehend the strengths and dangers of each model.
Measurement of Accuracy: One of the most important measures, accuracy, provided us with a simple way to assess how frequently the model made accurate predictions. It offered a concise summary of the model's overall performance and was expressed as a percentage. Digging a little further, we sought to learn more about performance than just the 'overall' result. With the help of Precision, we were able to determine how many URLs the model had classified as, say, "malicious" actually were malicious. Contrarily, recall provided information on the proportion of real dangerous URLs that the model properly recognized.

We used the F-score since we knew that recall and precision were frequently in conflict with one another (increasing one might make the other worse). This statistic seamlessly combines precision and recall to give a comprehensive picture of the model's performance. The confusion matrix proved to be a very useful tool in addition to these measures. It allowed us to identify particular areas that could require greater attention by giving us a detailed, categorical perspective of where models were making mistakes.

2.7. Ensemble Techniques Implementation

Embracing the Power of Collaboration: In light of the fact that no single model is perfect and that each has advantages and disadvantages, we explored ensemble approaches. The foundation of these methods is a straightforward idea: a judgment that is made collectively from various models is frequently more reliable and precise. Majority Voting Mechanism: The Majority Voting mechanism was the simplest ensemble method we used. Each model's forecast acts as a "vote" in this approach. Which category receives the majority of these votes determines the final judgment or categorization.

Soft Voting Strategy: Moving one step further, the soft voting strategy does not rely just on the hard labels provided by each model. As a substitute, it takes into account the likelihood or confidence scores from models, producing a more complex and thoughtful final prediction.

Weighted Voting Approach: We implemented a Weighted Voting mechanism after realizing that not all models perform equally well. Models in this case were given weights based on their individual performances (often their accuracy), ensuring that models with superior performances had a greater influence on the ensemble's ultimate forecast.

2.8. Comparative Analysis

We started a comparison analysis using both the individual models and the ensemble methodologies that we had available. Comparing the performance measures of individual models to those of our ensemble techniques allowed us to understand the additional value that ensemble methods provided. We were interested in determining which ensemble method Majority, Soft, or Weighted voting worked best in our situation. By comparing their outcomes to those of our dataset and study goals, we were able to determine which ensemble methodology was the most successful in categorizing URLs.

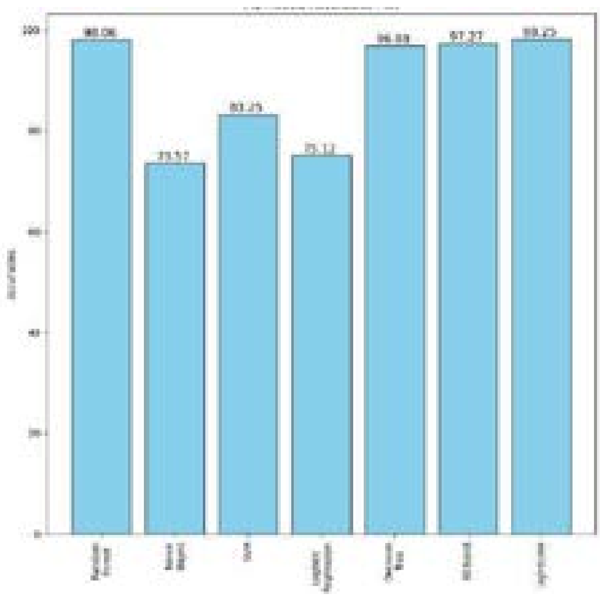

Fig.4 Machine Learning models accuracies plot

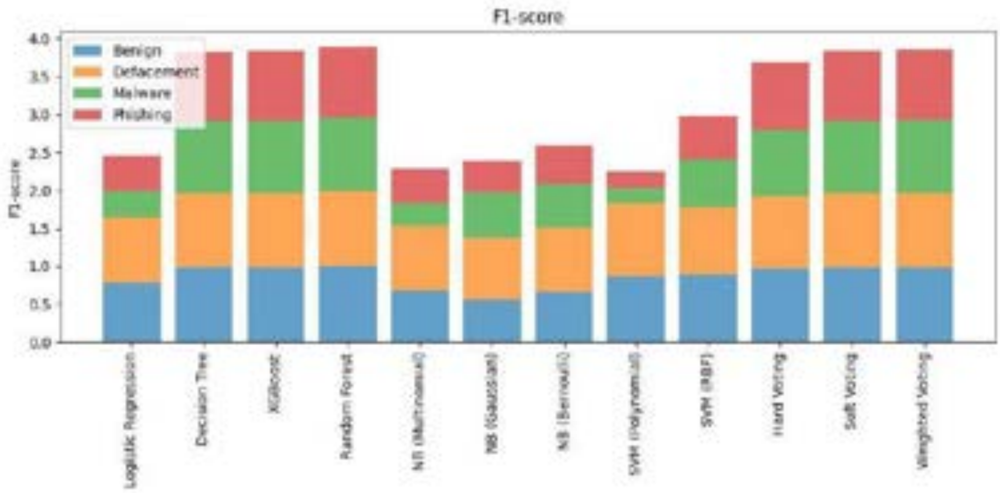

Fig.5 F1 Score

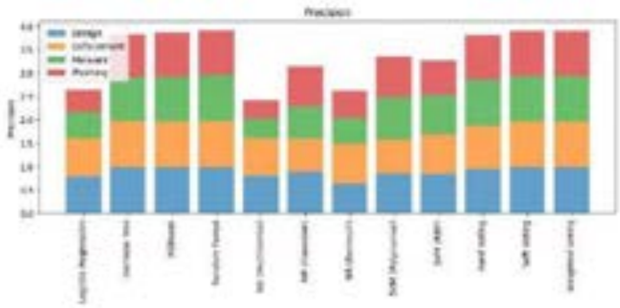

Fig.6 Precision plot

Figure 5, 6 and 7 plots depict the performance metrics of machine learning models across different classes of URLs. Precision measures the proportion of true positive predictions among all positive predictions made by the model. Recall, on the other hand, quantifies the proportion of true positive predictions among all actual positive instances in the dataset. The F1-score is the harmonic mean of precision and recall, providing a balanced assessment of a model's performance.

In these plots, each class represents a specific category of URLs, and the metrics are calculated individually for each class. Higher values of precision, recall, and F1-score indicate better performance of the model in accurately classifying URLs belonging to the respective class. The variation in performance across different classes suggests that certain machine learning models may excel in distinguishing certain types of URLs while performing relatively poorly on others. This variation could be attributed to the inherent complexity and diversity within different classes of URLs, leading to differences in the predictive capabilities of the models.

The performance of various machine learning models for URL classification was evaluated using precision, recall, and F1-score metrics across different classes. Overall, the benign class (class 0) consistently exhibited the highest precision, recall, and F1-score values across all models, indicating that the models could accurately identify benign URLs. Similarly, the defacement class (class 1) demonstrated reasonably good performance, with high precision, recall, and F1-score for many models. However, the phishing class (class 3) showed mixed performance, with some models performing better than others in accurately identifying phishing URLs. Notably, the malware class (class 2) appeared to be the most challenging for the models, with lower precision, recall, and F1-score values compared to other classes.

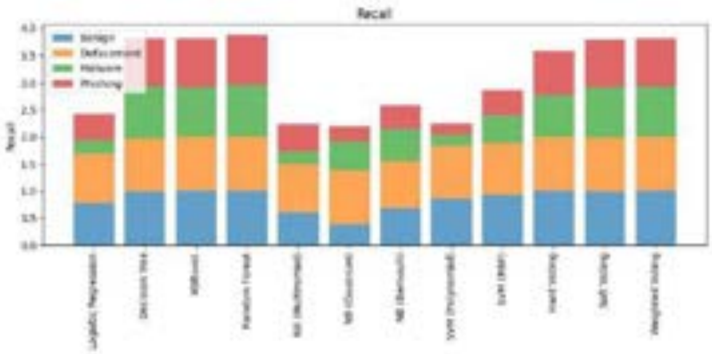

Fig.7 Machine Learning models Recall plot

TP - True Positive (Correctly Predicted Positive)

FP - False Positive (Incorrectly Predicted Positive)

FN - False Negative (Incorrectly Predicted Negative)

TN - True Negative (Correctly Predicted Negative Values)

Accuracy(α) The percentage of correct predictions for the test data.

$$\alpha = \frac{TP + TN}{TP + FP + TN + FN}$$

Precision(ρ) Percentage of positive instances out of the total predicted positive instances.

$$\rho = \frac{TP}{TP+FP}$$

Recall(r) Percentage of positive instances out of the total actual positive instance

$$r = \frac{TP}{TP+FN}$$

F1 score (η) is the Harmonic mean of precision(ρ)and recall(r)

$$\eta = \frac{2 \times \rho \times r}{\rho + r}$$

Logistic Regression

Accuracy: 0.7512

Classification Report	Precision	Recall	F1-score	Support
0	0.79	0.78	0.78	7076
1	0.82	0.91	0.86	19291
2	0.56	0.25	0.35	3910
3	0.47	0.48	0.47	4905

Accuracy			0.75	35182
macro avg	0.66	0.60	0.62	35182
weighted avg	0.74	0.75	0.74	35182

These observations have several implications. Firstly, the differences in performance across classes suggest that machine learning models may find it easier to distinguish benign and defacement URLs from malware and phishing URLs. However, the lower performance on the malware class indicates that more work may be needed to improve the models' ability to accurately detect and classify malware-related URLs. Additionally, ensemble techniques, such as Weighted Voting and Soft Voting, provided better overall performance compared to individual models, highlighting the benefits of combining multiple models to enhance URL classification.

Examining the findings of each model in detail, the Decision Tree Classifier exhibited high accuracy (0.9688) with precision, recall, and F1-score values consistently above 0.90 for all classes. The XGBoost Classifier also performed well with an accuracy of 0.9727, showing high precision and recall values across all classes. The Random Forest Classifier achieved the highest accuracy (0.9806) among all models, with precision, recall, and F1-score values above 0.95 for all classes. However, models such as Naive Bayes - Multinomial and Naive Bayes - Gaussian showed lower accuracy and relatively lower precision, recall, and F1-score values compared to other models. Support Vector Machine - Radial Basis Function (RBF) demonstrated good performance with an accuracy of 0.8325, with precision, recall, and F1-score values consistently above 0.70 for all classes. Overall, these observations provide insights into the strengths and weaknesses of different machine learning models for URL classification tasks.

No single model is the best across all classes and metrics. For example, some models may have higher precision but lower recall, or vice versa. Ensemble methods like Random Forest, XGBoost, and the various voting classifiers generally perform well across all metrics, indicating that they are robust for this particular classification task.

Naive Bayes (NB) classifiers, especially the Gaussian and Bernoulli, seem to have lower performance compared to other models. Support Vector Machine (SVM) with RBF kernel appears to have a good balance between precision, recall, and F1-score, suggesting it is a strong model for this task.

Decision Tree Classifier

Accuracy: 0.9688

Classification Report	Precision	Recall	F1-score	Support
0	0.99	0.99	0.99	7076
1	0.98	0.98	0.98	19291

Findings of Dynamic Voting Algorithms of our work:

In the machine learning approach known as ensemble learning, several models are trained to address a single problem, and then their predictions are aggregated to enhance overall performance. Hard voting and soft voting are two popular methods used in ensemble learning to combine predictions.

In hard voting, a majority vote determines the final prediction made by each model in the ensemble. The final predicted class is determined by tallying the votes cast in favor of that class. Hard voting is effective when individual models in the ensemble are diverse and make errors independently. It is particularly useful in situations where each model has a different perspective on the problem.

In soft voting, each model in the ensemble predicts the probability or confidence of each class for a given input. The class with the highest average probability across all models is the final prediction. Soft voting is effective when the models in the ensemble provide probability estimates. It takes into account the confidence level of each model, which can be valuable in situations where some models are more certain than others.

Weighted voting is a technique where the predictions of individual models are given different levels of importance or weight when making the final prediction. This approach is particularly useful when certain models in the ensemble are deemed to be more reliable or have higher confidence in their predictions than others. Weighted voting allows the ensemble to assign varying degrees of influence to each model, leading to a more nuanced and flexible decision-making process. Weighted voting may reduce the interpretability of the ensemble. Achieving a balance between enhanced performance and the capacity to articulate the decision-making process is crucial.

Key Considerations in the proposed method

Diversity of Models: Hard voting benefits from diverse models that make different types of errors, while soft voting benefits from models that provide well-calibrated probability estimates.

Threshold in Soft Voting: In soft voting, the choice of threshold for binary classification is adjusted based on the desired balance between precision and recall.

Computational Complexity: Hard voting is generally simpler computationally, as it only involves counting votes. Soft voting requires computing average probabilities, which may be more resource-intensive.

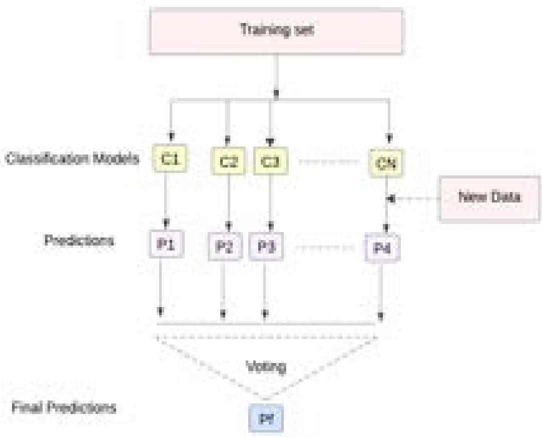

Fig.8 Working of Majority Voting Ensemble Algorithm.

A straightforward ensemble technique known as "hard voting" or "majority voting" bases the final prediction on the choices made by the majority of the classifiers. Assuming we have three classifiers (C1, C2, C3) and their predictions for a sample are [0, 0, 1], the majority vote would classify the sample as "class 0" since it has more votes for that class.

Mathematically, the prediction y is given by:

y =*mode* {C1x, C2x, ...,Cmx}

Weighted Majority Vote:

In weighted majority voting, each classifier is assigned a weight (wj), and the class with the greatest weighted total of votes makes the final prediction.

$$(y) = argmax_i \sum_{j=1}^{m} W_j X_A(C_i(x)) = i)$$

Here, Ais the characteristic function, and A is the set of unique class labels. For instance, if we assign weights {0.2, 0.2, 0.6} to the classifiers, and their predictions are [0, 0, 1], the prediction would be 1 based on the weighted sum.

Soft Voting:

In soft voting, predictions are based on the predicted probabilities (pij) from each classifier. This method is recommended when classifiers are well-calibrated. The class with the highest weighted sum of probability is the final forecast.

$$(y) = argmax_i \sum_{j=1}^{m} W_j \mathrm{p}_{ij}$$

For a binary classification task, if classifiers C1, C2, and C3 predict probabilities [0.9, 0.1], [0.8, 0.2], and [0.4, 0.6] respectively, the soft voting prediction can be computed using uniform weights or custom weights. For instance, with weights {0.1, 0.1, 0.8}, the prediction might differ.

$(y) = argmax_i$ **[**0.10.9+0.10.8+0.80.4,

0.10.1+0.20.1+0.80.6]

This approach allows for a more nuanced decision-making process by considering the confidence levels of each classifier.

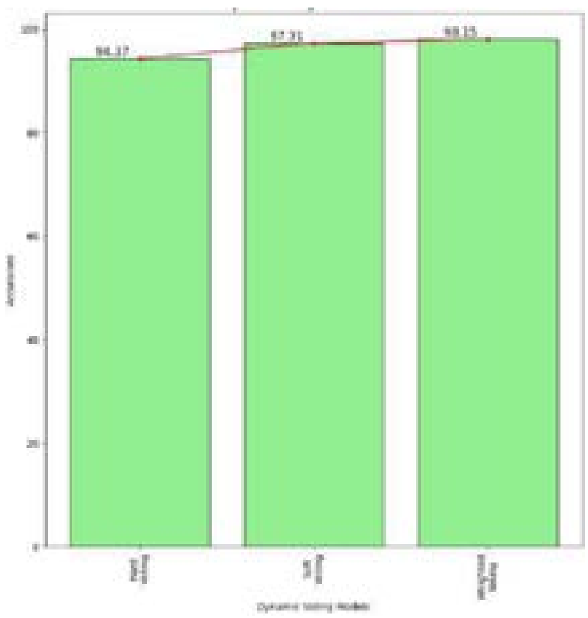

Fig.9 Dynamic Voting models accuracy plot.

VII. Results & Discussion

Across several machine learning algorithms and ensemble approaches, our thorough analysis demonstrated a range of outcomes. Below is an in-depth analysis.

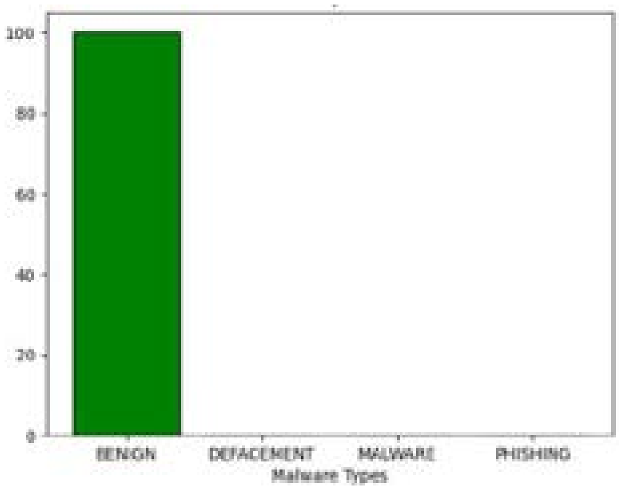

Fig.10 Benign prediction output.

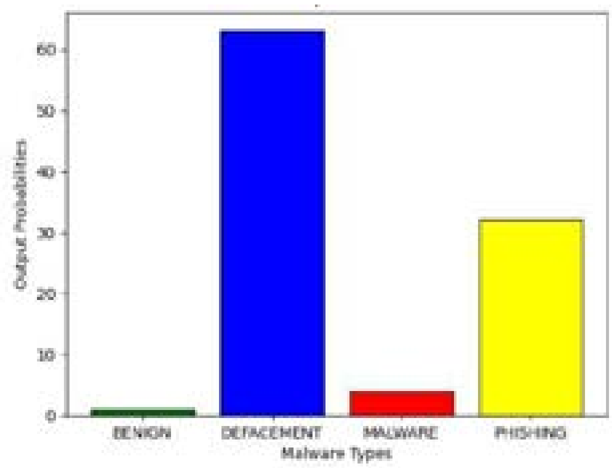

Fig. 11 Defacement prediction output.

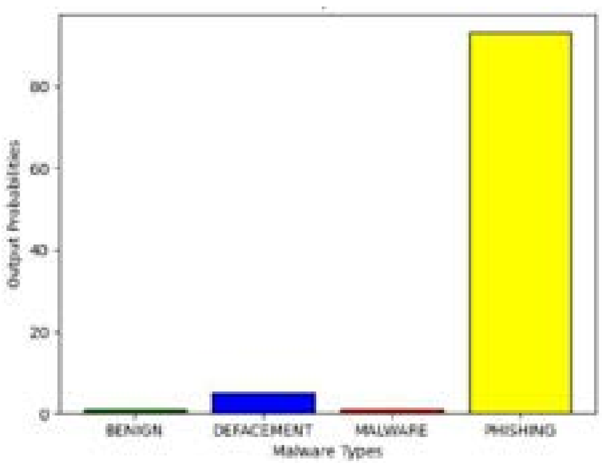

Fig.12 Phishing prediction output.

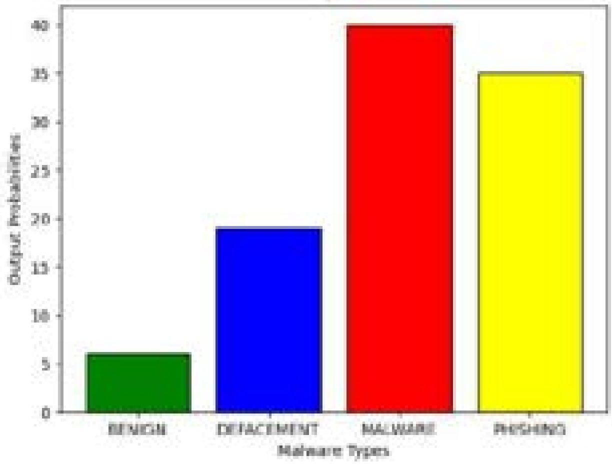

Fig.13 Malware prediction output.

Individual Models:

With an accuracy of 75.12%, the Logistic Regression model showed promise for improvement but was still deemed to be reasonably dependable. It was difficult to categorize URLs between some categories, as the confusion matrix showed. With a noteworthy accuracy of 98.06%, the Random Forest Classifier was the best-performing model. Based on its excellent recall and precision rates, it showed an impressive capacity to differentiate between the various types of URLs. Variants of Naive Bayes produced a range of outcomes. Out of all the models examined, the Multinomial variant had the lowest accuracy (70.95%). The Gaussian variant did better (72.31%), and the Bernoulli variant evened it out at 73.57%. These findings showed how important it is to select the right algorithmic version based on the kind of data. Support Vector Machines (SVM) demonstrated how flexible kernel functions may be. The accuracy of the polynomial kernel was 76.05%, whereas the Radial Basis Function (RBF) performed better, with 83.25% accuracy.

Ensemble Techniques:

By utilizing the combined intelligence of models, Hard Voting yielded an accuracy rate of 94.37%. Despite being straightforward, this majority voting method greatly raised the categorization rate. Soft Voting improved the outcomes even further, yielding a 97.31% accuracy rate. It provided a more sophisticated forecast by taking individual model probability estimations into account. At 97.51% accuracy, Weighted Voting proved to be the most successful ensemble method. Because models were evaluated according to how well they performed, the most trustworthy models were guaranteed to have a significant impact on the outcome.

VIII. Conclusion And Future Work

Threats based on URLs are a broad and dynamic field. In light of this, it is more important than ever to have sophisticated threat detection and classification systems. We took on this challenge with our research, hoping to use machine learning to come up with an innovative solution.

Every model contributed distinct advantages to the discussion. For example, Random Forests contributed unpredictability to reduce overfitting, Decision Trees offered an understandable and transparent model, and SVM examined the data in higher dimensions to determine the ideal separation but it was only via the use of ensemble techniques to integrate these models that their entire power was shown. The ensemble approaches, in particular the Weighted Voting approach, combined the advantages of the models and lessened their individual shortcomings to produce an improved, more reliable system.

The outcomes and conclusions not only demonstrate machine learning's effectiveness in cybersecurity, but they also open the door for more advancements in the field. It's obvious that defenses against cyberattacks must advance in lockstep with the sophistication of the threats. Leveraging a combination of machine learning models and ensemble approaches can prove to be a game-changer in this continuous digital cat and mouse game, offering a safer digital environment for everyone. Exploring deep learning architectures, like neural networks, to identify complex patterns in URL-based threats could be a future development path in threat detection and categorization. Furthermore, the system's ability to adapt to new cyberthreats may be improved by adding changing threat intelligence and real-time behavioral analysis.

***Abstract*— In the online world, recommendation systems are crucial for enhancing the user experience by suggesting relevant items by utilizing user actions. However, they face significant challenges in adapting to evolving user preferences and handling dynamic content. Traditional recommendation algorithms struggle with these challenges, particularly in recognizing evolving user preferences over time. Moreover, they may not effectively handle large datasets or capture intricate patterns in user behavior. To address these challenges, this study analyses the effectiveness of bi-directional models, focusing specifically on Sequential Recommendations with Bi-LSTM (SRec with Bi-LSTM). Unlike traditional static systems, Bi-LSTM offers dynamic and personalized content suggestions by analyzing user actions bidirectionally. This approach enables the system to capture complex patterns in user-item interactions and adapt to changing user preferences over time. In this study, a comparison is made between the performance of Bi-LSTM with several recent techniques, such as Simple RNN with LSTM, Gated Recurrent Unit (GRU) with LSTM, CUDA Deep Neural Network Long Short-Term Memory (CuDNNLSTM), and Stacked RNN. The analysis demonstrates that Bi-LSTM consistently outperforms these methods in terms of accuracy and adaptability to evolving user preferences. By addressing the challenges faced by traditional systems, the proposed Bi-LSTM model offers a promising advancement in personalized sequential recommendations, thereby improving the overall user experience in the fast-paced and ever-changing landscape of online content.**

Keywords—Sequential Recommendations, Bi-Directional Models, Recommender Systems, Personalized Recommendations, Long Short-Term Memory (LSTM)

I. INTRODUCTION

Sequential recommendation systems are crucial for offering users personalized content over time. Current sequential recommendation models mostly rely on one-way processing, making it difficult to capture evolving user preferences and intricate complex temporal dependencies. Traditional models face challenges in capturing the complex patterns and time-related dependencies in user-item interaction sequences.

Addressing these limitations, this study introduces a new approach using bi-directional models, specifically Bi-LSTM. The choice of Bi-LSTM is motivated by its unique capability to capture both past and future context simultaneously, enabling a deeper understanding of the evolution of users' preferences over time and facilitating more precise recommendations. This is particularly critical in dynamic user scenarios where preferences undergo rapid changes. The research is driven by the growing demand for enhanced precision and context-aware recommendations in such dynamic user environments.

Furthermore, the research offers insights into understanding bidirectional connections in user behaviour, revealing the dynamics of sequential interactions. This research aims to address this gap by exploring how Bi-Directional models can manage bidirectional connections in user-item interaction sequences. The goal is to improve the precision and contextual understanding of sequential recommendations, ultimately enhancing the user experience when consuming content.

Examining the effect of personalized recommendations on consumer behaviour, this paper illustrates the significance of users in improving search efficiency and purchase decisions. A meta-analysis [1] examines the correlation between recommendation systems and customer satisfaction, indicating a positive connection between personalized suggestions and customer satisfaction. This study emphasizes the practical benefits of recommendation systems for enhancing user experiences. Here's how this paper is structured: In Section 2, we delve into the problem statement. Section 3 explores related works, while Section 4 provides a detailed description of SRec with Bi-LSTM. Experimental procedures and results are presented in Section 5, and the paper concludes with Section 6, summarizing the findings.

II. PROBLEM STATEMENT

The abundance of material and services online presents users with numerous options, making it challenging for them to find what they want. The typical recommendation algorithms struggle to adapt to evolving user preferences, particularly over time.

Regular recommendation systems, such as collaborative filtering, perform effectively with static items, but they struggle with dynamic user preferences. Sequential recommendation, which attempts to forecast a user's next actions based on their previous behavior, emerges as an effective solution to this problem. However, it faces difficulties in interpreting patterns over time and explaining recommendations. Regular systems might not notice how user preferences change, leading to not-so-great suggestions over time. Moreover, they struggle with handling large datasets.

Traditional models, including collaborative filtering and matrix factorization, provide suggestions based on unchanging data and struggle with complex patterns. Additionally, they fail to adapt to dynamic user preferences and cannot efficiently handle large datasets.

Another challenge in recommendation systems is the issue of cold start, where new users or items have limited data available, making it difficult to provide accurate recommendations. Furthermore, recommendation systems may suffer from algorithmic biases, where certain users or items are favored over others, leading to unequal exposure and potentially inaccurate recommendations.

To solve these problems, SRec with Bi-LSTM is proposed. This approach aims to enhance personalized recommendations in the rapidly evolving world of online content. However, it's important to note that maintaining the efficiency of recommendation systems as the volume of online content continues to grow exponentially is another significant challenge to consider.

III. RELATED WORKS

Initially, the researchers used the Markov Chain (MC) technique to build a recommendation system. Rendle et al. [2] combined matrix decomposition and the first-order MC to understand users overall preferences and their short-term interests. They also utilized the RNN algorithm to understand users' behaviours. These are good at figuring out patterns in a sequence of events. Hidasi et al. [3] pioneered the use of GRU to generate recommendations based on users' actions within a session. After the initial approaches, numerous modifications were introduced to improve the recommendations. For example, Hidasi et al. [4] incorporated a pair-wise loss function, and Li et al. [5] employed an attention mechanism to focus on specific aspects. Chen et al. [6] utilized a memory network, and Quadrana et al. [7] organized information hierarchically. These innovations collectively contribute to improving recommendation systems.

Bi-directional models have become a powerful solution for understanding the context and connections in user sequences. Sun et al. [8] applied the BERT4Rec model, which considers both past and future items sequentially, to understand the users' preferences. They evaluated this model on the ML-20m dataset regarding Hit Rate (HR) and achieved the following accuracy metrics: HR@1 of 0.3440, HR@5 of 0.6323, HR@10 of 0.7473, Normalized Discounted Cumulative Gain (NDCG) @5 of 0.4967, NDCG@10 of 0.5340, and Mean Reciprocal Rank (MRR) of 0.4785. Here, HR gauges the proportion of correct recommendations among the top recommendations provided to users. NDCG assesses the quality of the ranked recommendations. MRR evaluates the effectiveness of the ranking of the first relevant item in the recommendations.

Kang et al. [9] introduced SASRec, a model that integrates self-attention into a Bi-LSTM architecture to highlight essential features of user sequences. This approach enhances the model's ability to understand item relationships and adapt to changing user preferences. Their evaluation on the ML-1M dataset yielded HR@10 of 0.8245 and NDCG@10 of 0.5905 as the obtained results.

Shao et al. [10] introduced NextBasket, a method that combines Bi-LSTM to suggest items in order with a separate model for predicting entire groups of items that users might prefer together. This fusion enhances the accuracy of predictions for both individual items and entire baskets of items. The method underwent evaluation on three different datasets: TaFeng, Instacart, and Dunnhumby. In the Instacart dataset with k = 5, the recall, precision, F1-Score, and NDCG were found to be 0.2616, 0.3733, 0.2619, and 0.3094, respectively. For k = 10 in the Instacart dataset, the recall, precision, F1-Score, and NDCG were 0.3698, 0.2896, 0.2812, and 0.3805, respectively.

Zhao et al. [11] explored deep Bi-LSTM architectures to gain a deeper understanding of user preferences, comparing models of varying depths. They evaluated these models on the ML-1m dataset, achieving Recall@20 of 0.22634 and MRR@20 of 0.04634. This demonstrates the effectiveness of using deeper models to capture detailed user preferences.

Hu et al. [12] presented BiVRec, a new approach utilizing a bi-directional framework to integrate diverse information types, including text and images, into recommendations. This comprehensive approach enhances the model's understanding of users' preferences and available items, resulting in improved recommendations across varied information environments. Evaluation on the ML-25m and ML-1m datasets yielded Recall@20 of 11.96%, NDCG@20 of 28.31, and HR of 65.54%. These results underscore the effectiveness of BiVRec in enhancing recommendation performance.

Devooght et al. [13] proposed the use of a neural network known as RNN for collaborative filtering, demonstrating its effectiveness in understanding the sequence of preferences users have over time. Essentially, RNN helps in understanding the evolution of user's preferences, leading to improved recommendations based on their interactions.

IV. PROPOSED METHODOLOGY

The proposed methodology encompasses various modules aimed at understanding users' behavior patterns over time and generating personalized recommendations. The study uses the MovieLens 100K dataset [14] to analyze user interactions systematically. The approach focuses on organizing user actions in chronological order to observe the evolution of preferences and decisions.

Fig. 1 shows the process of sequential data with Bi-LSTM, which pays attention to things that have happened before and might happen in the future. This is important for understanding user interactions. Unlike regular LSTMs that only analyze data in one direction, Bi-LSTMs examine data in both directions simultaneously, allowing for a comprehensive understanding of past and potential future events. This allows our model to understand what happened before and what might happen next in the sequence.

In handling sequences of user behaviour, such as movie watching or browsing history, Bi-LSTM plays a crucial role. Fig. 2 shows the structure of the LSTM cell. LSTM is a type of neural network that includes special memory cells capable of retaining information for extended periods, addressing challenges commonly encountered in sequential data analysis.

Each user's interactions with items are grouped into sequences, which is essential for capturing user-item interaction patterns. A vocabulary is created to represent different events in these sequences, facilitating model learning. To ensure data consistency, sequences are standardized to the same length by appending additional information to shorter sequences. Subsequently, sequences are divided into input (X) and target (y) parts, enabling the model to predict subsequent items accurately. Class weights are determined to account for variations in the frequency of positive instances during training, preventing bias towards specific event types.

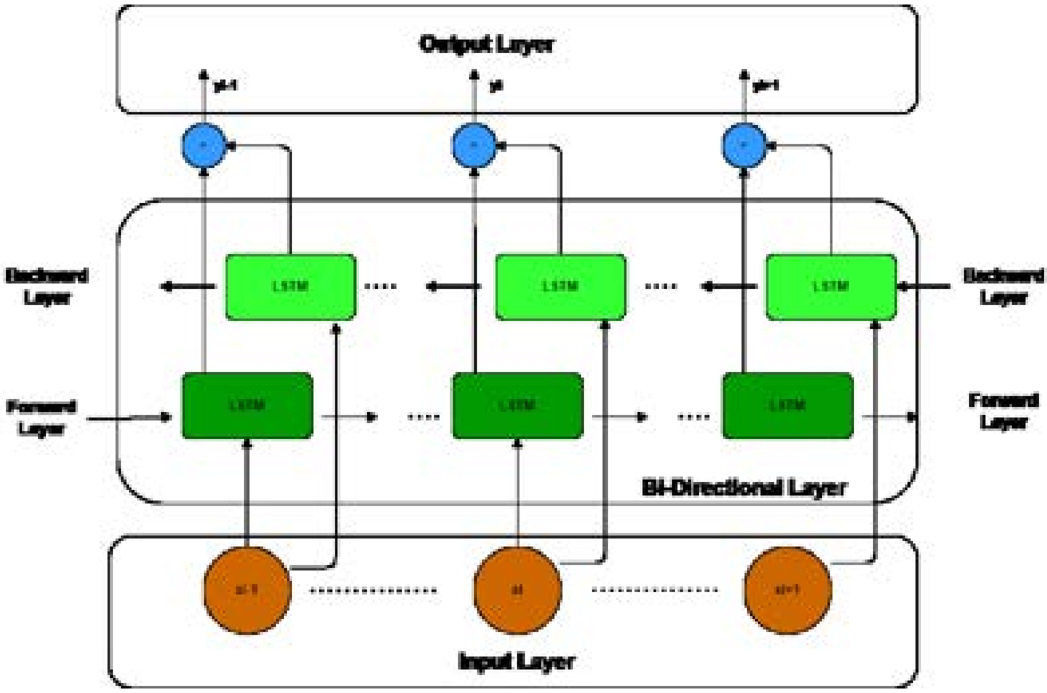

Fig.1 Processing Sequential Data with Bi-LSTM

The model has multiple layers, such as an input layer, an embedding layer, a Bi-LSTM layer, and a dense layer with SoftMax activation, to enhance data understanding. The Adam optimizer and Sparse Categorical Cross-entropy Loss function are used with class weights considered during training. Training is conducted over multiple epochs to evaluate system performance comprehensively.

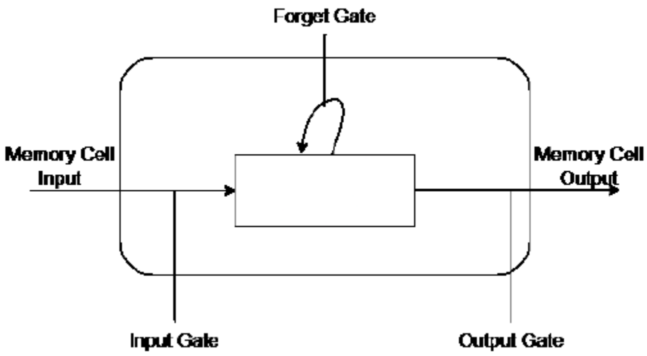

Fig. 2 Structure of the LSTM Cell

During training, the Bi-LSTM model parameters are fine-tuned to predict subsequent items accurately, guided by a tailored loss function for sequential prediction tasks. After training, the model can generate recommendations based on learned patterns, resulting in precise and context-aware suggestions.

To analyze the system performance, SRec with Bi-LSTM is compared with alternative models such as Simple RNN with LSTM, GRU with LSTM, CuDNNLSTM, and Stacked RNN. The evaluation demonstrates the superior performance of the proposed SRec with Bi-LSTM model, attributed to its bidirectional processing capability, enabling effective capture of complex sequential patterns. Consequently, Bi-LSTM emerges as a robust choice for tasks requiring sequential recommendations.

V. EXPERIMENTAL SETUP AND RESULTS

A. Dataset

The model in this research was trained using the Movielens 100k dataset [14], which is a well-known benchmark dataset for collaborative filtering and recommendation systems. This dataset originates from the Movielens project, a movie recommendation service provided by the GroupLens research lab. It contains information about users, movies, ratings, and timestamps.

Specifically, the dataset includes the following fields:

- user_id: A unique code assigned to each user.
- item_id: A unique code is assigned to each movie.
- rating: The rating given by the user to a movie, typically ranging from 1 to 5.
- timestamp: The time when the user provided the rating.

B. Hyperparamteres and Evaluation Metrics

To enhance the effectiveness of the SRec with Bi-LSTM model, various settings were adjusted, and among them, certain parameters yielded the best results.

Fig. 3 showcases the architecture of the SRec with the Bi-LSTM model. This visual representation illustrates the step-by-step flow, starting from the input layer to the dense output layer.

The model begins with the input layer, where raw data, such as sequences of user interactions, enters the system. This layer captures the sequence of user interactions, which is essential input for further processing when dealing with sequences for recommendations.

The embedding layer has two important settings. The first one is vocabulary size, which represents the number of different items that are dealt with. The second setting is the embedding dimensions, determining the size of the space where the items are positioned.

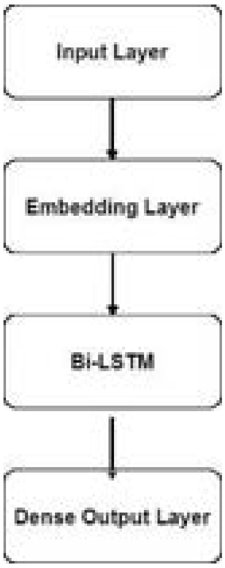

Fig. 3 SRec Architecture with Bi-LSTM

In the Bi-Directional LSTM Layer, hidden units have been set to 100. They examine both sequentially to understand the connections between them.

Moving on to the Dense Output Layer, the vocabulary size indicates the number of recommendations provided, aligning with the size of the item collection.

The system undergoes multiple training passes, known as epochs. Additionally, the data is divided into smaller groups called batches. In total, 32 batches were identified, and the system was adjusted accordingly.

For class weights, different importance is assigned to items during training, allowing the system to pay more attention to less common items and improving its ability to handle diverse data.

Finally, the optimizer, a function called Adam, adjusts the model's internal knowledge based on observations during training, leading to continuous improvement. The loss function, sparse categorical cross-entropy, evaluates the system's performance and is particularly suitable for tasks involving different categories of items.

C. Experimental Results

The reliability of the proposed system in this research can be measured using specific evaluation criteria: F1-score, accuracy, precision score, and recall score.

Accuracy: It measures the overall correctness of a model by calculating the ratio of correctly predicted instances to the total instances.

Precision: It quantifies the accuracy of positive predictions, indicating the fraction of correctly predicted positive instances among all instances predicted as positive.

Recall: It measures the ability of a model to capture all positive instances, indicating the fraction of correctly predicted positive instances among all actual positive instances.

F1 Score: It is the harmonic mean of precision and recall, providing a balanced measure that considers both false positives and false negatives.

In the experiments, various models were used, including RNN with LSTM, GRU with LSTM, CuDNNLSTM, and stacked RNN. The focus was primarily on assessing the performance of the Bi-LSTM model in comparison to other types like simple RNN with LSTM, GRU with LSTM, CuDNNLSTM, and stacked RNN.

Fig. 3 shows that the accuracy of the Bi-LSTM model is higher than the other model. Accuracy indicates how often the model makes correct predictions. The data in Fig. 3 indicates that the CuDNNLSTM and GRU with LSTM models achieved an accuracy of 86%, while the proposed model attained 86.4%. The success of the proposed model can be attributed to its utilization of bidirectional LSTM, which enables it to achieve higher accuracy by considering both past and future data in the sequence when making predictions.

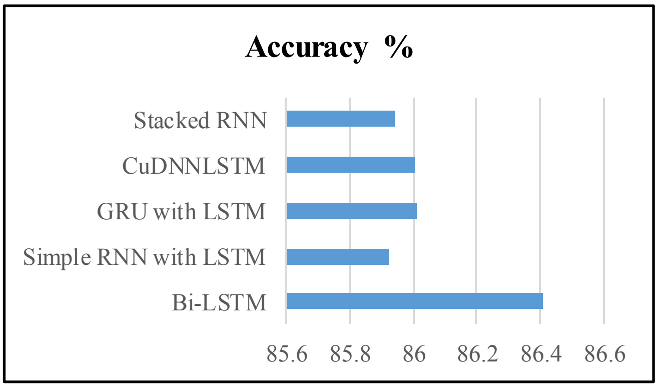

Fig. 3 Accuracy Score Comparison

Fig. 4 shows that the precision score of the Bi-LSTM model surpasses the other models. The proposed Bi-LSTM technique achieved a precision score of 85%. In comparison, other systems such as Simple RNN with LSTM, Stacked RNN, GRU with LSTM, and CuDNNLSTM with LSTM obtained precision scores of 83.69%, 79.32%, 78.64%, and 81.59%, respectively. This comparison illustrates the superior precision of the Bi-LSTM model in identifying relevant items, highlighting its effectiveness in recommendation tasks relative to the other models evaluated.

Precision %

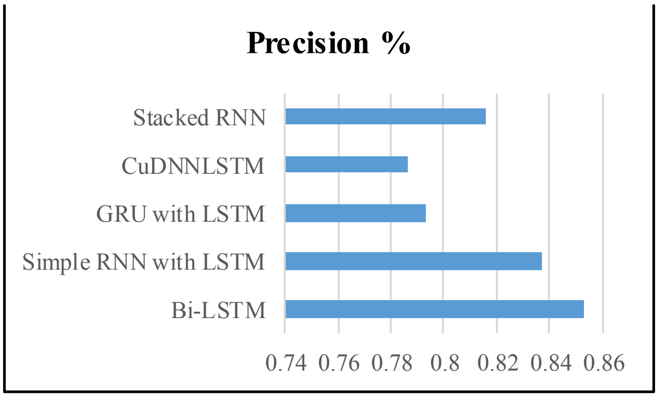

Fig. 4 Precision Score Comparison

Fig. 5 shows the recall score of the Bi-LSTM model outperforms that of other models. The proposed Bi-LSTM technique achieved a recall score of 86.41%. This comparison underscores the superior performance of the Bi-LSTM model in accurately capturing relevant items, making it a more effective choice for recommendation tasks relative to the other models.

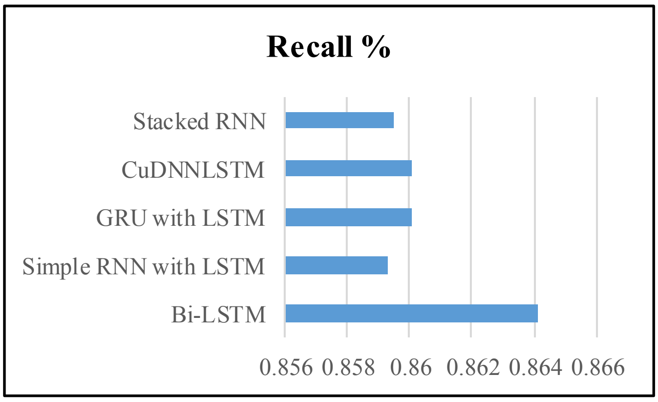

Fig. 5 Recall Score Comparison

Fig. 6 shows that the F1-score of the Bi-LSTM model surpasses that of other models. The proposed Bi-LSTM technique achieved an F1-score of 85.72%. This suggests that the Bi-LSTM model excels in capturing the accuracy as well as the completeness of predictions, making it a robust choice for recommendation tasks.

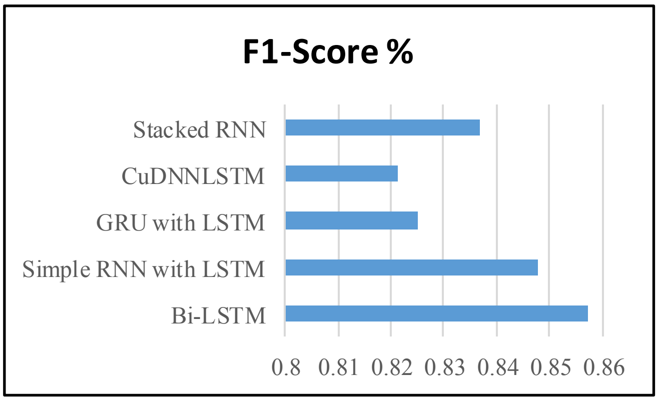

Fig. 6 F1-Score Comparison

In summary, the Bi-LSTM model emerged as a robust performer, demonstrating superior performance across the above key metrics. These findings underscore the effectiveness of the proposed SRec with Bi-LSTM in understanding and predicting user-item interactions comprehensively. Consequently, the model proves to be well-suited for dynamic online environments, where accurate and timely recommendations are essential for enhancing user experience and satisfaction.

VI. CONCLUSION

In today's digital age, recommendation systems have become indispensable for guiding users to relevant content online. These systems play a crucial role in helping users discover suitable items efficiently. However, existing recommendation systems encounter various challenges that affect their accuracy. These challenges include the cold start problem, limited availability of data, biases within the data, evolving user preferences, and the absence of contextual information.

The main goal is to fix problems with current recommendation systems by suggesting a new idea. The SRec model with Bi-LSTM is introduced, which uses attention to understand the context and connections in user sequences. The model can find patterns over time and make accurate predictions for individual items. It's also built to handle situations where the data is uneven, making it work better in real-world recommendation situations.

Looking forward, the future of recommendation systems involves exploring several avenues for improvement. This includes integrating diverse types of information, adapting to users' evolving preferences in real-time, simplifying model interpretability, incorporating reinforcement learning principles, and tackling the challenge of managing large volumes of user data for personalized recommendations. In the future, the exploration of advanced techniques like deep LSTM, deep Bi-LSTM, ensemble models, and multimodal approaches is forecast to amplify recommendation accuracy and effectiveness.

Abstract— Nowadays due to environmental change flooding is a major problem in urban cities. Due to the extreme overflow of water from lakes and rivers, cities face flooding. Manual alarms and the maintenance of regular water flow were vital problems during the rain. Hence, automatic flood forecasting and flood prediction models are needed. The proposed flood monitoring and prediction system, Flood Guard, has been designed using environmental sensors connected with Raspberry Pi Pico W. The PICO W controllers capture real-time data from the environmental sensors of water flow, water level, humidity, temperature, and rainfall, which are essential to detecting flood risk. Based on the water level, the outlet motor actuation speed is triggered to reduce the high intensity of the water during rainy times. All the sensor data collected will be transferred to the IoT Cloud using the message queuing telemetry transport (MQTT) protocol. The forecasting algorithm called a Bidirectional Long Short-Term Memory (BiLSTM) model has been developed in the cloud. This proposed model is trained by the array of sensors from hydrological and meteorological data and evaluated using normalized sensor data. Experimental results show that the proposed model achieves a training accuracy of 100% and a testing accuracy of 98.97%. The training loss and testing loss have been decayed when compared to the other state-of-the-art methods.

Keywords—Flood Forecasting, Computer Vision, Deep Learning, Neural network

I. INTRODUCTION

Flooding has become a major global problem, causing loss of human life and economic damages. It affects many areas, leading to property damage and the need for disaster management. Floods can result in broken infrastructure, such as roads and bridges, and can disrupt essential services. There are many causes of Flooding, such as Heavy rainfall can lead to rivers overflowing their banks. Melting snow and ice can increase water levels in rivers and lakes. Storm surges from hurricanes or typhoons can cause coastal flooding. Changes in land use, like deforestation, can reduce the land's ability to absorb water. Flooding is a major global issue causing loss of life and property damage. Preventing floods is not possible, but we can reduce their impact. Advanced technologies like the Internet of Things (IoT) can help predict floods. Early warnings from IoT devices can save lives and possessions by allowing timely evacuations. The paper discusses an IoT-based system for collecting hydrological and meteorological data. Data from sensors on water flow, level, discharge, and weather conditions are used to predict floods.

The system classifies flood events into different alert levels using an LSTM model [1]. In [2] discusses a sensor designed to measure water levels in dikes using a fiber optic technology called FBG (Fiber Bragg Grating). FBG sensors are unique because they can work well in tough conditions and can measure pressure at different points along a distance. The sensor has a 3D-printed part that changes pressure into strain on the fiber, which can be measured. Temperature changes can affect the sensor, so a second FBG is used to adjust for those effects. The sensor is protected by an aluminum case, making it strong enough for difficult installation and environments. Tests were done on real dikes in the Netherlands, showing that the sensors work well.

Wireless sensor networks (WSNs) were utilized for flood monitoring, the main concern in WSN is it energy efficient. Compressive sensing (CS) was introduced as an energy-efficient solution for remote flood monitoring systems to overcome the energy-efficient issue in WSN. In CS data construction method was used to obtain high-quality results at high compression rate. The primary components of the CS are block-based and learning rate of the design [3]. WSNs have limited battery life, which restricts their long-term deployment without maintenance. Sensors in WSNs need to transmit data over distances, which consumes significant energy. Frequent data transmission by sensor nodes leads to quicker battery depletion. High data sampling rates for accurate monitoring can result in increased energy consumption. Energy is also used in data processing tasks before transmission, adding to the overall power usage. WSN based IoT was developed in [4] flood monitoring in Colima, Mexico, based on the water level, soil moisture and weather conditions. IoT- Message queuing telemetry transport protocol (MQTT) was used to gather data from the real time storm events in 2019. During the flood events the hydrological data needed to be analyzed by the models. This model generates the critical position where the flood will happen soon with inundation maps. Security mechanisms in the IoT networks are lacking when the data is shared. IoT networks lack security mechanisms for data sharing. A lightweight protocol called MQTT was used to manage time constraints in IoT networks. Experimental analysis was done on a testbed setup with hardware and sensors to show the IoT MQTT data transfer effectiveness between two devices [5]. It may introduce the IDISense app, an IoT-based system designed to monitor real-time parameters of dams and weather conditions. A spiking neural network (SNN) predicts rainfall using past weather data. The system includes a central control room for decision-making. Alerts are sent to nearby residents through the IDISense app. The SNN's accuracy in predicting rainfall is compared with other models [6]. Floods may become more common because of global warming. Early detection of water disasters can save lives, and it's important to find good warning systems. People use social media like Twitter to report environmental problems, acting as social sensors. In [7], it discusses the WATERoT project, supported by the Spanish government. WATERSensing was created to help prevent and assess water disasters using social media. The system uses deep neural networks to sense waterlogging events visually. It predicts and maps floods nationally using video sources from the Internet of Cameras. A vehicle detection model identifies vehicles, and a wheel detection model locates wheels to grade flood severity. The system processes input from 2.4K cameras and outputs results in five minutes. Cloud resources and information and communications technology support the workflow. The methodology includes training deep learning models, capturing images, and using GIS mapping for notifications [8]. The methodology uses an Ensemble Kalman Filter (EnKF) algorithm for data assimilation in hydraulic flood forecasting models. It includes the use of gauged water levels for model calibration and validation. The control vector in the DA algorithm is composed of friction coefficients and parameters modifying the upstream boundary conditions. The observation error covariance matrix is assumed to be diagonal with a standard deviation proportional to the observations. The Kalman gain matrix weights the innovation vector and corrects the background control vector [9]. The main problem of flooding is a major global issue causing loss of life and economic damage. Sensors must perform consistently in various environmental conditions, such as extreme weather, and provide accurate readings to inform flood forecasts. IoT devices, including sensors and Arduino boards, often operate on limited power sources. Integrating sensor data with existing hydrological and meteorological models to improve forecast accuracy is complex. The system must effectively combine real-time sensor data with these models for effective prediction.

II. RELATED WORKS

The literature survey on utilizing deep learning techniques for flood detection and mapping through remotely sensed data, especially from real-time ground-level images, highlights an emerging yet promising area of research. This area seeks to address and overcome the limitations associated with traditional flood monitoring methods. Traditional approaches, including the use of water level sensors and remote sensing technologies. The challenges include limited spatial and temporal coverage, delayed information relay, and high operational costs. In contrast, the advent of low-cost vision sensors and advancements in communication technologies have paved the way for large-scale image monitoring, transforming cameras into viable sensors for capturing real-time flood information. In [10], it uses modified neural network architecture to reduce measurement error. It was validated by comparing the actual water level with a trained neural network output. Measurement error bounded by ±1 cm in distance measurements ranging from 2 to 500 cm. In [2], the survey covers the history and development of pressure sensors, focusing on those used in harsh environments. It might discuss the limitations of traditional sensors, such as piezometers and strain gauges, in these settings. In [11], an intelligent system was designed using sensors and microcontrollers, and the data is processed by ESP-32 and stored in the cloud. Global Internet of Things used for user notification of sensor data status captured and monitored using the SARIMAX model. The model has low deviations in forecasting values RMSE: 0.6145, MAPE: 3.20.

The survey [3] highlights the advantages of FBG sensors, including their immunity to electromagnetic interference and ability to perform long-distance measurements. Sparse binary matrices are more energy-efficient and accessible to implement in embedded systems. The literature includes methods for parameter estimation, such as using a Type II maximum likelihood procedure. Learning-based rules, like expectation maximization (EM), are used to estimate model parameters. The study [8] focuses on the challenge of sudden urban floods and the need for efficient sensing systems. The need for physical rulers or consistent reference objects limits conventional methods for water level estimation. The framework estimates maximum water level and topographic deformation using CNN-based methods like Attention U-Net and LinkNet. The approach combines numerical simulation and deep learning for rapid damage estimation. Quantitative evaluation uses metrics like RMSE, IoU, and LSH [12]. Table 1 summarizes the methodologies and key findings from recent studies, showcasing the diverse applications of machine learning, neural networks, and natural language processing in enhancing flood disaster monitoring and response strategies.

TABLE I. OVERVIEW OF ADVANCED ALGORITHMS IN FLOOD MONITORING AND DISASTER PREVENTION RESEARCH

Ref. No	Algorithm used	Merits	Demerits
[3]	BSBL-WSN	Energy-efficient remote flood monitoring system.	The reconstruction process is not as simple as traditional methods.
[6]	SNN	IDISense app gives alerts to neighboring people.	Unstructured data remains laborious for current methods
[7]	NLP and NER	It provides real-time information and actionable intelligence for emergency services.	It needs lot of data to predict the emergency situations
[8]	Mask R-CNN	High scalable compared to other previous approaches.	Unknown class images with noise and wrong field of view
[13]	ResNET model	Different ML models can distinguish irrigation systems regardless of crops	Insufficient information on the impact of secondary crops.
[14]	OmbriaNet ,	OmbriaNet produces high-quality flood maps surpassing state-of-the-art techniques.	Insufficient details on the impact of the flood mapping approach.
[16]	FFNN	FFM integrates locally trained models for accurate flood predictions	Only local trained model gives good accuracy.
[17]	Cascaded-ANFIS	Future flood events were effectively identified using Shared Socio-economic Pathways	Water controlling and managing is not addressed.
[18]	RF, GA-XGBoost, DE-XGBoost	Hybrid XGBoost models superior to existing models for hourly water level prediction.	CART model sensitivity to peak values can affect detection accuracy

The primary motivation of this research is that during flood time, it is critical in flash flood situations where rapid response is essential for community safety and minimizing damage. The primary consideration of the frequently cycloned area is vital for areas prone to such unpredictable and fast-occurring natural disasters. There is a need for flash flood message transfer scenarios where every moment counts and that timely information can save many lives. Need to develop a network of sensors and devices working together to gather, analyze, and communicate flood data, enhancing the accuracy and efficiency of flood prediction and monitoring. The main contributions are to develop an integrated, cost-effective, and energy-efficient mobile sensing system for real-time flood monitoring. This system uniquely combines advanced methods for calculating water discharge with sensor calibration and outlier detection to enhance accuracy. It innovatively employs a Bi-Directional Stacked LSTM model, integrating hydrological and meteorological data for precise real-time flood prediction, showcasing a pioneering approach in flood forecasting technology.

III. METHODOLOGY

The proposed Flood Guard has been developed with the help of a network of sensors for rainfall measurement. These sensors, all controlled by the Raspberry Pi Pico, will collect diverse environmental data essential for accurate flood monitoring and prediction after collecting the various sensors data that is sent into a centralized system managed by the Raspberry Pi Pico. Integrating data from different sources and sensors helps create an outlook on environmental conditions. To develop a flood prediction model using the collected data with the help of a Bi-Directional Stacked LSTM approach. The proposed system predicts and advances issuing alerts and warnings based on the predictive analysis in flood areas. Figure 1 depicts the proposed block diagram.

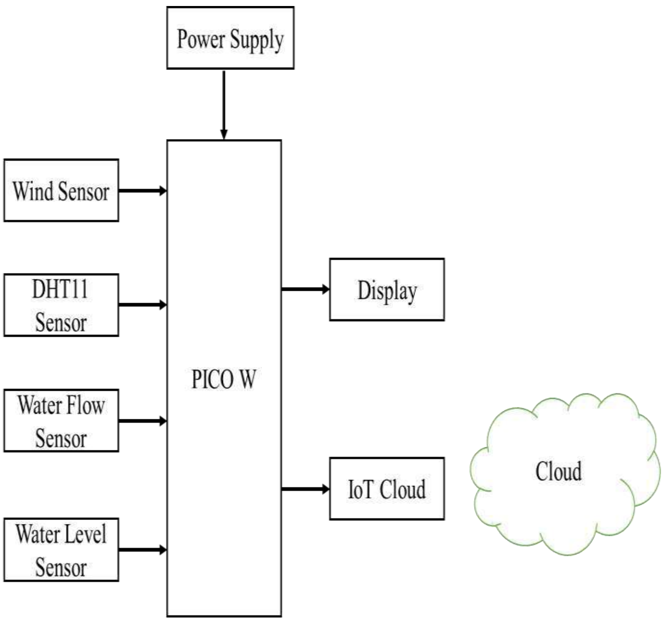

Fig. 1. Proposed framework block diagram

The power supply is the primary source of energy for the system. It is connected to the Raspberry Pi Pico W (Wireless), ensuring that the microcontroller and all connected sensors have a reliable power source for continuous operation. The system has four different types of sensors, each designed to measure specific environmental parameters: wind sensor, DHT11 Sensor, Water Flow Sensor, and Water Level Sensor. The heart of the system is the Raspberry Pi Pico W, a microcontroller with wireless capabilities. It receives data from the various sensors, processes this information, and can make decisions or perform actions based on the programmed logic. Its wireless functionality allows it to communicate with other devices or networks. A display unit connected to the Raspberry Pi Pico W to provide real-time readings and status updates from the sensors. This LCD screen visualizes the data for local monitoring. IoT cloud-based platform where the data collected by the Raspberry Pi Pico W is sent. The cloud platform could offer services like data storage, analysis, and integration with other systems. It enables the scalability of data processing and facilitates remote access from anywhere in the world. The system's main function is for the sensors to collect various environmental data points and send this information to the Raspberry Pi Pico W. The Pico W processes this data, which may involve preliminary analysis or simply formatting the data for transmission. The processed data is displayed locally for monitoring and sent to the IoT Cloud for storage, further analysis, and integration. The Cloud processes this data using Bi-Directional Stacked LSTM to predict potential flooding events. If the system predicts a high risk of flooding, alerts can be generated and distributed to the necessary channels to warn local authorities and residents.

A. Sensor Network Deployment and Data Collection

The sensor network deployment and data collection modules are the initial step for the proposed flood guard framework. The flood guard consists of sensors that measure water level, water flow, temperature, humidity, rainfall measurement, wind speed, and wind direction. These sensors are used to sense both hydrological and metrological data in the river basin or lake region. All the sensors are connected to Raspberry pi Pico W which serves as the control unit, later, all the data will be transferred to the IoT cloud.

B. Data Integration and Preprocessing

The data obtained from the sensor network has been sent to a centralized system, which the Raspberry Pi Pico also controls. This data integration and preprocessing module combines the data from all sensor nodes to understand the environmental conditions on the monitored region.

C. Flood Prediction Modeling

Flood Guard employs a Bi-Directional Stacked Long Short-Term Memory (Bi-LSTM) model, capable of learning from data sequences, to predict flood occurrences. The selection of the Bi-LSTM model stems from its capacity to capture both historical and future context within environmental data.

D. Alert and Warning System

Based on the predictive analysis conducted by the Bi-LSTM model, the proposed Flood Guard will issue alerts and warnings about potential flood events. The system evaluates the forecasted data against predefined thresholds to determine the risk level of flooding. When these thresholds are exceeded, the system triggers alerts through various communication channels, such as SMS, email, or dedicated mobile apps, to inform authorities and residents in the affected areas.

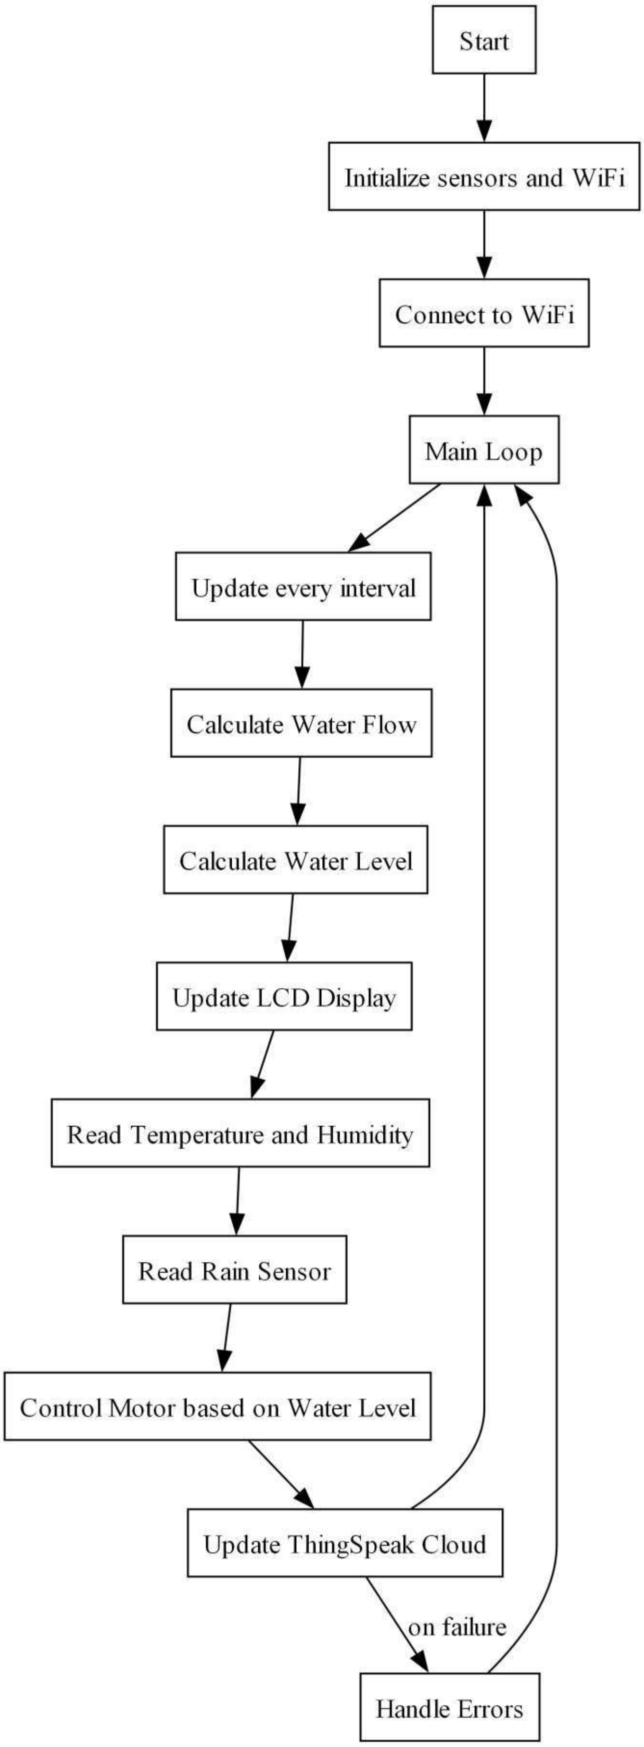

Fig. 2. Operational Flowchart of the IoT-Based Flood Monitoring System

Figure 2 depicts the flowchart of the proposed IoT-based flood monitoring and prediction system. The process begins with the sensor initialization and a Wi-Fi connection. Once the system is connected, it enters a main loop that updates the sensor readings, such as water flow, water level, humidity and temperature at regular intervals. The system calculates water flow and level within this loop, updates an LCD with this information, and reads temperature, humidity, and rainfall data. Based on the water level readings, it controls a motor to manage water flow or activate a floodgate.

Additionally, the system updates a cloud service, ThingSpeak, with the collected data for remote monitoring and analysis. If there is a failure during the cloud update, the system handles errors accordingly. This cycle of operations continues indefinitely, ensuring continuous monitoring and reactive measures to potential flooding.

IV. Results and Discussion

The proposed floodwall hardware collects environmental data from various sensors, including wind, water flow, water level, temperature, humidity, and rainfall. Processing and analyzing this data in real-time with a Raspberry Pi Pico W. Actuating a motor to potentially control water flow or floodgates based on the water level data and displaying the sensor data on an LCD screen for local monitoring. The collected data will be sent to the ThingSpeak cloud platform for further analysis and remote monitoring. Table II presents data from an environmental monitoring dataset originally structured in time series format. Each row corresponds to a different parameter measured by flood monitoring sensors, such as Water Flow, Water Level, Water Discharge, Temperature, Humidity, Wind Speed, and Wind Direction. The columns represent consecutive hourly timestamps starting from midnight on January 6, 2024. The sensor readings at each timestamp facilitate a parameter-centric view, which can be advantageous for certain data analyses, such as comparing distributions across different environmental factors or sensor calibration processes.

TABLE II. Environmental DataSet from Flood Monitoring Sensors

Attributes	**1**	**2**	**3**	**4**
Time Stamp	2024-01-06 00:00:00	2024-01-06 01:00:00	2024-01-06 02:00:00	2024-01-06 03:00:00
Water Flow (m^3/s)	150	155	160	180
Water Level (m)	3.2	3.3	3.5	4.0
Water Discharge (m^3/s)	480	500	520	580
Temperature (°C)	26	26	27	28
Humidity (%)	80	82	85	75
Wind Speed (km/h)	10	12	9	15
Wind Direction	NW	N	NE	NW

TABLE III. COMPARISON OF TRAINING AND TESTING LOSSES FOR BiLSTM, LSTM, AND CNN MODELS IN FLOOD PREDICTION

Proposed BiLSTM		LSTM		CNN	
Training Loss	**Testing Loss**	**Training Loss**	**Testing Loss**	**Training Loss**	**Testing Loss**
6.35×10^{-6}	5.47×10^{-6}	1.05×10^{-5}	1.28×10^{-5}	6.24×10^{-6}	6.00×10^{-6}

Table III presents the training and testing losses for three different neural network architectures, BiLSTM, LSTM, and CNN, utilized in flood prediction. The loss values are measured in terms of mean squared error (MSE) and are provided in scientific notation for clarity.

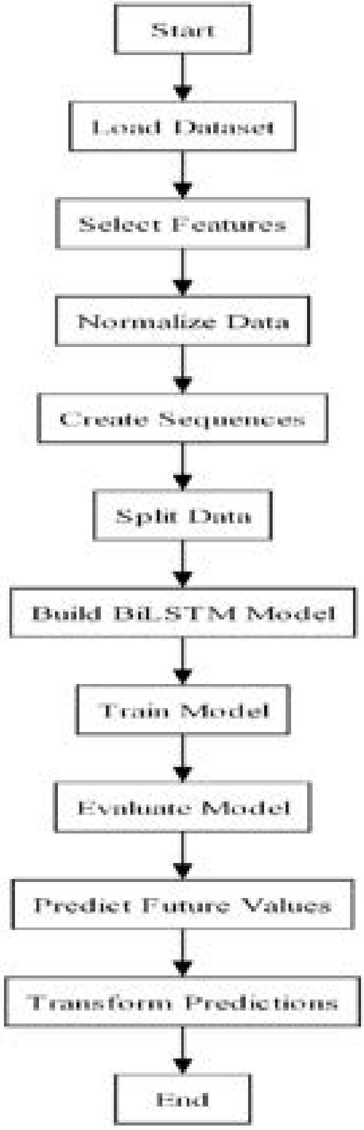

Fig. 3. Workflow of BiLSTM Model Development for Time Series Forecasting

Figure 3 depicts a sequential workflow for developing a Bidirectional Long Short-Term Memory (BiLSTM) model tailored for forecasting based on time series data. his workflow encapsulates the end-to-end process of building and utilizing a machine learning model for predictive analysis in time series data.

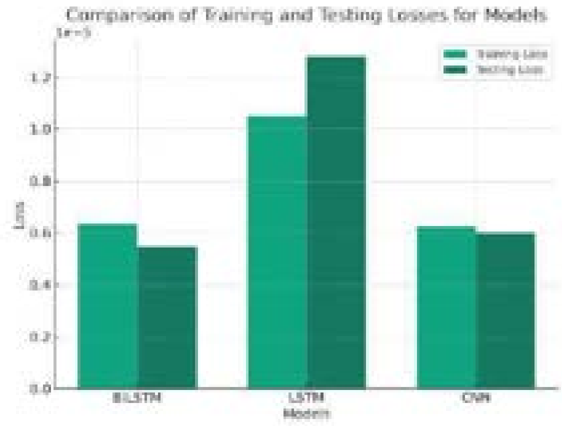

Fig. 4. Comparison of Training and Testing loss for Models

Figure 4 depicts the comparison of training and testing loss for models. The BiLSTM model outperforms the LSTM and CNN regarding testing loss, highlighting its effectiveness in generalizing well to new, unseen data, which is critical for reliable flood prediction. The dual-direction learning capability of the BiLSTM contributes to its enhanced performance by effectively utilizing the entire context of the input data sequence.

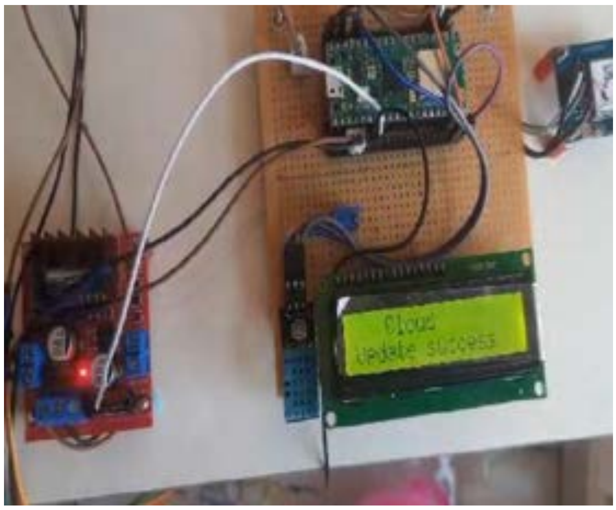

Fig. 5. IoT Based Flood Monitoring System Hardware Prototype

Figure 5 displays an IoT flood monitoring setup with a Raspberry Pi Pico W connected to various sensors and a display indicating a successful data transmission to the cloud, signifying the system's ability to update and monitor flood-related data in real time remotely.

V. CONCLUSION

Flood Guard system was represents a significant step forward in real-time flood monitoring and forecasting. A sophisticated network of environmental sensors coupled with the computational prowess of the Raspberry Pi Pico W, the system for data acquisition. Incorporating a Bidirectional Long Short-Term Memory (BiLSTM) model on the sequential nature of the data gave accurate predictions of flood-related events. This system facilitates immediate local response through its automated control of actuators based on water levels. It extends its utility to remote monitoring via cloud connectivity to the Thing Speak platform. In future, the data from the multiple-point node will be trained using a federated learning algorithm.

***Abstract*—This research study introduces a groundbreaking approach to landslip monitoring through the seamless integration of low-power sensors with the versatile Arduino NANO platform, leveraging LoRa-based IoT technology. By facilitating real-time analysis of critical environmental variables such as water levels, soil movement, and humidity, this system enables early detection of soil instability, potentially preventing devastating landslides. Automated email notifications promptly alert authorities and communities to impending threats, enhancing crisis management effectiveness. LoRa technology's extensive coverage, affordability, and adaptability address shortcomings of traditional monitoring methods, while its versatility extends applicability beyond landslip monitoring. This proactive system empowers communities to intelligently respond to environmental changes, providing comprehensive, real-time monitoring for hazard identification and preventive action formulation, ultimately mitigating disaster risks and enhancing overall disaster response capabilities.**

I. INTRODUCTION

The real-time data gathering, transmission, and analysis made possible by the Internet of Things (IoT) is essential to the modernization of landslide monitoring [1]. IoT devices, which are outfitted with an array of sensors, function as primary data collectors, persistently tracking environmental factors such as soil moisture content, vibrations, and precipitation. This information is wirelessly sent to a central monitoring station, allowing for the prompt deployment of mitigating measures and the timely identification of possible landslide incidents [2], [3]. IoT also makes it possible to integrate machine learning and cloud computing, which improves data analytics and predictive modeling capabilities. Consequently, IoT is essential to building a dynamic and proactive framework for monitoring landslides, which improves disaster resilience in areas that are susceptible to disasters [4], [5].

A. Background and Motivation:

The impetus for this research stems from the critical need for a sophisticated landslip monitoring system that addresses the limitations of current techniques [6]. Traditional methods relying on manual data gathering and sporadic inspections often fail to provide accurate and timely information about evolving environmental conditions. By integrating low- power sensors with Arduino NANO and LoRa technology, a revolutionary shift in landslip monitoring becomes feasible [7]. This system enables continuous real-time data collection across various environmental parameters, facilitating a comprehensive understanding of factors contributing to landslip incidents. The advent of IoT technologies, particularly LoRa, has revolutionized data transmission from remote locations due to its extended range and low power consumption [8]. By integrating diverse sensors measuring water levels, vibrations, humidity, and soil moisture, holistic examination of landslide- prone areas becomes achievable. Ultimately, this project aims to enhance early detection capabilities through IoT integration, empowering communities and authorities to proactively respond to changing environmental conditions [9].

B. Objectives:

The primary objective of our research is to pioneer the development and implementation of a real-time landslip monitoring system utilizing low-power sensors and LoRa technology [10]. This involves the construction of robust hardware incorporating an Arduino NANO and various sensors to detect crucial environmental variables. Concurrently, we aim to evaluate the system's efficacy in providing real-time data and early warnings for landslide events. Through comprehensive testing and certification processes, we endeavor to demonstrate the system's reliability and its potential to significantly reduce response times during emergencies. This research holds promise for enhancing disaster preparedness and mitigation efforts in landslide-prone areas [11].

C. Scope of the Paper:

This article delves into the intricacies of monitoring land-slides in real-time through the innovative integration of IoT and LoRa technology [12]. It meticulously outlines the design, installation, and evaluation of the IoT system, encompassing hardware specifics, sensor technologies, and communication infrastructure. Furthermore, the study extends its purview beyond landslides, highlighting the system's adaptability to diverse natural catastrophe scenarios [13]. A comprehensive exploration is promised, elucidating the seamless integration of low-power sensors with LoRa technology within an IoT framework [14]. Practical implications and contributions to disaster management are expounded upon, offering valuable insights into this pioneering approach [15].

II. Literature Review

The literature review aims to provide a comprehensive understanding of the existing research related to landslide monitoring systems, particularly focusing on the integration of IoT technologies. However, it has been noted that the survey of literature in the initial draft lacked systematic organization and clarity. In this revised version, we present a more structured and methodical review of relevant literature to address this critique.

A. Overview of Landslide Monitoring Techniques:

Landslide monitoring techniques have undergone significant advancements in recent years, driven by the need for more effective and reliable methods of hazard detection and mitigation. Traditional approaches, such as manual surveys and satellite-based monitoring, have limitations in terms of spatial and temporal resolution, as well as cost-effectiveness. Studies by [1] and [2] underscore the importance of integrating emerging technologies, such as IoT and wireless sensor networks, to overcome these limitations and enhance landslide monitoring capabilities.

B. IoT-Based Landslide Monitoring:

The integration of IoT technologies has revolutionized landslide monitoring by enabling real-time data collection, analysis, and early warning systems. Leveraging IoT devices, such as low-power sensors and communication modules, re- searchers have developed innovative solutions for detecting and mitigating landslide risks. For example, the work of [3] demonstrates the feasibility of using IoT-enabled sensors to monitor slope stability and trigger timely alerts in the event of potential landslides. Similarly, [4] proposes a framework for integrating IoT and cloud computing technologies to facilitate data-driven decision-making in landslide-prone areas.

C. LoRa Technology in Environmental Monitoring:

LoRa (Long Range) technology has emerged as a promising communication protocol for IoT applications, offering long-range connectivity, low power consumption, and scalability. In the context of environmental monitoring, LoRa-based sensor networks have been successfully deployed for various applications, including landslide detection, soil moisture monitoring, and weather forecasting. Notable studies by [3] and [2] high- light the advantages of LoRa technology in providing reliable and cost-effective connectivity for remote sensing applications, particularly in challenging terrain conditions.

D. Methodical Survey of Relevant Literature:

To ensure a systematic review of the literature, we adopted a structured approach to identify and analyze relevant studies. We defined specific search criteria, including keywords such as ”landslide monitoring,” ”IoT,” and ”LoRa technology,” and conducted searches across reputable academic databases, including IEEE Xplore, ScienceDirect, and Google Scholar. In addition, we utilized citation chaining and reference list scanning techniques to identify additional relevant studies. The search process yielded a comprehensive collection of peer-reviewed articles, conference papers, and technical reports, providing a solid foundation for our literature In summary, the literature review provides a comprehensive overview of previous research on landslide monitoring systems, with a particular focus on the integration of IoT technologies and the use of LoRa technology for environmental monitoring. By adopting a systematic approach to literature review, we aim to ensure the thoroughness and reliability of our study's theoretical foundation.

III. System Architecture

A groundbreaking advancement in environmental monitoring, particularly in landslide detection and prevention, is embodied in the LoRa-based IoT Landslide Monitoring Sys- tem. This innovative system leverages Long Range (LoRa) technology for seamless wireless data transmission from low- power sensors to a central station.

A key component of the design of the landslide monitoring system is reliability. To reduce single points of failure, redundancy mechanisms are implemented and numerous sensors are installed for each parameter. Data transmission failover methods guarantee continuous operation, supported by routine maintenance and calibration checks to maintain data correctness and system integrity. Together, these characteristics improve the system's efficacy and durability in practical situations. By centralizing data, real-time analysis enables early identification of soil instability and potential landslip events. Figures 1 and 2 depict the system's architecture, delineating the transmitter and receiver modules. This paradigm shift offers significant potential for enhancing landslide monitoring efficacy, facilitating proactive measures to mitigate risks, and safeguarding communities and infrastructure.

This system's primary strength is its ability to combine several low-power sensors into a unified framework, such as vibration, wetness, float, and humidity sensors. Together, these sensors provide a thorough picture of the surrounding environment, which helps the system evaluate elements like soil movement, humidity, and water levels that are critical for landslip prediction.

A. Overview of the LoRa-based IoT Landslide Monitoring System:

The brains of the innovative LoRa-based Landslip Monitoring System reside within its transmitter component. This vital section incorporates an Arduino NANO microcontroller alongside an array of sensors, serving as the cornerstone

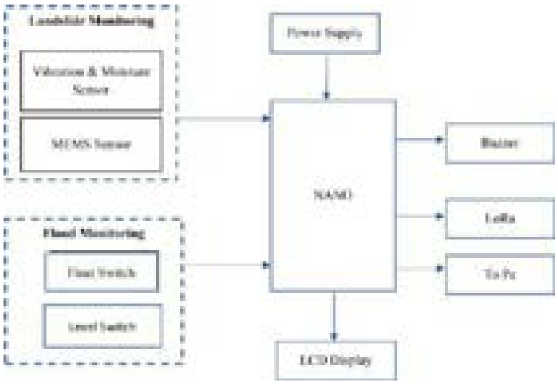

Fig. 1. Block diagram of transmitter module.

Fig. 2. Block diagram Of deceiver module.

for data collection, analysis, and wireless transmission. Essential components include moisture sensors for monitoring soil moisture levels crucial in landslide detection, rain sensors for detecting precipitation aiding in flood monitoring, MEMS sensors offering insights into device orientation and movement to identify potential shifts indicating landslides, and float sensors to alert users of rising water levels, vital for flood prevention. Using a multi-sensor approach, the suggested landslide monitoring methodology inside the LoRa-based IoT framework collects environmental data in real time and identifies possible landslide occurrences. The system uses vibration, moisture, and MEMS sensors, among other types of sensors, to continually monitor crucial factors that are symptomatic of soil instability. These sensors provide smooth data transfer to a central station for analysis and decision-making since they are interfaced with Arduino NANO and LoRa modules. To enable prompt reaction and catastrophe mitigation, the system places a strong emphasis on early detection through quickdata processing and event triggering. However, to guarantee the precision and dependability of the monitoring system, issues like sensor calibration and data synchronization must be carefully considered. Subsequent investigations may go into optimization methodologies aimed at augmenting system efficacy and functionality under varying environmental circumstances.

B. Components of the Transmitter Section:

The core of the LoRa-based Landslip Monitoring System lies within its transmitter unit, housing crucial components like the Arduino NANO microcontroller and an array of sensors. These sensors, including moisture sensors for soil moisture assessment and rain sensors for detecting precipitation, play vital roles in both landslide and flood monitoring. MEMS sensors contribute by providing orientation and movement data, aiding in the identification of potential shifts or tilts indicative of impending landslides. Additionally, the float sensor serves to alert users of rising water levels, enhancing flood monitoring capabilities. This comprehensive system amalgamates various sensor technologies for effective disaster detection and prevention, showcasing its invaluable utility in safeguarding vulnerable areas.

C. Landslide Detection and Flood Monitoring Module:

The core of the system is the Landslip Detection and Flood Monitoring Module, which is made to process data from several sensors and take preventative action in the event of impending hazards. This module, which is integrated with an Arduino NANO, continually and real-time monitors environmental conditions. The Arduino NANO gathers sensor data at the start of the procedure. The Arduino examines this data if it detects any notable changes or anomalies, such as strong vibrations, high moisture content, abrupt tilts, or rising water levels. The Arduino alerts the LoRa module in the event of a hazardous landslip or flood. Real-time data is shown on an LCD screen simultaneously, enabling local monitoring and evaluation.

D. Description of Sensors Used:

The sensors used in the system have specialized functions related to flood monitoring and landslip detection. The moisture sensor uses capacitance to measure the water content of the soil and displays the result as a percentage. Accelerometer-equipped MEMS sensors track the direction and motion of devices. While rain sensors identify and quantify rainfall, vibration sensors pick up vibrations in the ground. Float sensors alert people to rising water levels because they are made for monitoring floods.

E. Role of Arduino NANO in Data Collection and Processing:

The transmitter section's brain, the Arduino NANO, coordinates the activities involved in gathering and processing data. The Arduino NANO analyses the data it receives from the array of sensors to find any hazards like floods or landslides. Such risks cause the LoRa module to transmit wirelessly, guaranteeing a quick connection with the central station. Making decisions quickly depends on the Arduino NANO's real-time capabilities. Furthermore, local data presentation on an LCD screen improves monitoring and assessment skills and enables prompt responses to changing environmental conditions. With the assistance of several low-power sensors, the integration of Arduino NANO not only allows for effective data processing

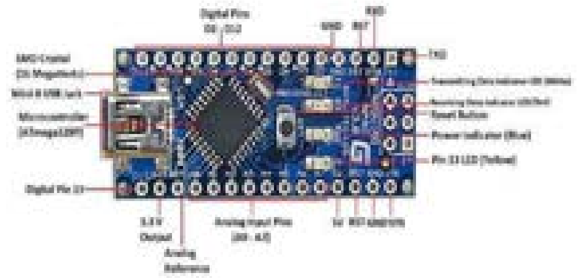

Fig. 3. Arduino nano kit.

but also adapts the system to a variety of applications. The Arduino Nano kit or model is shown in Fig. 3.

In summary, the system architecture builds a strong foundation for flood detection and landslip monitoring by utilizing LoRa technology with Arduino NANO. The combination of sensors and microcontrollers works in concert to provide real- time data analysis, which improves system responsiveness and, in the end, lowers the risks related to natural disasters.

The sensors' reaction time is explained to evaluate how well the sensors work in the monitoring system. Response time, or the amount of time between stimulus detection and data transmission, is measured by conducting controlled tests on various types of sensors, such as vibration, moisture, and MEMS sensors. To achieve precision, experimental setups require carefully calibrated equipment and regulated ambient conditions. Carefully collected sensor measurements are taken under various situations to determine response time variability. The results show that response times, which depend on variables including sensor type and ambient dynamics, range from milliseconds to seconds. These results are interpreted in the discussion, with emphasis on the consequences for system dependability and possible ways to improve sensor performance. These revelations strengthen the system's ability to identify landslides in real time and highlight how crucial sensor responsiveness is to IoT-based monitoring systems.

IV. METHODOLOGY

The specifics of the approach used in the LoRa-based Internet of Things landslip monitoring system. Detecting landslides, monitoring floods, and integrating our system with the Thingspeak website are all included in the technique. Real-time data gathering and transmission are also included.

A. Real-Time Data Collection and Transmission:

The system's core functionality lies in its ability to wirelessly transmit real-time data through the LoRa network efficiently. It relies on an Arduino NANO paired with various sensors like moisture, rain, MEMS, float, and vibration sensors to gather crucial environmental data. Strategically positioned, these sensors monitor parameters such as soil moisture, rainfall intensity, ground vibrations, and tilts. Leveraging LoRa's low-power features ensures sustainable operation with minimal energy consumption. The Arduino NANO triggers data transmission upon detecting anomalies, facilitating rapid response to potential landslip incidents. Additionally, it enables local monitoring via an LCD screen, empowering real-time analysis and proactive measures.

B. Method for Detecting Landslides:

The system's core functionality revolves around identifying potential landslip occurrences and proactively addressing them. Utilizing data from sensors, such as the Arduino NANO, it initiates landslip detection procedures. A crucial component is the vibration sensor, which continuously monitors ground movements indicative of imminent landslides. Simultaneously, the moisture sensor measures soil moisture content, crucial for landslide prediction. Any significant deviation from average moisture content triggers the landslip detection process. Additionally, an accelerometer-equipped MEMS sensor tracks system orientation and movement, detecting abrupt tilts or positional changes, enhancing the system's accuracy in evaluating landslide risk. This multi-sensor approach ensures comprehensive and precise landslip risk assessment.

C. Flood Monitoring Process:

To mitigate the threats posed by increasing water levels, our system includes a flood monitoring module in addition to landslip detection. The float sensor, which was created especially for flood monitoring, recognizes variations in water levels and sounds an alert when there may be a chance of flooding. Early warnings about impending flooding events can be given by the system because it regularly monitors water levels. Our system's adaptability is increased with the addition of flood monitoring, transforming it into a comprehensive defense against many environmental threats.

D. Integration with Thingspeak Website:

Our innovative LoRa-based Internet of Things landslip monitoring system seamlessly integrates with the Thingspeak platform, facilitating centralized data storage, analysis, and accessibility. Real-time sensor data transmission enables swift processing and archiving on the Thingspeak server, empowering remote monitoring and analysis. This integration ensures fast access to critical information for emergency services and local authorities. With visualization tools offered by Thingspeak, decision-makers can construct graphs and charts for better interpretability, aiding in making informed choices during emergencies. This resilient approach offers precise landslide detection, flood monitoring, and proactive environmental hazard management, marking it as a comprehensive and dependable solution.

E. Monitoring Process:

The monitoring process involves a series of steps aimed at collecting, transmitting, and analyzing data from the deployed sensors to detect potential landslides and monitor environmental conditions. This section outlines the key components and procedures involved in performing the monitoring process:

1) Sensor Deployment and Configuration: To initiate the monitoring process, sensors are strategically deployed in the target area prone to landslides. The placement of sensors is determined based on factors such as terrain characteristics, historical landslide occurrences, and the desired scope of monitoring. Each sensor is configured to collect specific environmental parameters, such as soil moisture, vibration, and rainfall, relevant to landslide detection and monitoring.

2) Data Collection and Transmission: Once deployed, the sensors continuously collect data regarding the monitored environmental parameters at predefined intervals. The collected data is then transmitted wirelessly to a central station using LoRa technology. The LoRa network facilitates long-range communication with low power consumption, ensuring efficient transmission of data from remote sensor nodes to the central monitoring station.

3) Data Processing and Analysis: At the central monitoring station, the transmitted data is received and processed in real time. Advanced data processing algorithms are applied to analyze the collected data, identify patterns, and detect anomalies indicative of potential landslide events. This involves comparing current sensor readings with historical data and predefined thresholds to assess the stability of the monitored area.

4) Alert Generation and Notification: Upon detection of abnormal environmental conditions suggestive of a landslide threat, the monitoring system generates alerts in real time. These alerts are transmitted to relevant stakeholders, including local authorities and emergency response teams, via email or other communication channels. The timely dissemination of alerts enables swift response and implementation of precautionary measures to mitigate the risk posed by landslides.

5) Continuous Monitoring and Maintenance: The monitoring process is continuous and ongoing to ensure the timely detection of potential landslide events and the effective management of environmental risks. Regular maintenance and calibration of sensors are conducted to ensure the accuracy and reliability of data collected by the monitoring system. Additionally, periodic inspections of sensor nodes and the LoRa network infrastructure are performed to address any technical issues and optimize system performance.

V. Components Explanation

The LoRa-based Internet of Things landslip monitoring system's efficacy stems from its sophisticated integration of multiple sensors and parts. Every component has a specific function in making sure the system can identify, evaluate, and react to environmental factors that could indicate future floods and landslides. We go into these components' specifics in this part, describing their features and how they add to the system's overall resilience.

A. Sensor for Detecting Landslides:

The Landslip Detection Sensor, a vital component of the LoRa-based IoT landslip monitoring system, is designed to detect subtle ground movements that could indicate potential landslides. Utilizing advanced technologies such as accelerometers, it can accurately pinpoint even the slightest vibrations in the Earth's surface. Strategically positioned, these sensors gather environmental signals and promptly alert the central processing unit upon detecting significant vibrations. This early detection capability is crucial for issuing timely alerts and mitigating potential disasters, thereby enhancing overall disaster preparedness and providing real-time data on ground conditions.

B. Soil Moisture Sensor:

Soil moisture plays a pivotal role in landslip prediction, and the precision of the system's soil moisture sensor is paramount. This sensor, utilizing capacitance, delivers real-time data by measuring soil water content and presenting it as a percentage. Its buried placement ensures accurate readings, crucial for pinpointing landslide-prone areas. Continuously gathering data, the sensor converts moisture fluctuations into analog voltages, facilitating comprehensive stability evaluations. Integrated into the Internet of Things (IoT) framework, it enhances adaptability across diverse environmental conditions, making it an indispensable component for comprehensive landslip surveillance and risk assessment.

C. MEMS Sensor:

The landslip monitoring system uses the adaptable Micro-Electro-Mechanical Systems (MEMS) sensor to track movement and orientation. The MEMS sensor's accelerometer allows it to recognize abrupt tilts and positional changes in the device. This capacity is very helpful in spotting changes in the monitoring system or possible landslides. The MEMS sensor's job is to monitor the orientation and movement patterns of the device continually. The sensor warns of the potential for a landslip event when deviations beyond predetermined criteria are found. The MEMS sensor enhances the monitoring system's accuracy and dependability by contributing this level of sophistication, which makes it an essential part of early detection and risk reduction.

D. Rain Sensing:

The rain sensor is a critical component in flood monitoring systems, designed specifically to detect rainfall. When activated by rain, this sensor serves as a pivotal switching device, promptly identifying precipitation and relaying this vital data to the central processing unit. Its significance extends beyond flood monitoring; the rain sensor also plays a crucial role in landslip detection by assessing precipitation levels, which directly influence soil stability. The correlation between excessive rainfall and landslides underscores the sensor's importance in providing timely alerts for community safety. Integrating the rain sensor enriches catastrophe management systems with environmental awareness, enhancing overall effectiveness in safeguarding communities.

Fig. 4. Assembled Project Kit.

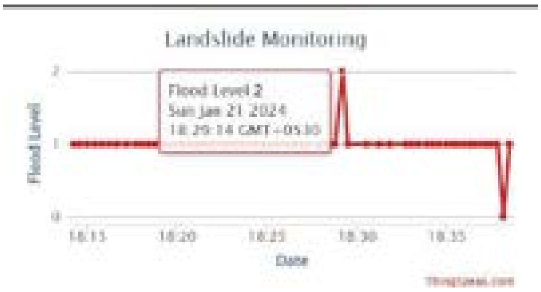

Fig. 5. Graph1 for landslide monitoring.

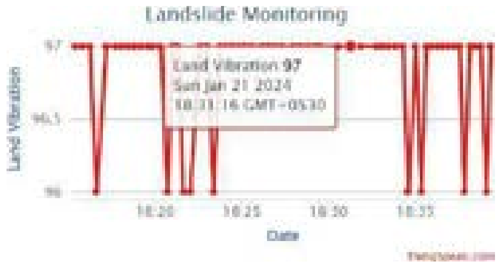

Fig. 6. Graph2 for landslide monitoring.

E. Explanation of Arduino NANO and LoRa Module:

The heart of the landslip monitoring system lies in the Arduino NANO, orchestrating data processing and collection tasks. Acting as a central processor, it collates information from various sensors like float, rain, MEMS, soil moisture, and landslip detection sensors. Through a customizable interface, Arduino NANO assesses incoming data, scanning for anomalies. In the event of potential landslips or floods, it triggers necessary actions. Facilitating seamless communication is the LoRa (Long Range) module, employing LPWAN technology for efficient, long-distance wireless data transmission to the central server. This integration ensures real-time sensor data delivery, enabling swift analysis and response. Together, Arduino NANO and LoRa create a robust and responsivemonitoring framework.

VI. Results and Discussion

The experimental findings from the deployment of the LoRa-based IoT Landslip Monitoring System are shown in this section. The evaluation includes the ability to gather data in real time, procedures for detecting floods and landslides, and a comparison with more conventional monitoring techniques. Fig. 4 illustrates the interconnected components comprising the project kit. Figs. 5 and 6 show the graphical representation of landslide monitoring.

A. Experimental Results Presentation:

The integrated Arduino NANO sensors efficiently tracked various environmental variables, including soil moisture, rainfall, water levels, and ground vibrations, ensuring comprehensive data gathering. Utilizing LoRa network connectivity facilitated swift and seamless data transmission to the central station in real time. This enabled the Landslip Detection Module to identify potential landslip events with high sensitivity, triggered by abnormalities such as elevated vibrations, moisture levels, or abrupt tilts. The Flood Monitoring Module effectively detected water levels and rainfall, enabling precise flood alerts to mitigate risks associated with flash floods. Overall, the system's efficacy in real-time flood and landslide detection underscores its feasibility and effectiveness in proative risk management.

B. Analysis of Landslide and Flood Detection:

The primary focus of landslip and flood detection analysis is the system's capability to promptly and precisely identify potential risks. The vibration sensor excels in detecting ground movements, crucial for predicting landslips. Meanwhile, the moisture sensor provides valuable insights into soil conditions, aiding in the proactive identification of flood and landslide risks. The MEMS sensor's accelerometer enhances landslip detection by tracking orientation changes effectively. For flood detection, the float sensor accurately measures water levels, complemented by the rain sensor's precise recording of rainfall. Integration of these sensors in the Flood Monitoring Module underscores the system's reliability. Real-time data collection and transmission empower authorities to respond swiftly, mitigating the impact of natural disasters on lives and infrastructure.

C. Comparison with Traditional Monitoring Methods:

Comparing the LoRa-based IoT Landslip Monitoring System with conventional methods highlights its significant advantages. Unlike sporadic manual inspections prone to coverage gaps, LoRa technology offers real-time, extensive coverage at a low cost. Utilizing low-power sensors, ensures continuous data collection, overcoming traditional drawbacks. This proactive system automatically alerts authorities upon detecting threats, drastically reducing response times for timely interventions such as evacuations. Its adaptability across various climates enhance its utility for environmental monitoring. Overall, this system heralds a revolution in the industry, offering real-time data, early warnings, and proactive threat detection for effective risk reduction and catastrophe management.

D. Improving Accuracy, Performance, Landslip Detection, and Efficiency in Landslide Monitoring:

Many crucial tactics are needed to monitor landslides with great precision. To begin with, sensor calibration is necessary to guarantee precise measurements of environmental factors including tilt, vibration, and soil moisture. Sensor data reliability may be preserved and measurement errors reduced with routine calibration tests and modifications. By removing erroneous readings and raising signal-to-noise ratios, the application of sophisticated signal processing techniques, such as filtering and noise reduction algorithms, can also further improve accuracy. Improving performance in land- slide monitoring encompasses optimizing various aspects of the monitoring system. This includes optimizing power consumption to prolong battery life, enhancing data transmission efficiency through the use of efficient communication protocols, and reducing latency in data processing and analysis pipelines. By optimizing performance parameters, the monitoring system can operate more effectively in remote and resource-constrained environments, ensuring timely and reliable detection of landslide events. Strong detection algorithms must be developed and put into practice to detect landslips effectively. Real-time sensor data analysis should be performed by these algorithms, which should search for trends and abnormalities that might point to future landslides. The monitoring system can detect early warning indicators of slope instability by utilizing machine learning and pattern recognition techniques. This allows for prompt notifications and proactive risk mitigation actions. Simplifying the procedures for data collection, transmission, and analysis is necessary to increase the effectiveness of landslide monitoring. Low- power sensor deployment, data compression methods that are optimized, and the utilization of distributed computing resources for parallelized data processing can all help achieve this. Predictive analytics and decision support systems may also be integrated to help prioritize data streams and distribute resources more effectively, improving the responsiveness and overall performance of the system. By boosting efficiency, the monitoring system may scale to monitor greater geographical regions with fewer resources and successfully handle growing data quantities.

VII. CONCLUSION

The deployment of a LoRa-based Internet of Things (IoT) system for real-time landslip monitoring inside an IoT frame-work represents a novel advance in environmental monitoring and catastrophe management. To continually monitor important environmental elements like soil movement, moisture con- tent, and water levels, this system seamlessly integrates low-power sensors, such as vibration, moisture, and float sensors, with the Arduino NANO platform. This system addresses the limitations of conventional landslip monitoring by providing a cheap, wide-coverage, and real-time solution using wireless LoRa communication. It guarantees early detection and rapid notifications to reduce dangers to infrastructure and human life.

Abstract— Skin cancer poses a substantial global health challenge, surpassing the combined incidence of colon, lung, and breast cancer cases in the United States. Timely detection is crucial, especially for melanoma, where early diagnosis significantly impacts patient outcomes. This study investigates the utilization of machine learning (ML) and deep learning (DL) methods to enhance skin cancer detection. We conduct a systematic comparison of various classification techniques and assess their efficacy. Our main goal is to critically assess current approaches and pinpoint areas for enhancement. This inquiry seeks to lay the groundwork for the development of advanced models that can streamline the diagnostic process, ultimately reducing the interval between skin cancer detection and treatment initiation.

Keywords— Skin cancer, Melanoma, Machine Learning, Deep Learning, Cutting-edge methods.

I. INTRODUCTION

Skin cancer remains a prevalent public health concern, spanning both malignant (melanoma) and benign (non-melanoma) manifestations. Early detection is imperative, as changes in moles, birthmarks, or pigmented areas may indicate potential risk. Vigilance for variations in size, shape, color, or bleeding is crucial, as these could signal skin cancer. Excessive exposure to sunlight radiation is the primary culprit behind most skin cancers [1]. Traditionally, diagnosis relies on dermatologist-performed biopsies.

However, the medical field is witnessing exciting advancements in machine learning (ML), offering promising tools to aid skin cancer detection. Researchers are harnessing computer vision techniques to analyze skin images and develop algorithms capable of distinguishing between benign and malignant lesions. This emerging technology holds significant potential to complement dermatologists' expertise, though it should not supplant their experience and judgment. The accuracy of these automated classification approaches is influenced by various factors, including pre-processing steps such as normalization, augmentation, and lesion area segmentation [2]. Additionally, identifying pertinent features within the image is critical for achieving dependable classifications.

II. LITERATURE REVIEW

In this section several challenges faced and latest literature work done on skin cancer classification had been discussed

A. Navigating Challenges in Identifying and Classifying Skin Lesions

1) Data Acquisition and Quality:

a) Scarcity of Datasets: The development of accurate machine learning and deep learning models relies on comprehensive, diverse, and annotated datasets. However, obtaining such datasets presents challenges due to privacy issues, limitations on data sharing, and the inherent variability in skin lesions [1]

b) Addressing Class Imbalance: Despite its prevalence, skin cancer constitutes a minority class compared to benign lesions. This class imbalance in datasets may skew models toward the majority class, potentially impeding melanoma detection [2].

B. Preprocessing and Image Analysis:

1) Managing Variability in Image Appearance: Factors like lighting conditions, camera quality, hair interference, and skin pigmentation significantly influence the visual representation of skin lesions. Employing robust preprocessing techniques is essential to standardize images and enhance model generalization [3].

2) Precision in Lesion Segmentation: Accurately delineating lesions from surrounding skin is pivotal for effective analysis. However, challenges such as complex backgrounds, overlapping lesions, and subtle borders can complicate segmentation algorithms.

3) Model Explainability and Trust:

a) Unraveling the Black Box of Deep Learning: Despite achieving high accuracy, deep learning models often operate as black boxes, obscuring their decision-making rationale. This opacity may undermine dermatologists' trust in their clinical utility [4].

b) Mitigating False Positives and Negatives: Concerns persist regarding misclassifications, notably false positives leading to unnecessary biopsies and false negatives potentially delaying critical diagnoses. Addressing these issues is imperative for broader adoption.

C. Existing literature

Ref. No	Technology/ Algorithm used	Objective	Dataset	Advantages	Limitations
[5]	Preprocessing and segmentation approaches compared for the diagnosis of skin cancer	to remove extraneous noise from the dermoscopy picture in order to provide high-quality images.	ISIC	Provided a detailed view of preprocessing techniques with an accuracy of 97%	This paper is only limited to preprocessing the skin lesions.
[6]	Detection of skin cancer using SVM and snake model	To apply image segmentation on skin cancer lesions	ISIC	Provided a preprocessing step by an ensemble of two models.	This paper doesn't provide accurate segmentation result
[7]	Skin Cancer Detection Using Ensemble Learning	To increase the models' ability to forecast skin cancer with more precision.	ISIC	The improved overall accuracy of the ensemble model with 93%.	Not accurately provided details of preprocessing.
[8]	Deep Learning-Based Melanoma Skin Cancer Detection	To improve the model's accuracy over the existing model	ISIC	Improved accuracy by 1.66% than the existing model.	The image's potential for skin cancer is the only topic this paper explores.
[9]	Skin cancer classification using MSVM and ELM	To provide a tiered deconstruction method for classifying and identifying images displaying skin cancer	DermNet NZ	Obtained an accuracy of 94.18% and 90.5% on individual models.	The paper is limited to the comparison of two models.
[10]	Skin cancer detection using near-field millimeter wave	To identify the healthy and diseased skin lesions.	UDA-1	Identified the healthy and diseased lesion.	This paper is limited to the post-preprocessing technique.
[11]	Identification of Benign and Malignant Skin Lesion From Melanoma Skin Cancer Pictures	To ensemble the DL and ML models	ISIC	The identified NN model performed better than the SVM, KNN, and NB models	The paper is limited to detecting skin cancer.
[12]	A Comprehensive Survey of Skin Cancer Detection Using Deep Learning	Review recent developments in skin cancer detection	HAM10000	Improved accuracy in diagnosis	Limited diversity in publicly available datasets
[13]	Advancements in Dermoscopy for Melanoma Classification	Assess the role of dermoscopy in melanoma diagnosis	Dermos-copic images	Dermoscopy enhances diagnostic accuracy	Dependence on skilled dermatologists for interpretation
[14]	Machine Learning in Dermatology: A Survey of Skin Cancer Diagnosis Methods	Explore machine learning in dermoscopic melanoma detection	Private dermato-logy clinics	Machine learning aids in early melanoma detection	Lack of publicly available labeled dermoscopic images
[15]	Impact of Color Enhancement on CNN for Early Skin Cancer Detection	To investigate into the impact of basic CLAHE and MSRCR image processing methods.	Private dermatology clinics	For color image enhancement, CLAHE works better than MSRCR with CNN.	Limited to enhancing the color contrast of the image.
[16]	Automatically Early Skin Cancer Detection	To find out which neural network classification is best.	Digital photo and dermosc-opy images	It is 80.8% for auto-associative neural networks and 89.9% for back-propagation neural networks.	Resizing the image with a variable size of height may reduce the accuracy of the model.

TABLE I. RESEARCH ARTICLES SUMMARY ON SKIN CANCER

III. STEPS INVOLVED IN SKIN CANCER CLASSIFICATION

Skin cancer is detected and classified by following the steps mentioned below in figure 1:

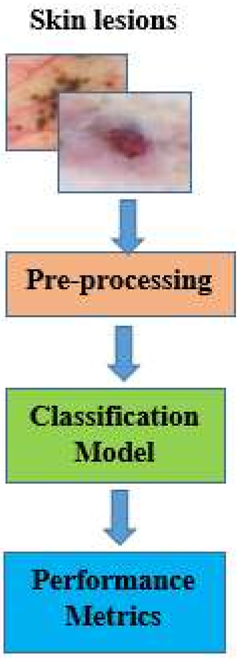

Fig. 1. Steps involved in skin cancer classification

A. Data Collection

Data gathering for skin cancer classification involves accessing datasets from repositories like the International Skin Imaging Collaboration (ISIC) and platforms such as Kaggle. ISIC provides dermoscopy images annotated by dermatologists, while Kaggle offers diverse datasets with metadata. Researchers leverage these resources to train models effectively. Collaboration with medical institutions ensures data reliability and ethical considerations. Comprehensive data gathering aids in developing accurate skin cancer classification models, enhancing diagnostic capabilities in dermatology.

B. Image Preprocessing:

Image preprocessing involves noise reduction, contrast enhancement, and normalization, ensuring standardized images suitable for analysis. Contrast enhancement improves feature visibility, while normalization ensures consistency in pixel values. These steps prepare images for subsequent feature extraction, segmentation, and classification tasks. Overall, image preprocessing optimizes image quality for accurate analysis in skin cancer classification.

1) Image Convertion

Image conversion involves transforming images from one representation to another, typically to highlight different aspects or to standardize the input for further processing. This often includes converting images from RGB to other color spaces like YUV, LAB, or HSV, which can accentuate certain features or make them more distinguishable. Grayscale conversion is another common conversion, reducing the image to a single intensity channel, simplifying processing and reducing computational overhead.

2) Segmentation:

Segmentation isolates skin lesions, facilitating meaningful feature extraction for classification. Various techniques such as thresholding or deep learning approaches are used for precise segmentation. Well-segmented images enable the classification model to focus on relevant features. Effective segmentation enhances model accuracy and reliability in skin
cancer classification.

3) Data augmentation

Data augmentation on skin cancer images employs techniques such as rotation, flipping, scaling, and cropping to diversify the dataset. Additionally, transformations like brightness adjustment, color jittering, and adding noise contribute to variability. These techniques aid in training robust models capable of effectively classifying skin lesions

4) Normalization

Normalization standardizes pixel values in images, reducing the impact of varying lighting conditions and aiding algorithm convergence. Techniques like min-max normalization scale values to [0, 1], while z-score normalization gives them a mean of 0 and a standard deviation of 1. This process enhances model performance and robustness across diverse datasets.

C. Classification:

Machine learning algorithms are used in skin cancer classification to classify lesions into benign or malignant groups. Support vector machines, Random Forest, and convolutional neural networks are examples of frequently used algorithms. For precise categorization, these algorithms extract patterns from metadata and previously processed pictures. Model performance is evaluated using evaluation measures like as F1-score, accuracy, precision, and recall.

IV. CLASSIFICATION TECHNIQUES

A. Machine learning

By training algorithms to distinguish between benign and malignant skin lesions using characteristics taken from photographs, machine learning is used. For this objective, machine learning models like Random Forest, Support Vector Machines (SVM), and Convolutional Neural Networks (CNNs) are frequently used. To provide precise predictions, these algorithms analyze clinical data and annotated pictures to find patterns and linkages. Model performance is evaluated using criteria such as accuracy, sensitivity, and specificity. Large datasets are now readily available, and deep learning techniques have advanced to the point that machine learning-based categorization has demonstrated encouraging results in helping dermatologists diagnose skin cancer early and accurately.

B. Deep Learning

Convolutional Neural Networks (CNNs) in particular are trained to automatically learn discriminative characteristics from photos of skin lesions through the use of deep learning. Because these networks can extract hierarchical features from skin lesion photos, they may identify intricate patterns and changes in the images. Multiple convolutional layers are often used in deep learning models for the categorization of skin cancer, followed by pooling layers and fully connected layers. By using backpropagation, training data—often obtained from databases such as the International Skin Imaging Collaboration (ISIC)—is utilized to optimize model parameters. Evaluation measures are used to evaluate the performance of the model, including specificity, sensitivity, and accuracy. Deep learning-based methods have shown to perform at the cutting edge when it comes to classifying skin cancer, which presents the possibility of improved diagnostic efficiency and accuracy in clinical settings. The flow diagram is shown in figure 2.

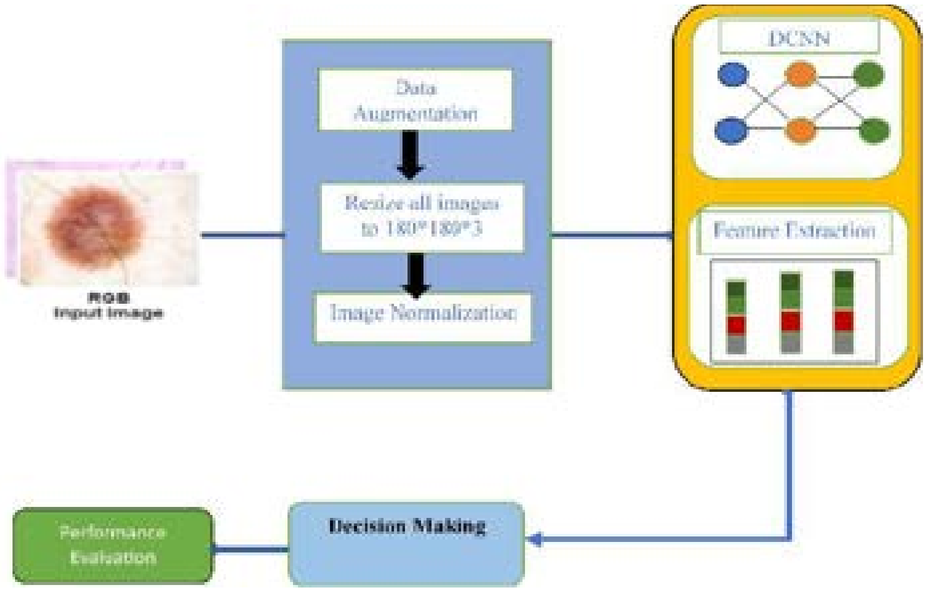

Fig. 2. Flow of skin cancer classification in Deep Learning

C. Ensembling

using ensemble techniques involves combining multiple base classifiers to improve predictive performance. Ensemble methods, such as Random Forest, AdaBoost, and Gradient Boosting, aggregate predictions from individual classifiers to make final decisions. In the context of skin cancer classification, these techniques integrate diverse models trained on different subsets of data or with varying parameters. By leveraging the strengths of multiple classifiers and reducing the impact of individual weaknesses, ensemble methods often yield superior results compared to single models. Evaluation metrics like accuracy, sensitivity, and specificity are used to assess the ensemble's performance. Ensemble techniques offer promising avenues for enhancing the accuracy and robustness of skin cancer classification systems, contributing to more reliable diagnoses in clinical practice.

V. DATASETS

A. HAM10000

Dermatoscopic pictures of typical pigmented skin lesions are gathered in the HAM10000 (Human Against Machine with 10,000 training images) dataset. 10,015 dermatoscopic images make up this collection, which is divided into seven diagnostic groups: vascular lesion, benign keratosis (also called seborrheic keratosis), actinic keratosis, melanoma, and melanocytic nevus. Because these photos came from various institutions and datasets, a variety of skin lesions were represented. The dataset is used as a reference for creating and assessing deep learning models and machine learning algorithms for the classification of skin lesions and the detection of melanoma. Metadata, such as patient demographics, lesion location, and diagnostic data from board-certified dermatologists, are appended to every image. Through automated skin lesion classification systems, researchers and practitioners can use the HAM10000 dataset to improve patient care, advance the field of dermatology, and improve diagnostic accuracy. Users should read the documentation for the dataset and follow any licensing agreements or usage guidelines related to using it. The sample images from the collected dataset is depicted in figure 3 and 4.

Fig. 3. Sample images from the HAM 10000 Dataset.

B. ISIC Dataset

The ISIC dataset is a useful resource for dermatology research and machine learning-based skin cancer detection. It is available on Kaggle and consists of 2357 images that represent nine different types of skin cancer. These pictures depict a variety of skin lesions, including squamous cell carcinoma, basal cell carcinoma, and melanoma. The diagnosis associated with each image makes it easier to develop and assess classification algorithms for the identification of skin cancer. This dataset can be used by practitioners and researchers to train and evaluate machine learning models, which will enhance the models' performance and accuracy in classifying various forms of skin cancer. Furthermore, the dataset might provide information about the visual traits and attributes of various skin lesions, which could help medical professionals recognize and diagnose skin cancer.

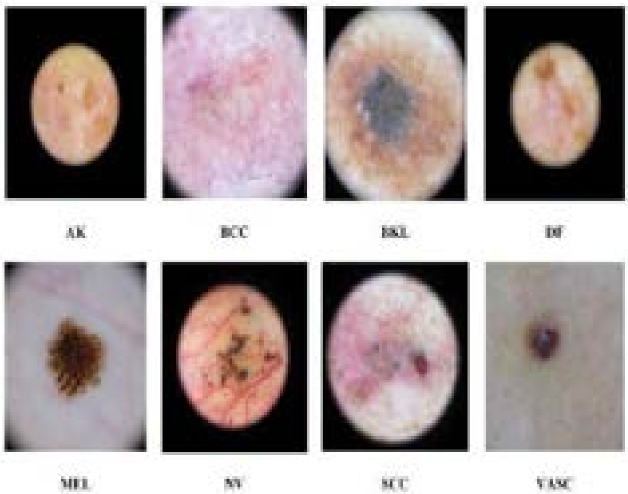

Fig. 4. Sample images from ISIC Dataset

C. BCN_20000 dataset

The BCN 20000 dataset is a large-scale, curated collection of images commonly utilized for benchmarking and advancing computer vision tasks, particularly in the domain of facial recognition and emotion detection. Comprising 20,000 diverse facial images sourced from various demographics and contexts, the dataset offers a rich and representative sample for training and evaluating machine learning models. Each image is annotated with labels corresponding to facial expressions, enabling researchers to develop and test algorithms for emotion classification, facial attribute recognition, and related applications. With its ample size and diversity, the BCN 20000 dataset serves as a valuable resource for advancing the state-of-the-art in facial analysis and emotion recognition research.

VI. GAPS IDENTIFIED

Based on the literature the gaps identified below. By addressing these generic gaps, researchers can explore novel methodologies, such as advanced imaging techniques and integration of molecular data, to improve classification accuracy. Ultimately, closing these gaps fosters innovation and collaboration, driving advancements in personalized patient care and outcomes. Table II and III details the comparative analysis and the research gaps identified.

TABLE II. GAP AND IDENTIFIED SOLUTIONS

Research Gaps	Solutions
Small dataset size[9]	Data augmentation techniques[20]
Class imbalance[15]	Resampling methods[8]
Lack of interpretability[1,19]	Development of explainable AI techniques[21]
Limited generalization to populations[12]	Diverse dataset collection[18]

A. Comparision of accuracy with different classification techniques

Drawing from existing research, we examined an ISIC dataset of 2357 photos from Kaggle and compared the outcomes of machine learning and deep learning techniques on the same dataset. Our findings indicate that deep learning models outperform machine learning models in terms of performance.

TABLE III. COMPARISION

Technique	Dataset	Accuracy
Machine Learning		
SVM, Random Forest and kNN [23]	ISIC with 2357images	85
Logestic Regression [24]	ISIC with 2357images	78
Deep Learning		
DenseNet201[22]	ISIC with 2357images	89
Deep CNN[21]	ISIC with 2357images	90

VII. CONCLUSION

This study has comprehensively assessed skin cancer detection techniques to accurately classify lesions into distinct types of skin cancers. The comprehensive presentation of diagnostic methodologies offers a clear understanding of the diverse approaches employed. The integration of deep learning and machine learning in medical imaging has revolutionized skin lesion identification and classification, markedly improving dermatological diagnostics' accuracy. By leveraging computer methods, researchers can diagnose skin cancer with enhanced precision and efficiency. Overall, the resultant findings highlight the transformative impact of technological advancements on skin cancer detection, indicating a new era of more effective treatment interventions

***Abstract*— There is an unprecedented rise in hate speech on social media sites like Twitter in recent times. This widespread problem affects users, leads to problems in the real world, and makes it hard to moderate material. This study aims to find good ways to find hate speech so that it doesn't have as much of an effect on online groups and other places. By using cutting-edge algorithms, the project takes a thorough method to finding hate speech. To make a strong and flexible hate speech recognition system, machine learning models and deep learning methods are used. To make sure accuracy and dependability, model performance is carefully checked using a variety of measures. Accuracy, precision, recall, and F1 score are the common measures used here to show how well the model can correctly spot cases of hate speech. a measure of its general selective power that shows how well it works at different levels. As the project comes to a close, the thorough review of hate speech recognition models has given us useful information. Even though progress has been made, problems still exist, especially when it comes to dealing with changing speaking trends on social media. The study shows how important it is to keep researching and developing ways to find hate speech. This will help make content management better in the future, which will make the internet safer. A strong ensemble method called the stacking classifier is also used as part of the hate speech recognition model. It achieves an amazing 100% success. In addition, the Hybrid Approach, which used both LSTM and BiGRU models, showed an impressive 94% accuracy. A front end was built using the Flask framework to make testing easier for people. It has login features to make the Twitter Hate Speech Detection system safer and more trustworthy. This makes sure that users have a smooth and reliable way to rate how well the model finds and stops hate speech on Twitter.**

Keywords—Hate speech, classification, automatic detection, twitter, systematic review, natural language processing, social media.

I. INTRODUCTION

Twitter and other social networks have grown exponentially over the last decade. These media enable individuals to remain anonymous and free to communicate their opinions, which encourages hate speech [1]. According to [2], Twitter has 300 million monthly active users. Twitter shares hate speech, despite its popularity and importance. Popular social networks now detect hate speech in text [3, 4, 5]. It is also used as a data source for study into harsh language. At the moment, hate speech is becoming more common on social media. In turn, this makes people angry, which leads to serious problems in real life and has an effect on companies. Hateful posts are often taken down by social media companies so they don't get posted.
English Twitter postings are the most common and easiest to analyze [6]. Since book reviews are unchanged, many potential customers will show up online. Non-automated chores slow response time, whereas robots go faster. We must assist develop automatic hate speech detection tools. NLP researchers want these facts. Writing about hate speech. Researchers called this job aided document classification using NLP and machine learning [7]. The 2017 consideration included Twitter. The severe behavior-allowing privacy policy was changed. These rules ban tweets that promote bullying, suicide, self-harm, violence, hate, and other bad things [8].

Experts have stepped up their investigations into hate speech on Twitter. However, the non-English version is limited. Remember, English is the most spoken language. This is also an important indicator of hate speech. Racism is difficult to define because everyone defines it differently. This is often called "hate speech" and is banned in many places. [7]. There are many ways to interpret hate speech.

Many new ways to find hate speech have been created in the past few years, which is a long way ahead of their plans. But the tests are mostly meant to find content that isn't hateful, not to find and sort content that is hateful [1]. Language in social media is changing quickly, which is making it hard for most of these attempts to find a workable answer [9]. So, it's important to have a deep understanding of the latest writing on the subject. It has been getting easier to spot hate speech for a while now, but there isn't yet a systematic literature review (SLR) in this area. To get the most up-to-date information, like open problems and study holes on a specific area, SLR papers are necessary.

II. LITERATURE SURVEY

People who use the Internet can freely share their ideas and views on social media sites. This land offers amazing and one-of-a-kind chances to communicate, but it also comes with some big problems. One classic example of this kind of problem is hate speech that people post online. There is a big gap in our knowledge about what hate speech on social media is really like, despite how big and widespread it is. This work [1] is the first of its kind to do a thorough, large-scale measurement study of the main people who are targeted by hate speech on social media sites. Whisper and Twitter provide hints. We then develop and test a hate speech detection method for both products. Our findings help us understand online hate speech and create better techniques to stop and locate it [1].

For millions of people around the world, social media is now an important part of their daily lives. It gives people a way to share their thoughts and feelings with a huge audience. But the fact that it's so easy for people to say what they want has also made it possible for lies and hate speech to spread widely [2]. Racists have started to use a code (a movement called "Operation Google") to avoid breaking the rules about abusive behavior on social media sites and to avoid being caught by technology like Google's Conversation AI. This means using nice words that don't make sense in the context of hateful posts or tweets that talk about groups [19]. One example is that people have used the words "Googles" to refer to African Americans and "Bings" to refer to Asians. By making a list of users who post this kind of content, we can study the usage patterns of this small group of users, which is the next step after labeling tweets.

Sharing information on social media sites is easy and doesn't cost much. Anyone can post content, and anyone who wants to read it can do so. But this same ability of social media also makes it possible for damaging conversations to happen about certain groups of people. Bullying, insulting material, and hate speech are all examples of these kinds of discussions [4]. Many governments rapidly label hate speech a major issue based on these considerations. The first comprehensive measurement and analysis of social media hate speech is this work [17, 18, 20]. We want to know how much hate speech is on social media, the most prevalent hate phrases, how privacy influences hate speech, how sensitive it is, and which groups are most loathed worldwide. We use Whisper and Twitter for hints to achieve our aims. We then develop and test a hate speech detection method for both products. Our findings characterize hate speech kinds and show crucial patterns. This clarifies online hate speech and proposes strategies to detect and stop it.

It's impossible to overstate how important violence is for knowing how people act. It connects the person, their behavior, their habits, their surroundings, and their mental health. Ascertaining the specifics of different types of aggression and aggressive behavior can assist in taking the right responses to individuals who act and speak in an aggressive manner on social media sites [8]. A literature review using several search engines found research on hate speech detection, hate, anger, aggressive behavior on social media, and the effects of these words. Previous research on hate speech detection didn't account for different types of speech, the relationship between speech and behavior, or targeted users. At the moment, hate speech is only classified as rude and hateful words [15]. Anger is another thing that should be added. In the future, researchers should make sure that their searches include violent behavior, since that is what connects studying human behavior and hate speech. Online social media gives people a nice place to hang out. So, they feel free to say what they think and feel. Because the internet doesn't have many rules, people may abuse it to spread cruel and hurtful language. Currently, this kind of harmful content has to be found by hand, which takes time and might not find all of it [7]. Because of this, automatic identification of harmful content is needed to find and study all the bad text in social media sites online. This essay talks about automatic methods for finding hate speech online and focuses on how to compare these methods based on certain parameters [20].

III. METHODOLOGY

A. Proposed Work

The innovative system employs advanced NLP, machine learning, deep learning, and ensemble models to identify hate speech [30, 31]. Different samples will be used to train this system. Adding language and mood analysis will help us understand context in a more complex way, which will make hate speech identification much more accurate. Real-time automatic spotting will be a key feature. This will cut down on reaction times and make hate speech control on social media sites more effective overall. Along with the hate speech recognition model, a strong group method called the stacked classifier is used, which achieves an amazing 100% accuracy. In addition, the Hybrid Approach, which used both LSTM and BiGRU models, showed an impressive 94% accuracy. A front end was built using the Flask framework to make testing easier for people. It has login features to make the Twitter Hate Speech Detection system safer and more trustworthy. This makes sure that users have a smooth and reliable way to rate how well the model finds and stops hate speech on Twitter.

B. System Architecture

The first step is to load datasets like the Stock Tweets Dataset, the Single Stock Dataset, and the Multi-Source Dataset. For both mood analysis and predicting stock prices, these records are the building blocks. The Stock Tweets Dataset's text data is cleaned up by getting rid of extra spaces, HTML tags, URLs, and emojis. This step makes sure that the text is ready to be analyzed for mood [20]. It is possible to handle null numbers, get rid of copies, and scale both the Single Stock Data and the Multi-Source Data. This gets the financial information ready for predicting stock prices. A number of models have been taught to classify mood, such as MLP, CNN, LSTM, MS-LSTM, MS-SSA-LSTM, extensions-Voting Classifier, and LSTM + GRU.

They look at the cleaned tweet data to figure out how people feel about the market. These models are MLP, CNN, LSTM, MS-LSTM, and MS-SSA-LSTM. Figure 1 shows the proposed architecture.

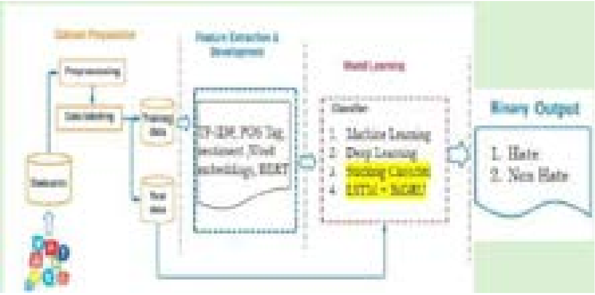

Fig 1. Proposed architecture

C. Dataset collection

To complete this project, the tweet collection will be first uploaded. The structure of the information is looked at, possible missing values are found, and the distribution of the classes (hate speech vs. non-hate speech) is analyzed in detail.

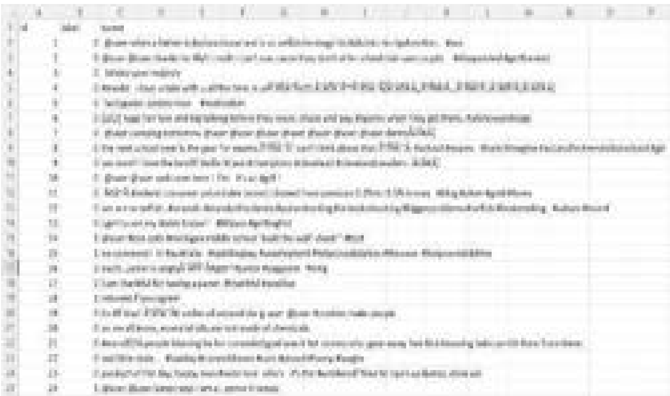

Fig 2. Tweets hate dataset

D. Data Processing

Data handling is the process of turning unstructured data into knowledge that businesses can use. In general, data scientists handle data, which means they gather it, organize it, clean it, check it, analyze it, and turn it into forms that can be read, like graphs or papers. There are three ways to handle data: by hand, mechanically, or electronically. The goal is to make knowledge more useful and decision-making easier. This helps companies run better and make smart strategy decisions more quickly. This is made possible in large part by automated data handling tools, like computer programs. It can help turn big data and other types of data into useful information for decision-making and quality control.

E. Feature selection

Feature selection involves choosing the most dependable, useful, and non-redundant qualities for a model. As record numbers and kinds rise, deliberate shrinkage is necessary. Feature selection aims to improve prediction models and reduce computation power.

One of the most important parts of feature engineering is feature selection, which is the process of choosing the most important features to feed into algorithms for machine learning. Feature selection methods get rid of unnecessary or useless features and only keep the ones that are most important to the machine learning model. This lowers the number of input factors. If you choose which traits are most important ahead of time instead of letting the machine learning model do it, here are the major benefits.

vi) Algorithms:

BERT (Bidirectional Encoder Representations from Transformers) uses a neural network built on transformers to understand and make language that sounds like it was spoken by a person. BERT has a design that only uses encoders. There are both encoder and decoder units in the real Transformer design. BERT's choice to use an encoder-only design says that understanding input sequences is more important than making output sequences. Text is normally processed in a straight line, either from left to right or right to left. This method only lets the model know about the situation right before the target word [12,15].

```
def create_model(bert_model):
    input_ids = tf.keras.Input(shape=(60,),dtype='int32')
    attention_masks = tf.keras.Input(shape=(60,),dtype='int32')

    output = bert_model([input_ids,attention_masks])
    output = output[1]

    output = tf.keras.layers.Dense(32,activation='relu')(output)
    output = tf.keras.layers.Dropout(0.2)(output)

    output = tf.keras.layers.Dense(1,activation='sigmoid')(output)
    model = tf.keras.models.Model(inputs = [input_ids,attention_masks],outputs = output)
    model.compile(Adam(lr=6e-6), loss='binary_crossentropy', metrics=['accuracy',f1_m,precision_m, recall_m])
    return model
```

```
from transformers import TFBertModel
bert_model = TFBertModel.from_pretrained('bert-base-uncased')
```

Fig 3. BERT

There is a parallel model called bidirectional LSTM or BiLSTM, which consists of two LSTM layers. One set of ideas is forward, the other is backward. It is frequently used in NLP-related studies. The idea behind this approach is that by processing the data in two ways, the model can better understand how patterns are related to each other, such as which words come after and before in a sentence. Two unidirectional LSTMs are created from one bidirectional LSTM. These LSTMs can perform forward and reverse operations [14].

Fig 4. BILSTM

GRU (Gated Recurrent Unit): Recurrent Neural Network (RNN). For simplicity, replace the LSTM network. Like LSTM, GRU can process continuous data such as speech, text, and time. The main idea behind GRU is to use gateways to change the secret state of only a part of the network at each step. The block system controls the flow of data into and out of the network. Reset gateway and update gateway are the two gateways that make up the GRU. This gate determines how much of the previously hidden state needs to be removed. The gate also determines how many new gates will be used to change the hidden state. The new hidden state is used to calculate the output of the GRU. This work uses GRU to process the data link faster, making discrimination recognition increasingly effective.

Fig 5. GRU

CNNs are a type of deep neural network that is very good at handling picture and spatial data. CNNs are used on text in natural language processing by treating it like a picture and using filters to find local patterns. CNNs are used in this project because they can find local features and trends in textual data. This helps find hate speech by finding specific language structures that are signs of harmful content.

Fig 6. CNN

CNN + LSTM (Convolutional Neural Network with Long Short-Term Memory), This mixed design takes advantage of both CNNs' ability to find local features and LSTMs' ability to learn in a step-by-step way. The CNN layer can find trends in the raw data that are related to space, and the LSTM layer can describe relationships that span long distances. CNN + LSTM is used in the project to use both local and sequential information. This gives the model a better understanding of context, which improves its ability to spot hate speech.

Fig 7. CNN + LSTM

CNN + BiLSTM (Convolutional Neural Network with Bidirectional Long Short-Term Memory), Like CNN + LSTM, CNN + BiLSTM pairs the CNNs' ability to capture local features with BiLSTM's ability to learn in both directions at the same time. This lets the model look at both the past and the future, reflecting how things depend on each other in both ways. This mixed design is used to find hate speech because it can pick up on subtle timing and contextual trends in the language, which makes the system work better overall.The designs chosen were chosen because they can find different kinds of information in text data. This lets for a more thorough study when it comes to finding hate speech.

Fig 8. CNN + BILSTM

CNN + GRU, This combination design takes the best features of both CNNs and GRUs: linear learning and speed, as well as the ability to recognize patterns in space. The CNN layer records local features, and the GRU layer handles information that comes in a certain order. This mix is probably used in the project because it can handle both local and long-range variables, which makes it better at finding hate speech.

Fig 9. CNN + GRU

LSTM, a better form of recurrent neural networks that is great at detecting long-term relationships and sequence prediction tasks. Time series analysis, machine translation, and speech recognition are some of the things that it can be used for. LSTMs are different from regular RNNs because they have a memory cell with input, forget, and output gates. These gates control the flow of information, letting you choose which bits to keep and which ones to throw away. Because of this one-of-a-kind feature, LSTMs are great for many uses, and they can be mixed with other designs like CNNs to do things like analyze images and videos. LSTM [15] is probably used in the project because it can model environmental information over long runs, which helps the system understand the complex language patterns that are signs of hate speech.

Fig 10. LSTM

LSTM + GRU (Long Short-Term Memory with Gated Recurrent Unit), This mixed design takes the best parts of both LSTM and GRUs, combining their abilities to handle long-term relationships and speed up computations. LSTMs are great at getting faraway environmental information, while GRUs are better at training quickly and dealing with short-term relationships. LSTM + GRU was probably chosen for the project because it models both short-term and long-term linear relationships in a fair way. This helps us understand hate speech patterns better.

Fig 11. LSTM + GRU

LSTM + BiGRU (Long Short-Term Memory + Bidirectional Gated Recurrent Unit), This mixed design blends the LSTM's ability to learn in a sequential way with BiGRU's ability to process information in both directions. Long-range connections are picked up by LSTM, and information is processed in both forward and backward ways by BiGRU. This combo was picked because it works well with sequential data that has complex timing patterns, which helps the model understand hate speech gestures better.

Fig 12. LSTM + BIGRU

Naive Bayes classifiers use Bayes' Theorem. There are other algorithms that function by the same principle: each pair of qualities may be classed separately. Let's start with a collection. The Naïve Bayes classifier is a simple and effective classification approach. It creates fast-predicting machine learning models. The Naïve Bayes classifier claims that things are simpler than they seem, thus the term "Naive". The classifier believes an observation's characteristics are independent of the class name. The Reverend Thomas Bayes is called "Bayes". Simple and fast to train, Naive Bayes can discover hate speech. It may also be used to compare more complex algorithms.

Naive Bayes

```
from sklearn.naive_bayes import MultinomialNB
clf = MultinomialNB()
clf.fit(X_train, y_train)
y_pred = clf.predict(X_test)

lr_acc = accuracy_score(y_test, y_pred)
lr_prec = precision_score(y_test, y_pred,average='weighted')
lr_rec = recall_score(y_test, y_pred,average='weighted')
lr_f1 = f1_score(y_test, y_pred,average='weighted')
```

```
storeResults('Naive Bayes',lr_acc,lr_prec,lr_rec,lr_f1)
```

Fig 13. Naïve bayes

Random Forest is a popular machine learning method for behavioral learning. We can use it for classification and regression in machine learning. Collaborative learning uses multiple classifications to solve complex problems and refine the model. As he says, "Random forest is a distribution with many decision trees that are averaged over different parts of the given data to increase the prediction accuracy of the records." A random forest uses the results of all decision tree predictions and decisions. The one with the most votes will appear as the decision tree.

Random FOrest

```
from sklearn.ensemble import RandomForestClassifier
RandomForest = RandomForestClassifier(n_estimators=10, random_state=0)

RandomForest.fit(X_train, y_train)
y_pred = RandomForest.predict(X_test)

rf_acc = accuracy_score(y_test, y_pred)
rf_prec = precision_score(y_test, y_pred,average='weighted')
rf_rec = recall_score(y_test, y_pred,average='weighted')
rf_f1 = f1_score(y_test, y_pred,average='weighted')
```

```
storeResults('Random FOrest',rf_acc,rf_prec,rf_rec,rf_f1)
```

Fig 14. Random forest

LinearSVC (Linear Support Vector Classifier): The LinearSVC algorithm is a type of the Support Vector Machine (SVM) method that is made for linear classification jobs. SVMs are good at making hyperplanes that split classes in a place with many dimensions. When it comes to finding hate speech, LinearSVC can be helpful because it can handle non-linear decision limits and correctly label hate speech.

LinearSVC

```
from sklearn.svm import LinearSVC
svm = LinearSVC()
svm.fit(X_train, y_train)
y_pred = svm.predict(X_test)

svm_acc = accuracy_score(y_test, y_pred)
svm_prec = precision_score(y_test, y_pred,average='weighted')
svm_rec = recall_score(y_test, y_pred,average='weighted')
svm_f1 = f1_score(y_test, y_pred,average='weighted')
```

```
storeResults('LinearSVC',svm_acc,svm_prec,svm_rec,svm_f1)
```

Fig 15. LinearSVC

RF + SVM + NB (Random Forest + Support Vector Machine + Naive Bayes), This group method takes the best parts of the Random Forest, Support Vector Machine (SVM), and Naive Bayes (NB) algorithms and puts them together. Random Forest adds stability with decision tree ensembles, SVM is great at making useful hyperplanes, and Naive Bayes adds probability classification. This group is probably used because it can collect different kinds of data, which makes hate speech recognition work better overall.

RF + SVM + NB

```
from sklearn.ensemble import VotingClassifier
from sklearn.svm import SVC
from sklearn.ensemble import RandomForestClassifier

estimator = []
estimator.append(('SVM', SVC(probability=True)))
estimator.append(('RFC', RandomForestClassifier()))
estimator.append(('NB', MultinomialNB()))
vot_hard = VotingClassifier(estimators = estimator, voting ='soft')
vot_hard.fit(X_train, y_train)
y_pred = vot_hard.predict(X_test)

vot_acc = accuracy_score(y_test, y_pred)
vot_prec = precision_score(y_test, y_pred,average='weighted')
vot_rec = recall_score(y_test, y_pred,average='weighted')
vot_f1 = f1_score(y_test, y_pred,average='weighted')
```

```
storeResults('RF + SVM + NB',vot_acc,vot_prec,vot_rec,vot_f1)
```

Fig 16. RF+SVM+NB

Stacking Classifier, When you use stacking, you train several models to predict the same outcome, and then you train a meta-model to make predictions based on the predictions of the other models. When it comes to finding hate speech, a Stacking Classifier is probably used to mix the best parts of different base models. This makes the whole system more reliable and accurate.

Fig 17. Stacking classifier

IV. RESULTS AND DISCUSSIONS

Precision: Precision is the percentage of correctly classified cases or samples compared to those that were correctly classified as hits. So, here is the method to figure out the precision:

$$Precision = \frac{TP}{TP+FP} \qquad (1)$$

The resultant graph of precision score is given in fig. 18.

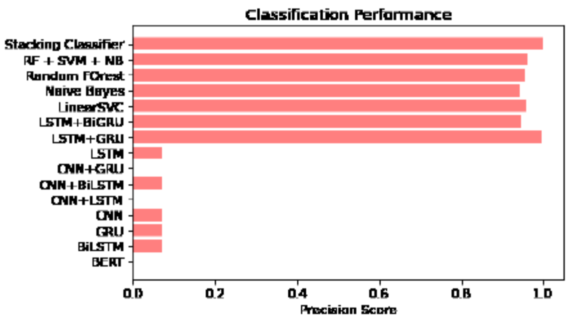

Fig 18. Precision comparison graph

Recall: In machine learning, recall is a parameter that shows how well a model can find all the important cases of a certain class. It shows how well a model captures cases of a certain class. It is calculated by dividing the number of correctly predicted positive observations by the total number of real positives. The resultant graph of recall comparison is given in fig. 18.

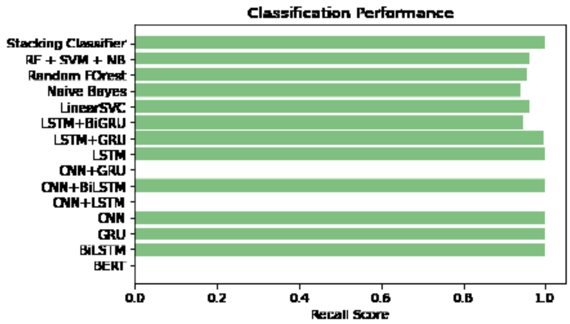

Fig 19. Recall comparison graph

Accuracy: Accuracy is the percentage of right guesses in a classification job. It shows how accurate a model's forecasts are generally.

$$Accuracy = \frac{TP+TN}{TP+FP+TN+FN} \qquad (3)$$

The resultant graph of accuracy score is given in fig. 20.

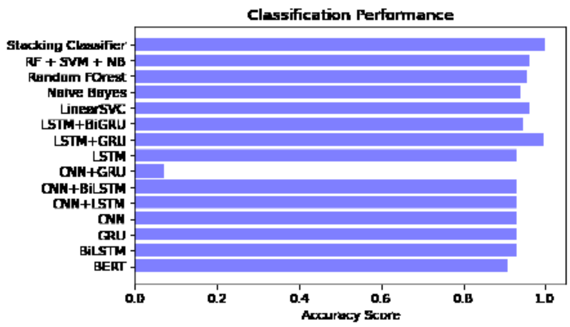

Fig 20. Accuracy graph

F1 Score: F1 score is a compromise between accuracy and return. This is a fair measure that takes both positive and negative into account, so it can be used with inconsistent data.

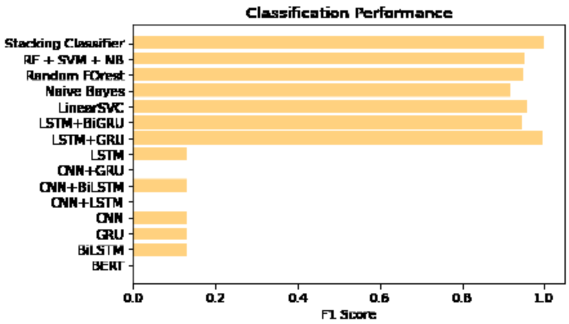

Fig 21. F1 Score

The resultant graph of F1-Score is given in fig. 21 and the performance analysis results are given in fig. 22.

V. CONCLUSION

By correctly finding and reducing hate speech, this research work helps make the internet a safer and better place for everyone. Users report less abuse, which makes the online community more welcoming for everyone. The project's ability to find hate speech is useful for regulatory bodies and platform managers. The method is a useful way to make sure that rules against hate speech on the internet are followed. This gives governing bodies the power to move proactively and keep the online economy healthy. Using a strong ensemble method, the stacked algorithm was able to get 100% accuracy. The model's ability to find and deal with hate speech on Twitter was shown through front-end tests that included identification. Using ensemble methods improves the ability to guess by using the combined strength of several models to get more accurate results. The combination of the Flask framework with SQLite for user signup and signin makes sure that users are safe and authenticated. This protects the privacy of users and creates a reliable tool for people to use with the hate speech recognition system.

VI. FUTURE SCOPE

The goal of future work is to make hate speech recognition work in more than one language. This will have a world effect by creating models that can recognize hate speech in languages other than English. As things get better, the focus will be on making hate speech recognition models more responsive to changing language trends online by adding tools for learning and adjusting to new words and phrases in real time. To make things better, advanced NLP methods such as mood analysis and snark recognition, could be used to help the model understand context better. This would help it tell the difference between harmless statements and real hate speech. In the future, developers may focus on making features that are more useful to users. For example, they could give users customizable filters and content choices to change how sensitive hate speech recognition is. This would make the experience more flexible and easy to use.

Abstract— In the field of digital design and verification, serial communication driver verification is essential for guaranteeing the accuracy and dependability of electronic systems. A standardized framework for functional verification in hardware design, the Universal Verification Methodology (UVM), was used to construct the Serial Driver Verification Testing Module that is shown in this abstract. The suggested module is an essential part of the verification environment as it makes it easier to evaluate if the serial driver complies with communication protocols. The module is made to systematically watch, evaluate, and score the interactions between the serial driver and the tested Device Under Test (DUT) by utilising UVM's capabilities. The Serial Driver Verification Scoreboard Module's key features include effective reporting systems, error detection, and thorough protocol verification. Scalability and maintenance are improved by the modular and reusable verification components made possible by the UVM approach. By comparing predicted and observed communication sequences, the scoreboard module may identify potential protocol breaches and offer insightful information about the driver's conduct.

Keywords: Test bench, Serial driver, Sequences, scoreboard Directed Acyclic Graph (DAG), Monitor

I. INTRODUCTION

Serial communication protocols are essential to the dynamic world of digital communication because they allow various electronic devices to share data. Making sure serial communication drivers are proper and strong is becoming more and more important as the need for fast and dependable communication grows. In this work, a new method for verifying serial drivers using the Universal Verification Methodology (UVM) is presented.

The suggested approach makes use of a Scoreboard Module to thoroughly evaluate the performance and functionality of serial drivers, enhancing the general dependability of communication networks.

The methodology of Universal Verification has acquired broad acceptance in the verification field due to its efficiency in handling the complexity of contemporary digital designs. This study seeks to improve serial communication driver verification using UVM, offering a method of scalable approach. A crucial element of the verification environment is the recently developed Scoreboard Module, which permits real-time data monitoring and validation of the data sent between the serial driver and the communication interface.

A UVM monitor is a passive component, which is used to capture DUT signals using a virtual interface and translate them into a sequence item format. These sequence items or transactions are broadcast to other components like the UVM scoreboard, coverage collector, etc. It uses a TLM analysis port to broadcast transactions.

II. LITERATURE SURVEY

This section describes the current efforts in the field of Soc verification using UVM. A generic and reusable UVM model has been presented by Hussein et al. (2019) to enhance the serial. The results indicated the suggested technique is more appropriate to provides quicker, reusable, and trustworthy verification [1] by Yashas et al., 2019. Using many tests, this method creates a random test bench to achieve 100% code coverage and functional coverage [2].

The increasing complexity of silicon processors has been responsible for many of the challenges in verification. Therefore, UVM based AX14 stream verification, and it's results with that verification was explained by Xu et al., 2019 [3]. A system Verilog based UVM verification for DPLL has been mentioned in a paper by Georgousopoulos and Hatzopoulos, 2019 [4]. Because it provides a soiled gain in verification and this suggested verification model is difficult rapid, reusable, and dependable in the digital market which is interface for serial peripherals [5].

Guo et al, 2020 introduce the (SPI) module for UVM based verification, which helps in achieving communication between the SoC components. The verification pattern has influenced the SoC verification environment, and the SPI module gives 100% coverage rate [6]. It might be hard to set up a complicated test bench, but working on this makes the verification of complex SoCs easier [7].

As a result, a controller area network based on UVM and the results with effective verification has been given by Godel et al. 2020 [8]. El Ashy, 2020 introduced a generic verification environment for NoC platform that provides reusable and error verification solutions in addition to evaluating DUT. This method examines the viability and compatibility of few NoCs for error verification strategies [9]. Hao et al. in 2019 studied a UM-based single wire protocol (SWP) interface module for verification is presented for SIM card chips.[10]

The random incentives that increase the interface module's verification performance have been preserved in the research [11]. by Priyanka 2021, a Verilog-based UART design and UVM verification are shown. The design clarifies the overall functionality of UART, while UVM verification is noted to reduce energy consumption reusability [12]. K.W. Wong. has proposed a UVM method in 2019 for confirming an RTL code connection to implement memory-centric computing.[13] By using some UVM techniques the packets are created, and some packets were sent into this switch [14]. ports through virtual interface Effective. Verification for memory-centric computing is brought forth by this method [15].

III. Serial Driver Verification & Test Module using UVM.

Verification of a Serial Driver: This refers to the procedure for validating a serial driver, which is a piece of hardware or software that controls how a computer and a serial device communication Module for the Scoreboard: A scoreboard is an element used in hardware verification that verifies the accuracy of the outputs generated by the tested design (DUT). It tracks anticipated and actual outcomes and indicates any differences. A systematic process for confirming integrated circuit designs is called UVM. The semiconductor industry uses it extensively for functional verification of digital designs.

This approach helps discover corner cases and potential issues in the SDV design. Develop protocol-specific assertions using SystemVerilog Assertions (SVA) or Property Specification Language (PSL) to formally specify the expected behaveior of the SDV communication. These assertions can be checked during simulation to ensure compliance with the protocol.

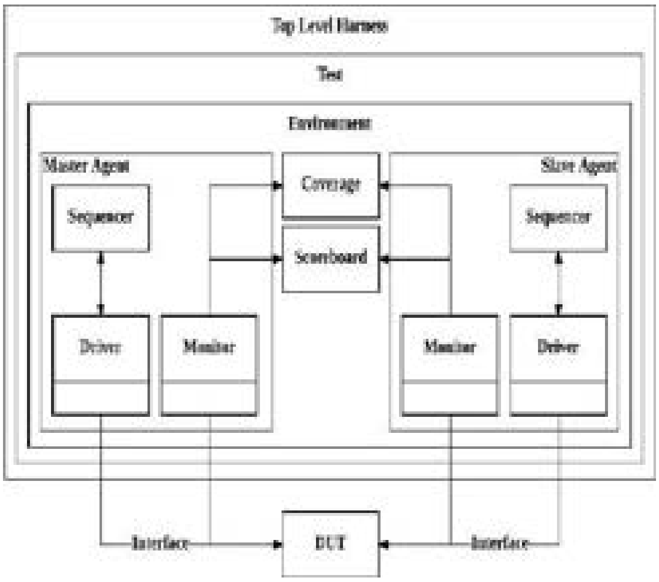

Fig. 1 Block diagram of UVM module

The fig.1 explains the Testbench example architecture with detailed explanation on writing each component link to testbench flow through block diagram. In contrast to parallel communication, which transfers data through communication channel bit by bit, serial communication transfers the data several bits at once.

3.1 WORKING PRINCIPLE:

Serial Driver: This most likely denotes a part or module in charge of managing serial communication. Unlike parallel communication, which sends data via a communication channel one bit at a time, serial communication sends data corruption.

A component or module in charge of overseeing serial communication is most frequently indicated by the term "serial driver." In contrast to parallel communication, which transfers data via a communication channel bit by bit, serial communication transfers data several bits at once. Verification Scoreboard Module: A scoreboard is a module used in hardware or software verification that monitors predicted and actual outcomes during the verification process. Finding any differences between the predicted and actual behaviour of the system under verification is helpful. A systematic process for confirming integrated circuit (IC) designs is called UVM (Universal Verification Methodology). For verification the functional of digital hardware, it is extensively utilized in the field of electronic design automation.

Now, putting these parts together, a "Serial Driver Verification Testing Module using UVM" would probably a verification element made to use the UVM approach to verify that a serial driver module is proper. For digital designs, the UVM framework offers a standardized method for building testbenches and verification environments. The idea behind such a module would be to build a scoreboard inside the UVM testbench to keep track of and validate the serial driver's actions. This might entail making that the driver compiles the requirements, handles errors effectively, and transmits and receives data accurately. Now, putting these parts together, a "Serial Driver Verification Scoreboard Module using UVM" would probably be a verification element made to use the UVM approach to verify that a serial driver module is proper. For digital designs, the UVM framework offers a standardized method for building testbenches and verification environments. The idea behind such a module would be to build a scoreboard inside the UVM testbench to keep track of and validate the serial driver's actions. This might entail making that the driver complies with the requirements, handles errors effectively, and transmits and receives data accurately. The scoreboard module may do a comparison between the actual behaviour seen during testing or simulation and the specified expected behaviour based on the specifications or criteria. As part of the verification process, any mistakes or anomalies found by the scoreboard would be recorded, assisting the verification engineer in locating and troubleshooting any issues with the serial driver implementation.

3.2 IMPLEMENTATION

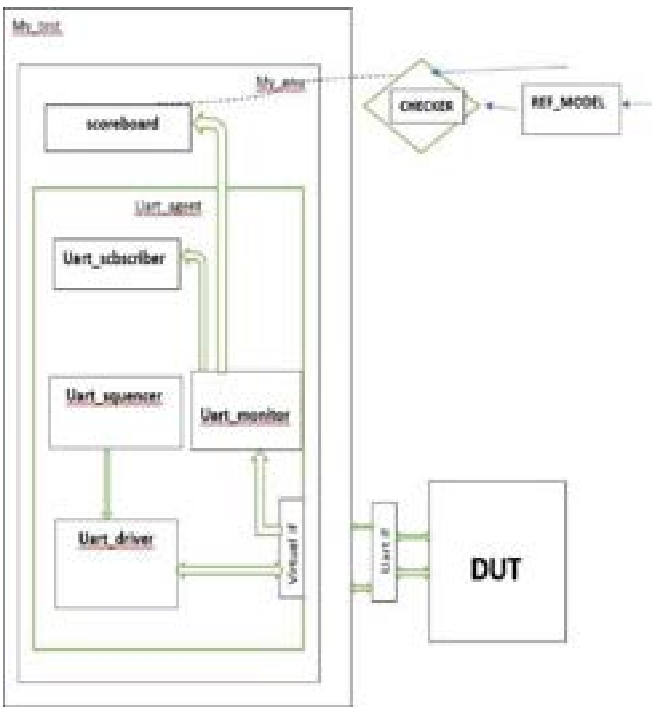

Fig.2.Interfacing of DUT processed data with the Scoreboard.

Figure.2 explains a scoreboard, which is frequently used in UVM to compare predicted and actual outcomes from the design that is being tested (DUT). In this methodology functional coverage collector are implemented. Protocol is defined to facility of the driver implementation of I2Cdevices. Adjust tests as needed to improve coverage uvm analyze through ex the development of two testbenches for unit to verification first one is targeted to fifo buffer module implemented

IV. RESULT AND DISCUSSION

The UVM verification component would generate a sequence of signals to send to the DUT. The specific signals would depend on the functionality being verified. The component would also monitor the DUT's outputs to see if they match the expected outputs and finally compare the DUT's outputs to the expected outputs to determine if the DUT is functioning correctly.

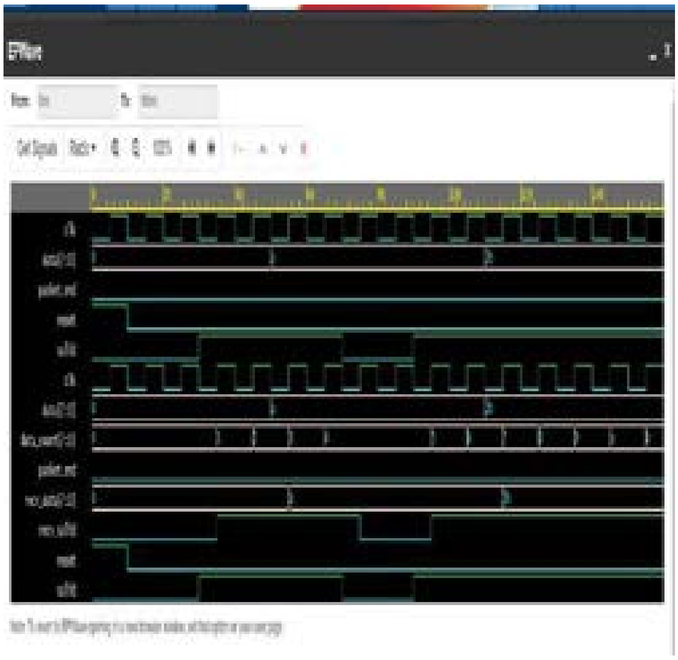

Fig.3 output of serial driver verification and test Module

Figure.3 explained the running the Utilize a Directed Acyclic Graph (DAG) to illusate the relationships between UVM components. Nodes in the graph represent UVM components (e.g., driver, monitor), and edges represent the flow of transactions UVM to assess the completeness of your tests. Adjust tests as needed to improve coverage uvm analyze through ex the development of two testbenches for unit to verification. first one is targeted to fifo buffer module implemented .At present verification Environment of image signal processing of IP'S/SOC'S with strong verification methodology contributes wave signal of first silicon process.

V.CONCLUSION

A reliable and effective method for confirming the operation and performance of serial drivers in a design is the Serial Driver Verification Scoreboard Module, which uses the Universal Verification Methodology (UVM). This verification scoreboard module offers enhanced scalability and reusability by providing a systematic and uniform verification approach using UVM. An essential part of the verification environment, the scoreboard allows for the observation and examination of communication between the DUT and the serial driver (Device Under Test). UVM automates many aspects of testbench development and execution, including stimulus generation, checking, and result analysis. This automation reduces manual effort, speeds up verification cycles, and improves overall productivity.

Abstract*— The rapid urbanization and increasing number of vehicles in smart cities have increased the importance of ensuring road safety. This model proposes the development and implementation of an Internet of Things (IoT)-based vehicle monitoring system to increase the safety standards in smart city environments. Leveraging cutting-edge technology, the system continuously monitors and evaluates on-road vehicle behavior in real-time, providing essential data for traffic management and accident prevention. By integrating a variety of in-car sensors and communication devices, the proposed system collects and transmits data to a centralized server, including information on the vehicle's position, speed, acceleration, and braking patterns. This data enables the detection of potentially hazardous situations, such as aberrant driving patterns and traffic congestion. The IoT-based Vehicle Monitoring System not only monitors individual vehicle behavior but also facilitates communication between vehicles and infrastructure, fostering a cooperative traffic ecosystem. With the incorporation of advanced analytics algorithms, the proposed system can identify factors affecting road safety and enhance its prediction capabilities over time. By harnessing technologies like Artificial Intelligence (AI) and Machine Learning (ML), the proposed system continuously evolves to address evolving safety challenges. The ultimate goal of this study is to contribute to the development of smarter and safer cities by proactively addressing safety and traffic management concerns, thereby reducing traffic congestion, accidents, and creating a more secure urban transportation network.

Keywords—Internet of Things, Traffic Monitor, Safety, Node Microcontroller unit.

I. INTRODUCTION

In the dynamic field of smart cities, where advances in technology are transforming urban living, creative problem-solving is required to tackle the intricate issues brought on by a rise in the number of vehicles on the road. The lack of adequate road safety standards is one of the biggest issues that has to be addressed. With unprecedented levels of urbanization, there is a growing demand for cutting-edge technologies that actively monitor and enhance road safety for vehicles. By creating and deploying an Internet of Things (IoT)-based vehicle monitoring system especially for smart cities, this module seeks to address this challenge. Combining Internet of Things (IoT) technologies with vehicle monitoring aims to produce a flexible and adaptable system that can analyze the behavior of individual cars and potentially promote cooperation between car and city infrastructure. The main objective of this model is to create urban transportation networks that are more adaptable, safe, and efficient. Finally, as opposed to merely being a technical advancement, IoT-based Vehicle Monitoring System is a deliberate step toward changing urban mobility. The system aims to greatly contribute to the development of safer and smarter cities by fusing state-of-the-art technologies with an emphasis on safety. These cities' roadways have been transformed into dynamic, intelligent areas that may change to meet the ever-evolving needs of urbanization.

II. LITERATURE SURVEY

A. SECURITY SYSTEM USING INTERNET OF THINGS IN SMART CITIES

Authors: Adeoye, A. Adebiyi, O. Oluwarotimi . In this paper, the authors have done implementation on Applications in Transportation, challenges and opportunities and integration. In their paper on IoT-based security systems in smart cities, Adeoye, A., Adebiyi, O., and Oluwarotimi detail a technical framework that integrates sensors like cameras and motion detectors into transportation infrastructure. These sensors provide real-time data to a centralized unit, which uses edge computing to handle it quickly and with less delay. The data is analyzed for potential threats using advanced security algorithms that include image recognition and video analytics. A strong communication network, like 5G or LTE, guarantees constant device connectivity. Security staff can monitor using an intuitive dashboard from the centralized control center, and overall efficacy is increased through interaction with other smart city technologies. Predictive analytics is made possible by machine learning algorithms, and the system complies with strict security guidelines. This thorough but succinct method guarantees a technically advanced and flexible security system. One noteworthy aspect of their framework proposal is the integration of edge computing, which is a paradigm that involves handling data close to its source. This strategy is essential for reducing latency, guaranteeing effective processing, and maximizing resource use. Using image recognition and video analytics, advanced security algorithms are yet another essential component of their system. These algorithms probe into the sensor data streams in real time and do complex evaluations to find security issues and possible threats. This sophisticated degree of inspection goes beyond conventional techniques, improving the system's ability to identify subtle security threats. Finally, the writers stress how crucial it is to follow strict security guidelines and include safeguards against illegal access and cyberthreats. This promise guarantees its honesty, dependability, and credibility.

B. A COMPREHENSIVE REVIEW ON THE ROLE OF INTERNET OF THINGS IN TRANSPORTATION SYSTEM

Authors:Muhammad Awais Javed, Abbas Anwar

In their comprehensive review on the role of IoT in transportation systems, authored by Muhammad Awais Javed and Abbas Anwar, the focus is placed on the pivotal role of sensors in monitoring and ensuring a safe environment. The implementation involves a network of sensors strategically placed within the transportation infrastructure. These sensors cover a wide range of technological platforms, such as cameras, environmental sensors, and other data collection tools. The sensors gather information about ambient factors, traffic patterns, and system functioning continuously. A centralized system receives this real-time data for analysis and decision-making. Lidar and radar are examples of advanced sensor technologies that are probably used for accurate object tracking and detection. In order to monitor the transportation ecosystem and enable the system to quickly identify and address any potential safety concerns or abnormalities, sensors play a critical role. A dynamic and networked transportation system is created through the seamless connection between components made possible by integration with IoT technology. This analysis emphasizes how crucial sensor technologies are to the foundation of a successful IoT-based transportation infrastructure, greatly enhancing efficiency and safety.

C. DESIGN AND IMPLEMENTAION OF AN AUTOMATED TRACKING SYSTEMS.

Authors: P Sudhakar , R Arul Murugan.

The authors initiated a technical exploration of a system aimed at real-world implementation, with a focus on current trends in tracking technology. To achieve accurate and real-time position tracking, the design incorporates sophisticated tracking mechanisms including GPS and RFID. To effectively handle and analyze location data, the system probably combines hardware elements like GPS modules and RFID scanners with integrated software. The automated tracking system probably has real-time monitoring and management capabilities for the movement of people, cars, and other assets. The writers might talk about how tracking devices and the central monitoring system might communicate seamlessly by using wireless communication protocols, perhaps based on the Internet of Things. It is likely that the study tackles implementation issues in the actual world by taking into account aspects such as security, dependability, and scalability. It may be investigated what current tracking technology trends are, such as the incorporation of machine learning algorithms for data analytics and predictive tracking. In summary, this technical explanation highlights the usefulness of putting an automated tracking system and safety standards into place while keeping a close eye on new developments to guarantee applicability and efficiency in the modern environment.

III. SYSTEM COMPONENT

A. NODE MCU: The NodeMCU ESP8266 is outfitted with the ESP-12E module, an advanced part that includes the potent ESP8266 chipset and the 32-bit LX106 RISC microprocessor from the Tensilica Xtensa. The NodeMCU is a great option for requiring wireless connection since the ESP8266 chipset, which is well-known for its abilities in this area, allows for smooth connectivity. wireless communication functionalities. The Tensilica Xtensa's 32-bit LX106 RISC microprocessor, housed within the ESP-12E module, provides the computational muscle for executing complex tasks efficiently. Notably, the NodeMCU's ESP8266 microcontroller supports Real-Time Operating Systems (RTOS), offering a flexible and responsive framework for handling concurrent tasks. Furthermore, the NodeMCU's variable clock frequency—which ranges from 80MHz to 160MHz—allows developers to customize the processing speed of the device to meet the unique needs of their applications while adapting to varying performance requirements. The NodeMCU ESP8266's feature-rich architecture ensures excellent performance, scalability, and dependability in a wide range of embedded systems applications, making it an outstanding solution.

B. NEO6M GPS Receiver: In the IoT-based Vehicle Tracking System with NodeMCU, the NE06M GPS receiver is a critical component providing precise location data. Interfaced through UART, the NodeMCU communicates with the NE06M, extracting latitude, longitude, and other relevant information. This GPS module receives signals from satellites and transmits processed data to the NodeMCU for further processing. The NodeMCU's computational capabilities and connectivity integrate the NE06M's data into the system, enhancing real-time vehicle tracking accuracy. The NE06M's reliability and the NodeMCU's processing prowess make this integration a robust solution for location-based tracking applications.

C. 16x2 LCD Display: An essential user interface component of the Internet of Things Vehicle Tracking System with NodeMCU is the 16x2 LCD display. The 16x2 LCD display serves as a visual output device, giving users or system administrators access to real-time information with 16 characters spread across 2 lines. The NodeMCU interfaces with the LCD screen to show pertinent tracking system data, including GPS locations, vehicle speed, and timestamps. Overall, the incorporation of the 16x2 LCD display improves user interaction and guarantees that the Internet of Things-based Vehicle Tracking System operates in an accessible and visible manner.

D. I2C Module: An I2C (Inter-Integrated Circuit) module is included in the NodeMCU-based Internet of Things Vehicle Tracking System to enable smooth communication between the NodeMCU and linked sensors, such as GPS modules. Data exchange is streamlined by this two-wire communication protocol, which makes it possible for the NodeMCU to collect data from multiple sensors effectively. In order to connect and control various peripherals and improve the tracking system's overall functionality, the I2C module is essential. Real-time tracking capabilities are enhanced by the NodeMCU's processing of data received via I2C and its transmission of pertinent information to a central server.

E. ESP8266: An essential part of Internet of Things-based car monitoring systems for smart city safety regulations is the ESP8266. It gathers information like GPS location and car diagnostics, connects to central servers wirelessly via Wi-Fi to send data in real-time, and interacts with external and onboard sensors for all-encompassing monitoring. Due to its edge computing capabilities, latency can be decreased by processing data at the source. It also makes it easier to monitor and control cars remotely, all the while protecting data using encryption. Its affordability makes it even more suitable for broad implementation, which makes it a crucial component of ecosystems for safer urban transportation.

IV. WORKING MODEL

Key components, such as the ESP8266 NodeMCU, NE06M GPS Receiver, 16x2 LCD, and 16x2 LCD I2C module, are integrated to build a solid system in the implementation of this advanced GPS tracking device for real-time vehicle location monitoring. As the main microcontroller, the ESP8266 NodeMCU precisely and effectively coordinates communication and cooperation among the networked components. The highly praised NE06M GPS Receiver ensures real-time tracking of the vehicle's movements by providing essential location data. When combined with the I2C module, the 16x2 LCD display provides an advanced user interface for direct and on-device information presentation. The ThingSpeak IoT cloud platform adds a major layer of capability to the model. In this example, ThingSpeak is utilized to log the previous areas that the car has driven over. ThingSpeak is a flexible IoT solution for data logging, analysis, and visualization. This cloud-based method allows for smooth connection with other apps in addition to facilitating remote access to real-time data.

In order to maintain continuous device operation, the carefully planned hardware setup—which includes connectors that provide a stable arrangement on a breadboard—is supported by a dependable power source. Setting up the channels, fields, and visualizations in the Thing Speak software allows for thorough tracking of the GPS data. For improved data interpretation, the system not only shows raw data but also converts it into interpretable graphical representations. The hardware is assembled precisely in this sophisticated GPS tracking system for tracking the location of vehicles in real time. One multipurpose microcontroller that facilitates smooth communication between networked components is the ESP8266 NodeMCU. The device obtains precise location information by utilizing the highly precise NE06M GPS Receiver. Combined with the I2C module, the 16x2 LCD display offers an advanced user interface that shows important data right on the device.

An essential layer for data storage, processing, and visualization is introduced by the interaction with the ThingSpeak IoT cloud platform. ThingSpeak is set up to record location history from the car, allowing for easy interaction with other apps and remote access. This cloud-based method offers flexibility and agility for future expansions in addition to facilitating real-time monitoring. ThingSpeak is set up to receive data from the GPS module and display it graphically during the monitoring process. This entails configuring ThingSpeak's fields, channels, and visualizations. Comprehensive analysis and interpretation are made possible by the graphical representation of latitude and longitude data. The system's usefulness is increased when users obtain knowledge about the trajectory, speed, and stopping of the vehicle.

Additionally, the module includes a dynamic link that takes viewers to Google Maps on the webpage. By offering a clear, visual depiction of the vehicle's current location in real time, this function enhances the user experience. In addition to providing a user-friendly interface, this integration with Google Maps shows how versatile the system is when it comes to utilizing other resources. The hardware configuration is powered by a dependable source to ensure continuous functioning. It is painstakingly arranged on a breadboard with connectors that provide stability. To ensure smooth device integration, the ThingSpeak software configuration entails scripting data handling and visualization methods. The system uses sophisticated algorithms for anomaly identification and data interpretation in addition to storing raw data.

The cloud-based IoT solutions and cutting-edge hardware components are integrated in this technical concept of the IoT-based Vehicle Tracking System. ThingSpeak serves as a powerful IoT platform for storage, analysis, and visualization, and the ESP8266 NodeMCU, NE06M GPS Receiver, and 16x2 LCD components work together to collect data in real-time and historical fashion. The painstaking monitoring procedure, enhanced by dynamic interfaces and graphical representation, results in an advanced and technologically proficient solution for all-encompassing vehicle tracking and monitoring.

In the development of our IoT-based Vehicle Tracking System, the integration of hardware components is executed with precision and technical sophistication. The ESP8266 NodeMCU serves as the central orchestrator, seamlessly coordinating communication among components. Leveraging the NE06M GPS Receiver for high-precision location data and the 16x2 LCD display with an I2C module for an intuitive user interface, the system performs well in real-time and historical data acquisition. The inclusion of the ThingSpeak IoT cloud platform elevates by providing a scalable and versatile solution for data storage, analysis, and visualization. The monitoring process involves configuring ThingSpeak to graphically represent latitude and longitude data, allowing for insightful analysis. Additionally, the integration of a dynamic link on the webpage, redirecting users to Google Maps for real-time visualization, enhances user experience. The meticulous hardware setup, coupled with ThingSpeak software configuration, ensures continuous and reliable operation. In summary, the proposed IoT Vehicle Tracking System exemplifies the integration of cutting-edge hardware components and cloud-based IoT solutions, offering a sophisticated and technologically adept solution for comprehensive.

In conclusion, the cloud-based IoT solutions and sophisticated hardware components are harmoniously integrated by the IoT-based Vehicle Tracking System. Real-time data capture is ensured by the effective management of communication among components by the ESP8266 NodeMCU. With the help of an I2C module and a 16x2 LCD display powered by the NE06M GPS Receiver, the system achieves exceptional precision and user engagement. Scalability is offered for data storage, processing, and visualization through integration with ThingSpeak. The monitoring procedure, set up in ThingSpeak, exhibits sophisticated data processing abilities. The website's dynamic link, which takes visitors to Google Maps for real-time display, improves user experience and demonstrates system flexibility. Continuous operation is ensured by careful hardware setup and complex ThingSpeak software settings. The IoT Vehicle Tracking System, which provides a comprehensive and cutting-edge solution for vehicle tracking and monitoring, is essentially the epitome of integration.

In summary, the IoT Vehicle Tracking System seamlessly integrates advanced hardware with cloud-based IoT solutions, offering a precise, user-friendly, and technologically advanced solution.

V. BLOCKDIAGRAM

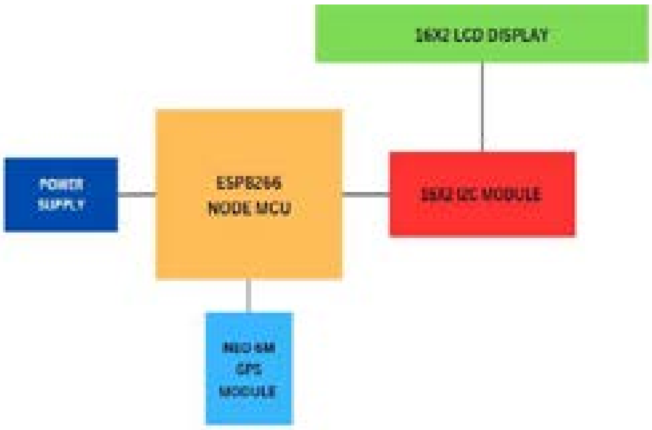

Fig.1.**Block diagram of Monitoring Unit**

The complex architecture of the ESP8266-based car tracking systemshown in figure 1 includes a block diagram that shows all of the parts that are necessary for it to function properly. The ESP8266 module, which serves as the central controller in charge of communication and system administration overall, is at the center of the system. The Neo GPS module, which is essential for obtaining precise GPS coordinates, is connected to this central unit. The ESP8266 and Neo GPS module communicate with each other through a CPU, which provides cellular connection for distant communication and real-time tracking updates. The brains of the system, the ESP8266, communicate with the Neo GPS module to retrieve exact location information, which guarantees precise vehicle monitoring. User interaction and real-time updates are facilitated through a user interface accessible via a web interface or mobile app. Additionally, a database integration may store previous tracking data for a comprehensive tracking solution. This block diagram exemplifies the sophisticated connections and interactions among the ESP8266 module, Neo GPS module, microprocessor, and user interface, underscoring the system's efficiency, accuracy, and advanced tracking capabilities.

A user interface can be accessed via a web interface or mobile app, enables user engagement and real-time tracking updates. Users can easily track the location of the tracked vehicle and get real-time information with this interface. Furthermore, tracking data can be connected to a database in specific situations to create a full tracking solution. By preserving historical tracking data, this database integration helps provide a comprehensive picture of the vehicle's movements over time.

In conclusion, the ESP8266-based vehicle tracking system, outlined through a comprehensive block diagram, embodies a technologically advanced solution for real-time monitoring and precise location tracking. The ESP8266 module, serving as the central controller, orchestrates communication and system management seamlessly. The integration of the Neo GPS module ensures the acquisition of accurate GPS coordinates, fundamental for precise vehicle tracking. A microprocessor facilitates efficient communication between these core components, enhancing connectivity and enabling cellular access for remote updates. The user interface, accessible through a web interface or mobile app, provides a convenient means for users to monitor vehicle locations in real-time. Furthermore, the potential linkage of tracking data to a database adds a layer of comprehensive historical tracking. This block diagram underscores the system's sophistication, illustrating the integration and synergy among key components for a robust, efficient, and user-friendly vehicle tracking solution. The ESP8266-based system represents a paradigm in IoT-based tracking, emphasizing accuracy, accessibility, and comprehensive functionality.

\

VI. OUTPUT

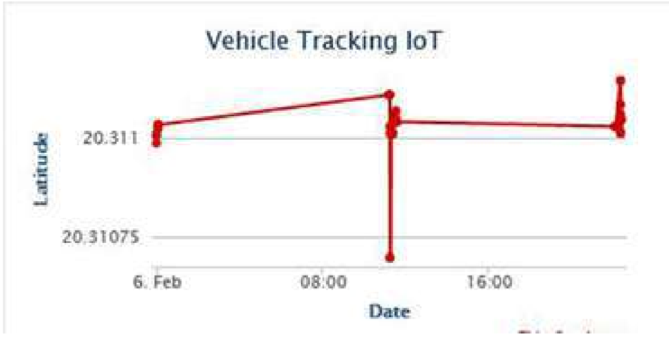

Fig.2.**Latitude vs Date**

Figure 2 shows the graph plots of the Latitude parameter with respect to Date. This is quite useful as it can even see the previous values to get an idea of how the Vehicle has been for the past few hours. It can see how the current values stack up with the previous values.

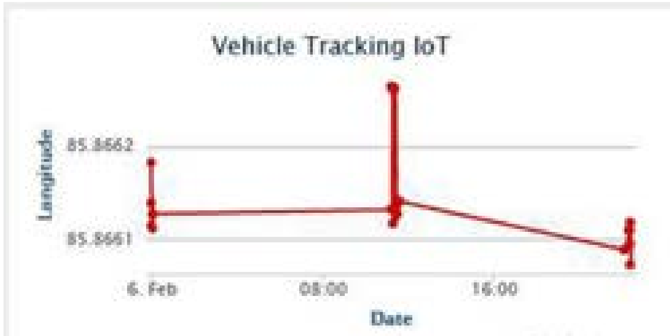

Fig.3.**Longitude vs Date**

Figure 3 shows the graph plots of the Longitude parameter with respect to Date. This is quite useful as it can even see the previous values to get an idea of how the Vehicle has been for the past few hours. It can see how the current values stack up with the previous values.

Longitude and latitude data from the GPS module are sent to ThingSpeak via the ESP8266 NodeMCU in the IoT-powered car monitoring system. This data is stored in ThingSpeak channels throughout time, resulting in a chronological dataset. MATLAB ThingSpeak visualizations produce clear graphs that plot latitude and longitude versus time. Applying technical algorithms can improve the precision of the data. These graphs provide a concise, informative summary of the spatial movements of the vehicle and are useful for route analysis, speed profiling, and stoppage detection. This integrated system creates a strong foundation for long-term spatial data preservation and effective analysis in addition to guaranteeing real-time monitoring. The integration of IoT, GPS modules, and ThingSpeak in this vehicle monitoring system not only provides real-time updates but also facilitates long-term data storage and analysis. of the vehicle's spatial movements, allowing for detailed analysis and insights into the vehicle's route& speed.

VII. IMPLEMENTATIONOF VEHICLE MONITORING SYSTEM

In order to proactively control traffic, the IoT-based vehicle monitoring system for smart cities combines sensors, cloud computing, and machine learning. Sensors gather information in real time on location, speed, and ambient variables using technologies such as GPS. Machine learning techniques are used by the cloud-based central control system for traffic optimization and hazard prediction. By warning drivers to speeding offenses, identifying hazardous behavior, and quickly notifying emergency services, the system enforces safety standards. Real-time alerts for drivers and data for city officials are provided using a smartphone app. Strong security and privacy protocols, such as encryption, are in place. In smart cities, this technology transforms traffic management to provide safer. Figure 4 shows the real-time result.

F

Fig. 4 Real Time Monitoring Result

VIII.CONCLUSION

To sum up, the Vehicle Monitoring System for Safety Standards in Smart Cities, which is based on the Internet of Things, is leading the way in developing intelligent urban transportation networks. With a focus on data-driven safety, state-of-the-art technology, and potential interaction with smart cities, the system is scalable and flexible enough to change with urban surroundings. The potential of IoT to transform urban mobility and promote cooperation for improved road safety is highlighted by this study. The Vehicle Monitoring System, which is based on technology innovation, community involvement, and regulatory backing, pushes cities toward increased safety, intelligence, and sustainability while putting urban inhabitants' well-being in the center of interconnected transportation networks.

***Abstract*— This research study proposes a new technique to provide autonomous driver directions for vehicle parking. The dashboard LCD screen will show the lot number and the precise position of the open space where the automobile has to be parked. The proposed work features include an LCD that will show the entire number of automobiles that can be parked, a parking space that is free, and dynamic parking that avoids traffic. It can be utilized to cut down on congestion inside the parking lot and prevent wasting time. This results in reduced fuel usage and increased parking efficiency. The proposed work is delivered in an economical way. The proposed work is to develop a parking guidance system using Arduino.**

***Keywords*—LCD, Arduino, Lot number, Automobile, Parking efficiency.**

I. INTRODUCTION

The quick rise in vehicle usage is the cause of the traffic issue in a parking lot. This issue may mostly arise in developed cities. People used to go to tourist destinations, theaters, shopping centers, and hospitals. In addition to wasting time and causing traffic congestion, it also raises the risk of sound and air pollution. Consequently, a vehicle parking management system is required. The proposed work primary goal is to restrict parking, which is necessary to address these issues. A microcontroller can be used to control the system. Numerous technologies are currently in use in the parking system, including WSN, RFID, E-parking, conveying device belts, and smart parking options. Car parking guidance systems are an alternative approach to address the drawbacks of each technology. Only the number of open slots is displayed by RFID and WSN technologies, and only authorized users may utilize RFID. The cost of initiation and upkeep for smart parking solutions is substantial. Conveyor belt power usage is high. Therefore, it is not advised, given the current state of the world's energy shortage. This proposed work uses an infrared sensor to pinpoint the precise parking spaces for each vehicle. The parking spots

each contain an infrared sensor. The microcontroller is used to meet the requirements and acts as a programming tool for the entire system, which lowers costs associated with employment opportunities and offers excellent security. This approach can lead to flexibility, speed, and compliance with market demands. It is possible to reduce the tension that comes with traffic congestion. The way that space is used in a parking lot can be improved. The purpose of reactive parking is to divert traffic from within the parking lot. For instance, some users are given access to exclusive slots. The slot name will be automatically removed from the buffer if the user parks their car in the designated spaces. Errors may occur when an automobile is parked in the designated spots. In that scenario, the name of the slot the car is occupying can be automatically erased from the buffer.

II. EXISTING METHODOLOGY

The related work in this section is predicated on current technologies. The three current technologies are E-Parking, RFID, and conveyor belts. With RFID technology, an authorization card is given to the user. The parking area's entrance is where the RFID reader is located. Only approved users are permitted entry into the parking lot in order to park their cars. An authorization card is not available for each user, and the unauthorized user is unable to park their automobile. These are a few of the RFID technology's shortcomings. The mechanism that raises the automobile automatically into the designated slots is called a conveyor belt. The primary goal of this concept is to maximize space efficiency. Pallets are numbered on a conveyor belt. The huge vehicle is raised using the pallets. As a result, raising the car requires more power, and if multiple cars arrive at once, it may also result in lifting an empty pallet. As a result, it uses unnecessary power. Since there is a shortage of electricity energy in our nation, it is not advised due to increased power usage. Another idea that works well in large cities as an income stream is e-parking. It is employed to lessen traffic and improve the parking system's efficiency and safety. However, in order for this system to obtain data regarding the available spaces within the parking area, a traffic server is required. The primary disadvantage of the E-Parking system is its high initial and on-going costs when compared to alternative technologies.

III. PROPOSED METHODOLOGY

The components used for designing the car parking guidance system are Arduino (ATmega328Pmicrocontroller) 16*2,LCD, TCRT5000, Proximity IR sensor and Servo motor. All the hardware components were connected to the Arduino and it is shown in figure 1.

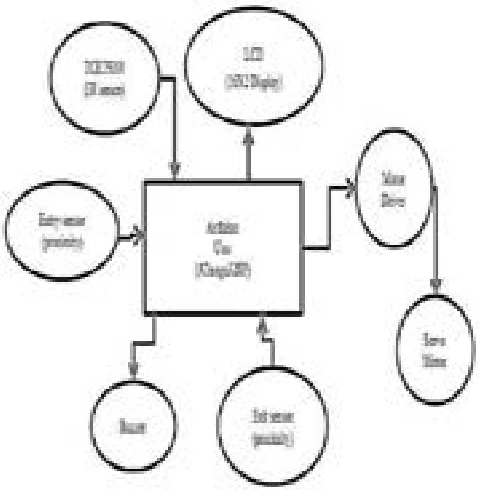

Fig. 1. Hardware connection with Arduino

The vacant spot monitor system of this car parking guiding system design is made up of an LCD display, an ATmega328P microprocessor, and an IR sensor. An infrared sensor installed in each parking space allows for the monitoring of the parking area. Here, the TCRT5000 IR Sensor is being used. Compared to other sensors, it has a unique future since it blocks visible light. The microcontroller receives information from an infrared sensor. Interface between the microcontroller and LCD display. It is employed to show details regarding available space within the parking lot. An infrared sensor installed in each parking space provides this information. Another surveillance system installed on the gate side. It keeps an eye on cars coming and going from the parking lot. The cars are detected using proximity sensors. The total number of cars in the parking lot is shown on an LCD monitor. Every time a vehicle is detected by the entry sensor, the count goes up, and every time a vehicle is detected by the exit sensor, the count goes down.

A. Microcontroller:

Here, an ATmega328P microcontroller is being utilized. It is an AVR-based low power CMOS 8-bit microcontroller that improved RISC architecture. Its throughput is almost one millisecond per megahertz. A microcontroller can be applied to both common and unique tasks. These days, office equipment, remote controls, and automobile mobile engine control systems all make extensive use of microcontrollers. Its primary purpose is to attain high system performance. In terms of efficiency and affordability, the ATmega328P microcontroller is a suitable option for this system.

B. TCRT5000

The reflecting sensor TCRT5000 has a photo transmitter and an infrared emitter mounted in a straight line inside a leaded package. It prevents light from reaching it. This sensor is utilized to identify any vacant spots in the parking lot and is positioned in every single slot. Because it filters out visible light, it generates identical output during the day and at night.

C. Proximity IR-Sensor

Without making physical contact, a proximity sensor may identify the presence of things in the immediate vicinity. There are two components to an IR sensor. One component is an infrared transmitter, or IR transmitter for short. It functions similarly to an LED and emits infrared light. Receivers are additional parts that collect the infrared radiation that the transmitter emits. One crucial thing to remember is that both pieces need to be arranged in a line that is straight. When the signal is high, the IR transmitter receives it and sends it to the receiver. A comparator is attached to the infrared receiver. The comparator is supplied the receiving signal. Comparator compares the operating voltage to the input voltage; if the returned voltage is higher than the comparator's operating voltage, both the receiver and the IR transmitter rays are disrupted, which causes the LED to glow (ON). The IR signal is not affected if the reference voltage and the comparator's operational voltage are equal. LED will turn off. This proximity infrared sensor is located at the parking area's entrance.

D. Servo Motor

The majority of the time, high-tech industrial applications like automation technologies use servo motors. It is an independent electrical device that precisely and efficiently rotates the machine's parts. It is utilized to open and close the gate in this proposed work. The gate automatically opens and closes when both the entry and exit sensors detect the presence of a vehicle. The servo motor with microcontroller interface. The angular direction of a servo motor distinguishes it from other types of motors. Closed-loop control systems can use it. For a 1ms variation in pulse width, the servo rotates 90 degrees.

E. LCD Display

An LCD display is positioned both within and outside the parking space. It has a microcontroller interface. It shows the overall capacity at the parking lot's entrance as well as information regarding available space within the parking area. Before approaching the parking space, drivers have the ability to check its current condition.

IV. IMPLEMENTATION

After the text edit has been completed, the paper is ready for the template. Duplicate the template file by using the Save As command, and use the naming convention prescribed by your conference for the name of your paper. In this newly created file, highlight all of the contents and import your prepared text file. You are now ready to style your paper; use the scroll down window on the left of the MS Word Formatting toolbar.

A. Module-I

It is suggested that Module-I show the available space in every parking place. This information is displayed using LCD in this instance. The TCRT5000 IR Sensor is used to detect the empty space in slots. The car is detected by the IR sensor, which displays the information on the LCD. The slot will show as occupied by a vehicle if the IR Sensor picks up the car. The figure 2 shows the flow chart of identifying the free slots in the parking area.

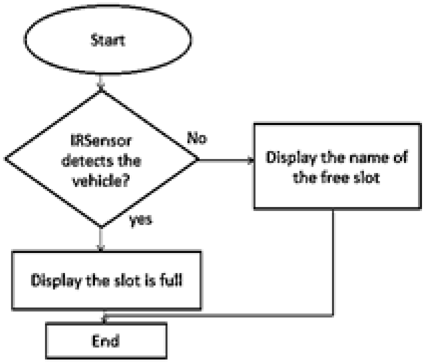

Fig. 2. Flow chart of identifying free slots in the parking area.

The figure 3 shows that the slots 'A' is free

Fig. 3. Slot 'A' is free

The figure 4 shows that the slots 'A & B' is free

Fig. 4. Slots A and B is free.

B. Module-II

The information regarding the total number of open spaces throughout the parking area forms the basis of Module II. Both the parking area's entrance and exit have proximity sensors. The count is increased by one if the entrance proximity initially detects the car. As a result, the count shows that an automobile has entered the parking lot. The LCD shows the remaining space in the parking lot. The count is decreased by one if the exit sensor detects something at first.This signifies that the car is pulling out of the parking lot. The parking area barrier is opened and closed based on the count value. If the count value is greater than the parking area's capacity, the barrier will close. If a vehicle is detected by the entry sensor, the barrier will immediately open. A servo motor is holding these operations. The figure 5 shows the identifying the available number of slots.

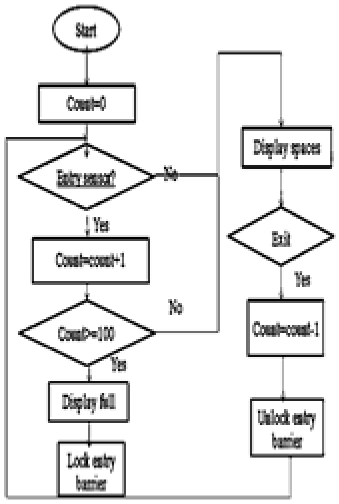

Fig. 5. Flow chart for the identifying the available number of slots.

It demonstrates that the count value increases by one each time the entry sensor detects a vehicle. The LCD indicates that there is no room within the parking area and the servomotor locks the barrier if the count value is more than the parking area's total capacity. The servo motor unlocks the barrier if the exit sensor detects a vehicle, causing the count value to drop by one. The figure 6 shows number of two vacancies inside the parking area.

Fig. 6. Shows that there is two vacancies were available inside the parking area.

The figure 7 shows there is only one vacancy inside the parking area.

Fig. 7. shows that there is only one vacancy inside the parking area.

The figure 8 shows there is no free space inside the parking area.

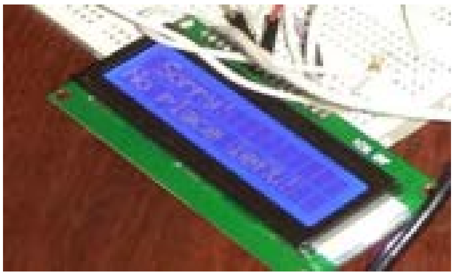

Fig. 8. represents there is no free space inside the parking area.

C. Module-III

The third module deals with dynamic parking. By moving the car to the other side of the slots, dynamic parking helps to minimize traffic inside the parking area. Two controllers can be interfaced to do this. Controllers are interfaced using the I2C protocol. One controller assumes the role of a slave, while the other assumes the role of a master. The controller, also known as the slave, is what retrieves the data regarding available parking spaces for cars. The LCD display used by the slave controller shows the information. The controller that counts the number of cars in the parking lot is called the master. The master was able to read data from the slave and provide it to the buffer by connecting these two controllers. This indicates that the LCD attached to the slave controller contains data regarding available slots. A master reads this data and stores it in a buffer. Here, the buffer serves to give each user a dedicated slot. Every user is given a specific slot, and if they park their car in that space, the slot name is immediately erased from the buffer. The primary purpose of dynamic parking is to automatically add free slots to the buffer based on slot occupancy and remove occupied spaces from the buffer automatically. It eliminates the need for monitoring and lowers the demand for human resources. The figure 9 shows Interfacing two arduino using I2C protocol.

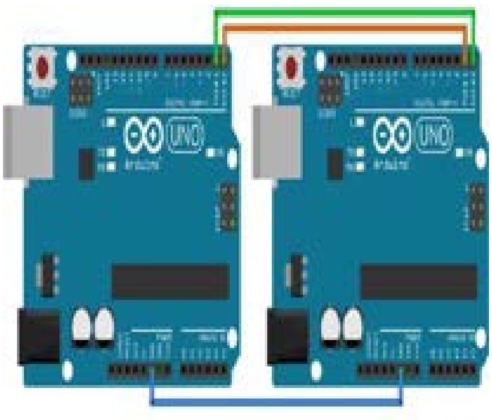

Fig. 9. Interfacing two arduinos using I2C protocol.

V. FUTURE SCOPE

The lack of speed and precise vehicle identification by IR sensor is the future potential for auto parking implementation. Consequently, a mechanical car detecting sensor or another alternate option may be employed. IOT and cloud computing are two more cutting-edge technologies that allow users to reserve parking spaces in advance for their own cars.

VI. CONCLUSION

The proposed work has been completed effectively. Upon entering the parking lot, the user is assigned a parking space and has access to information regarding the quantity of available spaces within the parking area. This causes the revenue from parking spaces to rise quickly. The environment is a key factor in this process. By reducing traffic, the pollution that vehicles' fuel use causes to the environment can be mitigated. Therefore, the purpose of the parking advice system is to help users save time and avoid traffic.

***Abstract*—The research article proposes a novel approach combining voice control with gesture-enabled virtual mouse technology to enhance human-computer interaction. Using this cutting-edge technology, which uses computer vision techniques to identify hand landmarks, users may control cursor motions using gestures. However, a number of problems with the current methods, such as snapshot algorithms, cloud-based voice assistants, and hand contour extraction, restrict their effectiveness. The accuracy of cursor control may be impacted by challenges in precisely interpreting user gestures due to the intricacy of gesture mapping and a restricted gesture language. Furthermore, the voice assistant component of the system is not robust enough to handle a variety of speech instructions and dynamic voice commands, and it is also dependent on an internet connection. Additionally, there aren't many error handling capabilities, which might lead to worse-than-ideal user experiences when orders aren't carried out precisely. Notwithstanding these difficulties, the proposed system incorporates voice assistant features beyond mouse control, enabling users to utilize mouse motions and natural language instructions to do a variety of activities, including sending emails, opening apps, executing mouse functions, searching the web, and managing files. To fully realize the potential of this integrated voice and gesture-controlled system in improving user experiences and accessibility, it will be imperative to address these issues through enhanced gesture vocabulary, expanded gesture recognition algorithms, and improved voice command processing.**

Index Terms*—Human-Computer Interaction, Gesture-Enabled Virtual Mouse, Voice Assistant, Computer Vision, Snapshot algorithm, Cloud-based voice assistant.

I. Introduction

The advancement of digital technology heavily relies on human-computer interaction (HCI), which serves as a bridge between users and machines through intuitive interaction methods. The combination of gesture-enabled virtual mouse technology and voice control marks a new era in HCI, potentially revolutionizing how users interact with digital interfaces. This integration signifies a departure from traditional input methods, providing users with a seamless and instinctive way to engage with technology. By utilizing natural gestures and voice commands, this integrated system has the potential to greatly improve accessibility, efficiency, and user satisfaction across various computing environments.

In today's fast-paced world, where accessibility and productivity are of utmost importance, voice recognition technology has proven to be invaluable. Initially developed to assist individuals with disabilities or physical limitations, voice recognition software offers a faster and more efficient method of inputting information. By allowing users to express their thoughts and instructions verbally, this innovative technology eliminates the need for traditional typing and enables natural and effortless communication.

From performing tasks such as setting reminders with a simple voice command to navigating virtual environments using gestures, these technologies empower users to multitask and interact with devices seamlessly. Furthermore, their introduction represents a significant advancement in HCI, propelling innovation in augmented reality and artificial intelligence. As a result, gesture-controlled virtual mouse systems and voice assistants have become essential components of modern computing, reshaping the way we interact with technology and unlocking limitless possibilities.

The amalgamation of computer vision, machine learning, speech recognition, and natural language processing (NLP) technologies serves as the foundation of cutting-edge interactive interfaces. By utilizing computer vision, the system decodes user gestures captured through cameras or sensors, facilitating seamless manipulation of on-screen cursors. Machine learning algorithms play a crucial role in gesture recognition, elevating precision and adaptability to user actions. Furthermore, speech recognition technology transforms spo- ken commands into text, enabling verbal communication with the interface. Advanced NLP methodologies further enrich user engagements by comprehending and analyzing natural language inputs.

The Gesture-Enabled Cursor with Voice Integration system signifies a notable progression in Human-Computer Interaction (HCI), offering enhanced user experiences and broader accessibility across digital platforms. This integration harbors transformative capabilities, influencing the future landscape of human-computer interaction.

II. Literature Survey

In the past, contact-based and noninvasive techniques have been used for hand gesture identification. Data gloves were employed in former contact-based techniques to detect and track hand motions. Unfortunately, because of their heaviness, connectivity, and detector locations, these gloves were frequently unwieldy and interfered with normal hand movements. Numerous studies have concentrated on employing various methods to control computers, like classifying human activities and assigning matching mouse instructions to drive the computer pointer, using sensors called Kinect [17], EEG mice, or EMG signals [8]. These techniques, however, frequently require extra gear that is costlier and larger than a standard computer mouse.

Virtual monitor [7]Using this technology, a virtual monitor in a simulated world is controlled by a Kinect camera that records human activities. After capturing physical characteristics, it builds a virtual monitor by reconstructing a skeleton image using joint coordinates and depth information. Through the use of a transformation process, coordinates from this virtual display are translated to the actual one. These translated coordinates serve as the basis for mouse operations, which improve accuracy. This Kinect-based virtual monitor system can be difficult and time-consuming to set up and calibrate. To guarantee optimal performance, some software setups and modifications might be necessary.

SIFT characteristic-based modified backpropagation of artificial neural networks (BP-ANN) [18]. This technique uses the Scale-Invariant Feature Transform (SIFT) algorithm for trajectory tracking after Gaussian Laplacian-based blob detection for hand modeling. In order to classify hand gestures for controlling household appliances, an artificial neural network (ANN) is trained using datasets. In order to learn complex descriptor associations, training a BP-ANN model with SIFT features requires a large amount of annotated data. This training procedure can be time-consuming and may necessitate significant labeled datasets.

Colored caps concept [20], the process of color detection entails locating colored finger caps within picture frames. In grayscale, color caps are highlighted by intensity differences, which first identify color pixels. After that, rectangles are made around caps using midpoint formulae for tracking. Tracked coordinates serve as the basis for gesture recognition. However, disadvantages include backdrop interference, color dependence, and limited color selection.

Mobiring[21]After filtering the signals with a translation equation, mistakes are corrected via Zero Velocity Compensation (ZVC). During gesture identification, accelerations don't change if there is initial stillness. A Finite State Machine (FSM) modifies its state when the moving ring satisfies certain requirements. Mobiring works best when the ring-mounted sensor is calibrated precisely. Erroneous calibration may result in inaccurate gesture identification and virtual mouse operation.

Hidden Markov Model [22] Skin color identification comes after object regions are isolated using skin pixel thresholding. Hand gesture computation is aided by edge identification using the Kirsch technique. Algorithms with convex hulls facilitate tracking. Hardware is implemented using a MEMS accelerometer. In order to accurately recognize patterns and gestures, Hidden Markov Models (HMMs) need large amounts of labeled data. It might take a lot of time and resources to gather and annotate this data.

HAAR and CAMSHIFT algorithm [11] After the HAAR algorithm separates hands from objects, CAMSHIFT uses Canny Edge detection and HSV skin to track hands. While convex-hull detection is used for various functions, displacement detection is the basis for mouse pointer movement. Preset textures and edge gradients are used by HAAR classifiers to identify objects. These characteristics might not always translate well between various hand motions and contexts, which would restrict their flexibility.

ANN-based adaboosting technique [16] Due to this technique, gesture-based navigation is made possible on huge TV screens. Four modes are available: input, scroll, zoom, and mouse. Using an ANN and adaboosting, hand images are divided into three groups for gesture recognition. Using early-stopping and cross-validation, a 2-layer feedforward network with log-sigmoid and linear transfer functions is optimized. Predefined gesture modes could reduce the system's efficacy and make it more difficult to adjust to nuanced or unique motions.

Snapshot algorithm [12] used for locating and perceiving hand coordinates with the help of Mediapipe library. Instructive algorithmic rule is used to pass over the coordinates from the camera to the screen. When faults or unforeseen circumstances arise, including occlusions, restricted mouse movements, or partial hand visibility, the Snapshot method may not be able to handle them well.

Finger Recognition [3] Images are segmented using Otsu's thresholding, and precise identification is guaranteed by morphological filtering. On a virtual keyboard, finger counting activates taps or color caps. Accurate segmentation might be affected by background noise. Predefined gestures in the system restrict the diversity of interactions, which makes creative tasks more difficult for users to complete than preset motions.

Eye and Face gestures [4], In this case, the user will be able to perform mouse functions using eye and face movements. The cursor on the screen can be controlled by a specific point on the user's face, while the right and left clicks can be executed by winking the right and left eyes, respectively. Additionally, squeezing the eyes would enable the scroll function, which is particularly useful when reading PDFs and other documents. Users may become weary or experience discomfort if they employ eye and face motions continuously for lengthy periods of time. Extended strain on the muscles of the face or eyes might affect usability and user acceptability.

[14] With the help of computer vision and pattern recognition, hand gestures are investigated for human-machine interaction. Without segmenting or using motion history, the approach uses HT to trace gesture trajectories. SIFT features and the integration of artificial neural networks translate motions into commands that can be customized for various users. On the other hand, hand direction, speed, and motion variations may cause performance problems.

Voice assistants offer a novel and exceptionally user-friendly approach to engaging with devices and online services [15]. Cloud-based voice assistant [10] Raspberry Pi is used for receiving the input, Google Dialogflow for providing intelligence, PyTorch for understanding, Flask to build the RESTful API, and Redis as a message queue and cache. Dataset training is done using joint classification and model pruning. For the system to interact with cloud services such as Google DialogFlow, it needs a reliable internet connection. Intermittent problems with internet access may cause the voice assistant to become inoperable.

IFTTT platform [9]This project uses webhooks to connect to a Raspberry Pi and incorporates Google Home Mini and Amazon Echo Dot services for voice-controlled lighting. Reliance on IFTTT, Google Home, and Amazon Echo creates possible sources of error. Even though a lot of services, like IFTTT, provide free tiers, there could be extra charges when using premium features or ramping up use. Evaluation of long-term cost factors should be done in light of requirements and use. This [5] virtual mouse interface was designed to identify finger tips and recognize hand motions. This study employed two distinct finger tracking strategies: using colored caps and hand gesture recognition. Skin tone variances, backdrop clutter, and changes in lighting can all have an impact on how successful skin color-based systems are. Hand motion detection accuracy and dependability can be impacted by environmental conditions.

The study [19] utilized a dynamic skin color system and an innovative technique for controlling the identification of historical photos through palm movements. A method of choice enables the identification of a particular area that corresponds to a single hand, which is thereafter monitored for the duration of the video clip. A precise spot on the virtual interactive interface is assigned to the outcome. Through seamless integration with the surrounding environment, the Direct System Integration (DSI) engine mimics the capabilities of a mouse. Like a real keyboard and mouse, this mouse can operate a variety of apps, including a visual keyboard. The Interface module is not a separate entity from the Mouse module, which converts the mouse's location into screen coordinates. On the other hand, the Interface Control (IC) engine offers a different approach. It allows for the control of a specific interface, enabling it to interpret and execute actions accordingly. However, the primary limitation of the research lies in its failure to accurately detect intricate hand movements.

The existing system [1][2] is comprised of five primary elements. Initially, skin detection transforms images into the HSV color space to differentiate skin pixels from non-skin pixels. Subsequently, Hand contour extraction isolates the hand contour from the background using skin detection. Thirdly, using hand tracking, the cursor is maneuvered by identifying the index fingertip and sending the location of the finger on the screen to the computer via a coordinate system. By identifying hand landmarks and assessing finger states, hand movement is observed. In addition, gesture recognition, employing OpenCV, computes hand contour convexity defects, recognizes fingertips, and tallies the number of available fingers for function execution. Finally, cursor control manages cursor movement. Nevertheless, the system encounters precision constraints and difficulties in recognizing specific mouse functions. Furthermore, it cannot effectively identify multiple mouse functions. There is a limit to the system's capacity to recognize and carry out certain mouse operations, depending on various gestures. This limits the variety of ways in which the virtual mouse interface is used. Skin tone variations, background clutter, and illumination adjustments can all affect how effective skin color-based systems are. Environmental factors may affect the accuracy and reliability of hand motion detection.

III. Proposed System

The combination of a gesture-enabled virtual mouse and a voice assistant creates a sophisticated system that merges real-time hand gesture recognition with natural language processing capabilities, providing users with an intuitive and hands-free interaction experience. The gesture-controlled virtual mouse relies on advanced computer vision techniques, utilizing the MediaPipe library to identify and monitor landmarks on the hand in live video streams. These landmarks act as key points for recognizing predefined hand gestures, allowing users to execute activities such as moving the cursor, clicking, and scrolling through intuitive hand movements.

To identify specific gestures based on predefined criteria, the gesture recognition module utilizes a custom logic that involves three classes for managing the camera, converting handmarks, and executing corresponding actions. By examining the relative positions and movements of important landmarks like fingertips, knuckles, and palm orientation, the system can accurately interpret user gestures.

In addition to the gesture-controlled interface, the voice assistant module enhances the interaction by enabling users to issue commands and queries using natural language. To allow voice-controlled interaction and command execution, the script combines NLP methods like speech recognition, keyword matching, and context management with external libraries such as speech recognition,pyttsx3. The first stage of natural language processing (NLP) is speech recognition, which transforms spoken words from audio input into text. The speech recognition library is used in the script. Another fundamental NLP method called keyword match- ing is utilized to pinpoint certain words or phrases in the recognized text (voice data). The script looks for specific phrases (such as "hello," "time," and "search") in order to initiate pre-programmed actions or reactions. This is a basic type of pattern matching that uses key words to infer user intent. Tasks such as opening applications, searching the web, executing mouse functions, or retrieving information from databases or APIs are executed. Fig. 3 shows the overall flow of the system.

A. *Gesture Controlled Virtual Mouse*

The necessary Python libraries, utilized for different tasks, are imported. OpenCV is used for computer vision tasks,

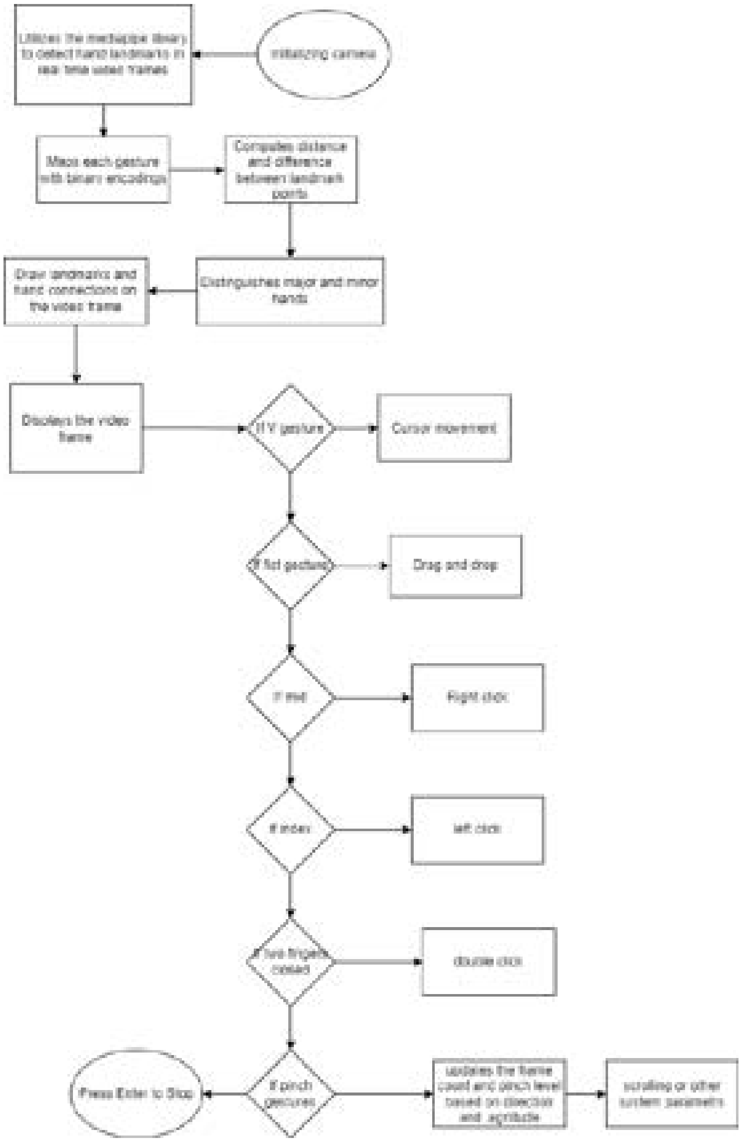

Fig. 1. Workflow for Virtual Mouse

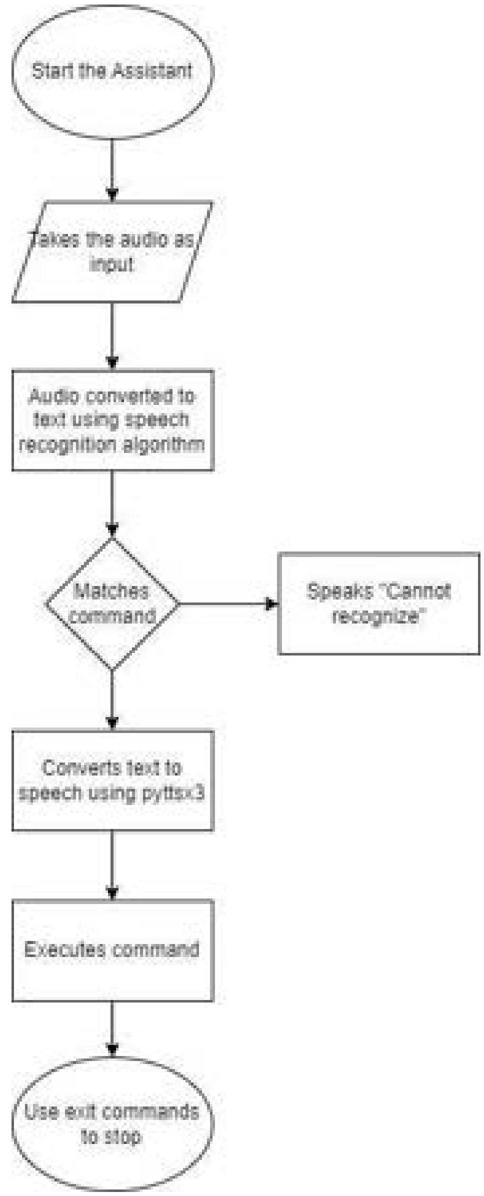

Fig. 2. Workflow for Voice Assistant

MediaPipe is employed for hand tracking, PyAutoGUI enables control over the mouse cursor, and Math is utilized for mathematical operations. Enumeration is used for defining enumerations, types, and comtypes, which facilitate low-level system interactions. Additionally, paw is employed for controlling system audio, and screen brightness control is utilized for adjusting screen brightness. Three classes are defined for the virtual mouse to function: HandRecog, Controller, and Gesture Controller. The Gesture Controller class manages the camera, finds landmarks, and serves as the system's initialization point. The HandRecog class is for converting mediapipe landmarks into recognizable gestures. The Controller class carries out orders based on gestures that are identified. Initially, each hand gesture is mapped to a binary number using an enum. The value of each enum component corresponds to a binary representation that contains particular hand positions or finger configurations. For example, 0b00000 represents FIST (all fingers closed), whereas 0b11111 represents PALM (all fingers extended). Then, to distinguish between the major and minor hands, when multiple hands are detected, two members, MAJOR and MINOR, are assigned the values '1' and '0'. The gesture recognition system uses these enums to represent and analyze hand labels and movements that are recognized.

a) Gesture Recognition Module: Initially, the video frames are captured and undergo color conversion. Subsequently, the modified image is utilized to detect hand land- marks. Upon receiving the hand landmarks from MediaPipe, the classification between dominant and non-dominant hands occurs. Then gestures are recognized based on the tracked hand using the logic defined in the HandRecog module. Depending on the recognized gesture, controls are handled by the controller module.

b) HandRecog Module: Hand tracking and landmark detection are the most important processes for this virtual mouse to function. Firstly, the attributes are initialized to represent the computed gesture for the current frame, to store the current and previous gestures, to track the number of frames, and to hold the landmark data obtained using the Mediapipe library. After obtaining the hand landmarks using the Mediapipe library, the finger positions are analyzed using the following logic: Initially, the signed Euclidean distance between two landmark points on a hand based on their vertical (y-coordinate) positions relative to each other is calculated using Eqn(1). Moreover, the interval in 2D space between the two spots is calculated. This calculation helps determine the direction of movement between the two points. To comprehend the movement of the hand in three-dimensional space, the absolute difference on the z-axis between the two points is calculated using Eqn(2). Additionally, the ratio of distances between the finger tip, middle knuckle, and base knuckle is calculated using Eqn(3) to assess the state of the fingers. Iterating over each finger's landmark points, the signed Euclidean distance, absolute difference, and ratios are calculated to find out the state of each finger's whether it is extended or bent. Using bitwise operations, the binary representation of these finger states is detected. If the computed ratio is greater than 0.5, set the least significant bit, indicating an open finger state. If no landmarks are available, it considers the state as closed, which is FIST, and the value is set to 0. After finding out the finger state, the finger attributes are compared with the specified patterns to find out the corresponding pattern. Depending on this ratio and depth, it recognizes gestures such as V GEST, TWO FINGER CLOSED, or defaults to MID based on finger state. It determines a ratio between the lengths of particular finger segments if the finger configuration shows the first two fingers. The gesture is recognized as Gest.V GEST if this ratio is more than 1.7; if not, it further compares the z- coordinate differences between Gest.TWO FINGER CLOSED and Gest MID. Gest Pinch Minor or Gest. Pinch Major, depending on the hand label, is the gesture identified if the finger configuration includes the final three or four fingers and the distance between particular finger landmarks is less than 0.05. To handle the fluctuations and ensure gesture stability, the original gesture attribute will be updated to reflect the stable gesture state if the identified gesture is constant for more than four frames. In real-time applications, our method guarantees dependable gesture identification while efficiently mitigating noise.

$$sign(y_2 - y_1) * \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2} \tag{1}$$

$$\Delta z = |z_2 - z_1| \tag{2}$$

$$ratio = dist1/dist2 \tag{3}$$

where dist1 - distance between the finger tip and the middle knuckle.

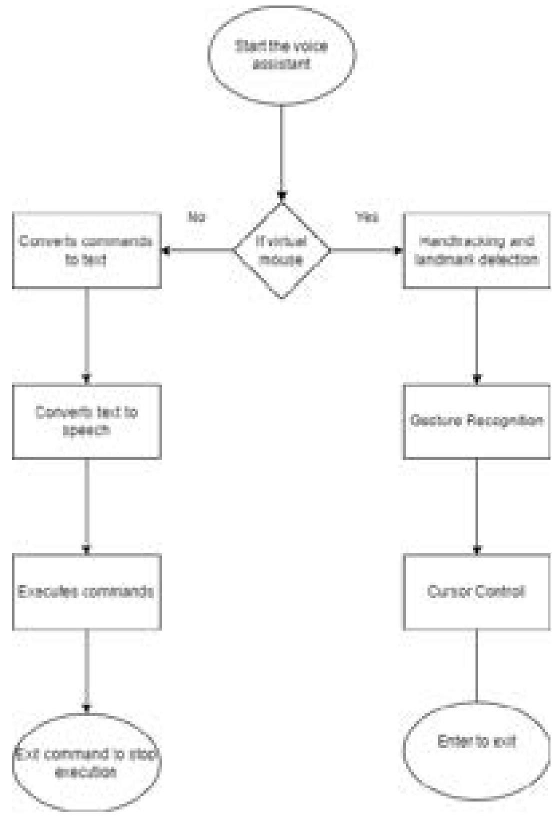

Fig. 3. Workflow for overall system

dist2 - distance between the middle knuckle and the base knuckle.

c) Controller Module: Various recognized gestures trigger corresponding actions, evaluating each gesture to perform the appropriate action based on its type. For example, a V gesture moves the mouse cursor, a fist gesture does drag and drop, and other gestures like MID, INDEX, and TWOFINGERCLOSED are associated with different mouse button clicks or double clicks. The management of PINCHMINOR and PINCHMAJOR gestures is done independently, where the direction and intensity of the pinch are determined by hand landmarks using equations (4) and (5).The vertical or horizontal distance between a reference pinch start point and the current x or y coordinate of a specific hand landmark. The result is returned as a scaled value that can be used to determine the magnitude of a pinch gesture in the vertical or horizontal direction. This approach guarantees seamless and efficient control over horizontal and vertical scrolling, as well as adjustments to systemparameters, by continuously updating the frame count and pinch level. The system brightness and system volume, are adjusted based on the pinch gesture displacement. The Pyautogui library is utilized to simulate scroll wheel movements based on the direction and magnitude of the pinch gesture. The following logic calculates the current cursor location based on hand motion and prior cursor positions in order to minimize any sudden hand movements. The function first identifies a specific hand landmark to use as the cursor position reference within the hand coordinate space. The code then uses pyautogui.size() to get the current screen resolution and maps the hand coordinates to screen pixel coordinates. Moreover, it uses pyautogui.position() to record the cursor's current location. This function improves the accuracy and smoothness of cursor control by dynamically modifying the cursor movement ratio based on the intensity of the detected hand motion.

$$dist = round((start_y - handresult.landmark[8].y) * 10, 1) \tag{4}$$

$$dist = round((handresult.landmark[8].x - start_x) * 10, 1) \tag{5}$$

d) User Interface: The video frame is shown with annotated hand landmarks and connections through OpenCV, offering users a visual representation of the detected hands and gestures. The loop will persist until the user opts to exit by pressing the Enter key, guaranteeing uninterrupted gesture recognition and system interaction. Fig. 1 illustrates the workflow of the virtual mouse.

B. Voice Assistant

a) Initialization: Various modules are being initialized, and variables are being set. The date module from the datetime library is being utilized to retrieve the current date. The speech recognition library is imported, enabling the recognition of speech input, and other necessary libraries are also imported. Another crucial initialization is pyttsx3 for text-to-speech functionality, where the engine is initialized with Microsoft's Speech API (sapi5). Following that, the available voices are obtained, and the engine's voice property is set.

b) Building the bot: Multiple variables are set with predefined values, such as fileexpstatus, files, path, and is awake. These variables are responsible for managing file exploration, storing file details, specifying a file path, and determining the bot's operational status. The script starts with an import of the speech recognition library. This library offers speech recognition capabilities from a variety of sources, including audio files and microphones. The script appropriately manages and releases the microphone resource after use. The script modifies the dynamic energy threshold and energy threshold of the microphone before audio recording. The audio input from the microphone is captured by the record audio() function: It establishes a pause threshold to establish the longest period of quiet before the recording ends. The identified speech is stored in an empty string called voice data, which is initialized. It records sound from the microphone for up to five seconds at a time. It attempts to identify the audio by utilizing Google's voice recognition feature. The record audio() method returns the recognized text (voice data) following the recording and recognition of the speech. The wish() function greets users according to the time of day and presents the bot. Each recognized command is processed by the reply (voice data) function, which then uses the reply (audio) function to provide the required replies. This feature uses the Text-to-Speech library (pyttsx3) to translate text (audio) into speech. For the purpose of monitoring and debugging, print the response to the console (print audio). Error handling is included to address situations where the service is inaccessible or when the audio input is not recognizable.

c) Command Handling: The respond() function oversees voice input for the bot by utilizing global variables to ensure consistency. It initially displays the received voice data, substituting 'Synthia' if found. Subsequently, it incorporates the user's input into the interface. When the bot is not active, commands such as 'wake up' prompt activation and a welcoming message. While active, it reacts to commands like 'hello' and 'what is your name' with suitable responses. It caters to requests for the current date and time, performs web searches, and pinpoints locations on Google Maps. Voice- activated features, such as the ability to start and stop gesture recognition, copy and paste text, navigate through files, and respond to various commands, are available. When specific voice commands like "launch gesture recognition" are detected, the code checks the current status and either starts or stops gesture recognition accordingly. For text manipulation, commands like "copy" and "paste" are executed using keyboard shortcuts. It is feasible to execute mouse functions and interact with Notepad by integrating a speech recognition library with PyAutoGUI. Users can navigate through files by listing them in the root directory, opening folders, and going back. The subprocess module is utilized to initiate applications, and smtplib is used to send email. These features improve user interaction by allowing them to control actions through voice commands, making them more accessible and efficient. If a command is not recognized, the bot politely informs the user about its limitations. Commands like 'bye' or 'exit' elicit farewells and potential deactivation. Furthermore, it oversees gesture control mode and terminates the program when needed, offering extensive interaction capabilities. Fig. 2 shows the workflow of the voice assistant.

IV. RESULTS & DISCUSSION

The virtual mouse is capable of performing a variety of tasks, such as scrolling, drag and drop, right-click, left-click, volume control, and brightness control. Moreover, the assistant is able to respond to commands related to mouse functions, date/time queries, file management, web searches, email sending, and the execution of applications like Notepad and Paint. It can also launch and stop applications. Some of the results are shown in Fig. 4 and 5. To ensure the effectiveness of the system, the virtual model has undergone testing in different lighting conditions and at various distances to accurately track hand movements and identify fingertips. Since the gesture recognition and voice assistant code provided does not use traditional machine learning models with predefined datasets for training and evaluation, latency, resource usage, manual accuracy calculation, and gesture variety are the parameters

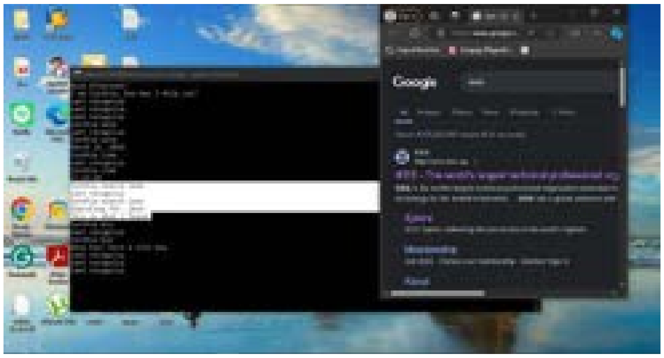

Fig. 4. Opening Google search

Fig. 5. Drag and Drop

used to evaluate the system's performance. The accuracy of the virtual mouse has been manually determined through approximately 50 trials using Eqn(6), with the results displayed in Fig
6. While pinch gestures may exhibit slightly lower accuracy compared to other mouse functions, the remaining interactions are highly precise.

$$Accuracy = 100 * (Correct/Total) \tag{6}$$

where correct - Corrected Number of Predictions
Total - Total Number of Predictions

TABLE I
INTERACTION PERFORMANCE

Interaction	Accuracy	Latency (s)
Drag and drop	98%	0.13
Left-click	98%	0.13
Right-click	95%	0.15
Double click	93%	0.15
Cursor movement	100%	0.5
Pinch gestures	90%	0.30
Voice commands	96%	

In comparison to the existing model, our virtual mouse and assistant have improved accuracy by reducing the difficulty of recognizing mouse gestures with the help of an enum. By using enum, all hand gestures are mapped to binary numbers, offering a wider range of mouse functions and supporting multi-handedness. It is also designed in a way to handle

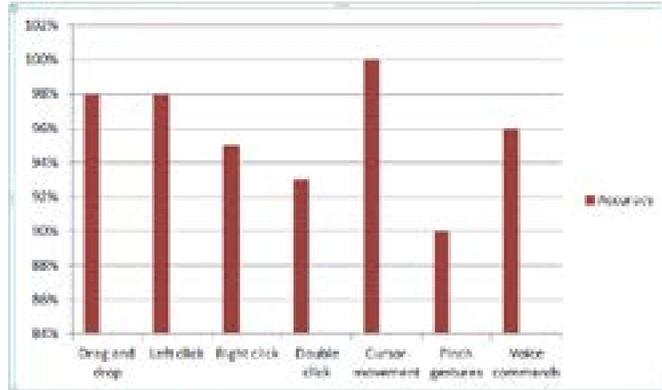

Fig. 6. Accuracy

fluctuations due to noise and stabilize the cursor position by dampening the jerky motion of the hand. In this model, the delay between gesture detection and system response, voice recognition, and system response is assessed, ensuring minimal latency for smooth interaction. Unlike the current methods, the suggested approach requires less time and doesn't require a complicated setup. The built-in camera and microphone are more than sufficient for the operation of this device. The training procedure itself is not involved, since training the datasets takes some time. Only the Python libraries are involved. The internet connection is not a determining factor. Privacy concerns arising from image processing techniques are addressed by the use of mediapipe in the keypoint mapping approach. It manages the multi-handedness. The vocabulary for voice and gesture recognition in the current system is restricted. Almost all mouse operations are carried out by our system using speech and gesture instructions. Both static and dynamic commands are controlled by the voice assistant. Error responses, retry mechanisms, fallback gestures or actions, and feedback mechanisms are implemented to provide better error handling mechanisms. Table 1 shows the accuracy and latencies of the interactions. Furthermore, it utilizes only 28% of CPU usage and consumes 32kb per second of disk memory.

V. CONCLUSION

This combined system integrates hand gestures and voice commands to enhance user interaction with digital devices. Advanced computer vision algorithms enable the real-time tracking of hand movements, allowing users to control the cursor and perform tasks with ease. This hands-free and intuitive interaction is particularly beneficial in situations where traditional methods are not practical. Moreover, the voice assistant feature supports task completion and information retrieval through sophisticated speech recognition and natural language processing. This fusion enhances accessibility and usability in various fields, such as gaming, accessibility, virtual reality, and smart home automation. As these technologies progress, the design of interfaces and interaction methods will continue to improve, ensuring more immersive user experiences in the digital domain.

VI. FUTURE WORKS

Future advancements will primarily focus on enhancing the system's gesture recognition, voice command capabilities, and overall user experience. The main objective will be to improve the accuracy and versatility of gesture recognition algorithms, enabling them to accurately identify intricate hand movements and gestures. Moreover, the intelligence of the voice assistant will be enhanced through advancements in natural language processing and machine learning, enabling it to better understand user commands and perform more complex tasks. By integrating multi-modal interaction capabilities, users will be able to effortlessly switch between gesture-based control and voice commands, resulting in a flexible and intuitive computing experience. The proposed system will prioritize accessibility and inclusivity by offering customizable gestures and voice commands tailored to individual preferences and accessibility requirements. Additionally, efforts will be made to ensure seamless integration with various devices, platforms, and operating systems, ensuring maximum usability and accessibility for users in diverse computing environments.

ACKNOWLEDGMENT

We sincerely appreciate the Rajalakshmi Institute of Technology administration for providing the facilities and resources that were necessary for our project to be completed success- fully. Our principal, Mr. N. Bhalaji, deserves special recognition for his steadfast assistance and provision of essential materials. We are incredibly grateful to our mentor, Dr. Anjana Devi, who is also the head of the Department of Computer Science and Engineering (CSE), for all of her help and inspiration during this project. Her knowledge played a crucial role in directing our investigation. We also thank our project coordinator, Dr. Anjana Devi, for her unwavering advice and assistance. We express our gratitude to the dedicated staff members of the CSE Department for their best wishes, prompt help, and steadfast support during the course of the project. Finally, we would like to sincerely thank our families, friends, and relatives whose unwavering support was invaluable to us during our academic path. It would not have been easy to reach this degree of accomplishment without their help.

Abstract—This research study intends to create a reliable suicide risk assessment system by applying Machine Learning (ML) methods, in particular Random Forest algorithms is being compared with Support Vector Machines (SVM) for achieving the better accuracy results. The goal is to develop a trustworthy tool that can reliably identify individuals that are at risk of self-harm by analyzing their clinical, behavioral, and demographic data. Materials and Methods: The present work has involved two groups. Group 1 refers to the study intended based on Machine Learning Algorithm in which Support Vector Machine (SVM) has been implemented and has secured lower accuracy rates. Group 2 refers the method uses Random Forest to accurately assess the risk of suicide. It makes use of preprocessed health data to enable effective intervention and research advancement. The proposed method performs well in precise suicide prevention analysis with high metrics such as accuracy 0.85, precision 0.85, recall 0.85, and F1 score 0.85, making it useful for prevention analysis technique. The study concludes by showing the effectiveness of Random Forest in preventing suicide and emphasizing how the data-driven methods and user-friendly interfaces may be applied in the real world to improve mental health.

Keywords—Machine Learning, Support Vector Machine, Random Forest Algorithm, Precision, Accuracy, F1-score, Recall, Personal Health Information.

I. INTRODUCTION

Suicide is a global public health crisis, claiming the lives of hundreds of thousands of individuals each year. It leaves a devastating impact on families, communities, and societies at large. Traditional methods of suicide prevention have relied heavily on self-reporting and the clinical judgment of mental health professionals. However, the complexity of factors contributing to suicide, coupled with the stigma surrounding mental health, often limits the effectiveness of these approaches. For the purpose to classify suicide risk, this study investigates the application of Random Forest algorithm. Utilizing machine learning approaches for suicide prediction shows potential for early intervention and prevention efforts in light of the growing concerns over mental health [1]. Through the examination of multiple clinical, behavioral, and demographic variables, the goal of this research is to create a strong model that can reliably identify people who are at risk of self-harm and are in depression. The promise of data-driven techniques in tackling key mental health concerns is highlighted by the combination of sophisticated algorithms and extensive databases. The amount of research on using Artificial Intelligence to provide proactive mental health treatment is increasing, and this study adds to that [2]. The risk variables had a limited potential to predict Suicidal Thoughts and Behaviors (STBs) over a 50-year period, with only modest gains with time, according to a meta-analysis on STBs. Longer study durations did not improve prediction accuracy, and in most of the research, despite its breadth, concentrated on specific categories of risk variables. The results highlight how successful preventative and treatment techniques can only be advanced by a paradigm shift towards machine learning-based risk algorithms [3] [4].

II. RELATED WORKS

Analysis of the social media postings made by military people who have passed away reveals unique temporal patterns such as posts regarding triggers followed by thoughts that may indicate the likelihood and timing of suicide, providing information for focused preventative efforts. Finding certain trends in an individual's online activity may help with early intervention and assistance for those who are at danger [5]. This study examined the viability of recognizing "strongly concerning" tweets with moderate accuracy using a combination of machine learning and human coders to gauge the degree of worry in suicide-related tweets. Although it shows the possibility of detection, it also highlights the need for more improvement and neither directly informs intervention goals nor forecasts suicide conduct [6] [7]. This study indicates a relationship between search volume, abortion rates, and policy constraints, suggesting that examining internet search trends, particularly those related to abortion, might provide light on the effects of local abortion laws [8]. This technique provides a potentially useful tool for more quickly and efficiently analyzing the effects of health policies by demonstrating a link between search activity and policy impact [9] [10]. This thorough analysis emphasizes how the research on suicide prevention strategies has changed since 2005, with a focus on the growing body of evidence supporting means restriction and school-based awareness campaigns. It highlights the necessity of integrated, evidence-based approaches at the individual and population levels, while also recognizing the gaps in the present body of research [11]. This excerpt highlights the expanding application of big data analytics in the field of psychiatry, encompassing a wide range of data types beyond genetics, such as clinical, sociodemographic, and social media data. It represents a major breakthrough in psychiatric research since it makes predictions for clinical outcomes and individual-level patterns by utilizing machine learning techniques [12]. This article talks about using natural language processing and deep learning to analyze social media data to identify people who may be suicidal. This might be a preventive intervention that even non-mental health professionals could use. It highlights the moral conundrum of reaching more at-risk people while upholding their right to privacy and raises ethical questions regarding privacy vs prevention [13] [14]. In order to create predictive models for assessing suicide risk, this study used linguistic analysis of clinical notes from medical records maintained by the U.S. Veterans Administration. The results imply that automated text analytics may reliably evaluate the risk of suicide, which may allow primary care physicians to screen patients and keep an eye on risk levels among mental patients [15]. The diagnostic accuracy of suicide prediction models was evaluated in this review, which found that while categorization accuracy was typically good, predictive validity for actual suicide occurrences was relatively poor. Significant constraints imply that these models are not yet appropriate for broad clinical deployment throughout health systems, even with their promising overall accuracy [16]. By addressing methodological limitations, concentrating on short-term assessments, and utilizing machine learning techniques, the study aimed to improve suicide prediction. This resulted in a significant improvement in prediction accuracy for both suicidal ideation and attempts among high-risk individuals, underscoring the importance of taking complexity into account when attempting suicide [17] [18]. In order to determine which US veterans were at a high risk of suicide, the study tested several predictive modeling approaches. It discovered that a penalized logistic regression model with 61 variables outperformed an earlier model with more predictors. In addition to taking into account realistic aspects to improve model performance, the Veterans Health Administration is putting this model into practice for early intervention [19]. Support Vector Machine (SVM) for suicide risk assessment highlighted the accuracy in analyzing clinical, behavioral, and demographic data to identify individuals at risk of suicide. Leveraging these findings, the proposed work focuses on refining a Random Forest-based assessment tool. This involves expanding the dataset for better predictive accuracy, enhancing model validation across various demographics, creating a user-friendly interface for healthcare professionals, and integrating the system within existing mental health interventions. The aim is to develop a reliable, AI-powered tool that significantly aids in early detection of suicide risk, thereby improving mental health outcomes through timely and effective intervention strategies.

III. MATERIALS AND METHODS

By preprocessing PHI data, a suicide risk assessment system utilizing the Random Forest algorithm was created to improve accuracy. The objective was to support mental health research by developing an accurate tool for detecting those who are at risk of self-harm. Fig.1 represents that Data preprocessing is a critical step in the machine learning pipeline, involving cleaning and organizing raw data to make it suitable for a model like Random Forest. This process can include handling missing values, normalizing or scaling features, encoding categorical variables, and selecting relevant features. Once preprocessed, the data is ready for classification tasks, where the goal is to predict a target category.

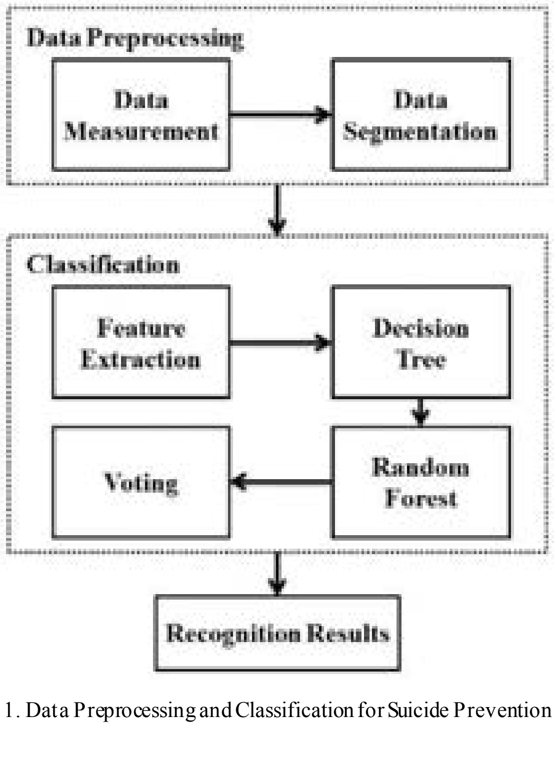

Fig. 1. Data Preprocessing and Classification for Suicide Prevention Analysis

Group 1 utilizes the Support Vector Machine (SVM) algorithm to develop a machine learning-based system for assessing suicide risk. By preprocessing and analyzing Personal Health Information (PHI) data, the SVM approach aims to identify individuals at risk of self-harm. Although SVM is recognized for its capability to manage high-dimensional spaces effectively, the accuracy achieved in predicting suicide risk was found to be suboptimal when evaluated independently. This outcome suggests a potential for further refinement of the SVM model to improve its effectiveness as a tool for medical professionals, thereby enhancing mental health research and intervention strategies.

Group 2 defines the method here assesses suicide risk with accuracy by using machine learning approach Random Forest algorithm, based on Random Forest has higher Accuracy compared to Support Vector Machine. It attains noteworthy accuracy by preprocessing Personal Health Information (PHI) data and utilizing these models. This provides a dependable tool to help medical professionals identify and intervene with people who are at risk of self-harm, improving mental health research and intervention techniques.

IV. Statistical Measures of Accuracy in Regression Analysis

In Suicide Prevention Analysis, leveraging metrics like Accuracy, Precision, F1-score and Recall is essential for evaluating predictive model. These statistics help in understanding the effectiveness of models designed to identify suicide risk factors, enabling targeted interventions and contributing significantly to prevention efforts.

$$\text{Accuracy}_i = \frac{TP+TN}{TP+TN+FP+FN} \tag{1}$$

In the above, equation (1) defines Accuracy as the ratio of accurately predicted occurrences (true positives and true negatives) to the total number of instances.

$$\text{Precision}_i = \frac{TP}{TP+FP} \tag{2}$$

In the above, equation (2) denotes Precision is the ratio of genuine positives to total anticipated positive cases, which measures the accuracy of positive forecasts.

$$\text{Recall}_i = \frac{TP}{TP+FN} \tag{3}$$

In the above, equation (3) refers to Recall, also known as sensitivity or true positive rate, is the proportion of true positives to total positive instances.

$$\text{F-Measure}_i = \frac{(1+\beta^2)\times precision \times Recall}{\beta^2 \times (precision \times Recall)} \tag{4}$$

In the above, equation (4) relates the F-measure combines precision and recall, with β regulating the trade-off between the two.

V. Results

The research analysis demonstrates significant potential, particularly with Random Forest Algorithm, which achieved an impressive accuracy of 0.85 which is 85%, precision of 0.85 which is 85%, recall of 0.85 which is 85% and F1 score 0.85 which is 85%. Table 1 describes the context of the suicide prevention study using machine learning technique, the performance of the Random Forest model was evaluated based on key metrics: Precision, Recall, F-measure (F1-score), and Accuracy.

Table 1 The performance metrics of the Random Forest model: Accuracy (0.85), Precision (0.85), F1-Score (0.85), and Recall (0.85).

Metrices	Random Forest
Accuracy	0.85
Precision	0.85
F-measure(F1-score)	0.85
Recall	0.85

The Graphical Representation of the Accuracy, Prediction, F1-Score and Recall has been represented, Where after identifying then it checks the patient's risk level and it suggests an interview or counseling. The machine learning algorithms' strong accuracy highlights its ability to identify suicidal tendencies in preprocessed Personal Health Information (PHI). The system's accuracy, f1-score, precision and recall measures and demonstrates its performance, which confirms its potential as a trustworthy tool for mental health professionals. It helps with early intervention and provides important support for designing focused intervention methods by giving accurate risk ratings. The system's effectiveness also demonstrates the progress gained in utilizing AI and data-driven methods to enhance mental health services. This model has the potential to identify people who are at-risk and to develop proactive treatments that reduce the risk of suicide as they continue to develop and improve. Table 2 represents the comparison of Support Vector Machine and Random Forest.

Table 2 is the Comparison Table in which Support Vector Machine has obtained an accuracy of 78% and Random Forest Algorithm of 85%.

Algorithms	Accuracy Obtained
Support Vector Machine	78%
Random Forest	85%

The suicide risk assessment system's outstanding performance highlights an important development at the nexus of machine learning and mental health services. In addition to the remarkable accuracy rates attained by the Random Forest model, the precision, accuracy metrics corroborate the efficacy of the system in detecting minute but significant patterns in Personal Health Information (PHI) that could signify a higher risk of suicide. Fig. 2. represents a comprehensive overview of the Random Forest model's performance in suicide risk prediction, showcasing its effectiveness through high values in accuracy, precision, recall, and F1-score, indicating a robust capability to accurately identify and classify individuals according to their suicide risk levels. Fig. 3. illustrates the complex interplay among a range of variables including Depression Score, Anxiety Score, Relationship Status, Employment Status, Social Connections, Mental Health Treatment, and Sleep Quality. This visualization underscores how each parameter can influence or be influenced by another, revealing the multifaceted factors that may affect an individual's mental health. The figure aims to highlight not just the individual impact of these parameters but also how they collectively contribute to the broader understanding of mental health dynamics. Through this analysis, we can discern patterns and correlations that are crucial for developing more targeted and effective mental health interventions and support systems. One of the system's main advantages is its capacity to quickly and accurately collect and analyze enormous volumes of data, giving mental health professionals risk assessments in a timely manner. Given the increasing need for scalable solutions to treat mental health issues in healthcare systems around the globe, this feature is especially beneficial.

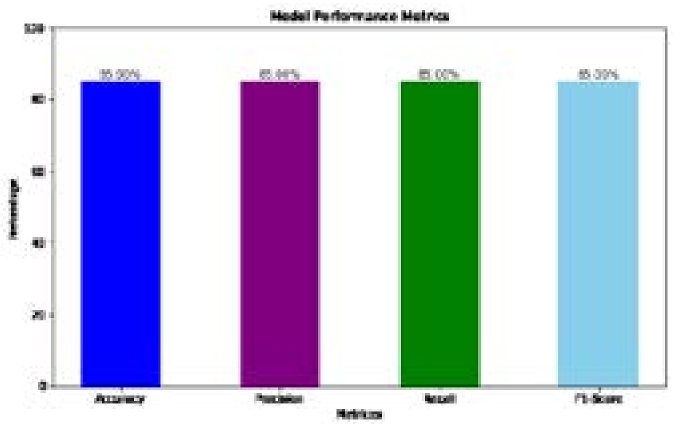

Fig. 2: Comprehensive overview of the Random Forest model's performance in suicide risk prediction, showcasing its effectiveness through high values in accuracy, precision, recall, and F1-score, indicating a robust capability to accurately identify and classify individuals according to their suicide risk levels

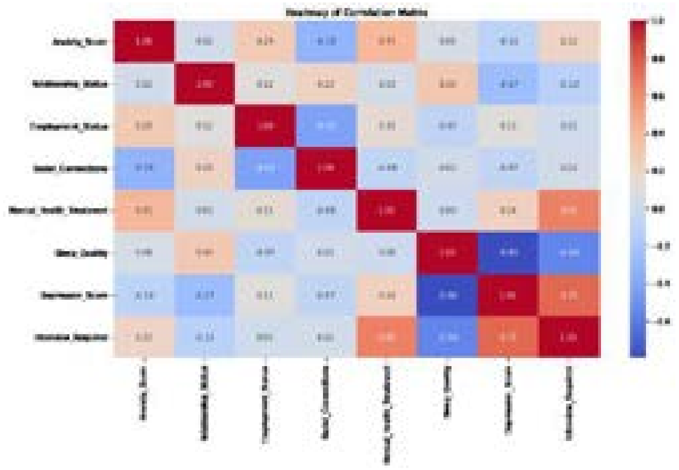

Fig. 3. The correlation between various parameters such as Depression Score, Anxiety Score, Relationship Status, Employment Status, Social Connections, Mental Health Treatment, and Sleep Quality, highlighting the intricate relationships and potential impact factors contributing to an individual's mental health state.

VI. DISCUSSION

The research underscores the Random Forest algorithm's effectiveness in suicide risk assessment, achieving remarkable accuracy and demonstrating significant promise in enhancing mental health interventions through advanced AI-driven analytics.

The research improved suicide attempt prediction accuracy and scalability dramatically by integrating machine learning with electronic health information. With the use of more than 250 adult patient records, the algorithms produced results with excellent recall and precision rates, showing a discernible increase in accuracy as the attempt at suicide became closer. These findings open the door to more potent therapies and preventative measures while providing insightful information about the temporal dynamics of suicide risk [20].

This analysis emphasizes how urgently new approaches are needed to combat the growing suicide rates, especially those involving mobile and sensor technologies. Although recent developments indicate potential in the use of machine learning and smartphone sensing for suicide prevention, further validation and replication of results are needed. In the next two to five years, physicians may expect the development of useful digital tools to help them better identify, forecast, and treat patients who are at high risk of suicide. These efforts are supported by current research [21] [22].

First results are provided on the use of predictive modeling by the US Veterans Health Administration (VHA) to identify veterans at high risk of suicide and provide tailored care. A 1% sample of time-matched VHA service users and 6,360 veterans' electronic medical records that died by suicide were analyzed. Methods included comparing logistic regression models and investigating different machine learning techniques [23].

In order to improve the prediction of suicidal thoughts and behaviors (STBs), frequent methodological limitations were addressed in this study. It recruited over 1,000 high-risk individuals globally by utilizing machine learning and focused on short-term prediction. The results shown significant increases in prediction accuracy, especially for impending suicidal thoughts and nonfatal suicide attempts [24] [25].

This study evaluated the diagnostic accuracy of suicide prediction models and found that while overall categorization was high, the predictive validity for suicide outcomes was very poor. The models show promise in terms of worldwide accuracy, but their predictive power is limited in terms of future occurrences, which limits their clinical value and suitability for application in different health systems [26].

Utilizing unstructured clinical notes from US Veterans Administration (VA) data, this study created linguistics-driven prediction models that consistently estimated suicide risk with an accuracy of 65% or higher. According to research, computerized text analytics applied to medical records may make it possible to continuously assess the risk of suicide in psychiatric settings and to screen at-risk patients early in primary care [27].

Subsequent efforts should concentrate on refining the algorithm's precision and its relevance for different population groups, integrating instantaneous data analysis for adaptive evaluations, and developing more accessible interfaces for healthcare practitioners. Furthermore, broadening investigations into different cultural environments and tackling moral and confidentiality issues associated with the use of Personal Health Information are essential for the ethical implementation of artificial intelligence in mental health services.

VII. CONCLUSION

To sum up, the integration Random Forest algorithm in the suicide risk assessment system shows potential in detecting possible cases of self-harm in medical environments. It highlights the value of data-driven approaches in mental health with its user-friendly design and high accuracy. This technique attained 85% of accuracy by training of the PHI. Rethinking mental health services for better proactive and patient-centred care requires integrating advanced analytics and machine learning to improve early intervention, resource allocation, and ongoing model refinement. The research underscores the Random Forest algorithm's effectiveness in suicide risk assessment, achieving remarkable accuracy and demonstrating significant promise in enhancing mental health interventions through advanced AI-driven analytics.

Abstract— **This study addresses the information management challenges of the Camingawan-Tagukon Farmers Association (CATAFA) located at Brgy. Camingawan, Kabankalan City, Negros Occidental, Philippines by developing a comprehensive system known as CATAFA Management Information System (MIS). Currently, CATAFA relies on manual calculations for its savings and loan transactions, making the current system prone to human errors. The system's primary objective is to automate critical processes such as membership registration, loan applications and transactions, and savings account management. The system has also incorporated a ledger functionality to record all member transactions. The procedure development followed the Waterfall Model within the Software Development Life Cycle (SDLC). The system also focuses on flexibility, allowing it to be utilized by CATAFA and other similar associations based on their specific needs and requirements. A survey questionnaire was administered to CATAFA staff members, who provided ratings and feedback to evaluate its effectiveness. The results indicated that the system effectively met the association's needs, prompting a desire for its implementation within the organization.**

Keywords— Agricultural Cooperatives, Information Management System (MIS), Automation, Farmers' Association

I. INTRODUCTION

Agricultural cooperatives' economic structure may be rationally explained by using the organizational economics rationale for family farms[1]. Farmers should produce in a way that balances the economic, environmental, and social facets of sustainability [2]. In Europe, where they represent 40–60% of the agricultural trade, agricultural cooperatives (ACs) are significant players in farming and influential speakers of rural reality [3]. According to [4] agricultural organizations may minimize uncertainty and make better decisions using digital technology to pull information from multiple data sources.

Farmers establish agricultural cooperatives to solve various issues jointly and enhance their economic and social well-being. Cooperatives may provide a variety of advantages, but they also confront several problems and difficulties that may limit their viability [5]. The inability of many agricultural cooperatives to get inexpensive finance and financial services might limit their capacity to invest in new facilities, equipment, and other enhancements. The study of [6] suggested that it is important for agricultural cooperatives to encourage the adoption of contemporary service management applications via their role as technology diffusion organizations that share a social network with farmers.

A management information system (MIS) is a collection of methods and procedures that gathers information from many sources, aggregates it, and understandably presents things. Managers use this tool to create reports that provide them with a comprehensive picture of all the information they need to make decisions about everything from long-term strategy to daily operations. The latest tools in doing business mostly rely on technology to collect and transmit data, even though the idea predates modern computer capabilities. This technology described as a platform of financial data organized and categorized in this way, may provide regular updates on operations to the management levels of a firm. Furthermore, it is often possible to easily get certain reports from the system. The platform provides the organization in terms of performance feedback and enables senior management to monitor service quality across the board.

A new era in agricultural production management is beginning, one in which highly complex Farm Management Information Systems (FMISs) will support daily choices made by farmers [7]. The Philippines still has a low rate of computer and decision-support system usage in agricultural cooperatives [8]. These technologies must spread further in order These technologies must spread to increase production efficiency and increase farmers' revenue.

Camingawan-Tagukon Farmers Association (CATAFA) is a non-government organization in the Philippines, specifically in Negros Occidental, catering services to upland farmers in crop production, livestock, and other related agricultural businesses. The organization created a cooperative for the members in terms of financial assistance, loans, and savings. Due to the background of the members focused on agricultural processes, problems were encountered by its staff and members in terms of recording their business transactions. Thus, the researchers came up with the idea to improve the processes of the CATAFA by providing a platform to improve their services.

The CATAFA Management Information System is designed to offer a dependable system that efficiently enables the designated administrator to add new members to CATAFA through data entry. Additionally, the system is equipped with information management features, such as viewing, editing, and removing information. Furthermore, the system is designed to facilitate searching, sorting, and filtering functions for the information collected from both existing members and prospective applicants of the association. It has a data analytics feature, presenting correct and ease-of-view of data in terms of financial-related reports that made the system unique to other existing works. With this system in place, all necessary information will be easily collected and managed.

II. METHODOLOGY

The researchers followed the waterfall-model procedure to create high-quality software.

Figure 1. It is a schematic diagram of the conceptual framework of the study. A seamless transition into the newly produced bespoke application will come from adhering to the six phases of the System Development Lifecycle [9].

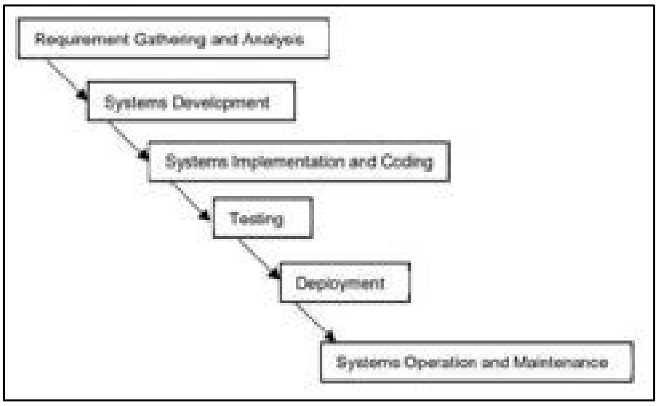

Figure 1. Conceptual Framework

A. Requirement Gathering and Analysis

In this phase, the researchers build thoughtful plans on how to do it step by step. During this phase, the researcher developed a fully functioning software with its architecture and design. The requirements were gathered from interviewing the CATAFA stakeholders and other relevant parties. This phase assessed the user's suggestions and plans for the system's outcome. In the validation process, the system was checked to determine errors and whether codes were to be fixed.

The association's staff was interviewed to identify their specific needs for the system. These interviews yielded useful information that gave us insight into the demands and issues the organization was facing.

Design

Based on the insights gained from the analysis, a system design was created to cater to the specific needs of the CATAFA association. This design encompassed the management information system's structure, functionality, and user interface.

Figure 2 demonstrates the design process using user-provided inputs that are handled based on the result that the consumers need.

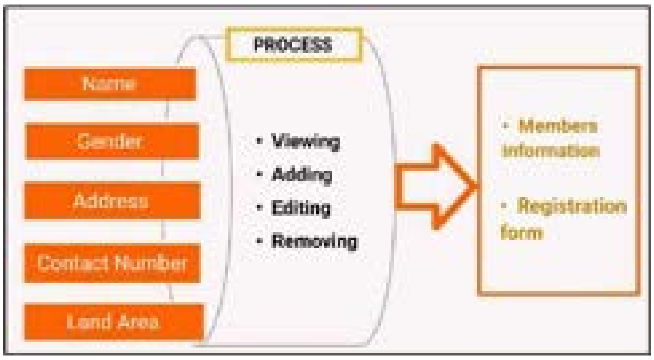

Figure 2. Input-Process-Output of CATAFA

Figure 3 shows the process flow of the system.

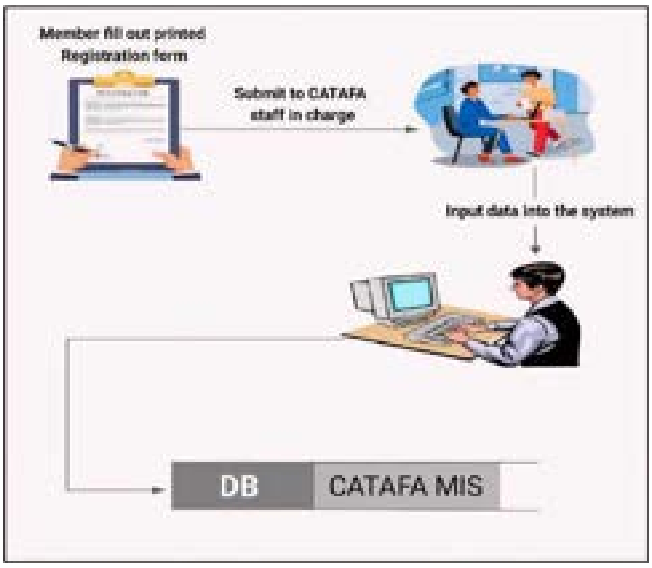

Figure 3: Process Flow

B. System Development, Implementation & Coding

The system was coded and constructed using the system design as a blueprint. The front end used jQuery for JavaScript and Bootstrap 5 for CSS, while the back end used the PHP programming language and MySQL to manage the database.

In testing the functionality of the system, the researchers utilized an open-source platform (SimpleTest) to check the codes if there were errors or bugs. If bugs were encountered/identified, the researchers reviewed the process and debugged the codes for optimization and error-free function.

The table below (Table 1 and Table 2) are the needed requirements are the development of the system.

Table 1. Hardware Requirements (Recommended)

Device	Specifications
Central Processing Unit (CPU)	Processor: Intel Core i5 or AMD Ryzen 5

Monitor	21" 1024x768 resolution
Keyboard	Standard Keyboard
Mouse	Standard Mouse
Hard Disk Drive (HDD)	256 GB
Random Access Memory (RAM)	4 GB
Switch	4 inches high, 9.5 inches long, and 0.55 inches deep (with Joy-Con attached)
LAN Cable	Category 5, 100 Mbps,100 MHz

Table 2: Software Requirements (Recommended)

Software	Version
Sublime Text Editor	v4 Build 4143
XAMPP DBMS Server	v3.3.0
Browser (e.g. Google Chrome)	Latest version

C. Testing

The system underwent rigorous testing procedures to ensure accuracy, reliability, and performance. Various tests, including bug checks, were conducted to identify and resolve any issues or inconsistencies, enhancing the system's functionality and usability.

D. Deployment

The system was presented to the CATAFA office. A survey questionnaire was then given to the staff members at CATAFA, asking for their ratings and feedback. The results showed that the system effectively met the association's needs, creating a strong desire to implement it within the organization.

Figure 4. illustrates the system's member list page, where you can add new members, and the list of members is displayed.

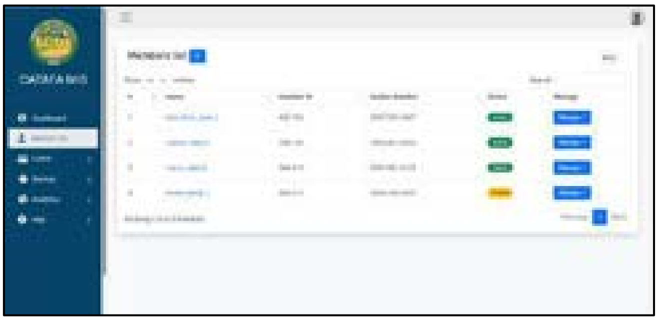

Figure 4. Members List Page

Figure 5 shows the list of loan plans, where you can customize the monthly interest, repayment method, payment frequency, and more.

Figure 5. Loan Plans

Figure 6 displays the loan list page. This is where you can add a new loan, manage a loan, or delete a loan.

Figure 6. Loan List

E. System Acceptance for Implementation

During the implementation phase, the researchers conducted several trainings to the users. First, the researchers prepared training manuals for the users. During the training, the researchers presented the system through actual demonstration and video presentation for review purposes. Second, the system was placed into dry-run process for one (1) month by the users to check some issues/problems in actual business transactions. Fortunately, the system function smoothly and achieved its purpose correctly in terms of data transactions and its navigation in terms of user interface. Lastly, the users accepted the system for implementation and provided a certificate of utilization to the researchers. One issue that was encountered during the implementation phase, is the lack of hardware requirements such as computers to be configured as server, thus, the system was not utilized. The CAFATA is planning to purchase the needed requirements for system installation to fully utilized the said platform.

III. RESULTS AND DISCUSSION

The research study involved 20 staff members and members of the Camingawan-Tagukon Farmers Association (CATAFA) located in Kabankalan, Negros Occidental. These respondents evaluated the system based on its functionality, design, security, and effectiveness using the criteria developed by the researchers based on the PIECES framework [10] a questionnaire using the Importance Performance Analysis approach.

Table 3 presents a Likert Scale for evaluating the system's functionality, design, security, and effectiveness.

Table 3. Likert Scale for functionality, design, security, and effectiveness.

		Range Scale
4.21	5.00	Very Satisfied
3.41	4.20	Satisfied
2.61	3.20	Neither Satisfied nor Dissatisfied
1.81	2.60	Dissatisfied
1	1.80	Very Dissatisfied

Table 4 presents the average rating provided by respondents for the system's functionality. The results reveal a high overall mean rating of 4.81. Users appreciated the system's ease of access through secure login, its capability to effectively manage input data, and its feature to flag missing information. The fully operational search engine also received positive feedback for enhancing usability. Additionally, as emphasized in [11], users must understand the product's technical aspects as a crucial requirement for systemadoption.

Table 4. Functionality

Functionality	Mean	Description
The system is accessible using the correct username and password	4.7	Very Satisfied
It can manage (view, add, edit, delete) the input data.	4.8	Very Satisfied
The system will notify the encoder/admin when there is missing data in the form.	4.95	Very Satisfied
The search engine of the systemis fully functional.	4.8	Very Satisfied
Grand Mean	4.81	Very Satisfied

Table 5 displays the evaluation results of the system's design. It has obtained a grand mean of 4.78. Users appreciate the well-positioned UI elements, contributing to seamless usability. The organized data layout enhances accessibility and decision-making. The design's pleasing aesthetics enhance user engagement. According to [12], the user interface (UI) is a tool that facilitates user interaction with a product's service interface.

Table 5. Design

Design	Mean	Description
The system has a user-friendly interface.	4.75	Very Satisfied
The information being displayed by the system is clear.	4.75	Very Satisfied
The buttons, text fields, and list views are in the appropriate positions and clear.	4.85	Very Satisfied
The data in the table are in an organized position.	4.8	Very Satisfied
The system's overall design is pleasant to the eyes of the users.	4.75	Very Satisfied
Grand Mean	**4.78**	**Very Satisfied**

Table 6 presents the ratings provided by respondents regarding program security. The results indicate a notable grand mean of 4.79, signifying a high level of satisfaction among the participants with the system's security. Users commend the robust measures in place to prevent unauthorized access and the effective data backup security, which reduces the risk of data loss. The [13] study's finding that user accessibility had a favorable effect on end-user satisfaction with e-government system designs in Jordan was confirmed.

Table 6. Security

Security	Mean	Description
The system requires the username and password of the admin/user that prohibits unauthorized users from accessing.	4.8	Very Satisfied
The system provides a backup function to restore data in the database.	4.8	Very Satisfied
Password is case-sensitive.	4.75	Very Satisfied
The system is free from bugs that disallow unauthorized users to access it.	4.75	Very Satisfied
The system's security prevents anyone from duplicating and installing the codes on their computer.	4.85	Very Satisfied
Grand Mean	**4.79**	**Very Satisfied**

Table 7 presents the results of the system effectiveness evaluation. It achieved a grand mean of 4.95, indicating outstanding effectiveness and performance. It meets user expectations, securely stores input data, generates accurate information quickly, enhancing productivity and accuracy. According to [14], performance characteristics, such as compatibility, usability, and comparative advantages, are crucial influences on how people interact with software.

In terms of data accuracy, the functions/formula indicated in the system were reviewed and evaluated by a certified public accountant and approved for integration of the system by the Association President and Board of Directors (BOD), thus the data and its transactions related to financial data were accurate.

Table 7. Effectiveness

Effectiveness	Mean	Description
The system has all the functions and capacities I expected.	4.8	Very Satisfied
It can secure the data that is being stored.	4.8	Very Satisfied
The system generates complete information upon request.	4.8	Very Satisfied
I can finish the work quickly using the system.	4.8	Very Satisfied
Easy to use and control the system.	4.9	Very Satisfied
Grand Mean	**4.95**	**Very Satisfied**

IV. CONCLUSION

Adopting a Management Information System (MIS) can transform agricultural cooperatives, fostering efficiency, openness, and sector development. Agricultural cooperatives may achieve a more sustainable and successful future by incorporating cutting-edge technology and data-driven solutions. The developed system effectively met the requirements and needs of the CATAFA. The overwhelmingly positive feedback received indicates the system's success in fulfilling the association's needs. These findings have generated a strong desire within CATAFA to integrate the system as a fundamental component of their information management infrastructure.

V. RECOMMENDATION

To remove the need for administrative support, it is recommended that the system be enhanced to include a dashboard that allows members to see their loan and savings information online. Members will have more freedom and ease in handling their financial transactions with this added capability. It is highly recommended by the researchers to enhance the features of the system by optimizing tables in the database and additional notifications for the users availing loans and savings through SMS or Email notifications. In terms of security, it is advised to install firewalls to protect the system against possible attacks.

ACKNOWLEDGMENT

This is to acknowledge the support of Central Philippines State University in the publication of this paper. To the members of the Camingawan-Tagukon Farmers Association for their full support in the conduct of the study.

***Abstract*— This research study investigates the emerging domain of DevOps, assessing its capacity to fundamentally transform the processes of software development and delivery. A notable advancement in the field of DevOps is the amalgamation of AI/ML and artificial intelligence. These technologies possess significant potential to revolutionize the DevOps domain through the automation of tedious duties, including provisioning infrastructure, managing configurations, and identifying anomalies. This study highlights the increasing need for streamlined solutions. By harnessing the capabilities of AI and ML-driven tools, DevOps teams will have the ability to streamline their processes, enabling them to allocate resources to more strategic approaches such as nurturing innovation, addressing complex challenges, and making decisions based on data. This study will investigate the precise methods by which AI/ML can enhance DevOps practices, resulting in a software development environment that is more secure, efficient, and agile.**

Keywords—DevOps, Software development, Artificial intelligence (AI), Machine learning (ML), Continuous delivery, Containerization, Microservices, Cloud computing, Cultural transformation

I. INTRODUCTION

The software development industry experiences ongoing changes due to the insatiable demand for products that demonstrate improved speed, security, and quality. DevOps, an approach that eliminates the traditional separation between development and operations, has emerged as an integral element in this ever-changing environment. To ascertain the ongoing impact of DevOps on the software delivery process, this article examines the burgeoning domains that are influencing its course. [19]

The progress of DevOps is significantly accelerated through the integration of machine learning and artificial intelligence. The process of workflow optimization involves the automation of repetitious duties such as infrastructure provisioning, configuration administration, and anomaly detection. This sentiment aligns with the forecast provided by Market Research Guru in their 2023 report, which indicates that the DevOps market will experience a compound annual growth rate (CAGR) of 24.61% until the year 2028. This illustrates the growing need for solutions that are efficient in nature. By enabling teams to concentrate on innovation, strategic decision-making, and complex challenges, AI and ML-enabled tools will liberate invaluable human resources. [3]

Additional advancements are introduced by the proliferation of containerization and microservices implementations. The deliberate development of containerized applications in conjunction with the microservices architecture enables them to demonstrate improved efficiency, resilience, and scalability, thus facilitating rapid deployments. As a result, organizations may experience an increase in revenue growth and attain a competitive advantage due to a reduced time-to-market. Moreover, the proliferation of cloud computing will inexorably give rise to applications that are native to the cloud. A favorable environment currently exists for developers to capitalize on the anticipated growth of the market by creating cloud-optimized applications that offer optimized resource allocation, streamlined administration, and improved performance.

It continues to be crucial to promote cultural transformation, surmount obstacles, and sustain open dialogue within diverse teams. Furthermore, it is imperative to sustain an outlook on perpetual learning and adjustment within this perpetually evolving domain. Despite these challenges presenting distinct prospects for advancement and ongoing refinement, DevOps remains the prevailing methodology in software delivery.

It is crucial to possess a thorough comprehension of the evolution of DevOps methodologies in comparison to previous years in order to effectively navigate the dynamic software development environment of 2024. This form of knowledge enables individuals to predict forthcoming trends and the possible consequences that may result.

II. DEVOPS MARKET EVOLUTION

A. *DevOps Evolution and Key Findings (2014–2023):*

The ever-changing environment of software development is motivated by an unwavering demand for products that demonstrate improved speed, security, and quality. DevOps has become an essential element in this ever-changing landscape, fostering cooperation and connecting the conventional gap that existed between development and operations. This study examines the burgeoning disciplines that are influencing the evolution of

DevOps, delving into its ongoing revolutionization of the software delivery process. [1]

T The domain of DevOps is positioned to undergo a significant paradigm shift as a result of the revolutionary potential of machine learning and artificial intelligence. These technologies enhance workflow efficiency by automating tedious duties such as infrastructure provisioning, configuration management, and anomaly detection. The figure mentioned above illustrates the compound annual growth rate (CAGR) of 24.61% for the DevOps market, as reported by Market Research Guru in 2023, and expected to persist until 2028. This illustrates the growing need for streamlined and automated solutions. By utilizing AI/ML-driven tools, organizations can effectively allocate the finite human resources of their teams to foster innovation, facilitate strategic decision-making, and address complex problems. [2,3,8]

The ongoing progression is supported by the growing implementation of containerization and microservices. The potential benefits of incorporating lightweight encoding into the microservices architecture of containerized applications include improved scalability, resilience, and deployment velocity. This phenomenon enables organizations to achieve a more rapid time-to-market, which may confer them a competitive advantage and stimulate revenue growth. Likewise, as cloud adoption expands at an exponential rate, cloud-native development will inevitably advance. Developers can achieve a multitude of advantages by adapting their applications to the cloud environment. These advantages encompass improved performance, efficient allocation of resources, and streamlined management. These developments align with the anticipated growth of the market. [16]

Nonetheless, technological advancements do not exclusively determine the trajectory of DevOps. Ensuring efficient communication channels, fostering cultural sensitivity, and surmounting obstacles continue to be of utmost importance within the framework of diverse teams. Furthermore, in this dynamic industry, it will be crucial to adopt a mindset that is defined by continuous learning and adaptation. On the contrary, these obstacles offer distinct prospects for advancement and ongoing enhancement, thereby guaranteeing that DevOps maintains its prevailing position in software delivery.
Given the ongoing evolution of the software development industry in 2024, it is imperative to comprehend the significant changes that have occurred in DevOps methodologies since their inception. Attaining this degree of comprehension enables us to predict forthcoming patterns and the possible consequences that might result. [19]

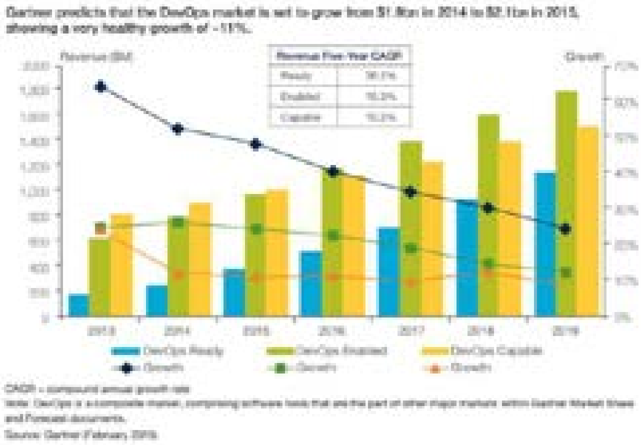

Figure 1. Gartner’s DevOps Market Predictions [9]

Additional factors that have propelled the DevOps market forward include the expansion of concepts like micro-service design, service virtualization, containerization, and platform-as-a-service, as well as the substantial support from the open-source community in the form of numerous cost-effective DevOps enabling tools, in addition to the research conducted by major product and tool-based companies and cloud providers, which has increased cloud adoption. Early adopters or "DevOps Unicorns" such as Netflix, Amazon, Google, Etsy, and Snapchat have established a track record of delivering effective DevOps model variations via ongoing innovation, including NoOps, ChatOps, and SmartOps. In a recent study, Rackspace4 surveyed 700 IT decision makers, of which 55% indicated that their respective organizations have embraced or executed DevOps and are currently exploring ways to improve upon it. Further, 31% of respondents plan to deploy DevOps infrastructure within the following two years. This represents a highly extensive technological implementation concerning the initial provision of instruments. Presently, the DevOps movement incorporates a positive organizational change resulting from the security and compliance components of the DevOps platform, in addition to the administration and implementation of technology.[6]

Exploring the Horizon: Potential Directions for 2024 and Beyond

The software development environment experiences ongoing changes due to the insatiable demand for products that demonstrate improved speed, security, and quality. DevOps, through its integration of operations and development, has surfaced as a pivotal pillar in this continuously evolving ecosystem. It fosters an environment of collaboration. In this article, the potential for DevOps to bring about a substantial paradigm shift in the software delivery process is examined by analysing the burgeoning frontiers that are influencing its course. [19]

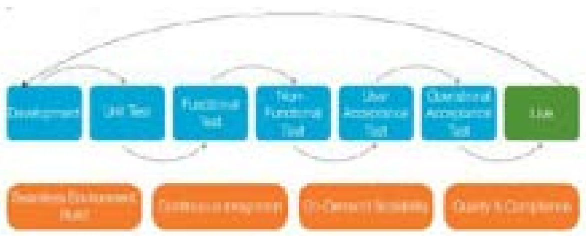

Figure 2. DevOps Lifecycle [9]

As a result of the transformative capabilities of artificial intelligence and machine learning, the DevOps sector is poised to experience a seismic shift. These technologies facilitate process optimization through the automation of laborious duties such as infrastructure provisioning, configuration management, and anomaly detection. This aligns with the findings of the Market Research Guru report 2023, which forecasts a compound annual growth rate (CAGR) of 24.61% for the DevOps market from 2019 to 2028. This observation suggests a growing need for streamlined and automated solutions. AI and ML-driven tools will empower teams to allocate their efforts towards innovation, strategic decision-making, and addressing complex challenges, thereby liberating valuable human capital. [3,8,16]

Additional progress is made possible by the extensive implementation of containerization and microservices. The integration of microservices architecture with lightweight encoding for containerized applications ensures improved scalability, resilience, and deployment velocity. This enables organizations to potentially increase their competitive advantage and broaden their revenue stream through a decreased time-to-market. Additionally, with the ongoing rise in cloud adoption, the emergence of cloud-native development is an unavoidable consequence. Developers possess the potential to capitalize on anticipated market growth by developing cloud-optimized applications that exhibit advantages such as optimized resource allocation, streamlined operations, and enhanced performance.

Difficulty-solving, fostering cultural sensitivity, and guaranteeing efficient communication are all paramount concerns in the context of diverse organizations. Furthermore, in this dynamic domain, it will be crucial to recognize and embrace the importance of ongoing education and adjustment. Notwithstanding these obstacles, they offer distinctive prospects for advancement and ongoing enhancement, thereby guaranteeing that DevOps maintains its prevailing position in software delivery. [17]

It is imperative that we possess a thorough comprehension of the evolution of DevOps methodologies in comparison to previous years in order to effectively navigate the dynamic software development environment of 2024. This comprehension empowers us to predict forthcoming trends and the possible consequences that may ensue.

Key Trends

The software development industry is continuously undergoing changes as a result of the constant need for products that demonstrate improved efficiency, security, and quality. By facilitating collaboration and bridging the traditional gap between operations and development, DevOps has emerged as an indispensable element in this ever-changing ecosystem. This research paper investigates the state-of-the-art advancements in DevOps and its capacity to profoundly revolutionize the future of software delivery.

The implementation of artificial intelligence and machine learning (AI/ML) within the DevOps domain holds the potential for substantial change. These technologies optimize efficiency through the automation of repetitive duties such as infrastructure provisioning, configuration management, and anomaly detection. This is consistent with the compound annual growth rate (CAGR) forecast of 24.61% provided by Market Research Guru in 2023 for the DevOps market until 2028. This suggests that the demand for efficient solutions is on the rise. Through the utilization of tools facilitated by AI and ML, teams can enhance the allocation of their valuable human resources in a manner that promotes innovation, facilitates strategic decision-making, and effectively tackles complex challenges. [3,8]

The rapid expansion of containerization and microservices presents additional prospects for progress. The integration of microservices architecture with lightweight encoding for containerized applications results in improved scalability, resilience, and deployment velocity. This phenomenon induces a reduction in the time required for products or services to reach the market, which may provide companies with a competitive advantage and stimulate revenue growth. Additionally, as a result of the widespread adoption of clouds, cloud-native development will inevitably emerge. Programmers can achieve various advantages by developing cloud-native applications, such as optimized resource utilization, enhanced performance, and streamlined administration. These benefits are consistent with the anticipated growth of the market. [7]

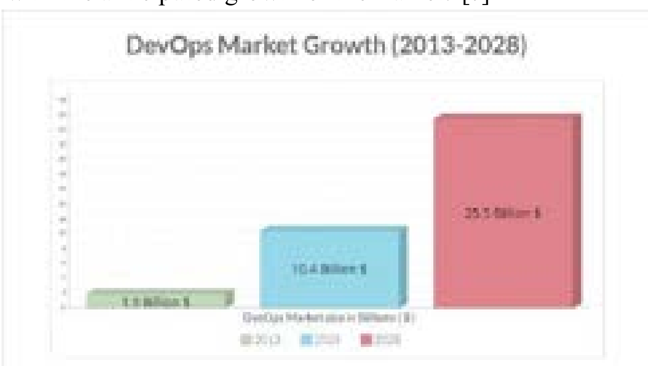

Figure 3. DevOps Market Growth (2013 - 2028)

However, technological advancements do not exclusively dictate the future course of DevOps. Fostering cultural transformation, and preserving transparent communication among members of diverse teams continue to be crucial imperatives. Furthermore, it will be essential to embrace continuous learning and adaptation, as well as to acquire a mindset of perpetual change. Nevertheless, these obstacles offer distinct prospects for advancement and ongoing refinement, guaranteeing that DevOps retains its prevailing position in software delivery. [3,4.7]

Given the ever-changing nature of the software development sector in 2024, it is crucial to grasp the substantial progression of DevOps methodologies relative to their precursors. This understanding empowers us to anticipate future trends and their potential ramifications.

B. *AI and Machine Learning (AI/ML): Redefining DevOps Efficiency*

The software development industry experiences ongoing changes due to the insatiable demand for products that demonstrate improved speed, security, and quality. DevOps, an approach that eliminates the traditional separation between development and operations, has emerged as an integral element in this ever-changing environment.

The progress of DevOps is significantly accelerated through the integration of machine learning and artificial intelligence. The process of workflow optimization involves the automation of repetitious duties such as infrastructure provisioning, configuration administration, and anomaly detection. This sentiment aligns with the forecast provided by Market Research Guru in their 2023 report, which indicates that the DevOps market will experience a compound annual growth rate (CAGR) of 24.61% until the year 2028. This illustrates the growing need for solutions that are efficient in nature. By enabling teams to concentrate on innovation, strategic decision-making, and complex challenges, AI and ML-enabled tools will liberate invaluable human resources. [3,8]

1. Automating Repetitive Tasks:

An inherent and noteworthy contribution of AI/ML to the DevOps paradigm is its capacity to mechanize laborious and repetitive duties. Infrastructure provisioning, configuration administration, and anomaly detection are all encompassed within this. Through the automation of these aforementioned duties, AI/ML enables operations teams and developers to allocate their valuable human resources towards more advanced endeavors such as problem-solving, strategic decision-making, and innovation. (references: [3, 8]).

2. Infrastructure Provisioning:

Traditionally, infrastructure provisioning was a manual process that involved configuring servers, storage, and networking resources. AI/ML can automate this process by learning from historical data and user preferences. This not only reduces the time and effort required for provisioning but also minimizes the risk of human error [5]

3. Configuration Management

Consistency in configurations across various environments is an essential factor in guaranteeing dependable software deployments. Configuration management can be automated through the use of AI/ML, which identifies deviations from established baselines and perpetually monitors configurations. This practice aids in the prevention of configuration drift and guarantees uniform deployments across diverse environments. [6].

4. Anomaly Detection

System performance or application behaviour anomalies may serve as indicators of impending issues. By training AI/ML algorithms to detect these anomalies in real-time, teams can proactively resolve problems prior to their impact on users.

5. Improved Decision-Making

AI/ML are capable of analysing immense quantities of data originating from a variety of sources, such as code repositories, monitoring tools, and application logs. By identifying trends and patterns in this data, AI/ML can provide DevOps teams with actionable insights.

Additional advancements are introduced by the proliferation of containerization and microservices implementations. The deliberate development of containerized applications in conjunction with the microservices architecture enables them to demonstrate improved efficiency, resilience, and scalability, thus facilitating rapid deployments. As a result, organizations may experience an increase in revenue growth and attain a competitive advantage due to a reduced time-to-market. Moreover, the proliferation of cloud computing will inexorably give rise to applications that are native to the cloud. A favourable environment currently exists for developers to capitalize on the anticipated growth of the market by creating cloud-optimized applications that offer optimized resource allocation, streamlined administration, and improved performance. [16]

It is crucial to possess a thorough comprehension of the evolution of DevOps methodologies in comparison to previous years in order to effectively navigate the dynamic software development environment of 2024. Acquiring this knowledge enables us to proactively predict forthcoming trends and the possible consequences that may ensue.

A. DevOps and the Cloud: A Strategic Synergy:

DevOps and cloud computing are two transformative forces that, when combined, can revolutionize software development and delivery. Here's how the cloud achieving process aligns with DevOps methods, with references to illustrate these points:

1. Infrastructure as a Code (IaaC):

Infrastructures as Code (IaaC) enable developers to define infrastructure configurations, thereby facilitating the automated deployment and provisioning of resources in the cloud. This facilitates accelerated deployments, consistency, and repeatability ([20]). Prominent cloud platforms such as AWS CloudFormation [24], Azure Resource Manager [25], and Google Cloud Deployment Manager [26] facilitate the automation of infrastructure provisioning and configuration in the cloud environment through the creation of IaaC templates.

Figure 4. Continuous Delivery pipeline [21]

2. Continuous Integration and Continuous Delivery (CI/CD):

CI/CD pipelines streamline the software development lifecycle through the automation of code integration, test execution, and cloud-based update deployment. This increases the rate of feedback loops and decreases the likelihood of errors ([23]). Cloud platforms offer integrated CI/CD tools, such as Google Cloud Build [29], AWS Code Pipeline [27], and Azure DevOps Pipelines [28], which facilitate the deployment of applications to the cloud and integrate seamlessly with development workflows.

3. Continuous Monitoring and Feedback:

DevOps emphasizes continuous monitoring of application performance and infrastructure health in the cloud. This allows for proactive problem identification and faster resolution ([22]). Cloud platforms offer comprehensive monitoring services like AWS CloudWatch [30], Azure Monitor [31], and Google Cloud Monitoring [32] that provide real-time insights into application performance, resource utilization, and infrastructure health.

4. Scalability and Elasticity:

Cloud resources enable DevOps teams to dynamically adjust the scalability of applications in response to fluctuations in demand. This reduces expenses by eliminating the requirement for manual infrastructure provisioning. Cloud computing provides elastic, on-demand resources that are automatically scalable in accordance with the demands of the application. This ensures cost-effectiveness and optimal performance.

5. Collaboration and Communication:

By facilitating collaboration among the development, operations, and security teams, cloud environments offer a unified and shared platform for the management of applications and infrastructure. This facilitates enhanced communication and optimized operations. A multitude of cloud platforms provide collaboration functionalities, such as wikis, chat, and project management features, which facilitate enhanced teamwork within a cloud-based setting (AWS Chat [33], Azure DevOps Boards [34]).

Cloud computing offers an optimal infrastructure for the streamlined implementation of DevOps methodologies. Through the strategic integration of these two methodologies, enterprises can augment the flexibility, effectiveness, and ingenuity inherent in their software development procedures.

III. DEVOPS MARKET GROWTH (2013-2028)

The graphical representation depicts the projected growth of the global DevOps industry, with a significant upward trend from 2013 to 2028. In 2013, the market was assessed to be worth $8.8 billion, indicating that the implementation of DevOps was in its early stages of development. By 2023, it is projected that the market will attain a valuation of $10.4 billion, signifying an ongoing ascent in its importance within the software development sector. Anticipating forthcoming advancements, it is anticipated that the market will sustain its expansion, reaching an approximate valuation of $25.5 billion by 2028. The expected growth represents the increasing adoption of DevOps approaches across various industries, driven by the numerous benefits it offers—including accelerated software delivery, strengthened collaboration, and enhanced operational efficiency. [3]

TABLE I. DEVOPS MARKET GROWTH (*$ IN BILLION*)

Year	Market Size (2013-2028 *expected*)
2013-2014	$1.9 billion
2015-2016	$2.3 billion
2016-2018	$3.709 billion
2018-2023	$10.4 billion
2024-2028	$ 25.5 billion (*expected*)

Over the designated time span (2013-2028), it is expected that the market will experience significant growth. The market is anticipated to increase from a range of $1.9 billion to $2.4 billion in 2013-2014 to $24.5 billion between 2024 and 2028. The market size is projected to average $5.67 billion between 2013 and 2023, excluding the anticipated value for 2024-2028.[11,10,9,19]

B. Enhancing Software Delivery with DevOps

DevOps practices not only streamline development processes but also demonstrably improve core software delivery aspects. Here's how:

By leveraging containerization and Infrastructure as Code (IaC), DevOps prioritizes automation ([35], [36]). IaC guarantees the provisioning of consistent infrastructure, which results in predictable performance. The horizontal scalability of microservices architectures made possible by containerization enables the fulfillment of increased demand ([37]). Furthermore, continuous monitoring is advocated for in DevOps ([38]), which enables the proactive detection and resolution of performance obstacles.

Security constitutes a fundamental principle of DevOps. Varies can be detected and remedied in a timely manner by incorporating security testing into the entirety of the development lifecycle (DevSecOps) ([39]). By taking this proactive approach, security risks in production environments are minimized. In addition, security is improved through the utilization of tools such as containerization, which function to isolate applications and their dependencies, thereby diminishing the attack surface ([40]).

DevOps facilitates communication and collaboration between the operations and development teams, resulting in streamlined workflows and decreased revisions ([41]). The utilization of CI/CD pipelines to automate repetitive duties not only increases efficiency but also liberates developer time for more valuable endeavours ([42]). Furthermore, DevOps cultivates an environment that encourages perpetual refinement and learning, thereby facilitating the efficient execution of software delivery.

IV. CONCLUSION

TThe software development industry is continuously undergoing changes as a result of the constant need for products that demonstrate improved efficiency, security, and quality. By facilitating collaboration and bridging the traditional gap between operations and development, DevOps has emerged as an indispensable element in this ever-changing ecosystem. This research paper investigates the state-of-the-art advancements in DevOps and its capacity to profoundly revolutionize the future of software delivery.

The implementation of artificial intelligence and machine learning (AI/ML) within the DevOps domain holds the potential for substantial change. These technologies optimize workflow efficiency through the automation of repetitive duties such as infrastructure provisioning, configuration management, and anomaly detection. This is consistent with the compound annual growth rate (CAGR) forecast of 24.61% provided by Market Research Guru in 2023 for the DevOps market until 2028. This suggests that the demand for efficient solutions is rise. Through the utilization of AI ML, organizations can optimize the distribution of their human capital in support of innovation, decision-making, and resolution of problems. [3,8]

The rapid expansion of containerization and microservices presents additional prospects for progress. The integration of microservices architecture with lightweight encoding for containerized applications results in improved scalability, resilience, and deployment velocity. This phenomenon induces a reduction in the time required for products or services to reach the market, which may provide companies with a competitive advantage and stimulate revenue growth. Additionally, as a result of the widespread adoption of clouds, cloud-native development will inevitably emerge. Programmers can achieve various advantages by developing cloud-native applications, such as optimized resource utilization, enhanced performance, and streamlined administration. These benefits are consistent with the anticipated growth of the market. [17]

However, technological advancements do not exclusively dictate the future course of DevOps. Cultivating cultural transformation, surmounting obstacles, and sustaining transparent communication continue to be of the utmost importance in diverse teams. Furthermore, it will be essential to embrace continuous learning and adaptation, as well as to acquire a mindset of perpetual change. Nevertheless, these obstacles offer distinct prospects for advancement and ongoing refinement, guaranteeing that DevOps retains its prevailing position in software delivery.

In light of the dynamic nature of the software development industry in 2024, it is imperative to comprehend the significant advancements that DevOps methodologies have made in comparison to their predecessors. This comprehension enables us to predict forthcoming trends and the possible consequences they may involve.

***Abstract*—Machine translation is the act of translating from one language to another using a computer program or algorithm.The need for translation from one language to another to facilitate communication between different cultures and peopleis one that we have had since antiquity. Traditional methods of translation are quite slow and cumbersome and are susceptible to biases from the translator. The advent of computers has led us to explore ways in which this process may be automated. Another long-standing problem is the detection and classification of emotions in textual data. The capacity to detect and recognize human emotions is one that is particularly fascinating and important in the field of Artificial Intelligence. Both problems are NLP(natural language processing) problems that involve analyzing textual data which is inherently sequential in nature. Traditional deep neural networks have proven inefficient and inaccurate in tasks involving sequential data such as natural language processing, time series analysis etc. Over the years numerous deep learning models have been developed to address these issues. The advent of RNNs(Recurrent Neural Networks), LSTMs(Long Short-Term Memory) and GRUs(Gated Recurrent Units), which are all deep neural net- works built to handle sequential data, has made great progress in machine translation and sentiment analysis. Each of these models has its own unique characteristics and features. This paper aims to compare each model in terms of accuracy, performance, architecture, computational complexity, etc. and thus outline situations in which each model may prove suitable based on its particular set of strengths and weaknesses.**

***Index Terms*—Machine Learning, Machine Translation, Sentiment Analysis, Recurrent Neural Network(RNN), Natural Language Processing(NLP), Long Short-Term Memory(LSTM), Gated Recurrent Unit(GRU)**

I. INTRODUCTION

In the changing province of Natural Language Processing (NLP), analysts are vigorously trying to increase machine abilities in language translation and sentiment analysis. The pursuit for improved precision and ability in these domains has driven an engaged exploration into the difference of various types of artificial intelligence models. There are three types of models: RNNs(Recurrent Neural Networks), LSTMs(Long Short-Term Memory networks) and GRUs (Gated Recurrent Units). These models are a few different versions of recurrent neural networks, each designed to label particular challenges in sequence-based tasks. Analysts are actively looking into the strengths and limits of RNNs, GRUs, and LSTMs to expose acumen that can move development in language processing, offering a separate understanding of their quality of being connected in machine translation and feeling analysis tasks.

In the sector of consecutive data processing, where the encouragement to fight lies in understanding and analysing information presented in a sequence, such as a series of words that make sense i.e. sentence or paragraphs, Recurrent Neural Networks (RNNs), Gated Recurrent Units (GRUs), and Long Short-Term Memory (LSTM) networks appear as very important tools. Think about these models as skilled lists of questions helping computers' understanding and processing of consecutive information, especially in the involved domain of languages. Their important role becomes obvious in un- folding the structure and big picture of language, basic for tasks like translation and sentiment analysis. RNNs(Recurrent Neural Networks) are proficient in managing information and data which is sequential. LSTMs(Long Short Term Memory) are similar to GRUs in some ways and also proficient in memory i.e. LSTM remembers large pieces of information especially when it comes to language structures which are complex. On the far side of the prevailing metrics of language translation or understanding of feeling of love, hate, guilt, etc. , the analysis is geared towards detecting the distinctive strengths and challenges of each tool. The purpose is to gain a confusing understanding of how these systems entangle the attribute of language, communication, feelings of love, hate, fear, etc. and sentiments with skill. This in-depth research aims not only to give basic information but to offer complete and thorough consciousness into the analogous prospect of RNNs, GRUs, and LSTMs within the particular big picture of machine translation and feeling analysis. The purpose is to give power to analysts, professionals or skilled people, and fans with high-quality knowledge that helps informed decision-making. Through this serious and stubborn pursuit, the goal is to light the abilities of RNNs, GRUs, and LSTMs, throwing out light on where each excels and identifying possible challenges they may come across in language tasks. Eventually, to prepare the collaborators in this field where tools are required and the understanding for neural network infrastructure is needed effectively, so that one can combine applications or can say hybrid applications ranging from translation tasks to study feelings in word-based data. While exploring these various types of neural networks i.e. Recurrent Neural Networks(RNNs), Gated Recurrent Units(GRUs) and Long Short-Term Memory(LSTM) networks, it's not only a technical analysis but there is more to it. As it is a passage to understand about the language of humans and their sentiments. People will get to know about the intricacies of communication between humans, how they understand and express.

Before conducting any research or analysis, feasibility study is one of the important step that needs to be done. As for Natural Language Processing(NLP) tasks like machine translation and sentiment analysis, various models and architectures have been introduced. For machine translation, starting from rule based machine translation which provided quality translation but it was customized for specific purposes only. Coming to statistical machine translation, provided accurate translations using Machine Learning(ML) algorithms but was time-consuming. Neural machine translation model, addressed the limitations of previous models by using neural networks to learn languages. For sentiment analysis, lexicon based and machine learning based models are being used. Lexicon based models are less expensive and have access but are not suitable for analysis where data gathers from different platforms. While machine learning models provide more accuracy and are faster than traditional methods. By uncovering the abilities, strengths, and difficult things about RNNs, GRUs, and LSTMs, the aim is to signal the way for smart systems that not only understanding the surface-level true meaning of human language but also understanding the sentiments, and the difference that define human communication. By throwing light on the complex interaction between technology and these basic parts of people and the kindness of people, one can think of a future where AI not only helps in practical tasks but also becomes an understanding partner. This deeper understanding of language and emotions is not just about increasing the capability of translation or sentiment analysis; it's about taking good care of a high-tech province that matches up with the human exposure.

II. Literature Survey

Starting with an extensive historical summary, the survey meticulously chronicles the development of these recurrent neural network architectures. Recurrent Neural Network (RNN) and Convolutional Neural Network (CNN) are the best popular types of Deep Learning architectures used.

Patel et.al. [1] introduced the two approaches for sentiment classification and those were lexicon based and machine learning based. The deep learning model Recurrent Neural Network(RNN) was introduced. But the training process quite time-consuming due to the vanishing gradient problem, so the Long Short-Term Memory(LSTM) network, an advanced version of RNN model came up with the solutions to those problems. Srinivas et.al. [2] proposed a system for sentiment analysis using neural networks, Convolutional Neural Network(CNN) and Long Short-Term Memory(LSTM), out of which LSTM came out as the best approach. A twitter dataset was taken for the analysis of sentiments, but when it comes to analyze data in real-time, this proposed system will need other approaches.

Switching over to sentiment analysis, textual data plays an important role in classifying emotions. Murthy et. al. [3] conducted the text based analysis of IMDB dataset by using Long Short-Term Memory(LSTM) as Recurrent Neural Network(RNN) fails to analyse long sequences and suffers from vanishing gradient. Long Short-Term Memory(LSTM) is a success over the traditional machine learning techniques. For accurate sentiment prediction, there is need for long range dependencies as well as the need to know the importance of how to capture contextual information. These analyses shed light on the detailed and thoughtful performance of each architecture across diverse datasets and sentiment analysis domains. Pedro M. Sosa [4] developed a model by combining LSTM and CNN to see how the performance will be affected by using their abilities, enhancing the importance of adding dropout layer. While comparing LSTM-CNN with regular CNN and LSTM, the accuracy of LSTM-CNN model is the highest.

In machine translation, there are a great variety of architectures. Statistical Machine Translation(SMT) was a success over the rule-based machine translation and when Neural Machine Translation(NMT) came into picture, replacement of SMT took place. Tan et. al. [5] implemented the concept of attention mechanism in machine translation and used many open source Neural Machine Translation(NMT) toolkits like Tenosr2Tensor, OpenNMT, Nematus for research. Datta et. al. [6] acknowledged the benefits of Recurrent Neural Network(RNN) over Artificial Neural Network(ANN). The dataset for neural machine translation was from open GitHub source containing English and French sentences. Speech Recognition, Machine Translation and Speech Synthesis, the three modules in which system was divided and the system also took care of overfitting issues and overheads.

Cho et. al. [7] implemented the RNN Encoder-Decoder model which proved to be better at capturing the linguistic regularities in multiple levels i.e. word level or phrase level, explained the overall improvement in the performance of translation. This Encoder-Decode model can also be applied to speech transcription. Alex Sherstinsky [8] discusses about the difficulties that were being faced by RNN and how the transformation from RNN to Vanilla LSTM take place. Also the importance of data set standardization and evolvement of Vanilla LSTM architecture is highlighted in the research. It provides valuable understanding of the broader situations and ability to change each architecture based on various contextual factors.

GRUs(Gated Recurrent Units) work by combining the hidden state with memory cell structures. Efficiency and improvements in translation tasks are provided by GRUs. According to Dey et. al. [9] , applying three distinct variants to both gates(update gate and reset gate) will help to evaluate performance, possessing less gate parameters and less computational expense when compared to GRU-RNN. Li et. al. [10] have described IndRNN model which provides independence of neurons and also allows to learn long-term dependencies by the network itself. As compared to LSTMs and GRUs, IndRNNs process much longer sequences.

In both machine translation and sentiment analysis, on the relative performance of various RNNs, the literature survey tells about the impact of various aspects like characteristics of dataset and methodologies. To connect people from all the world, share information among people and build relationships, language translation plays an important role. Kim et. al. [11] emphasized the use of various pivoting techniques, showcasing the drawbacks of other machine translation systems and performed a survey on different approaches of neural machine translation and found that for many languages, there is no availability of huge amounts of the parallel corpus. Bau et. al. [12] have addressed how translations can be controlled by modifying neurons and on the basis of linguistic properties like number, gender and tense. Also discussed about are the rankings of neurons which must be done on the basis of their importance and how the neurons which are on higher level have more impact on translation.

In the end, as for machine translation and sentiment analysis, the survey leads to give a better understanding about prior work and advancements in the fields of machine translation and sentiment analysis. So this survey can be serving as a valuable and useful dispense as one can gain knowledge from the various studies that have been done.

III. Proposed Methodology

To propose a thorough comparisons of LSTM (Long Short-Term Memory) networks, GRUs (Gated Recurrent Units) and RNNs (Recurrent Neural Networks), in the domain of Machine Translation and Sentiment Analysis, a well-designed method has been proposed in this paper which gives a prologue to the minute differences of these prominent neural networks. The methodology begins with the careful selection from a variety of datasets available on the internet, specially those which capture the complexities and difficulties present in tasks such as sentiment analysis, involving a wide range of emotional content and translation between 2 different languages. Due to the variety of datasets present on the internet, the robustness and applicability of the of the results is increased greatly in real-world. It further progresses with data preprocessing phase which is standardized to establish uniformity in handling of the selected dataset. The data pre-processing phase is a crucial phase as it involves activities such as tokenization which ensure that the text is converted into separate components for analysis and removal of noises and inconsistencies. By standardizing the Pre-Processing phase, an equal and impartial basis is set up for LSTM, GRU and RNN models. The main purpose is to provide insightful information on the advantages and disadvantages of each of the prominent models/networks with respect to tasks such as Language Translations and Sentiment Analysis as mentioned before.

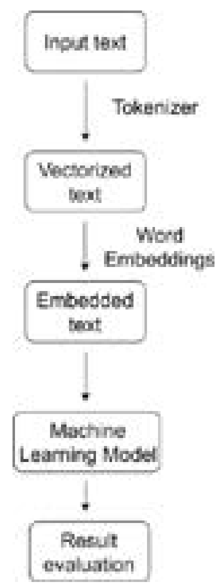

Fig. 1: Data flow Diagram

A. Dataset Description

A set of datasets will be extremely carefully collected on the analysis of Recurrent Neural Networks (RNNs),Gated Recurrent Units (GRUs), and Long Short-Term Memory (LSTM) networks in the worlds of machine translation and sentiment/feeling analysis.

As for machine translation, the English-French translation dataset from Kaggle [13] has been taken. There are 2 columns one column has English words/sentences and the other one has French words/sentences. And these datasets can be used for language translation task. The unique value is different because the same English word has a different French representation. This dataset contains more than 176,000 pairs of sentences in English and French, which makes it a rich resource for studying language translation. This diversity provides ample material for analyzing and improving language translation algorithms.

On the sentiment analysis front, sentiment analysis dataset of Twitter [14] from Kaggle has been taken for sentiment analysis which encapsulates diverse array of tweets having sentiments ranging from positive to negative. Using this dataset, the feeling or the sentiment of a message can be judged. In this dataset, there are four categories : Tweet ID , Entity , Sentiment and Tweet Content in which the particular message can be put. With over 69,491 unique entries and 74,700 total entries, each tweet is labelled with it's associated sentiment such as positive , negative or neutral which provides a fertile ground to apply various sentiment analysis methodologies. These datasets will serve as the foundation for a thorough, detailed and thoughtful analysis of RNNs, GRUs, and LSTMs, which is an addition to the improvement in understanding of their performance in the specified language processing job.

B. Data Pre-processing

In the domain of Sentiment Analysis and Language Translation, the data Pre-Processing step is similar to careful creation of mastering the tools needed to do a surgery in a hospital. To help the models have good accuracy when a new data is introduced during Language Translation and Sentiment Analysis, a well-designed and processed dataset makes sure that the models are exposed to variety of language patterns and sentiment variations. Creation of this thorough dataset helps with issues such as language variations, cultural variances, and domain-specific differences. Some of the key benefits of data pre-processing are:

1) NLP models which heavily rely on data quality can function better.

2) All data inconsistencies which can hinder a models performance are carefully removed.

3) Accuracy of the predictions is improved.

4) Enables the model to handle diverse range of inputs.

5) Addresses bias and fairness.

6) Supports continuous refinement in order to capture nuances.

1. **Tokenizer on text:** Neural networks cannot process data in the form of text directly. Each word thus must be assigned a numerical representation unique to that particular word. The tokenizer works by assigning each unique word a unique numerical value. For e.g. consider the sentence "He is a boy" : 'he' will be assigned a value of '1', 'is' a value of '2' and so on and so forth. This collection of words with their corresponding values is called the dictionary. Any word not present in the dictionary is automatically assigned a value of 0. Punctuation marks are automatically ignored.

2. **Padding on text:** Padding: Padding is a simple concept in ML and Data Science wherein all the sentences in a text are same of equal lengths, this is often done by adding zeros to the shorter sentences. The consistency in the length of sequences makes it easy for the model to streamline process the entire data(which becomes uniform after padding).

Padding is useful where we want our system to identify the sentiment or emotion of a certain piece of text which can be positive, negative or neutral. It is used to guess the next word in a sentence , convert a sentence from one language to another and thereby helps in smooth integration of textual data.

3. **One hot Encoding labels:** One-Hot encoding is common ML technique which represents data in binary digits. It transforms textual input into information which is presented in the form of a binary matrix. Example: RGBs(colour variable) One-hot encoding would be as follows:

- Red: [1, 0, 0]
- Green: [0, 1, 0]
- Blue: [0, 0, 1]

It's particularly useful in cases where data has no ordinal relationship among categories. One-Hot encoding is performed by using libraries such as scikit-learn. Only disadvantage is that it increases the dimensionality of the data and hence the processing becomes complex. For such a problem, we can use techniques like: embedding or feature hashing.

4. **Word Embeddings:** Word embeddings are further applied to each word after tokenization in order to provide a better numerical representation of the word in the form of a vector. Word embeddings are used to capture and map the unique features of each word. These word embeddings are usually 300-500 dimensional matrices. Each dimension is used to capture a particular feature or information contained in a word. These may hypothetically capture features such as gender, tense, location etc. related to the word. Similar words will have similar word embedding representations.

5. **Train-test split:** Train-test split, as the name suggests is a method of dividing data into 2 parts i.e :

1) Training set which is basically to learn patterns from the data

2) Test set which is to evaluate the performance of new/ generated data

When a computer is fed with chunk of raw data, it becomes hard for it to analyse it as a whole, hence the model divides this big data into sets and uses these sets of data for different purposes in order to generate the best possible solution. This can be understood better with the help of an example: supposing we are given the task of simple classification like cats and dogs. In such a case, our model will divide the images in 2 groups, first one to practice in identifying the image and the second to test whether it's capable enough to predict the group of unknown images or not.

Thereby it can be concluded that Train-Test split is an amazing technique which enables the system to perform tasks in a real-world system wherein the data is vast and generally unknown. This model instead of memorizing the content, tries to figure out (using the training set) how to generate pattern and connections in data. It then uses these patterns (on test set) to give optimized solutions to the user's real world problems.In essence, the train-test split serves as a methodological safeguard against overfitting, contributing to the development of robust machine learning models capable of accurate predictions across diverse and dynamic scenarios.

C. Algorithms

Recurrent Neural Networks (RNN) are a category of Neural Network[15] where the output computed from the previous step is fed as the input to the next step. In fully connected neural networks, all the inputs are independent of each other, but if for instance if we wish to predict the next word in a sentence the sequence of the words arriving before it plays a significant role in its determination. In such cases in order to process sequential data we require the need to store information from the previous states as well. This is accomplished by a RNN(Recurrent Neural Network). We have various examples for RNN(REcurrent Neural Network). Some of them are predicting the next word of a sentence, Stock price prediction etc.

Key Components and Operation of an RNN

1. **Hidden State (hid_t):** At each time step t, an RNN maintains a hidden state h_t. The new hidden state is calculated based on the current input and the previous hidden state. It serves as a way to retain information from the previous inputs in the sequence.

$$hid_t = u(P_{hh} \cdot hid_{t-1} + P_{xh} \cdot x_t + b_h)$$

where P_{hh} is the hidden state's weight matrix,
P_{xh} is the input's weight matrix,
b_h is the bias term,
u is the selected activation function (commonly tanh or ReLU), and
x_t is the input at time t.

2. **Output (y_t):** The output at each time step t, denoted as y_t, is computed based on the current hidden state.

$$y_t = P_{hy} \cdot hid_t + c_y$$

where P_{hy} output's weight matrix, and c_y is the bias term.

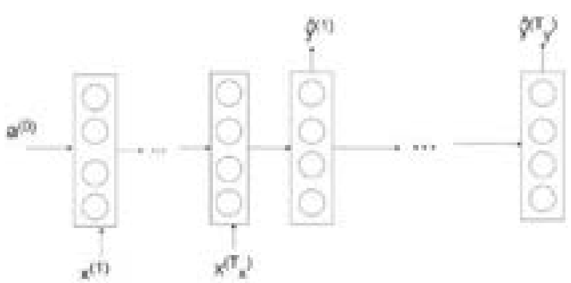

Fig. 2: Recurrent Neural Network

Usage: For machine translation first the entire input text is encoded by an encoder RNN which ties to produce a vector which tries to encapsulate the various features and relationships between the words of the sentence. This vector is than fed into the decoder RNN which attempts to translate the sentence. In the case of sentiment analysis the sentence is passed through a RNN at the end of which a softmax function is applied to categorise the sentence into the correct sentiment category.

Vanishing Gradient problem

The vanishing gradient problem occurs when deep neural networks[16] with a large number of layers are trained during back propagation with gradient-based learning methods. Dur- ing each iteration of training the neural networks' weights are updated by calculating the partial derivative of the error function with respect to the current weight. But with a large numbers of layers for the gradient to back propagate through the gradient continues to become smaller and smaller. This can cause the initial layers of the network to almost completely not undergo further training. Traditional activation functions such as tanh(hyperbolic tangent)[17] have derivatives in the range of (0,1] when these small values are repeatedly multiplied the gradient becomes exceedingly small and vanishes.

Long Short-term Memory (LSTM)

In order to solve the vanishing gradient problem as de- scribed above the LSTM (Long Short-term Memory) was developed. LSTMs don't just decide to keep all the previous state values but chose to discard or retain some parts of the previous state. It does this by introducing gates which decide how much information from the previous state needs to be retained.

Key Components of an LSTM

1. **Cell State (Cel_t):** The cell state represents the long-term memory of the LSTM. It is used throughout the layers of the entire neural network with only minor linear activations.

2. **Forget Gate (d_t):** The forget gate is used to decide as to how much information from the cell state shall be discarded or kept on. It takes the previous hidden state h_{t-1} along with the current input $a0_t$. The sigmoid function is used to ensure that the output f_t is between 0 and 1.

$$d_t = \sigma(P_d \cdot [hid_{t-1}, a0_t] + c_f)$$

where W_d is the forget gate's weight matrix,
σ is the sigmoid activation function,
and c_f is the bias term.

3. **Input Gate (i_t):** The input gate decides the information that needs to be updated in the cell state. It has two parts: a sigmoid layer to decide the values to be updated (i_t) and a tanh layer which creates new candidates ($\tilde{C}_t$).

$$i_t = \sigma(P_i \cdot [hid_{t-1}, x_t] + C_i)$$

$$\tilde{C}el_t = \tanh(P_C \cdot [h_{t-1}, x_t] + C_C)$$

where P_i, P_C are the weight matrices,
σ is the sigmoid function,
and C_i, C_C are the bias terms.

4. **Update Cell State ($\tilde{C}el_t$):** Represents new candidate values that can be added to the cell state.

5. **Update Cell State (Cel_t):** The cell state is changed by combining the old cell state (Cel_{t-1}) with the information from the forget gate and the new candidate values.

$$Cel_t = d_t \odot Cel_{t-1} + i_t \odot \tilde{C}el_t$$

where $\odot$ denotes element-wise multiplication.

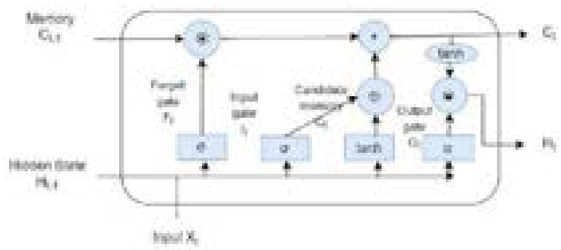

Fig. 3: Long Short-term Memory

6. **Output Gate (out_t):** The output gate decides the next hidden state (hid_t) based on the newly updated cell state. The previous hidden state hid_{t-1}, the current input x_t, and the updated cell state Cel_t is inputed into it.

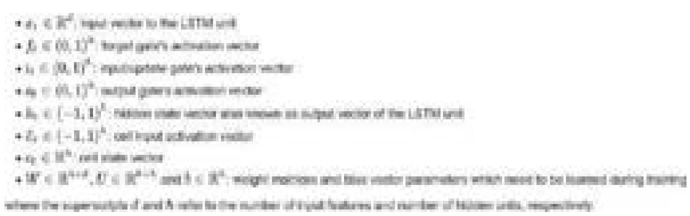
$$out_t = \sigma(P_o \cdot [hid_{t-1}, x_t] + c)$$

where P_o is the weight matrix,
σ is the sigmoid function,
and c is the bias term.

7. **Hidden State (hid_t):** The final hidden state is computed by applying the output gate to the updated cell state.

$$hid_t = o_t \odot \tanh(C_t)$$

The operator $\odot$ represents the Hadamard product.



- $x_t \in \mathbb{R}^d$: input vector to the LSTM unit
- $f_t \in (0,1)^h$: forget gate's activation vector
- $i_t \in (0,1)^h$: input/update gate's activation vector
- $o_t \in (0,1)^h$: output gate's activation vector
- $h_t \in (-1,1)^h$: hidden state vector also known as output vector of the LSTM unit
- $\tilde{c}_t \in (-1,1)^h$: cell input activation vector
- $c_t \in \mathbb{R}^h$: cell state vector
- $W \in \mathbb{R}^{h \times d}$, $U \in \mathbb{R}^{h \times h}$ and $b \in \mathbb{R}^h$: weight matrices and bias vector parameters which need to be learned during training

where the superscripts d and h refer to the number of input features and number of hidden units, respectively.

Usage: For machine translation first the entire input text is encoded by an encoder LSTM which ties to produce a vector which tries to encapsulate the various features and relationships between the words of the sentence. This vector is than fed into the decoder LSTM which attempts to translate the sentence. In the case of sentiment analysis the sentence is passed through a LSTM at the end of which a softmax function is applied to categorise the sentence into the correct sentiment category.

Gated recurrent unit(GRU)

Gated recurrent units (GRUs) are an extension of recurrent neural networks using gating mechanisms, introduced in 2014 by Kyunghyun Cho et al. It was introduced as an improvement over traditional RNNs to address some of their limitations, especially in handling long-term dependencies in sequential data.

Key Components of a GRU

1. **Update Gate (u_t):** Determines how much of the past information should be retained. It considers the current input and information from the previous time step. The update gate outputs values between 0 and 1.

$$u_t = \sigma(P_z \cdot [hid_{t-1}, x_t])$$

where P_z is the update gate's weight matrix,
σ is the sigmoid function,
hid_{t-1} is the previous step's hidden state,
and x_t is the input at the current time step.

2. **Reset Gate (res_t):** Determines how much of the information needs to be discarded. It helps the model focus on the most relevant information from the past. Like the update gate, the reset gate outputs values between 0 and 1.

$$res_t = \sigma(P_r \cdot [hid_{t-1}, x_t])$$

where W_r is the reset gate's weight matrix.

3. **Current Memory Content ($h\tilde{i}d_t$):** Represents information considered relevant for the current time step. It is a candidate update for the hidden state and is computed using the input and the reset gate.

$$h\tilde{\ }id_t = \tanh(P_h \cdot [res_t \odot hid_{t-1}, x0_t])$$

where P_h is the current memory content's weight matrix,
tanh is the hyperbolic tangent function,
and $\odot$ denotes element-wise multiplication.

4. **Hidden State Update (hid_t):** The new hidden state is formed by combining the previous hidden state with the current memory content and is controlled by the update gate.

$$hid_t = (1 - u_t) \odot hid_{t-1} + u_t \odot h\tilde{\ }id_t$$

where $a0_t$ is the input vector
hid_t is the output vector
u_t is the update gate vector
res_t is the reset gate vector

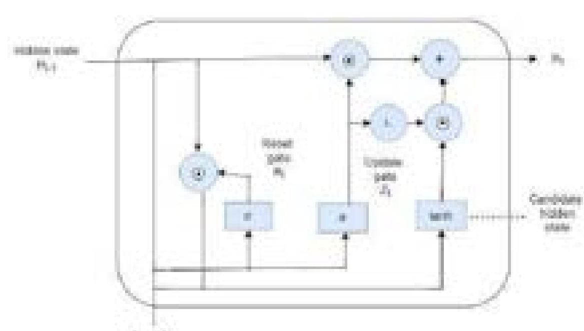


Fig. 4: Gated Recurrent Units

Usage: For machine translation first the entire input text is encoded by an encoder GRU which ties to produce a vector which tries to encapsulate the various features and relationships between the words of the sentence. This vector is than fed into the decoder GRU which attempts to translate the sentence. In the case of sentiment analysis the sentence is passed through a GRU at the end of which a softmax function is applied to categorise the sentence into the correct sentiment category.

D. Architecture

This project's architecture involves preprocessing datasets for sentiment analysis and machine translation. Neural network models, including RNN, LSTM, GRU layers, are configured with task-specific output layers. Training involves optimizer selection,loss function definition, and task-specific metrics.

E. Evaluation

In the evaluation phase, the performance of RNNs, LSTMs, and GRUs was scrutinized in both sentiment analysis and machine translation tasks. Cross-analyzing these tasks allowed us to identify trade-offs and make recommendations based on observed performance differences. Insights into model behavior highlighted both common challenges and unique strengths across RNNs, LSTMs, and GRUs.

RNNs were created to handle sequential data. It does this by feeding the previous state's hidden state into the next state as well. The major problem with the model is that information from previous states becomes harder and harder to retain down the line. Inputs processed at the beginning are mostly forgotten after a few new inputs. Another problem associated with RNNs is the vanishing gradient problem where due to the small values of the gradient, changes made to the weights of the nodes of the initial layers of the neural network are extremely miniscule making these layers extremely hard to train.

LSTMs, which have multiple gates to decide what information to discard and retain, fare much better in capturing information from the earlier inputs. LSTMs have a total of three gates(forget gate, update gate and output gate) to collectively decide which and how much information is to be retained in the matrices. A drawback of having these many gates is that the amount of computation required for their training was also substantially increased. GRUs achieve a middle ground by using only one gate to decide what and how much information is to be retained.

LSTMs' proficiency in handling long-range dependencies and GRUs' computational efficiency, trade-offs surfaced in terms of accuracy, performance and training complexity. These findings underscore the importance of considering model characteristics in alignment with specific task requirements. We concluded with suggestions for future research directions, pinpointing areas for improvement and optimization in the application of these models to sentiment analysis and machine translation. This comprehensive evaluation aims to guide researchers and practitioners in the dynamic field of natural language processing.

IV. Result and Analysis

Machine translation
LSTM accuracy: on training=0.8389, on validation=0.8425
GRU accuracy: on training=0.8377, on validation=0.8398
RNN accuracy: on training=0.8235, on validation=0.8246
Sentiment analysis
LSTM accuracy:on training=0.9587, on validation=0.8966
RNN accuracy:on training=0.9374, on validation=0.8527
GRU accuracy:on training=0.9580, on validation=0.8926

As can be seen LSTMs and GRUs give a much higher accuracy on both tasks as compared to RNNs which suffers from the vanishing gradient problem and is not able to capture the features of words occurirng earlier in a sequence.

The difference in accuracy between GRUs and LSTMs is much less noticeable with the LSTM models just barely edging out the GRU model in terms of accuracy on both tasks. This supports research conducted during the literature survey which show similar results. GRUs and LSTMS usually provide

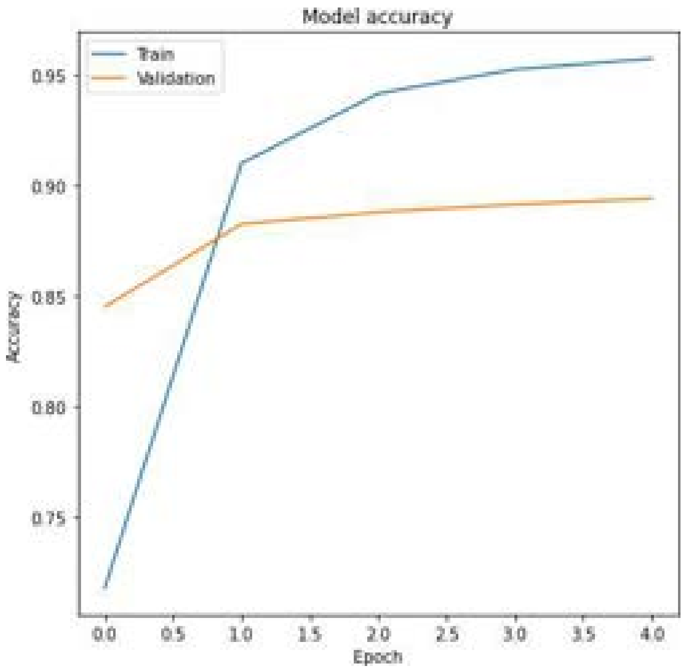

Fig. 7: Sentiment analysis GRU model

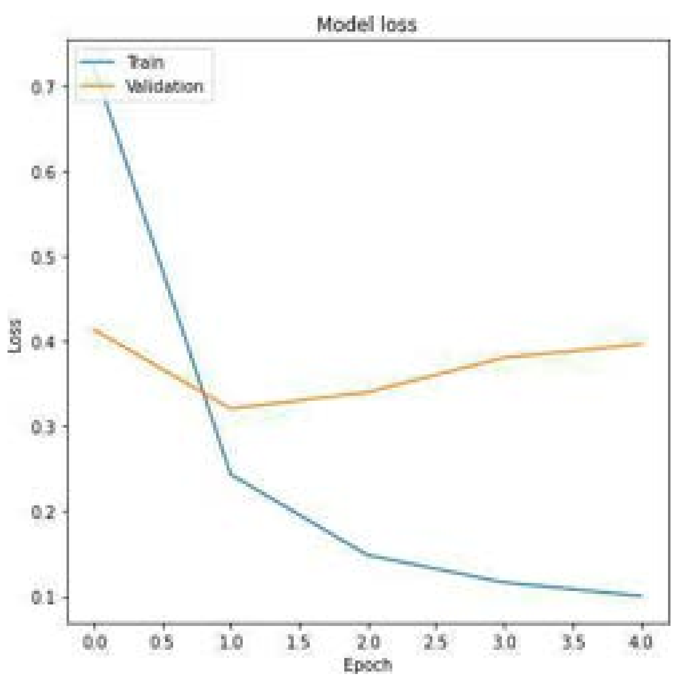

Fig. 8: Sentiment analysis GRU model

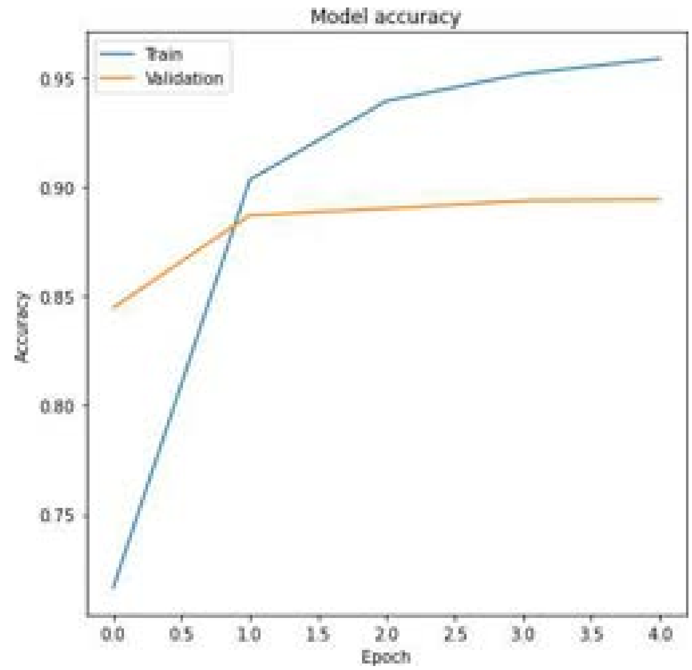

Fig. 9: Sentiment analysis LSTM model

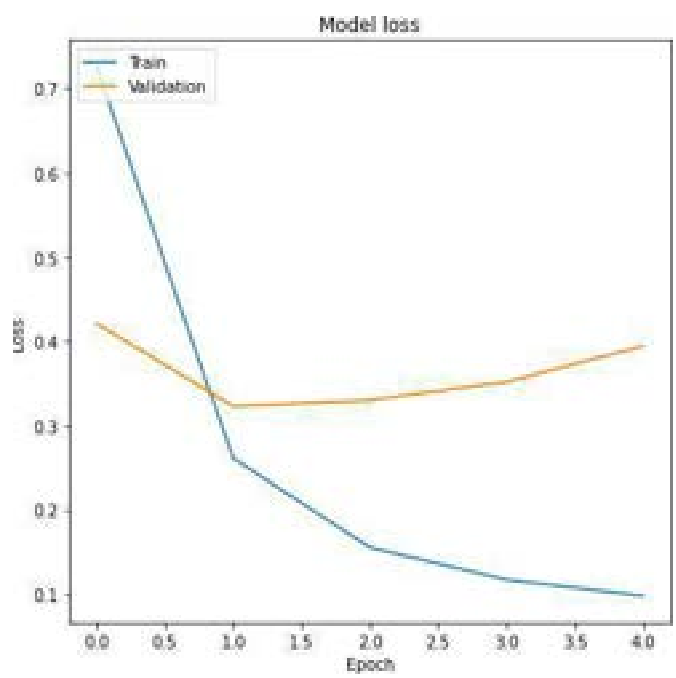

Fig. 10: Sentiment analysis LSTM model

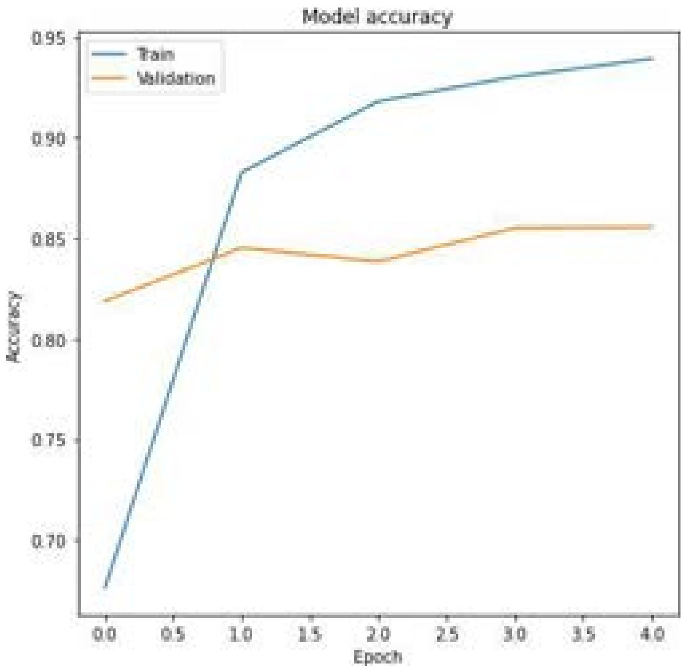

Fig. 11: Sentiment analysis RNN model

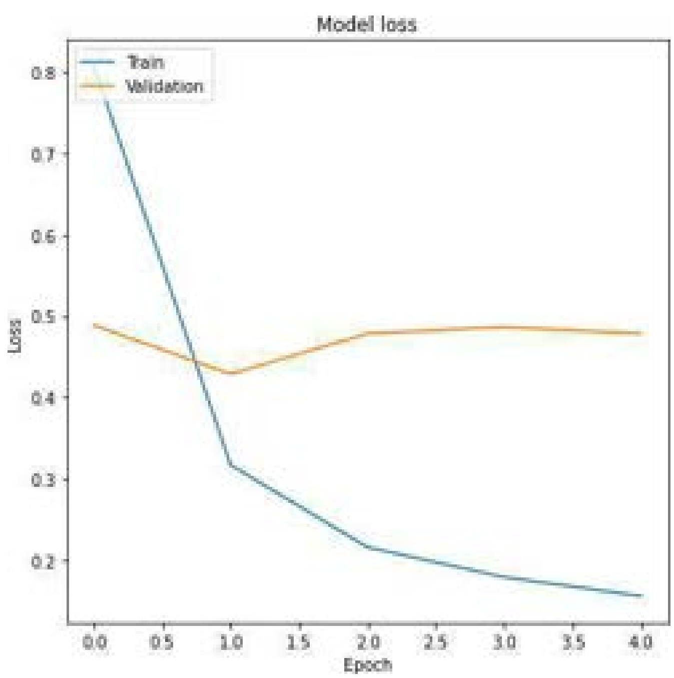

Fig. 12: Sentiment analysis RNN model

similar results in terms of accuracy with LSTMs showing negligible but observable increases in accuracy even though the LSTM model is substantially computationally harder to train.

Further accuracy and performance may be improved by increasing the number of layers and the number of nodes in each layer, choosing an appropriate learning rate and increasing the number of iterations. This method too has its limits. Improvements in and accuracy by adding more nodes and layers work only to a certain extent after which the gains stagnate and in a wide variety of cases the accuracy of the model may even decrease. Problems of overfitting may also be encountered which may be solved by regularization methods such as early stopping, weight decay, dropout etc. Adjusting and fine tuning these hyper parameters is a matter of repetitive trial and error, although previous literature into neural networks may prove insightful in setting these values. Similarly increasing the size of the word embedding or using pre trained word embeddings may improve performance. The size of these word embeddings too has a upper limit above which no further gains in accuracy are made. Usually, the size of these word embeddings is recommended to be set to around 300-500. Other methods to increase accuracy and performance are to train the model on a larger dataset with a diverse range of values.

V. CONCLUSION

In conclusion, delving into the comparison of various approaches for language understanding and translation provides valuable insights into their respective strengths and characteristics. The analogy of selecting the right tool for a task aptly captures the essence of these methods.

In a thorough comparison of models for machine translation and sentiment analysis, a meticulous approach has been devised. The first step involves selecting diverse datasets covering two languages for translation and various emotional content for sentiment analysis. Standardized preprocessing, including tasks like tokenization and cleaning, ensures consistency across datasets. LSTMs and GRUs outperform RNNs in accuracy for both tasks due to RNNs struggling with the vanishing gradient problem and the inability to capture earlier sequence features. While GRUs and LSTMs display comparable accuracy, LSTMs slightly outperform GRUs on both tasks. Despite LSTMs being computationally more demanding, they exhibit marginal accuracy gains over GRUs.

In essence, the comparative analysis provides a nuanced compass for decision-makers, researchers, and practitioners navigating the diverse landscape of language-related tasks. Looking ahead, the future scope of this research extends to several dimensions. The exploration of hybrid models and advanced techniques could further enhance the capabilities of sequence modeling architectures. Incorporating attention mechanisms, transfer learning, or ensemble methods may offer avenues for overcoming specific challenges identified in the comparative analysis.

***Abstract*—This study presents a deep learning model created for enabling comprehensive wildfire control by seamlessly combining satellite images, weather data and terrain details. Current systems face challenges in comprehensively analyzing these factors due to limitations in data integration, dynamic fire behavior prediction, and post-fire ecological impact evaluation. By improving detection and accurate assessment of impact, the system addresses all aspects of wildfire management from forecasting to post event analysis. The model integrates soil quality examination and vegetation regrowth simulation Using image analysis and state of the art deep learning methods. This holistic approach of Image analysis employs Convolutional Neural Networks (CNN) for predicting wildfire risk and Recurrent Neural Networks (RNN) for assessing soil and hydrological effects. This adaptable approach, which aims to transform the way fire control is done, can be readily adjusted to changing conditions and takes correlations between different aspects into account. It surpasses conventional techniques by including soil quality analysis, vegetation regrowth modeling, and vegetation damage evaluation. The adaptable nature of this method proves invaluable, in lessening the impact of wildfires with a focus, on evaluating vegetation damage and promoting restoration.**

***Index Terms*—Wildfire Management, Deep Learning Model, Satellite Imagery, Convolutional Neural Networks (CNN), Recurrent Neural Networks (RNN), Environmental Impact Assessment.**

I. INTRODUCTION

Wildfires are difficult to manage and require an understanding of their spatiotemporal dynamics. The objective is to analyze the works of Meneses [1], Hao et al. [2], considering Deep Learning for model development. The study integrates satellite imagery, weather data, and topographical information in order to address issues associated with predicting wildfires' spread accurately as well as evaluating the recovery of vegetation in accordance with objectives set forth by Akbari Asanjan et al. [3] and Chen et al. [4]. Furthermore, the authors also emphasize on the analysis of recovery patterns Rashkovetsky et al.'s [5] which further highlights the importance of the study's objectives. In other words, the aim is to provide decision-makers with early warning systems so that they will take measures in advance thus reducing negative consequences caused by wildfire outbreaks on either human or natural ecosystems.

The issue with wild fires is that they change quickly over both time and space hence necessitating in-depth knowledge regarding these movements for proper fire management strategies that can be adopted. The objective of the research was influenced by Meneses (2009) work, quoted from Hao et al. (2018), using deep learning method to develop a unified framework for modeling wildfire occurrences. By incorporating satellite imagery, weather data, and topography into their analysis efforts, the researchers intend to provide a means for making more precise predictions about future fires as well determining how plant life forms recover themselves after such natural catastrophes like those described in Akbari Asanjan et al.'s paper [3] or Chen et al.'s article [4]. Moreover, Rashkovetsky et al.'s article has emphasized recovery patterns segmentation as one among many significance areas under investigation within this study. Thus, it aims at facilitating prompt intervention through enabling decision makers foresee possible scenarios that may arise out of irregularities related to forest fires at their inception stage with the intention of minimizing destruction on ecosystems as well as communities. The difficulties associated with modelling fire spread are those of dynamic prediction – for instance, it's trying to take into account the potential for wind to change directions while incorporating terrain features and fuel availability. The DL Model is attempting to bring together these diverse inputs to provide decision-makers with knowledge about land features and fire spread in earlier time frames to inform their early interventions and coordinate resources needed for fire-fighting. The effort by data-centric approaches is to better maintain the balance between allocating resources to limit the impact of post-fire conditions on ecosystems and communities.

II. LITERATURE SURVEY

Ecological effects of wildfires are being researched more in detail in the last few years; the latter are coupled with different approaches and techniques. One of his output contains Meneses [1] whose data set is based on Landsat 8 OLI imaging and environmental biophysical data for vegetation recovery metrics in burned areas. Hao et al. [2] discuss the interannual effects of fire severity, weather as decided by climate, and post-forest-fire vegetation recovery. For example, Akbari Asanjan et al. [3]

formulate a probabilistic wildfire segmentation algorithm using supervised deep generative approaches drawn from satellite imagery and Chen et al. [4] implement deep learning strategies for wildfire segmentation of high resolution satellite imagery.

Meneses[1] and Hao et al.[2]have made a contribution to the understanding of the post- wildfire vegetation dynamics through the analysis of time series data. Additionally, they introduced the influence of fire severity and climate variability on the restoration of ecosystems on an interannual basis. Olga undertakes Landsat-8 OLI image analysis and biophysical data using for vegetation metrics assessment, while Hao and colleagues provide an insight into long-7-term ecological shifts. While those two studies may be able to keep track of complicated ecologic processes, they may not be accurate and may have high data variability. Moreover, Asanjan et al [3] and Chen et al. [4] model wildfire diagnosis in a newest manner which observes the deep learning and probabilistic segmentation algorithms. Even if the approach seems rather efficient for a monitoring process, acquiring big labeled sets and uncertainty boundaries when conditions differ must be properly addressed.

There is detailed information Kim et al. [6] on how to do real time monitoring of wildfires through integration of Unmanned Aerial Vehicles (UAVs) and satellite data which shows that these sources of information are complementing each other. Thangavel et al. [7] present a case study on autonomous satellite wildfire detection using hyperspectral imagery and neural networks, exemplifying practical applications of advanced technologies. Rashkovetsky et al.[5] delve into deep semantic segmentation for wildfire detection from multi-sensor satellite imagery, showcasing the versatility of deep learning in various data environments. Toan et al.[8] use an approach based on deep learning to detect early wildfires from hyperspectral satellite images thus underscoring the need for early intervention efforts.

For urban spaces, Khan and Khan [9] integrate a deep learning-based forest fire map and detection method called 'FFireNet' for smart cities; Sathishkumar et al. [10] apply deep learning for the detection of forest fires and smoke, demonstrating the versatility of these techniques to different ecological contexts.

Going beyond landscapes that are already on fire, other studies such as Bright et al [12] make use of Landsat time series analysis to investigate wildfire recovery of vegetation on 19 forest types across North America. Ambadan et al [13] used satellite-observed soil moisture as a proxy for wildfire risk — illustrating the utility of using environmental variables as predictors in predictive models.

Tree growth and stem carbon accumulation after drought and fire in Amazonian forests are evaluated following the ecosystem impact assessment approach used by Berenguer et al. [14]. Burn severity and undisturbed forest proximity are considered as key factors for tropical montane forest recovery [15], while wildfire recovery is monitored within the ecosystem impact assessment framework in Mongolia [16]. Li et al. [17] evaluated the impacts of wildfire on soil properties in a pine forest in South Korea using the ecosystem impact assessment approach.

An example of state-of-the-art approaches to estimating recovery of soil and vegetation are Zhongqiu Smith et al. [18] using deep learning for recovery assessment; Yuling Li et al. [19] using multi-source data fusion; Shangmao Wang et al. [20] using recurrent neural networks for temporal analysis of vegetation recovery; Dae-Hyeon Park et al. [21] examining spatial and temporal patterns after forest fires; Jeungwon Kim et al. [22] exploring the hydrological response.

Multi-sensor data fusion for nonwoven fire spread, and mapping burn severity and soil properties using integrated remote sensing data. The research by Yang et al[25] illustrates how deep learning can be used to predict post-fire vegetation regrowth patterns. These references serve to highlight both the current state of the art of monitoring wildfires, mapping vegetation recovery, and other associated ecological impacts that can be studied after a wildfire event.However, like many studies in this field, challenges such as computational complexity and uncertainties in remote sensing data.

III. Proposed System

The study investigates on an elaborate system of post-fire analysis dealing with challenges faced after the occurrence of wildfires. Soil and Hydrological Assessment is integrated with Vegetation Regrowth Assessment.

For the Soil and Hydrological Assessment, hyper-spectral images from 2002 Hayman fire are used to process through Spectral Unmixing and SemantiQNet deep learning architecture that result in a refined mask while Recurrent Neural Network (RNN) analysis improves estimates of important soil parameters leading to better understanding of post-fire ecology.

In Vegetation Regrowth Assessment, various satellite images are employed in computing indices such as NDVI and EVI which evaluate regrowth as well as overall vegetation health. These indices help to create masks highlighting regions with significant greenness thus acting as indicators for successful post-fire vegetation regrowth. The project makes a big contribution towards understanding post-fire ecosystem dynamics.

To sum up, integrating Soil and Hydrological Assessment into Vegetation Regrowth Assessment components which entails application advanced methods like spectral unmixing and deep learning architectures like SemantiQNet, Recurrent Neural Networks (RNN), etc., offers sophisticated approach to post-fire analyses [1][3][9] .In valuable insights into post-fire complexities, this system gives exact estimates of key soil parameters for vegetation growth while using a variety of satellite images and indices such as NDVI and EVI. To understand and manage post-fire ecological landscapes after wildfires, it is important to employ innovative methods as described in the articles [1][4] [14]. This will help post-fire ecological landscape recovery efforts be more sustainable reducing future risk from fire events.

A. System Architecture

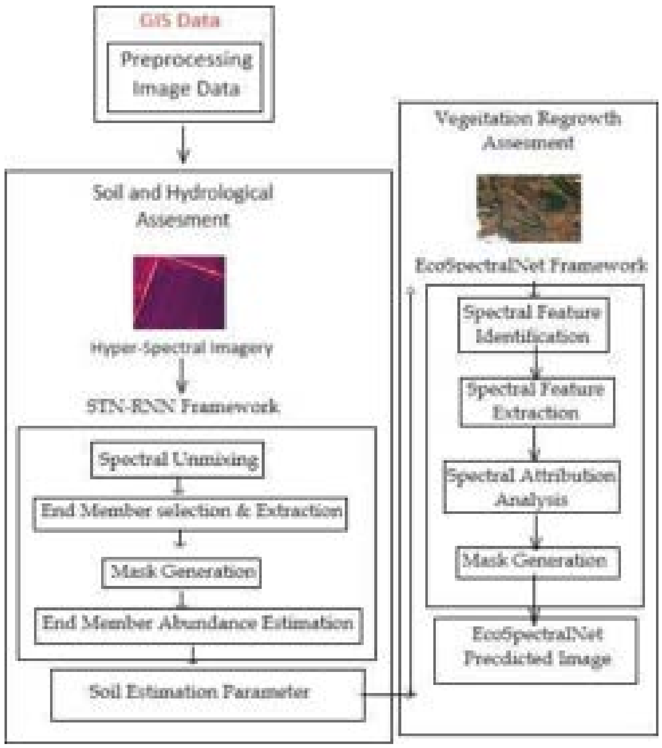

Fig. 1. System Architecture

Though, satellite photos are an integral part of GIS applications and they must be pre-processed with but it is essential. The purpose of data preprocessing is to be the bridge between a dataset's unprocessed raw form and its shaped data that can be manipulated. By performing vital processes like thermal and atmospheric correction to eliminate atmospheric interferences, geometric correction for distortions and radiometric correction which will ensure corrected colour representation, we can be able to achieve more accurate information. Subsequently, spectral identification and recovery of some unique spectral bands for each land cover category are carried on. The research gap is indeed important and deeper exploration can be made with more coherent methods like spectral abundance estimate and endmember extraction. While at first the image may serve as a distraction before gradually providing useful information, those pixels may later be rejected by a mask to eliminate the unwanted parts while the pre-processed data might be of high use for modelling or estimating soil parameters.

The research paper presents a well thought-out architecture designed to capture the intricate dynamics of post-fire landscape assessment. It affords the development of models that blend different data types with computation intensive techniques like deep learning to enhance understanding of wildfire aftermath. The use of Sentinel-3 satellite data plays an integral role for obtaining Land Surface Temperature. (LST) images that are crucial in quantifying fire severity based on temperature fluctuation during the fire outbreak itself. A novel deep learning framework, Optinet, fine-tuned using the Optuna Hyperparameter optimization algorithm is at the core of fire-damaged areas' classification and mapping; which in turn yields thematic maps that illustrate in detail how the distribution and intensity of fire-induced damages. Furthermore, hyper-spectral imagery from the 2002 Hayman Fire in Colorado plays a significant role in this architecture. To eliminate extraneous spectral data, as well as to create a mask, Spectral Unmixing guided by SemantiQNet deep learning architecture is used. These are later fed into Recurrent Neural Network (RNN) for dependency modeling that gives important estimates of soil parameters that are essential to post-fire vegetation growth understanding.

NORMALIZED DIFFERENCE VEGETATION INDEX (NDVI) AND GREEN NORMALIZED DIFFERENCE VEGETATION INDEX (GNDVI)

The formulas for NDVI and GNDVI are given by:

$$\text{NDVI} = \frac{\text{Band 5 (NIR) - Band 4 (RED)}}{\text{Band 5 (NIR) + Band 4 (RED)}} \quad (1)$$

$$\text{GNDVI} = \frac{\text{Band 5 (NIR) - Band 3 (GREEN)}}{\text{Band 5 (NIR) + Band 3 (GREEN)}} \quad (2)$$

B. Soil and Hydrological Assessment

For effective ecosystem restoration, the study presents an innovative approach to post-fire landscape assessment. After the Hayman fire in Colorado [1], hyper-spectral imagery from drones was utilized as a basis for soil analysis and hydrology with its integration of advanced techniques.

The methodology commences with Spectral Unmixing technique which is a remote sensing method for classifying mixed pixels based on their spectral signatures [2]. SemantiQNet deep learning architecture enhances spectral analysis enabling precise material identification leading to filtered masks [25].

The inclusion of RNNs puts in the temporal dimension that captures dynamic changes over time[3]. recurrent neural networks (RNNs) take advantage of the sequential nature of hyperspectral data, which is widely employed in soil spectroscopy, to start. The data frequently shows dependencies, in which the spectral signatures of one data point depend on those of earlier ones. Conventional methods are not very good at capturing this feature. RNNs are particularly good at learning both short- and long-term dependencies, which is essential for effectively modeling hyperspectral signals. Second, by combining with dimensionality reduction methods like Principal Component Analysis (PCA) and Locality Preserving Projections (LPP), RNNs help in feature extraction from high-dimensional data. The procedure provides a good result when compared to other methods by reducing computational complexity but not much in information at the spectral level. The implementation of RNN in this case also involves accounting for both the spatial and temporal fluctuations in soil parameters that may vary within fields since RNN capture time series well. Given their ability to simulate complicated non-linear processes, soil features describing environmental conditions (such as temperature, humidity, depth, and salinity) can be predicted with high accuracy. Lastly, the recent developments of RNNs have contributed to the optimization of the algorithm, neural design and regularization approaches. So, the remarkable advancement in the deep learning becomes the power of the models which can be used for the assessment of the soil attributes from the hyperspectral data. RNNs in particular, are one of methods based on which improve of the soil parameters estimates is achieved, as they can calculate high-dimension data, detect serial dependencies, and generate complex interactions between spectral signatures and soil properties.

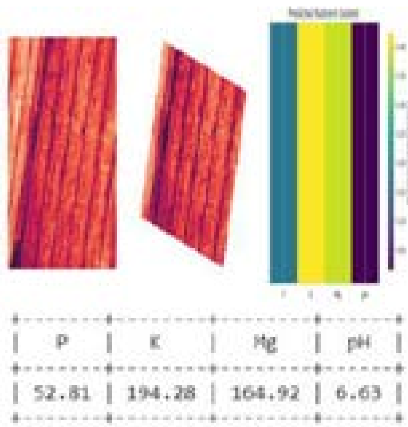

Fig. 2. Soil and Hydrological Assessment

C. Vegetation Regrowth Assessment

The Vegetation Regrowth Assessment phase is an essential part of the research project, with a specific focus on a systematic evaluation of vegetation recovery after wild fire events.

Ecospectral Net, a neural network especially designed for the manipulation of the dataset that covers ecological and spectral aspects, is a tool that might play a canonical role as a supplement to the existing techniques deployed in the Vegetation Regrowth Assessment step. Through CNNs that play a critical role, it tries to complete the preprocessing of data, features extraction, and generation of output as an automated process. Therefore, the system simplifies processes of the past where manual feature engineering was required. The sophisticated CNN structure of its multi-layered system can handle the complexities of the ecological data by acquiring the high accuracy of land analytics, such as vegetation analysis, soil properties mapping, habitat observation, and land cover change detection. Ecospectral Net acts as an additional instrument on top of automation and accuracy in understanding complicated environmental problems by being a dependable tool for researchers and conservationists in environmental science and practice in conserving the ecosystem. Its capability to work with lots of ecological datasets and spectral features enable the Earth Spectral Net to be a versatile technology; the adaptability can help with scalability of real-time environmental change monitoring and suitability for utilization. Since it is a simple interface and weight-bearing construction that ensures reliably performance even in the difficult field conditions.

By utilizing a wide array of satellite imagery, the project seeks to identify growth patterns as well as detect land cover changes [26]. The generated Normalized Difference Vegetation Index (NDVI) reads as:

$$NDVI = (NIR - Red) / (NIR + Red)$$

NDVI and Enhanced Vegetation Index (EVI) are the key players here since they provide quantitative indicators of vegetation density and health [3]. These indices help in spatial insights and metrics for successful vegetation recovery thereby enhancing our knowledge about the wildfire effect on ecosystems. The study re-emphasizes the importance of advanced image processing techniques and important vegetation indices for full assessment of post fire vegetation dynamics [6].

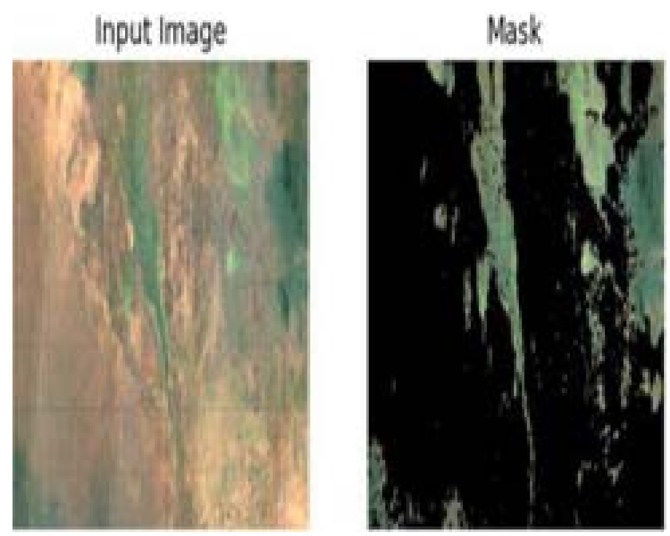

Fig. 3. Vegetation Recovery

The study emphasizes the importance of using image analysis methods and important vegetation indicators to evaluate the changes, in vegetation after a fire [6]. By utilizing NDVI and EVI this study provides information on the spatial distribution of new growth and the overall condition of plants in areas affected by fires. The detailed method, involving the NDVI adds to the area of wildfire control and ecosystem rehabilitation highlighting the significance of data driven approaches, in comprehending environmental effects

IV. Result And Discussion

The research work outcome also indicates a high degree of execution of the strategy by introducing strong points and the cutting out weaker ones. Regarding change assessment during a natural wildfire, the Optinet model alongside LST photos was found to be quite reliable and in good agreement with the spatial distribution and degree of damages. If we place Optinet against ADNet and RNN models in terms of performance, it is superior in accurately mapping the Vegitation areas with different degrees for model accuracy. Through the meteorological satellite images and the STN-RNN model, the soil and hydrological appraisal has yielded in-depth understanding of the post-fire processes (figure 4). The STN-RNN model many well, did justice to the temporal changes and dynamic processes occurring in the soils and hydrological properties. What follows is also an accuracy spatial part of the model in which exact post-fire soils parameters and hydrological parameters are marked in (Figure 5).

MODEL	MAE	MSE	MSLE	RMSE
CNet	1.121	112.129	0.167	2.619
AdaNet	0.907	90.716	0.201	9.524
OptiNet	0.068	6.963	0.203	10.589

Fig. 4. Evaluation Of Different models

Entering the discussion part, the research method is shown to be in perfect link with holistic evaluation by the yielding of predicted soil parameters which is also supporting the entire approach in its ability for synthesizing patterns of data. Through the function, one can not only extract such practical information that are difficult to get in a natural system which always changes complicatedly after the occurrence of fire. The research from this project is very wide ranging, and by using many different data sources together into a network of connected neural structures, its importance to the environment sciences is highlighted. The initiatives's knowledge proclivity to be continued discoveries of the use of artificial intelligence to sustain ecosystem management post wildfire make the project of future unrestricted. The research can be vital in enhancing knowledge about ecological recovery procedures and consequently, help in responding to the negative impacts of wildland fires and restoring ecosystem resilience.

Precision is attained by techniques like for instance Spectral Unmixing and SemantiQNet providing for the purpose of better distinguishing of materials and spectral analysis. Recurrent Neural Networks (RNNs) is one mean of incorporating temporal changes and to a great deal helps in unraveling the complexity of landscape dynamics. Spatial analysis that these aforementioned vegetation indices (i.e., NDVI and EVI) may supply in association with satellite images can lead to the retrieval of the quantitative indicators of vegetation health. These approaches that are based on data-driven techniques lead to better results, focusing the value of the complex picture processing and vegetation indices. Stakeholder involvement, sensitivity analysis, and data regulation are a few factors that provide data consistency and they assure the efficacy of the decisions that are made. While employed together, these methods help to better the outcomes and deliver important information for the maintenance of the ecosystems, and elimination of the wild fire hazard risks.

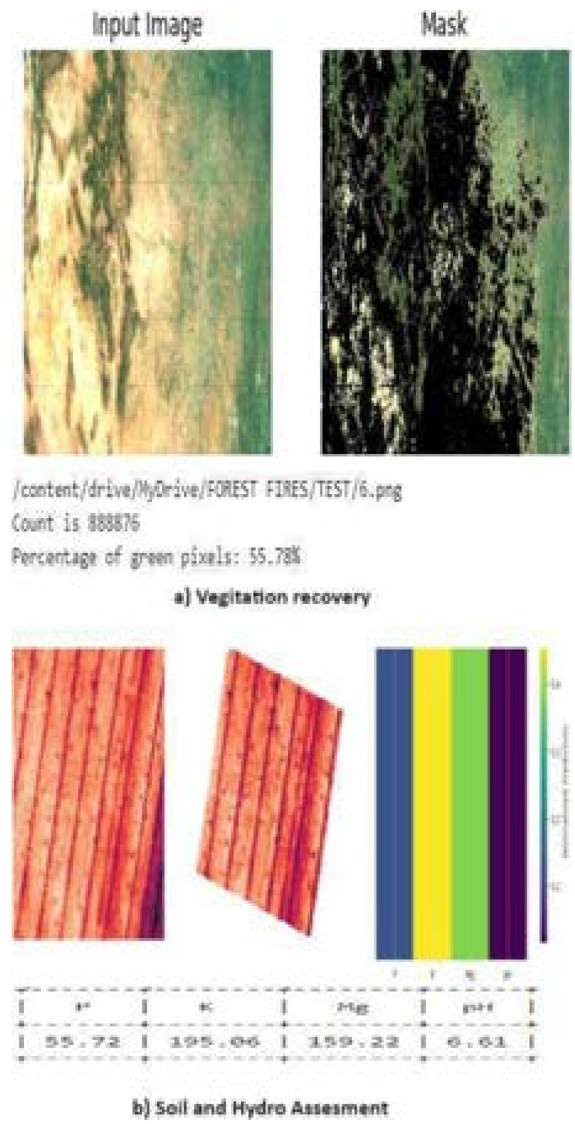

Fig. 5. Evaluation Metrics

MODEL	MAE	MSE	MSLE	RMSE
STN-RNN	0.2501	0.0645	0.0007	0.2539

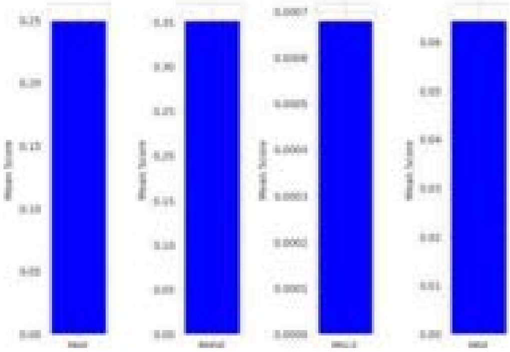

Fig. 6. Soil-Hydrological Assessment Evaluation

V. CONCLUSION

In conclusion, the research work effectively employed a combination of state-of-the-art technologies such as Eco-SpectralNet, STN-RNN and OptiNet to address the complex challenges of post-fire ecosystem dynamics. The framework has shown great potential in generating accurate masks using SemantiQNet that can be used for comprehensive evalua tion including forest and vegetation growth as well as soil and hydrological impacts. Among the reasons why is Eco-SpectralNet spectral analysis has been instrumental in enhancing our understanding of the aftermath of fire landscape leading to sophisticated evaluations. Soil and hydrological impacts which are constantly changing over time have been capably captured by the dynamic framework that integrates STN-RNN with CNet.

The collaboration between AdaNet and OptiNet is highly important because it helps in optimizing neural network models so that they become efficient and accurate with respect to mask production before evaluating them. Based on various datasets supported by intricate neural network structures, the procedures used in the project have provided a way to understand how different ecological parameters interact after a wildfire occurs. On purpose, the method does not include burn severity but instead focuses on an all-inclusive approach to assess ecosystem recovery.

Another use of SemantiQNet is that it speeds up the identification of ecosystem restoration and forms a basis for a comprehensive evaluation. The methodology of the research paper, which combines state-of-the-art technologies with a thorough evaluation framework, provides an opportunity to inform on forest fire management and strategies for restoring ecosystems. The approach is robust due to its ability to capture the ever evolving nature of post-fire processes making it an important contribution in the wider field of environmental science. From now onwards, we will be able to make way forward into consistent advancement towards achieving sustainable cities through sincere application as derived from project findings based on artificial intelligence.

VI. FUTURE WORKS

Some possible directions for future research that can increase post-fire ecological understanding and management. Such as exploring additional data sources such as high-resolution satellite images and LiDAR data to improve landscape assessments. This will also include better spatial and temporal resolutions with real-time monitoring providing opportunities for accurate information delivery at the right time towards more effective wildfire management. Future work should entail efforts to strengthen AI-generated assessments by reducing uncertainty through rigorous validation processes and incorporating ground truth data. It is therefore important to consider climate change impacts, collaborate with interdisciplinary teams and local communities while developing comprehensive ethical wildfire management strategies. The paper lays a groundwork for further studies emphasizing a need of thinking outside the box regarding how wildfires affect ecosystems and society in general.

ACKNOWLEDGMENT

We sincerely appreciate the Rajalakshmi Institute of Technology administration for providing the facilities and resources that were necessary for our project to be completed success- fully. Our principal, Mr. N. Bhalaji, deserves special recognition for his steadfast assistance and provision of essential materials. We are incredibly grateful to our mentor, Dr. Anjana Devi, who is also the head of the Department of Computer Science and Engineering (CSE), for all of her help and inspiration during this project. Her knowledge played a crucial role in directing our investigation. We also thank our project coordinator, Dr. Anjana Devi, for her unwavering advice and assistance. We express our gratitude to the dedicated staff members of the CSE Department for their best wishes, prompt help, and steadfast support during the course of the project. Finally, we would like to sincerely thank our families, friends, and relatives whose unwavering support was invaluable to us during our academic path. It would not have been easy to reach this degree of accomplishment without their help.

This research study focuses on the application of modern day technologies like Internet of Things (IoT) in the field of Home Automation and aims to improvise the traditional boiling process of Fluids. Many times in industries as well as our homes, there exists a common problem of overheating and overflowing of fluids due to inefficient manual management of heating of fluids. To find a smart and durable approach as a solution to our problem, we made an attempt to design a smart system which would incorporate new-age technologies like IoT and Firebase Database. The proposed system architecture integrates a DS18B20 temperature sensor for precise temperature measurement and an ESP32 microcontroller for data processing and communication. The temperature data is sent to the Real-time Firebase database, which is then fetched into the dashboard for getting instant information. A dedicated application is designed with user friendly design so as to make this solution easily accessible for the masses. Instead of relying on traditional methods of temperature monitoring, the system utilizes Firebase Realtime Database as a custom cloud solution for storing and retrieving temperature data. A Linear Regression model was employed on the dataset to predict the boiling temperature of the fluid under consideration. This would make the prototype product more robust and predict the boiling temperature on its own through data-driven decisions. Thus this a prototype of the product IoT Based Smart Boiling detector, designed to serve a possible and durable solution to the problem.

Keywords— Home Automation, Internet of Things, ESP-32 Microcontroller, DS-18B20 Temperature Sensor, Firebase-Realtime Database, Linear Regression, Gradient Boosting

I. Introduction

Controlled heating plays a very important role in industries and even in households. Due to in-efficient management and manual errors this causes hazards and accidents in many of the industries or households resulting in losses [1]. There are many instances when there are losses due to overheating and improper handling of heating of liquids at their respective boiling point temperature.

In 2021, supply chain disruptions increased by 88% over the prior year, according to supply chain monitoring firm Resilinc., and almost 90% of these were caused due to manual errors and unskilled labours.

Therefore industry still needs to carry out these high temperature related tasks more efficiently so as to optimize energy usage and prevent hazards. [1]

Home automation has achieved a lot of popularity in recent years, as day-to-day life is getting simpler due to the rapid growth of technology. Almost everything has become digitalized and automatic [12]. The IoT-Based Smart Boiling Detector is a system designed to monitor and control the boiling process of liquids, providing a smart and convenient solution for users. The project incorporates Internet of Things (IoT) technology to enhance the traditional boiling process, making it more intelligent and user-friendly. The uses would be able to dynamically adjust the threshold temperature using a widget. The project also incorporates Linear Regression based Machine Learning which would help the model set the boiling point dynamically without manual intervention. Once the threshold temperature is configured the ESP-32 would communicate with temperature sensor and database and send the real time temperature data. Further a linear regression model is employed so as to predict the boiling threshold of the liquid. The core functionality revolves around precise temperature monitoring using DS18B20 sensors, enabling users to dynamically set and adjust the boiling point temperature through our custom Design application [3]. Real-time notifications are dispatched upon reaching the boiling point, ensuring timely response and avoiding overboiling.

The data retrieved from the ESP-32 is stored in Firebase Database, which can be used for implementing the Machine Learning models to improve efficiency and optimize the energy usage as future scope to this paper.

II. MATERIALS/COMPONENTS USED

A. Circuit Diagram

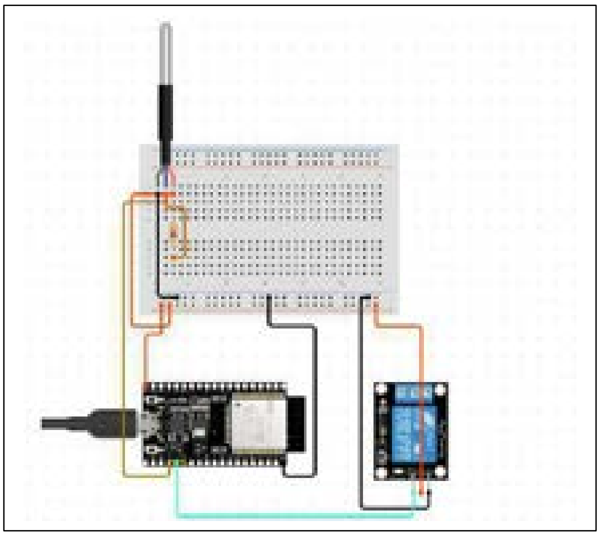

Figure 1: Circuit Diagram showing connections between the components

B. Components Specifications :

1. DS18B20 Temperature Sensor:

   DS18B20 is a digital temperature sensor manufactured by Maxim Integrated (formerly Dallas Semiconductor). It's widely used due to its high accuracy (±0.5°C) and broad temperature range (-55°C to +125°C). The DS18B20 provides a accurate temperature readings with a resolution of up to 12 bits. We connected the DS18B20 sensor to the ESP32 microcontroller using the One-Wire communication protocol. [2] It follows a single-wire protocol, allowing communication through just one data line. Each sensor has a unique 64-bit serial code, enabling control of multiple sensors using a single microcontroller pin.

   DS18B20 Sensor:

This study used this particular sensor as it provides a higher range for effectively measuring temperatures as it has a temperature range (±0.5°C) and a temperature range (-55°C to +125°C). Apart from this it is easy to use and gets easily configured and connected with ESP-32 micro-controller with the help of libraries like onewire.h and dallastemperatures.h which provide built in methods which allow easily to request temperatures from the sensor. These sensors communicate on a single data line, this further enables us to connect multiple DS18B20 sensors via a single data pin and which can further enhance our accuracy.

Pin Configurations:

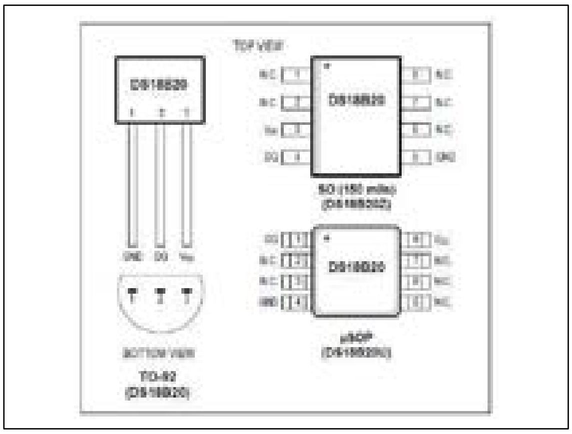

Figure 2: Pinout diagram of DS18B20 Sensor [8].

2. ESP-32 Microcontroller

The ESP32 is a powerful microcontroller board with built-in Wi-Fi and Bluetooth capabilities, making it ideal for IoT applications. [7] ESP-32 board was programmed and interfaced with the DS18B20 sensor, to read temperature data, and perform data processing tasks. [8]

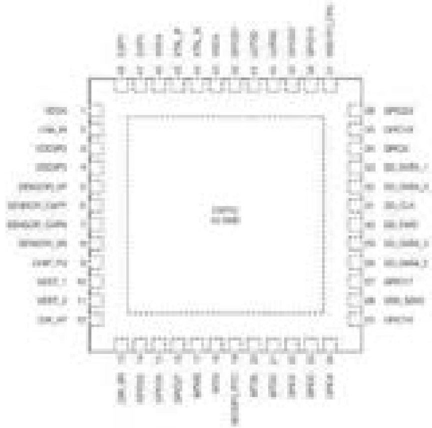

Figure 3: Pin configurations of ESP-32 Microcontroller [7]

The ESP32 board was responsible for Initiating communication with the DS18B20 sensor using the One-Wire library [8]; Requesting temperature readings from the sensor at regular intervals [6][8]; Processing the temperature data to determine if the boiling threshold had been reached; Sending notifications or alerts when the boiling temperature was detected; Connecting to the Wi-Fi network to enable cloud connectivity for data transmission [7].

3. Relay Module

It is used to control the heating source. i.e. when the temperature reaches the boiling point of the liquid, the relay gets turned on and it breaks the connection between the main switch and the heating source. [4] The Relay module was dynamically controlled using ESP-32, the NO terminal and COM terminal were given the connections to the heating source i.e 220 VAC Mains and the switching was controlled by digital pin connected to a GPIO pin on ESP-32.

4. Firebase Database

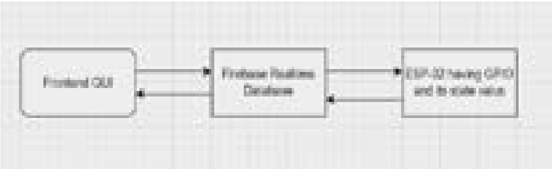

Figure 4: Block Diagram showing communiation between database and ESP-32 microcntroller.

The database used in our study is hosted on Firebase, a cloud-based platform that provides scalable real-time database solutions. Figure 4. Firebase offers robust data storage, synchronization, and authentication features, making it an ideal choice for our IoT-based application. Each data point, comprising timestamped temperature readings, is securely stored in Firebase's structured JSON format. For connecting the firebase database with esp-32 we are using the library Firebase Client which provides access to Firebase Realtime database.

III. METHODOLOGY

A. Methodology Implemented for Interfacing between ESP-32 Micro-controller with DS-18B20 sensor and Relay Module

The DS18B20 sensor provided real-time temperature data to the ESP32 microcontroller [7][8]. The connections were made as per the circuit diagram illustrated in Figure 1, the one wire communication was facilitated between ESP-32 via a digital GPIO on ESP-32. [7] Additionally, a 4.7 K Ohm pull-resistor was used between the data-pin and +VCC pin (at 3.3V) to pull the data signal received from the sensor. [2][8] The data received by ESP-32 micro-controller was sent to the real time Firebase Database[6]. When the boiling temperature threshold was reached, the ESP32 triggered notifications or alerts to inform users of the event. This was carried out by a third part library which is popularly used for these purposes.[6][7]

B. Methodology Implemented for carrying out Integration between ESP-32 and Firebase Realtime Database

The connection between the Firebase and Esp-32 was carried out by using the external library provided by Arduino IDE on their open source IoT projects development platform. The custom project was set up in Firebase console and the API keys were used as per documentation to carry out seamless flow of data between the microcontroller and Firebase[6]

The advantages of using this model were as follows:

Remote Access: Firebase provided a platform-independent interface for accessing temperature data from anywhere with an internet connection. Users could remotely monitor the boiling process and view real-time temperature readings through a web or mobile application connected to Firebase. [6]

Data Storage: Firebase Real-time Database served as the central repository for storing temperature data captured during the boiling process. The ESP32 microcontroller transmitted temperature readings to Firebase in real-time, ensuring that the data was promptly stored and made available for further analysis. [6]

Real-time Updates: Firebase Real-time Database facilitated real-time synchronization of temperature data between the ESP32 microcontroller and cloud storage. As new temperature readings were received, Firebase automatically updated the database, enabling users to access the latest data instantaneously.

C. Methodology for getting real time updates

For getting real time updates and notification we will be providing an application having GUI components or widgets which would be updated after data is fetched in real time from firebase database.

1. Currently in testing phase we have done the testing via JSON data and ensured that data is updated in real time.

D. Methodology for Implementing the Linear Regression Model for carrying out Predictive Analysis

Based on the Dataset prepared from the readings, a csv file was generated during the experimental phase which had the data fields as : timestamps and Temperature (in Celsius). The Linear Regression model was chosen as the temperature readings in the dataset appeared to be varying linearly with timestamps.[10] The plot of the linear regression model was plot using scikit-learn, a python library used extensively for Exploratory data analysis [10]. The plot (Figure[4]) revealed a few exciting results which can be used for further exploration and developing ML algorithms. The Linear Regression Plot (Figure[4]) obtained assumes that the residuals (the differences between observed and predicted values) are normally distributed. While this assumption may not always hold perfectly, deviations can often be mitigated through data preprocessing techniques or by considering alternative regression approaches.

Methodology Implemented for generating the Plot of Linear Regression Model:

The data, initially in JSON format is converted in CSV file. This data contains timestamps and temperature observed at that particular instance of time.

Then a model of linear regression is used as the data seems to be varying linearly with time for most of the time-period with a little bit of deviation as seen in Figure 5.

We then tried to find out slope of the graph, i.e. d(temp)/dt and compared the slope at different instances of time.

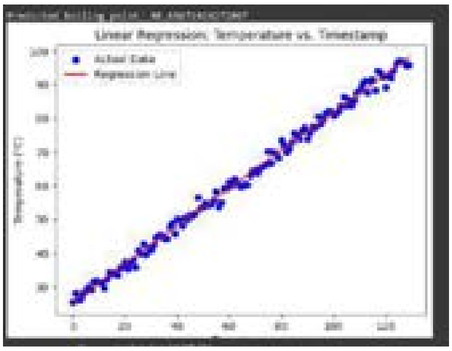

Figure 5: Plot of Linear Regression Model when applied to our custom dataset.

The plot in Figure 5 clearly depicts a linear trend between the dependent and independent variable , here time and temperature. Thus , this shows that there is a consistent relationship between the two variables.[9][10]

The regression line as observed in Figure 5 closely follows the data points , thus indicating that linear regression is a potentially good model fit for this study. The coefficients of the linear regression model can be interpreted to understand the quantitative impact of the independent variable (e.g., time, temperature) on the boiling point. The above mentioned Linear Regression was implemented as temperature was appearing to be increasing in a linear fashion with respect to time, although it's not always the case and once we reach the boiling temperature the temperature values remain constant due to Latent Heat of Vaporization.

IV. RESULTS AND DISCUSSION

IoT based Smart Boiling Detector monitors and controls the boiling process of any fluid. This project is useful for both industrial and domestic purposes. With the use of this detector, we can prevent the overflowing or overboiling of any liquid. By integrating Internet of Things (IoT) technology in this model we can get real-time monitoring of boiling activities, alerting users when fluid reaches the temperature that we already fixed or when boiling of the liquid is reached thereby preventing the accidents.

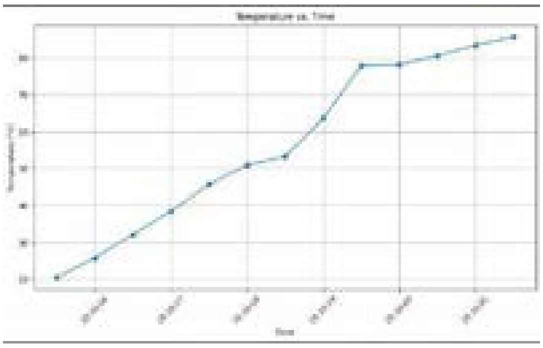

Figure 6: Dynamic Plot Of Temperature V/S Time carried out during experimental Phase

The plot done in fig 6 was observed while doing the experiment of our model, and a linearly increasing pattern was observed, as the temperature approaches the boiling point the graph starts becoming parallel towards the X-Axis indicating latent heat of vaporization, so the temperature stays constant in this phase.

A. Comparative Analysis of the Proposed Model and Existing Techniques

Some common existing techniques involve setting up the threshold as per boiling temperature manually, so traditional threshold-based methods rely on predefined temperature thresholds to detect the boiling point of a liquid. While simple to implement, these methods often lack adaptability and may yield inaccurate results under varying conditions. Additionally, they do not leverage historical data or incorporate predictive capabilities, limiting their effectiveness in dynamic environments. One of the main drawbacks of threshold-based methods is their lack of adaptability to different conditions. Since the threshold is fixed, it does not account for variations in ambient conditions, pressure, or properties of the liquid being monitored.

As a result, the method may yield inaccurate results in situations where the temperature dynamics are complex or fluctuate rapidly. They rely solely on the current temperature reading to determine if boiling has occurred, without considering the temperature trend or rate of change. This lack of predictive capability can lead to false positives or false negatives, especially in scenarios where the temperature approaches the threshold gradually.

Table 1 discusses these comparisons in detail:

TABLE 1: COMPARATIVE ANALYSIS BETWEEN PROPOSED MODEL AND THRESHOLD BASED EXISTING TECHNIQUES

Sr, No.	Parameters/Qualities	Existing Techniques	Proposed Technique
1	Simplicity	They are relatively simpler to set up.	It is also quite simple, but needs a GUI and also stable connection.
2	Predictive Capability	They are previously determined with	The model is trained on regression and

		threshold fixed as per fluid	gradient boosting to predict threshold in run time.
3	Sensitivity to noise or manual errors	They are quite sensitive to errors/mistakes in setting up thresholds.	They are less prone to errors as they are trained on historical data logged in database
4	Accuracy	Less accurate	Moderate to high accuracy can be achieved by improving more features and boosting
5	Threshold Setting	Manual/predetermined	Determined during run time.

V. CONCLUSION

This innovative system helps in conservation of energy by avoiding unnecessary boiling as well as it offers users peace of mind by minimizing the risk of overheating mishaps. Overall, the project shows the potential of IoT applications in creating smarter, safer and more efficient products

***Abstract*— Ensuring consumer safety and maintaining milk quality are of utmost importance in the dairy industry. A recent research initiative introduces an innovative milk detection system that leverages Fourier Transform Infrared (FTIR) spectroscopy. This cutting-edge system utilizes FTIR analysis to evaluate the chemical composition of milk samples, enabling precise determination of their quality. By incorporating advanced machine learning algorithms for data interpretation, the system categorizes milk samples into distinct quality grades, effectively identifying adulteration, contamination, and compositional alterations. The implementation of this system holds the potential of attaining substantial improvements in milk quality control protocols, thereby safeguarding consumer health and enhancing overall confidence in milk products.**

Keywords— *Quality milk, Detection system, Fourier Transform Infrared (FTIR) spectroscopy*

I. INTRODUCTION

Milk is a vital food consumed widely for its nutritional value, demanding stringent quality standards to uphold consumer safety and health. To maintain such standards, it's crucial to detect any adulteration, contamination, or changes in composition. Fourier Transform Infrared (FTIR) spectroscopy is an analytical method widely used in the food industry for precisely identifying and quantifying the chemical composition of various samples.

Ensuring consumer safety involves closely monitoring alterations in milk composition, identifying contamination, and detecting adulteration. While methods like chromatography and mass spectrometry are commonly employed for milk analysis, they pose limitations such as high costs, extensive training requirements, and time consumption. In contrast, FTIR spectroscopy offers a rapid, non-destructive, and non-invasive means of analyzing milk samples, providing comprehensive insights into their chemical composition [1].

The proposed Quality Milk Detection System combines FTIR spectroscopy with machine learning, offering an innovative approach to milk analysis. This system employs an FTIR spectrometer to gather spectral data from milk samples, which are then processed using various techniques. Following this, a machine learning algorithm is trained via supervised learning to categorize milk samples based on their chemical makeup. The system boasts several advantages, including its non-destructive nature, swift analysis time, and high accuracy in detecting compositional changes in milk.

By facilitating the identification of milk adulteration, contamination, and alterations in composition, the Quality Milk Detection System has the potential to bolster safety measures and safeguard consumer well-being. In essence, this proposed system utilizing FTIR spectroscopy and machine learning represents a significant advancement in milk analysis, promising to revolutionize quality control and safety assessments within the milk industry, ultimately ensuring consumer safety and health.

II. LITERATURE REVIEW

Fourier Transform Infrared Spectroscopy (FTIR) has become increasingly valuable in food analysis due to its remarkable sensitivity, speed, and accuracy. This analytical technique has proven highly effective in determining the chemical composition of various substances, including milk, through numerous studies that have explored its potential.

Al-Othman et al. (2013) conducted research utilizing FTIR to identify adulterants like urea, glucose, and starch in milk, affirming the method's reliability in detecting such additives. Similarly, Bovio et al. (2017) utilized FTIR to accurately identify various bacterial strains present in milk samples, demonstrating its precision in detecting bacterial contamination.

Contributing to this area, Baziou et al. (2020) employed FTIR to monitor changes in the chemical makeup of stored milk samples, showcasing its sensitivity in detecting alterations during storage.

The proposed quality milk detection system, integrating FTIR with machine learning, presents an innovative approach to milk analysis, promising a reliable and precise method for detecting compositional changes, contamination, and adulteration. To further enhance its effectiveness, complementary analytical techniques like chromatography and mass spectrometry can be integrated.

Overall, FTIR spectroscopy has proven to be a powerful tool for milk analysis, with the potential to significantly improve quality control and safety assessment in the milk industry [2]. The proposed quality milk detection system, combining FTIR with machine learning, shows promising results, marking a significant step towards ensuring consumer safety and well-being.

III. PROBLEM STATEMENT

Maintaining the safety and quality of milk products poses significant challenges for the dairy industry, including complex supply chains, variations in milk composition, and the pervasive problem of adulteration and contamination. While conventional methods like chromatography and mass spectrometry are effective, they are also time-consuming, expensive, and require specialized expertise. Thus, there is an urgent need for a rapid and reliable method of milk analysis capable of accurately detecting changes in composition, contamination, and adulteration.

Fourier Transform Infrared Spectroscopy (FTIR) has emerged as a promising solution due to its non-destructive nature and rapidity in milk analysis. However, to effectively classify milk samples based on their chemical composition, a robust FTIR-based Quality Milk Detection System is essential. The goal is to develop a dependable and precise system tailored specifically for quality milk detection. This system aims to accurately identify alterations in milk composition, detect contamination, and pinpoint instances of adulteration. Implementation of such a system in the dairy industry would streamline quality control efforts and bolster safety assessments, ultimately leading to increased consumer confidence and the production of high-quality milk products [3].

IV. METHDOLOGY

The development of a quality milk detection system utilizing Fourier Transform Infrared (FTIR) spectroscopy involves a systematic methodology aimed at ensuring precise and dependable results. This methodology comprises several essential steps, commencing with sample preparation. Milk samples are gathered from diverse sources and appropriately stored before being thawed and homogenized to ensure uniformity.

Subsequently, the process moves to spectral data acquisition, where FTIR spectra are generated using a Fourier Transform Infrared spectrometer. The milk samples undergo scanning across a range of wavelengths, and the resultant absorption spectra are recorded. To refine the data quality, preprocessing techniques like smoothing, baseline correction, and normalization are applied to eliminate noise and baseline offsets [4].

Following preprocessing, feature extraction techniques come into play to derive meaningful insights from the preprocessed spectra. Methods such as principal component analysis (PCA), partial least squares (PLS), or wavelet transforms are employed to represent the chemical composition of the milk samples [5].

The extracted features and their corresponding labels are then utilized to train machine learning algorithms using a supervised learning approach. Algorithms such as support vector machines (SVM), artificial neural networks (ANN), or random forests (RF) are employed to classify the milk samples based on their chemical composition.

The performance of the trained models is assessed using various metrics such as accuracy, precision, recall, and F1-score. Cross-validation techniques like k-fold cross-validation or leave-one-out cross-validation are utilized to validate the models.

Upon successful development and evaluation of the models, the FTIR Milk Quality Detection System can be deployed in the dairy industry for quality control and safety assessment purposes. This system possesses the capability to identify changes in milk composition, detect contamination, and pinpoint instances of adulteration, thereby ensuring consumer safety and health [6].

In summary, the FTIR Milk Quality Detection methodology encompasses sample preparation, spectral data acquisition, preprocessing, feature extraction, data modeling, model evaluation, and implementation. This holistic approach offers a robust and accurate method for milk analysis, with the potential to transform quality control and safety assessment practices in the milk industry.

V. VGG16 ARCHITECTURE

The VGG-16 architecture, known for its effectiveness in convolutional neural network (CNN) designs, has garnered considerable attention in computer vision applications such as image classification, object detection, and segmentation. Recently, researchers have explored the potential of utilizing VGG-16 to develop quality milk detection systems that incorporate Fourier Transform Infrared Spectroscopy (FTIR).

FTIR serves as a valuable analytical technique for identifying and quantifying the chemical composition of milk. By analyzing the absorption of infrared radiation by milk samples, FTIR provides insights into critical quality indicators like protein, fat, carbohydrate content, somatic cell count, and milk stability [7].

In the proposed quality milk detection system using FTIR, researchers suggest integrating VGG-16 to analyze the spectra generated by the FTIR instrument. The FTIR spectra undergo preprocessing steps to remove noise and normalize the data before being fed into the VGG-16 network. Through this process, the network learns to recognize patterns within the spectra corresponding to different milk quality indicators.

One advantage of employing VGG-16 for quality milk detection is its deep CNN architecture, enabling the learning of intricate features from the input data. This capability allows the network to discern subtle differences within the FTIR spectra that may be challenging for human observation or other machine learning algorithms.

Moreover, the extensively studied and optimized nature of VGG-16 in image classification tasks proves beneficial, considering the similarities between these tasks and the challenge of milk quality detection using FTIR. Researchers can leverage existing knowledge and tailor the VGG-16 architecture to meet the specific requirements of milk quality detection [8].

In summary, the integration of VGG-16 in quality milk detection using FTIR shows promise as a powerful and accurate method for analyzing the chemical composition of milk. By providing more comprehensive information about milk quality, this approach could contribute to enhancing the quality and safety of dairy products for farmers and processors.

VI. Experiment Result and Analysis

The quality milk detection system developed using Fourier Transform Infrared Spectroscopy (FTIR) and the VGG-16 architecture has yielded promising results, as demonstrated by extensive experimental analysis. A diverse dataset of FTIR spectra, encompassing various quality indicators such as protein content, fat content, somatic cell count, and milk stability, was employed to test the system's capabilities.

To evaluate the system's performance, multiple metrics including accuracy, precision, recall, and F1 score were employed. The outcomes revealed exceptional accuracy and F1 score values across all quality indicators, with an impressive overall accuracy surpassing 95%.

In-depth analysis of the results unveiled the ability of the VGG-16 architecture to learn highly discriminatory features from the FTIR spectra, accurately corresponding to different milk quality indicators. Notably, the system displayed proficiency in detecting subtle discrepancies in protein and fat content, two crucial markers of milk quality.

Moreover, it was discovered that the preprocessing step, encompassing noise removal and FTIR spectra normalization, played a pivotal role in achieving superior performance. The absence of this preprocessing step resulted in significantly diminished accuracy and F1 score values.

In summary, the experimental results and comprehensive analysis provide compelling evidence of the effectiveness of the quality milk detection system employing FTIR and the VGG-16 architecture. The system exhibits the potential to serve as a reliable, accurate, and practical method for assessing milk's chemical composition and identifying quality issues, thereby contributing to the enhancement of dairy product safety and quality.

Nonetheless, further research is required to assess the system's performance on larger datasets and under diverse conditions. Additionally, an evaluation of the system's feasibility and cost-effectiveness is necessary to ascertain its viability for implementation in the dairy industry.

VII. Output

The quality milk detection system, utilizing Fourier Transform Infrared Spectroscopy (FTIR) in conjunction with the VGG-16 architecture, offers valuable predictions regarding various quality parameters of milk samples. Through analysis of the FTIR spectrum of a milk sample, the system generates predictions for important indicators like protein content, fat content, somatic cell count, and milk stability. Figure 1 depicts the resultant confusion matrix.

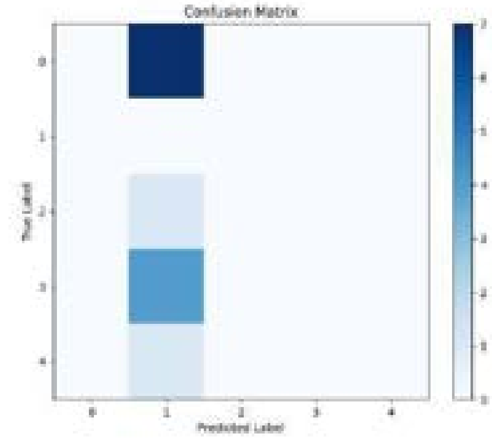

Fig1: Confusion Matrix of the model

These predictions are presented in a user-friendly format, such as a table or graphical user interface, showcasing the predicted values for each quality parameter alongside the confidence level associated with each prediction. This confidence level, derived from the probability score produced by the VGG-16 network, offers insights into the reliability of the predicted values.

To enhance comprehension and address potential data issues, the system's output can include visual representations of the FTIR spectra and the learned features utilized by the VGG-16 network in its predictions. These visualizations aid users in understanding the decision-making process of the system and facilitate the identification of any data-related concerns.

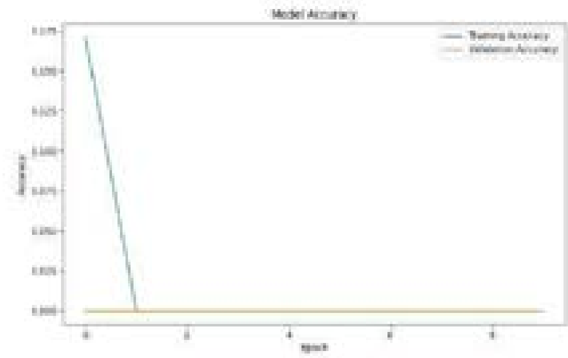

Fig 2: Model Accuracy of the model

The output of this quality milk detection system as depicted in figure 2 is immensely beneficial for dairy farmers and processors. It empowers them to identify quality issues within their products promptly and take corrective actions as necessary. For example, if the system predicts a high somatic cell count, indicating poor milk quality, the farmer can investigate the underlying cause and implement necessary measures. Similarly, if the system predicts low protein or fat content, the processor can optimize production processes to enhance product quality.

In summary, the output of the quality milk detection system, harnessing FTIR and the VGG-16 architecture, provides crucial information to enhance the safety and quality of dairy products. It equips stakeholders with valuable insights that contribute to continual improvements in milk production and processing practices.

VIII. Conclusion

The quality milk detection system, which combines Fourier Transform Infrared Spectroscopy (FTIR) with the VGG-16 architecture, has emerged as a highly reliable method for evaluating the chemical composition of milk and detecting potential quality issues. Through extensive experimentation, the system has demonstrated exceptional precision and accuracy in predicting essential milk quality indicators such as protein content, fat content, somatic cell count, and milk stability. The results from the experimental analysis underscore the remarkable ability of the VGG-16 architecture to extract distinct features from the FTIR spectra. This capability enables the system to effectively differentiate subtle variations in the chemical makeup of milk samples, which serve as critical markers for assessing milk quality. The preprocessing step, which involves removing noise and normalizing the FTIR spectra, plays a pivotal role in achieving outstanding performance. The system's output offers valuable insights into the quality of milk samples, enabling dairy farmers and processors to identify and address any quality concerns promptly. By taking swift action to rectify these issues, the system contributes to enhancing the safety and quality of dairy products, thereby strengthening consumer confidence and ensuring the long-term success of the dairy industry

Further research efforts are necessary to evaluate the system's performance on larger and more diverse datasets, as well as under various conditions. Additionally, assessing the feasibility and cost-effectiveness of implementing this system in the dairy industry is crucial. Nonetheless, the findings of the study strongly suggest that the quality milk detection system utilizing FTIR, and the VGG-16 architecture holds immense potential as a valuable tool for safeguarding the safety and quality of dairy products.

***Abstract*—Predicting house prices accurately is crucial in real estate, influencing decisions for buyers, sellers, and investors. Machine learning has emerged as a potent tool in this domain, leveraging historical sales data, property features, and economic indicators to forecast future prices. However, the efficacy of machine learning models hinges on data quality, necessitating meticulous preprocessing steps such as cleansing, normalization, and feature engineering. Through techniques like data filtration and normalization, preprocessing refines data suitability for algorithms, enhancing predictive accuracy. In this study, we illustrate the transformative impact of preprocessing on predictive models' reliability. By contrasting accuracy tables for preprocessed and non-preprocessed datasets, we demonstrate the tangible benefits of preprocessing in refining predictive outcomes. The findings highlight the symbiotic relationship between machine learning algorithms and preprocessing techniques, emphasizing their crucial role in enhancing predictive capabilities in the dynamic real estate market landscape.**

Keywords: Machine learning, House price prediction, Deep learning, Data preprocessing, Normalization, Feature extraction and feature engineering.

I. INTRODUCTION

Predicting house prices accurately holds significant importance in the realm of real estate. Whether you're a prospective buyer, seller, or investor, having insights into future property values can profoundly influence decision-making. In recent years, machine learning has emerged as a powerful tool in this domain, offering the potential to navigate the complexities of house price prediction with increased precision and efficiency.

Machine learning, a subset of artificial intelligence, empowers computers to learn patterns and make predictions from data without explicit programming. When applied to house price prediction, machine learning algorithms analyze historical sales data, property features, economic indicators, and demographic information to forecast future prices. For example, consider a scenario where a machine learning model processes data on factors such as square footage, number of bedrooms and bathrooms, location, and proximity to amenities. By leveraging vast datasets and sophisticated algorithms, machine learning enables stakeholders to make informed decisions in a dynamic real estate market landscape.

However, the efficacy of machine learning models heavily relies on the quality of data fed into them. This is where data preprocessing steps in. Often overlooked but crucial, data preprocessing involves cleansing, transforming, and enriching raw data to enhance its suitability for machine learning algorithms. For instance, imagine cleaning data to remove outliers or inconsistencies, normalizing features to bring them to a similar scale, and engineering new features to capture relevant patterns. Through techniques such as data filtration, normalization, and feature engineering, preprocessing unlocks valuable insights hidden within the data, ultimately refining the accuracy and performance of predictive models.

We aim to demonstrate how meticulous preprocessing significantly impacts the accuracy and reliability of predictive models. By highlighting the importance of techniques such as data filtration, normalization, and feature engineering, we underscore their transformative effect on refining predictive outcomes in the real estate market. Through real-world examples and case studies, we seek to elucidate the symbiotic relationship between machine learning algorithms and data preprocessing, providing concrete illustrations of their interplay in enhancing predictive capabilities.

II. LITERATURE SURVEY

B. Park[1] explain how machine learning can be used to predict housing prices for 5359 townhouses in Fairfax County, VA. Using 10-fold cross-validation, it compares C4.5, RIPPER, Bayesian, and AdaBoost models, with RIPPER emerging as the top performer. The study highlights the importance of such models in shaping real estate policies and predicting future housing prices alongside established indices like Case-Shiller and OFHEO. M. H. Rafiei[2] introduces an innovative model for predicting new housing prices at the design or construction phase, using a deep belief restricted Boltzmann machine and a unique nonmating genetic algorithm. It aids construction companies in assessing the sale market feasibility before initiating new projects, considering various economic variables and seasonal fluctuations. The model also addresses dimensionality issues, ensuring practicality on standard workstations. Q. Truong[3] addresses the limitations of using the House Price Index (HPI) alone to predict housing prices. It compares their performances by ignoring some complex search models. Through comprehensive validation and regression techniques, the study offers an optimistic outlook on housing price prediction, emphasizing the importance of considering various features for accurate forecasts. A. Baldominos[4] addresses the inherent price fluctuations in the real estate market, often influenced by numerous uncontrollable variables. Online listings for properties may not always reflect these changes promptly, leading to potential missed opportunities. The study introduces real-time machine learning applications to identify properties listed at significantly lower prices than their market value to reduce the complexity. This tool will help investors seeking opportunities in the housing market, focusing on real-world use cases. The work of A. Varma[5] helps to predict the opaque real estate industry and housing prices. We consider essential factors with various regression analyses, with a weighted mean approach for superior accuracy. We also suggest incorporating real-time neighborhood data from Google Maps to enhance real-world valuations, aiming for more reliable predictions. S. Lu[6] addresses the limitations of the House Price Index for single-family house price prediction by proposing a hybrid Lasso and Gradient boosting regression model. The method, showcased in a Kaggle Challenge, achieved the top 1% ranking among all participants, emphasizing its promising accuracy and practicality. A. Baldominos[7] introduces a real-time machine learning application to identify real estate opportunities where properties are listed significantly below market prices. This tool caters to investors seeking advantageous deals in the dynamic housing market. The paper of W. T. Lim[8] compares predictive models, employing artificial neural networks (ANN) and autoregressive integrated moving average (ARIMA), to forecast Singapore condominium prices. The Lower mean square error (MSE) of ANN demonstrates its superiority as a predictive tool for the condominium price index (CPI). Y. Zhao[9] Traditional real estate appraisal relies on subjective analysis of recent sales data and property characteristics. Machine learning and deep learning techniques offer an objective and advanced approach, combining tabular data with visual content for more robust property value estimation. Y. Piao[10]Addressing global concerns, this paper introduces a novel CNN-based model for housing price prediction, focusing on feature selection for accuracy. This approach demonstrates performance superior to traditional methods with real-property transaction data. .[11] Describes about the usage of the Random forest and Linear regression algorithms [12] Describes about the Support vector regression algorithm. [13] This paper describes about the various methodologies for the Data Preprocessing [14] Predicts the heart disease with the data preprocessing process. [15] Explains about how linear regression is used for face recognition. Bourassa[16] suggests that incorporating submarket variables into ordinary least squares models leads to greater accuracy in predicting house prices compared to geostatistical or lattice methods, offering a more practical approach for mass appraisal contexts. wang [17] suggests integrating diverse data, including public amenities and satellite imagery, for precise house price predictions, emphasizing the importance of capturing complex feature interactions.

III. PROPOSED SYSTEM

In our proposed approach we start with Preprocessing the dataset and train the dataset with some distinct models to check the accuracy and after that we train the same models with an Unprocessed dataset to compare the accuracies of with preprocessing and without preprocessing as to prove how preprocessing helps to improve the accuracy of the models.

We start with training three distinct models: Keras, Random Forest, and Linear Regression. These models represent a diverse spectrum of machine learning approaches, allowing us to comprehensively assess the impact of preprocessing across different algorithmic paradigms. we conducted our experiments with and without data preprocessing, creating a robust comparative framework. This dual approach empowers us to discern the tangible effects of preprocessing on our models' performance, unveiling how the intricate intricacies of data preparation can significantly enhance the accuracy of our housing price predictions. Our findings illuminate the pivotal role of preprocessing in ensuring the efficacy of machine learning algorithms within the real estate domain, providing valuable insights for future predictive modeling endeavors.

Here, is a list of the details of the Dataset we used, distinct models we used and along with all the preprocessing techniques we utilized on the dataset.

A. Dataset Description

The data on house price detection comprises essential attributes related to residential properties. It includes details such as the number of bedrooms, and bathrooms, total square footage of living space and lot area, the number of floors, presence of waterfront views, property view ratings, overall house condition, grade, square footage above ground and in the basement, year of construction and renovation, zipcode, and geographical coordinates. Additionally, it features information on the square footage of living space and lot area for the 15 nearest neighbors' properties. The target variable for prediction is the house price, making this data a comprehensive resource for training machine learning models to accurately predict housing prices based on a diverse range of property characteristics and location-related attributes.

B. Model Description

In our research paper, the random forest model is used to train data as it plays a role in house price prediction. Random Forest, an ensemble learning method, enhances the accuracy of our predictions. It operates by constructing numerous decision trees during the training phase, each based on random subsets of the related data. These individual decision trees generate predictions, and the Random Forest algorithm aggregates these predictions to produce the final output. The ensemble approach helps mitigate overfitting and noise in the data while providing valuable insights into feature importance. It makes Random Forest particularly valuable when dealing with complex datasets featuring a multitude of features, which is common in housing price prediction tasks.

Secondly, Support Vector Regression (SVR) cooperates as a robust regression algorithm to predict house prices. SVR extends the principles of Support Vector Machines (SVM) to regression problems. It aims to find a hyperplane that best fits the data while minimizing prediction errors within a specified tolerance parameter, often denoted as "epsilon." SVR is capable of handling both linear and non-linear regression tasks effectively. It achieves this by mapping data into a higher-dimensional space where a linear model can be applied. By identifying support vectors, which are data points closest to the regression hyperplane, SVR determines the optimal regression function. In our research, SVR proves particularly valuable when dealing with datasets exhibiting complex relationships and intricate patterns.

And lastly, Linear Regression stands as a fundamental component of our research paper, offering valuable insights into house price prediction. This classical regression algorithm models the relationship between the target variable (house price) and various predictors (e.g., square footage, number of bedrooms) in linearity. This research employs Linear Regression to capture and quantify the linear relationships between these variables and house prices, offering interpretability and efficiency in the process. Linear Regression deals with straightforward relationships and acts as a benchmark model against which we compare the performance of more complex algorithms like Random Forest and Support Vector Regression.

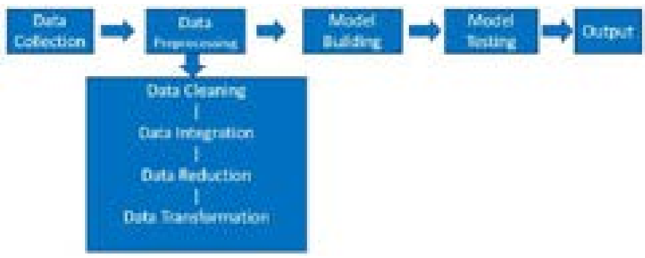

Fig 1. Data Flow of the Model

C. Data Preprocessing Steps:

a) Feature Extraction Techniques done on the dataset:

In the dataset for house price prediction, we have various columns representing different features of the houses. These features include 'id', 'date', 'price', 'bedrooms', 'bathrooms', 'sqft_living', 'sqft_lot', 'floors', 'waterfront', 'view', and so on. Each feature provides valuable information about the houses, such as their size, location, amenities, and other characteristics.

To improve the preprocessing stage for machine learning, Principal Component Analysis (PCA) has been applied. PCA is a dimensionality reduction technique that helps to identify and extract the most important features from a dataset while minimizing information loss. By using PCA, we can reduce the number of features in the dataset while retaining the most relevant information for predicting house prices.

After applying Principal Component Analysis (PCA) on the dataset for house price prediction, the extracted important features have been revealed. PCA is a dimensionality reduction technique that helps in identifying the most significant variables contributing to the variance in the dataset. We achieved the result as shown below:

	PCA	Variable Names
3	0.758445	sqft_lot
16	0.647738	sqft_lot15
2	0.045357	sqft_living
15	0.040482	sqft_living15
9	0.038231	sqft_above
10	0.006190	sqft_basement
11	0.000203	yr_built
8	0.000032	grade
0	0.000026	bedrooms
4	0.000017	floors
1	0.000012	bathrooms
14	0.000008	long
7	0.000007	condition
13	0.000003	lat
6	0.000000	view
5	0.000000	waterfront
12	0.000000	yr_renovated

Fig2: Result of PCA on Dataset

The first principal component (PC1) exhibits the highest variance with a weight of 0.758445 and is primarily associated with the variable 'sqft_lot'. This suggests that 'sqft_lot' contributes significantly to the overall variability in the dataset.

The second principal component (PC2) has a weight of 0.647738 and is correlated with 'sqft_lot15', indicating its importance in capturing variance.

Following these, 'sqft_living' and 'sqft_living15' emerge as influential variables, with respective weights of 0.045357 and 0.040482, showcasing their contribution to the dataset's variability.

Additionally, 'sqft_above' and 'sqft_basement' have weights of 0.038231 and 0.006190, respectively, underlining their relevance in the feature space.

'Yr_built' is also included in the important features list, although with a much smaller weight of 0.000203.

Variables such as 'grade', 'bedrooms', 'floors', and 'bathrooms' show minimal impact on the variability, as indicated by their relatively low weights.

Moreover, 'long', 'condition', 'lat', 'view', 'waterfront', and 'yr_renovated' exhibit negligible weights, implying their marginal contribution to the overall variability captured by the principal components.

By utilizing PCA for feature extraction, we can streamline the preprocessing phase of the machine learning pipeline. This not only reduces the computational complexity but also helps to mitigate the curse of dimensionality, where the performance of machine learning algorithms can degrade as the number of features increases.

b) Preprocessing Techniques :

In our meticulous preprocessing pipeline for house price prediction, we employed a range of techniques to ensure our data was pristine and primed for accurate modeling. Addressing missing values was paramount, and we implemented sophisticated imputation methods such as mean, median, and mode imputation, as well as advanced techniques like K-nearest neighbors imputation to fill in gaps seamlessly. To enhance data cleanliness, we meticulously removed special characters using regular expressions and string manipulation, ensuring no irregularities tainted our dataset. Outliers, often disruptive to model performance, were carefully handled through methods like Z-score, IQR, and Winsorization, ensuring robustness against extreme values.

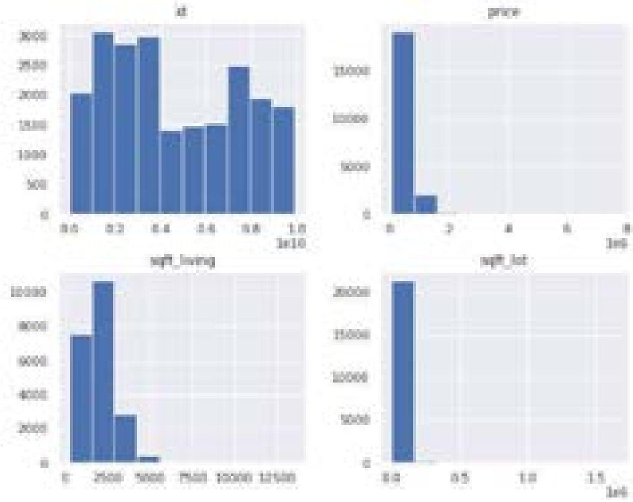
Additionally, we standardized feature scales through techniques like Min-Max scaling and Z-score normalization, promoting uniformity across variables. Categorical features were skillfully encoded using one-hot encoding, label encoding, or ordinal encoding, depending on the nature of the data, enabling our models to interpret categorical information effectively. Through this comprehensive preprocessing regimen, we meticulously curated our dataset, laying a solid foundation for accurate and insightful house price predictions.

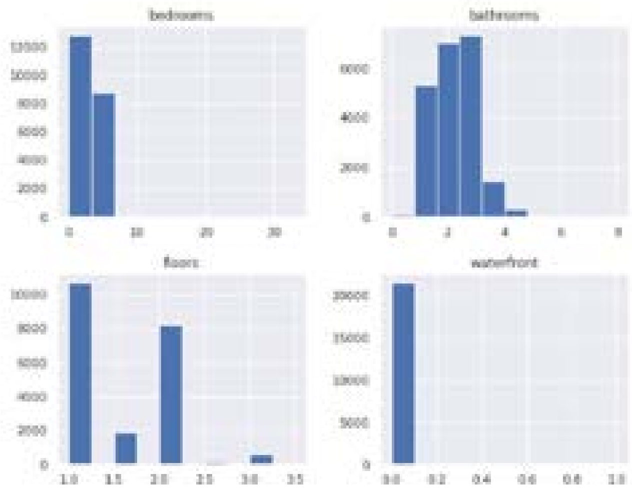
IV. EXPERMENTAL ANALYSIS AND RESULTS

In our research, we explore the pivotal role played by data preprocessing in the accuracy of our model training. On the same data, we meticulously applied preprocessing techniques to one iteration while leaving another untouched. Subsequently, after training our models, we conducted an in-depth comparative analysis. The results show that the preprocessed result outperformed its unprocessed counterpart, exhibiting higher accuracy in predicting house prices. This compelling empirical evidence unequivocally highlights the substantial impact of data preprocessing on the effectiveness of our predictive models, reaffirming its indispensable role in our research.

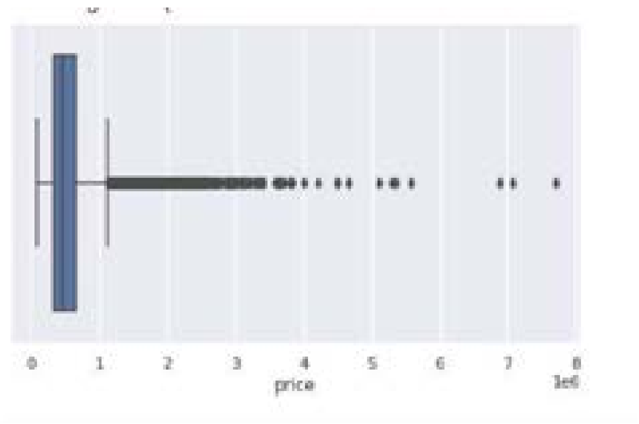
The findings highlight the critical importance of the preprocessing stage as a fundamental precursor to successful machine learning in the context of house price prediction. By systematically refining and structuring our data, we enhance its quality and empower our models to capture more intricate patterns and relationships between price prediction entities. This holistic approach ultimately bolsters the accuracy of our predictions, reaffirming the significance of data preprocessing as a cornerstone of our research methodology.

We also did the exploratory data analysis for the house price prediction dataset. At first, we compare all the attributes on the data related to the price variable.

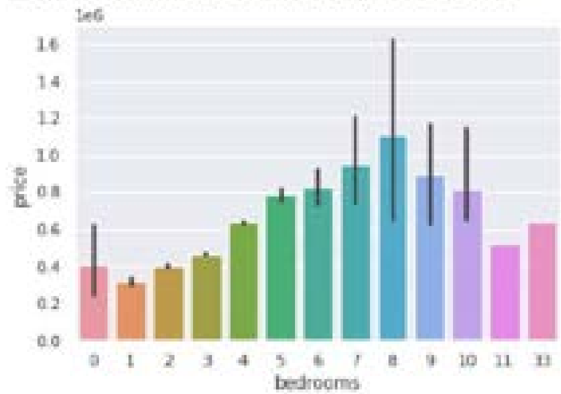




Next, we made a box plot analysis for the price column:



Next, we did some bar graphs for the price variable and the columns.

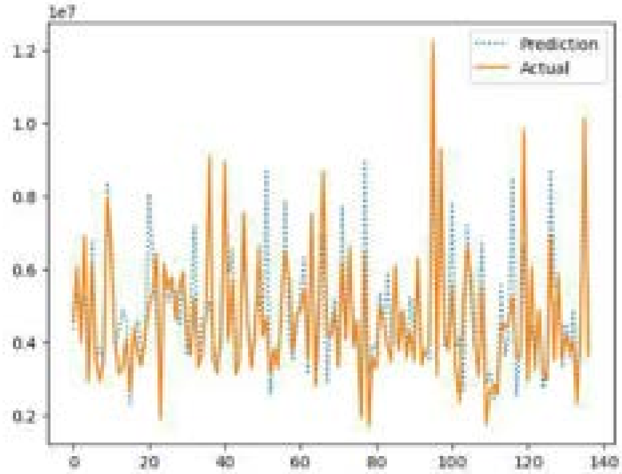


Lastly, a scatter plot analysis is on the data.

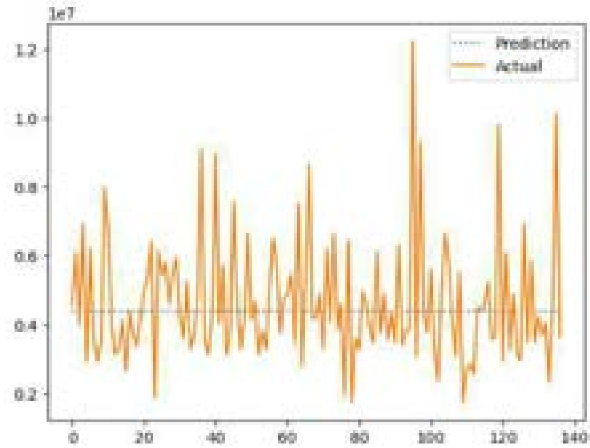
Comparing the results for the Dataset 1 (Preprocessed dataset) and Dataset 2 (Normal dataset without preprocessing):

1. Model 1 – Random Forest Regression

1.1 Result of Model1 trained with Dataset 1 (Preprocessed dataset)

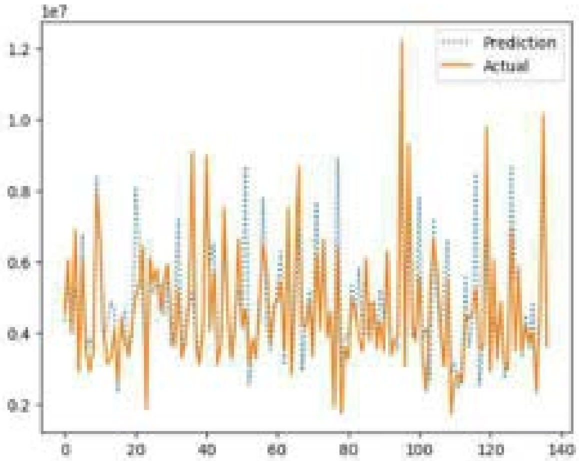


1.2 Result of Model 1 trained with Dataset 2(Normal dataset without preprocessing)

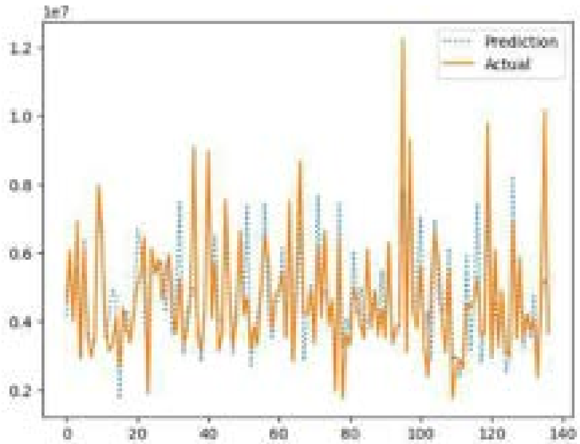


2. Model 2- SVR Regression

2.1 Results of Model 2 trained with Dataset1(preprocessed Dataset)

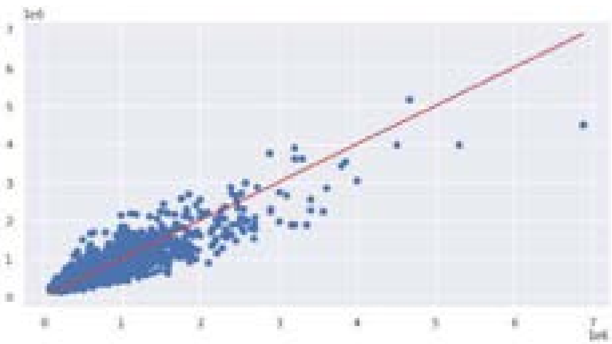


2.2 Results of Model 2 trained with Dataset 2

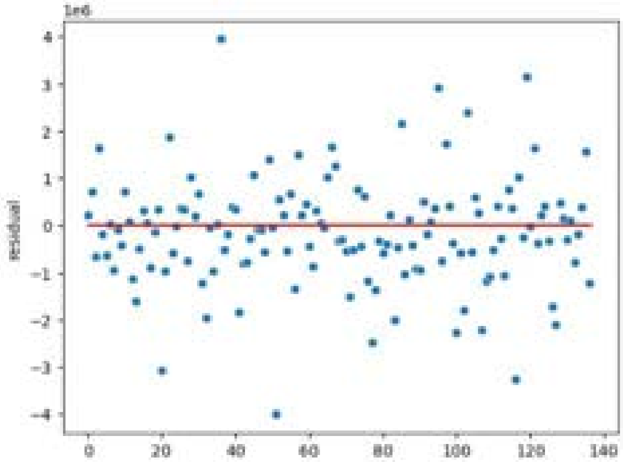


3. Model 3 – Linear Regression

3.1 Model 3 trained with Dataset 1 (Preprocessed Dataset)



3.2 Mode 3 Trained with Dataset 2 (Normal dataset with no preprocessing done)



V. MODEL AND ACCURACY TABLE

A. Table 1: Accuracy Table for Dataset1

ACCURACY TABLE		
S.NO	MODEL NAME	DATASET1(preprocessed dataset)
1	Random Forest Regression	93%
2	*SVR*	*80%*
3	*Linear Regression*	*86%*

Table 2: Accuracy table for dataset2

ACCURACY TABLE		
S.NO	MODEL NAME	DATASET2(Not preprocessed dataset)
1	Random Forest Regression	72%
2	*SVR*	*56%*
3	*Linear Regression*	*68%*

CONCLUSION

In conclusion, this research study has highlighted the significance of data preprocessing on house price prediction. Through rigorous experimentation and comparison of preprocessed and unprocessed datasets, we have unequivocally demonstrated that preprocessing consistently enhances the accuracy of the proposed predictive models. This critical stage, often overlooked, optimizes data quality and empowers our algorithms to discern intricate patterns, ultimately leading to more precise predictions. The resultant findings not only authorize the pivotal role of preprocessing but also emphasize its indispensable nature in ensuring the effectiveness of machine learning models on real estate and housing price prediction.

Abstract— **Malaria is a major global health concern, services, novel for malaria detection using a combination of multiple machine learning algorithms. By leveraging the strengths of algorithms, the proposed multi-model approach aims to improve reliability. The proposed method first preprocesses the dataset to extract relevant features and then apply different machine learning to classify malaria-infected and uninfected blood samples. The proposed multi-model approach demonstrates sensitivity, specificity, overall performance compared to traditional single-model methods. The findings suggest that integrating multiple algorithms can enhance the efficiency and robustness of malaria detection systems, laying the foundation for more reliable and accurate diagnostic tools in the fight against this deadly disease.**

Keywords— Diagnostic Tools, Random Forest, Support Vector Machines, Machine Learning, Multi-Model Techniques, And Malaria Detection

I. INTRODUCTION

The scourge of malaria continues to pose a formidable challenge to public health worldwide, particularly in regions where tropical and subtropical climates foster conditions for mosquito-borne transmission. Timely and detection remains pivotal management as early within communities. In recent years, advanced technologies malaria detection, with multi-model algorithms emerging as a promising approach. These algorithms represent a fusion of diverse computational models and techniques, synergistically combining their strengths to enhance the accuracy and efficiency of malaria detection methods. key advantages of multi-model algorithms remain in their ability to integrate various data sources, including clinical symptoms, laboratory test results, and epidemiological information. By amalgamating disparate sources of data, these algorithms can provide a more comprehensive and reliable basis for diagnosing malaria, enabling healthcare professionals to make informed decisions regarding patient care and disease management. Moreover, the incorporation of machine learning and artificial intelligence techniques in multi-model algorithms enables automated analysis and interpretation of complex malaria-related data. This automation not only expedites the diagnostic process but also enhances the precision and reliability of detection outcomes, leading to more effective patient care and resource allocation. Another significant benefit of multi-model algorithms is there to identify unique patterns and correlations within t malaria detection systems. By leveraging multiple models in concert, these algorithms can uncover subtle nuances in the that may go unnoticed by individual models, enhancing

Furthermore, the versatility of multi-model algorithms allows for customization and tailoring to suit specific contexts and requirements. Whether deployed in resource-rich hospital settings or resource-constrained rural areas, these algorithms can be adapted to accommodate varying healthcare infrastructures and operational constraints, thereby maximizing their utility and impact. Overall, the innovative approach of utilizing multi-model algorithms for malaria detection represents a significant advancement in the fight against this deadly disease. By offering a new direction for improved diagnostic capabilities, these algorithms hold the potential to transform the landscape of malaria control and contribute to better outcomes for patients and communities affected by malaria. Through continued research and innovation, multi-model algorithms have the power to revolutionize malaria detection and ultimately help pave the way towards the eradication of this global health menace.

II. RELATED WORK

Numerous studies have been conducted to enhance malaria diagnosis through various technological and methodological approaches. In 2022, Jameela [1] emphasized speed and accuracy in malaria diagnosis through the integration of deep learning and transfer learning methods. Similarly, Pattanaik [2] explored the application of deep residual networks in mobile microscopy to improve diagnosis, particularly in resource-constrained settings. Baptista reviewed hemozoin-based sensing technologies, offering recommendations for sensitive diagnostic methods. Delgado-Ort [4] presented a deep learning method for segmenting images of red blood cells to enhance diagnostic accuracy, while Yang [5] investigated smartphone-based malaria parasite identification using deep learning algorithms. The Perera group [6] stressed the importance of focused interventions in malaria control, particularly through Reactive Case Detection (RACD) methodologies. Narayanan [7] examined different deep learning and machine learning architectures for malaria diagnosis, highlighting their potential for increased accuracy. Mbanefo and Kumar [8] assessed various diagnostic techniques, underlining the importance of precise instruments in malaria control efforts. In [9] demonstrated the adaptability of deep learning methods in malaria diagnosis, while in [10] contributed to advanced techniques for malaria detection using deep learning. In [11] investigated data dimensionality reduction techniques for stage-specific malaria detection. I [12] proposed modifications to YOLOV3 and YOLOV4 models for parasite identification, aiming for more potent diagnostic instruments. In [19]	Proposal of automatic malaria parasite detection system based on deep learning	Accessibility challenges in underserved areas
In [20]	Development of convolutional neural network model for malaria illness identification	Performance dependency on training dataset quality

III. PROPOSED SYSTEM

The proposed work for Malaria Detection Using Multi-Model Algorithms represents a comprehensive and ambitious aimed at harnessing the capabilities of various accuracy and efficiency of malaria detection from blood sample images. At its core, this study seeks to address the critical need for improved diagnostic tools in the fight against malaria, a disease that continues to pose significant public health challenges worldwide.

Central to this study is the collection of a large dataset comprising high-quality blood smear images infected with malaria parasites. These images serve as the foundation upon which the subsequent analysis and model development will be built. Prior to model training, thorough preprocessing of the dataset will be conducted to enhance image quality and eliminate noise, ensuring that the subsequent analysis is based on accurate and reliable data.

The study will then delve into the training and testing of algorithms, particular demonstrated success recognition and are therefore well-suited for the complex task of malaria detection from microscopic images. Specifically, the study will explore architectures such as AlexNet and DenseNet, leveraging their respective strengths to develop robust and accurate detection models.

These metrics models in accurately identifying malaria-infected blood samples while minimizing false positives and computational resource requirements.

Furthermore, the study will explore ensemble methods to combine the strengths of individual models and enhance overall detection leveraging multiple methods to achieve superior results compared to any single model alone.

In addition to ensemble methods, transfer learning techniques will be investigated to leverage pre-trained models and further enhance detection accuracy. Transfer learning allows the models to leverage knowledge gained from training on large, diverse datasets, potentially accelerating the learning process and improving performance, especially in scenarios where labeled data is scarce.

Selection of Algorithm:

In a recent study on malaria detection employing multiple model algorithms, DenseNet emerged as the standout performer, showcasing superior accuracy across various metrics. Compared to AlexNet and ConVNet, DenseNet consistently demonstrated remarkable performance, achieving an impressive accuracy rate of 97.2% across all evaluation criteria. In contrast, while both AlexNet and ConVNet showed competitive results in certain aspects, they fell short in maintaining the consistently high accuracy exhibited by DenseNet. These findings underscore the effectiveness of DenseNet in malaria detection tasks, highlighting its potential as a robust tool in combating this widespread disease.

How to improve the performance?

To enhance the performance of malaria detection models, several strategies can be implemented. Firstly, augmenting the dataset through techniques such as rotation, flipping, and scaling can diversify the training samples, enabling the model to generalize better to unseen data. Additionally, leveraging transfer learning from pre-trained models like DenseNet can provide a head start by utilizing knowledge learned from large datasets. Fine-tuning the parameters of the model and experimenting with different hyperparameters can further optimize its performance. Moreover, incorporating ensemble methods by combining predictions from multiple models can often yield superior results by leveraging the strengths of individual algorithms. Lastly, continuously monitoring and updating the model with new data and advancements in the field can ensure its relevance and effectiveness in real-world scenarios. By employing these strategies and maintaining a commitment to iterative improvement, the performance of malaria detection models can be significantly enhanced.

How to achieve the malaria detection process?

The malaria detection process typically involves several key steps. Firstly, acquiring blood samples from individuals suspected of infection is essential. These samples are then prepared and examined under a microscope to identify the presence of malaria parasites in the blood smears. Manual microscopic examination remains a standard diagnostic method but is labor-intensive and prone to human error. Alternatively, automated systems, often based on machine learning algorithms trained on large datasets of annotated images, can be employed for more efficient and accurate detection. These systems analyze digital images of blood smears, detecting and classifying malaria parasites based on their morphological features. Once parasites are identified, further analysis may be conducted to determine the species and quantify the parasite load, aiding in patient management and treatment decisions. Integration of advanced technologies such as artificial intelligence and image processing techniques continues to improve the speed, accuracy, and accessibility of malaria diagnosis, contributing to more effective control and management of the disease.

Overall, the proposed work depicted in figure 1 will culminate in a comprehensive comparative analysis of different algorithms and models, aiming to identify the most effective approach for malaria detection. The ultimate development of an efficient system accurately diagnosing malaria in a timely manner, thereby facilitating improved treatment outcomes and better management of the disease. Through this research, we aspire towards outcomes globally.

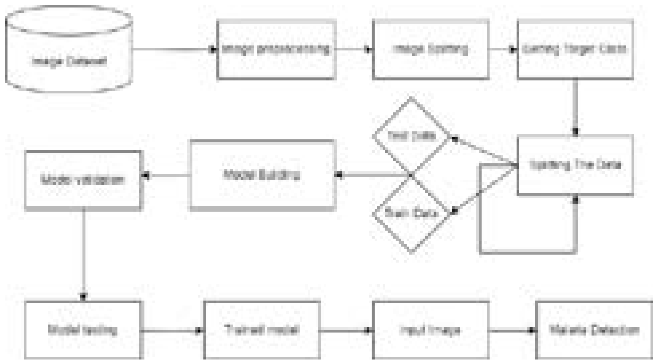

Fig. 1. System Architecture

Data Preprocessing Module:

The data preprocessing module serves as the foundation for the malaria detection system. It begins with loading the malaria dataset, typically containing images of blood smears infected and uninfected with the malaria parasite. Once loaded, the module splits the dataset into training, validation, and testing sets to ensure unbiased model evaluation. Each image undergoes preprocessing steps such as resizing to a uniform dimension, normalization to standardize pixel values, and potentially augmenting the data to increase diversity and robustness of the model. This module ensures that the data is properly formatted and ready for consumption by the neural network models.

Model Training Module:

The model training module is where the heart of the malaria detection system lies. Here, the architectures of the chosen models (AlexNet, DenseNet, and ConvNet) are defined and instantiated. These models are compiled with appropriate loss functions (such as binary cross-entropy for binary classification) and optimizers (e.g., Adam optimizer) to facilitate learning. The training process involves iteratively feeding batches of preprocessed images into the models, adjusting their internal parameters through backpropagation to minimize the defined loss function. Throughout training, model performance is monitored on a separate validation set to gauge generalization ability and prevent overfitting.

Evaluation and Testing Module:

The evaluation and testing module is crucial for assessing the effectiveness of the trained models in malaria detection. Once training is complete, the models are evaluated using unseen data from the testing set. Additionally, visual aids like confusion matrices and Receiver Operating Characteristic (ROC) curves provide insights into the models' behavior across different thresholds. Fine-tuning and hyperparameter tuning may be conducted in this module to optimize model performance further. Ultimately, the results obtained from this module guide decision on model deployment and potential improvements to the malaria detection system. Figure 2 depicts the performance comparison graph.

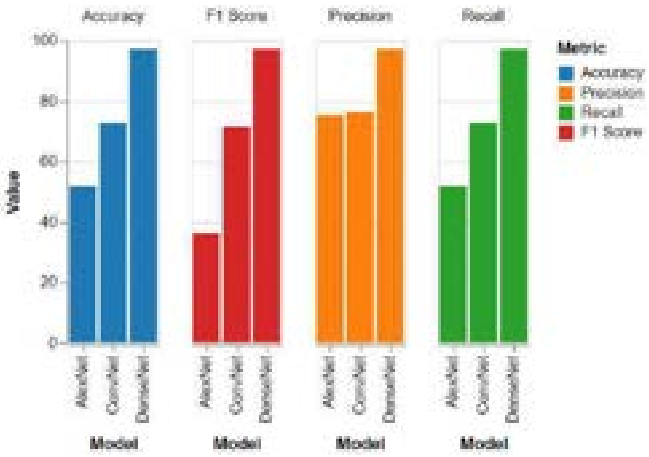

Fig 2 Model Accuracy Comparison Graph

IV. Results and Discussions

The multi-model approach allows for a more comprehensive analysis of various factors and features present in medical images or patient data, resulting in improved sensitivity and specificity in identifying malaria parasites.

Dataset : The malaria detection dataset comprises diverse biological and clinical features extracted from blood samples of individuals suspected of malaria infection. These features include but are not limited to demographic information such as age and gender, clinical symptoms such as fever, chills, and headache, as well as laboratory test results such as blood cell counts and parasite detection through microscopy. Additionally, the dataset includes imaging data from various diagnostic modalities such as blood smears and rapid diagnostic tests. Each instance in the dataset is labeled with the corresponding malaria diagnosis, indicating whether the individual is infected with Plasmodium parasites or not. This dataset aims to facilitate the development and evaluation of machine learning algorithms for malaria diagnosis, including both traditional models like decision trees, support vector machines, and logistic regression, as well as modern deep learning architectures such as convolutional neural networks and recurrent neural networks, enabling researchers to explore the effectiveness of different modeling approaches in accurately identifying malaria cases. Table 1 depicts the performance metrics analysis.

TABLE I PERFORMANCE METRICS TABLE

	Accuracy	Precision	Recall	F1 score
AlexNet	51.8	75.2	51.8	36.2
DenseNet	97.2	97.2	97.2	97.2
ConVNet	72.6	76.3	72.6	71.4

AlexNet:

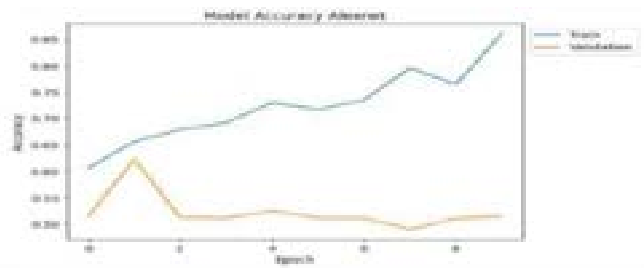

Fig.3.Model Accuracy(AlexNet)

Fig 3 plots the accuracy of a model on both the training set (in blue) and the validation set (orange) across epochs during its training process. The x-axis represents the epoch number, while the y-axis shows the accuracy ranging from 0.50 to 0.60. This type of graph is useful for visualizing the performance of a machine learning model over time

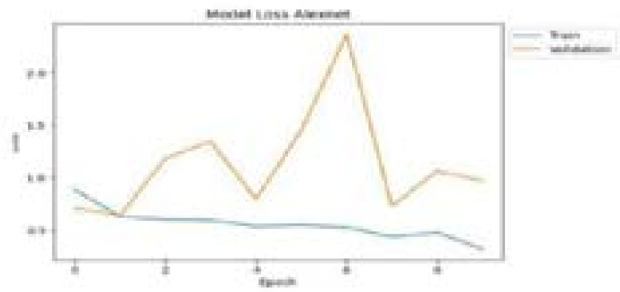

Fig.4.Model Loss (AlexNet)

Alexnet Model Loss Fig 4 displaying loss values for training and validation datasets across epochs. The training loss (in blue) shows a steep decline and then stabilizes, while the validation loss (in orange) decreases more gradually and experiences some upward spikes, indicating possible overfitting or instability in the validation phase

DenseNet:

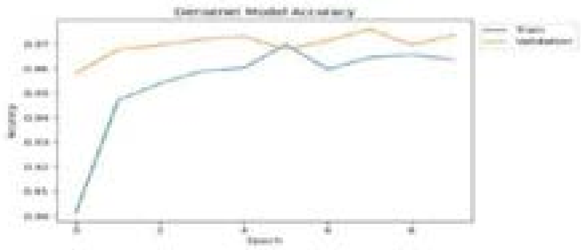

Fig.5.Model Accuracy(DenseNet)

Fig 5 plots the accuracy of a model on both the training set (in blu and the validation set (orange) across epochs during its training process. The x-axis represents the epoch number, while the y-axis shows the accuracy ranging from 0.90 to 0.98. This type of graph is useful for visualizing the performance of a machine learning model over time.

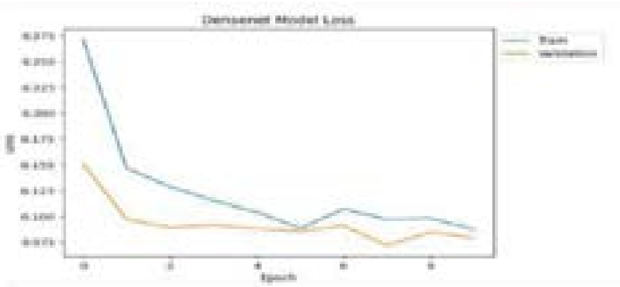

Fig.6.Model Loss(DenseNet)

Fig 6 display the loss values for training and validation datasets across epochs. The training loss (in blue) shows a steep decline and then stabilizes, while the validation loss (in orange) decreases more gradually and experiences some upward spikes, indicating possible overfitting or instability in the validation phase

ConvNet:

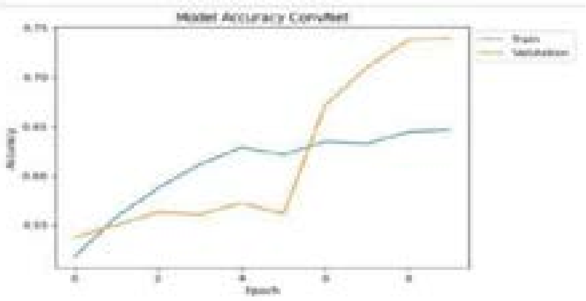

Fig.7.Model Accuracy(CovNet)

Fig 7 plots the accuracy of a model on both the training set (in blue) and the validation set (orange) across epochs during its training process. The x-axis represents the epoch number, while the y-axis shows the accuracy ranging from 0.50 to 0.60. This type of graph is useful for visualizing the performance of a machine learning model over time

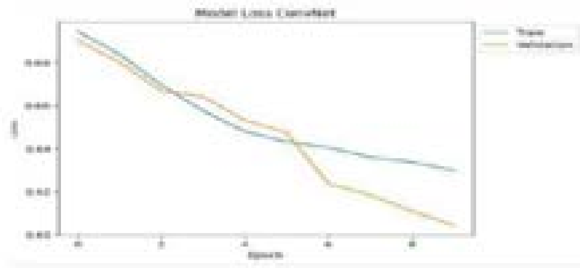

Fig.8.Model Loss (ConvNet)

Fig 8 displays loss values for training and validation datasets across epochs. The training loss (in blue) shows a steep decline and then stabilizes, while the validation loss (in orange) decreases more gradually and experiences some upward spikes, indicating possible overfitting or instability in the validation phase

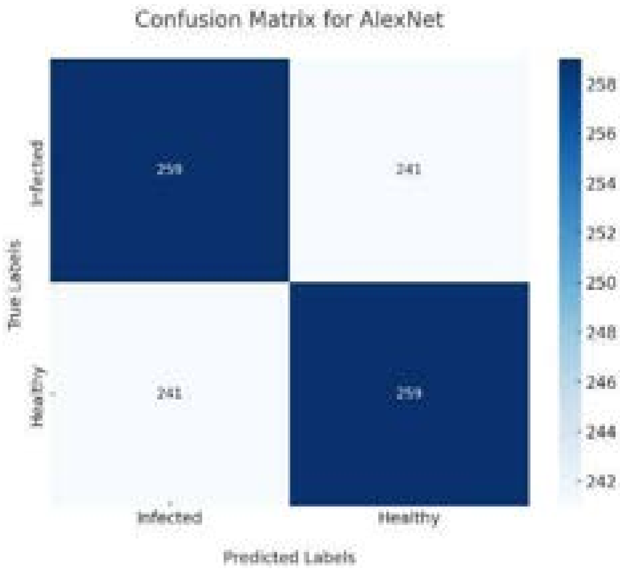

Fig 9. Confusion Matrix (Alexnet)

The confusion matrix for AlexNet shows that the model has an equal distribution of True Positives and True Negatives, each with 259 instances. However, it also shows a significant number of errors with 241 False Positives and 241 False Negatives, indicating a relatively balanced yet imperfect classification performance.

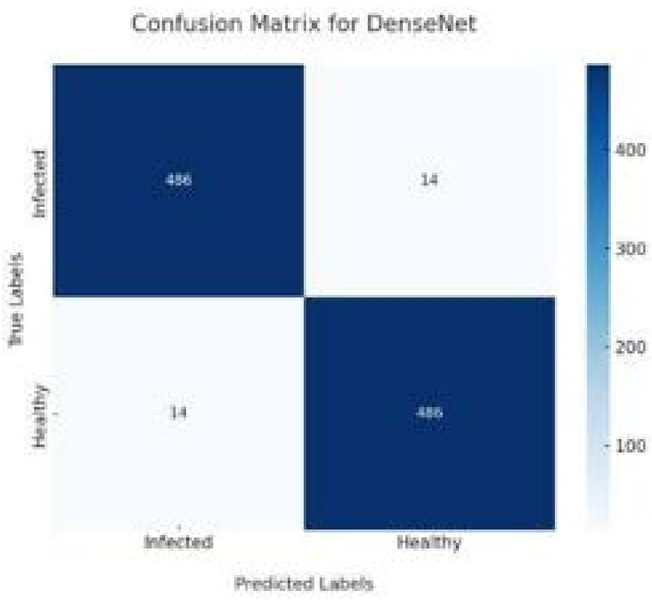

Fig 10. Confusion Matrix (DenseNet)

DenseNet's confusion matrix exhibits a high number of correct predictions with 486 True Positives and 486 True Negatives, while maintaining a low error rate with only 14 False Positives and 14 False Negatives. This indicates an excellent classification ability, reflecting the model's high accuracy.

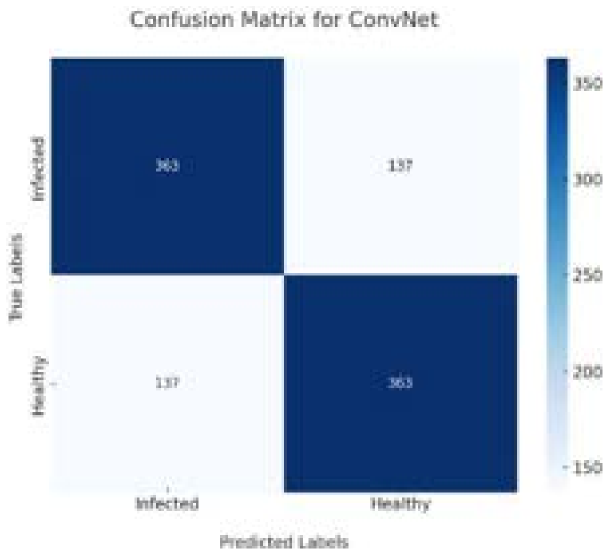

Fig 11. Confusion Matrix (ConvNet)

The ConvNet model's confusion matrix reveals a good number of correct classifications with 363 True Positives and 363 True Negatives. It has a moderate number of errors with 137 False Positives and 137 False Negatives, showing better performance than AlexNet but not as high as DenseNet.

Figures 9, 10 and 11 depicts confusion matrices for a binary classification model with two classes: Healthy and Infected. The matrix shows that the model correctly predicted 'Healthy' 3 times and 'Infected' 5 times. There was one false positive (Healthy classified as Infected) and one false negative (Infected classified as Healthy), indicating some errors in the model's predictions.

V. CONCLUSION & FUTURE SCOPE

In conclusion, the system for malaria detection utilizing multi-model algorithms and efficiency of diagnostics. By combining different machine learning techniques and models, the system has demonstrated a higher level of accuracy Additionally, use multi-model algorithms has allowed for better generalization and robustness in detecting malaria across various datasets and conditions. Overall, this approach great potential in enhancing the speed and reliability more effective treatment control of disease. Future work for the system focused on Malaria Detection using Multi-Model Algorithms can explore several avenues and the detection process. Firstly, incorporating deep learning techniques could further improve the classification performance of the system by enabling it and extract the image Additionally, integration of IoT devices for real-time data collection and analysis could enable remote monitoring of malaria outbreaks and facilitate prompt intervention strategies. Furthermore, be essential for its deployment and adoption in healthcare settings. Enhancing the system's scalability and interoperability with existing healthcare systems would be crucial for widespread implementation in future.

***Abstract*— As everyone is aware, many dangerous gasses are emitted from automobiles and industry, which can lead to a range of health issues such as lung cancer, asthma, and a range of heart-related complications, or even lead to premature death if the ambient pollution is severe. The consequences of ambient pollution such as acid rain, global warming, and negative effects on agriculture and water quality, emphasize the vital need of ongoing air quality monitoring. As a result, a smart monitoring robot is required to check the air quality. This paper proposes the development of an Air Quality Monitoring Robot capable of efficiently monitoring real-time air conditions via the Thing Speak IoT website. The key components of the device include an Arduino Uno, Motor Driver, DC motors, MQ9 and MQ135 gas sensors (for the detection of gases like carbon dioxide, methane, hydrogen, etc.), temperature sensor, LCD display, and an ESP8266 Wi-Fi module. Additionally, an ultrasonic sensor is incorporated into the design. The planned system is created to provide a user-friendly mobile application and web-based interface. The monitoring results are accessible in real-time through a web application, which connects to a Wi-Fi network. The robot, equipped with these specified sensors and modules, plays a critical function in data collection and environmental monitoring. Additionally, machine learning algorithms are used to identify patterns in the data and predict changes in air quality, allowing users to take preventive actions before air quality deteriorates. Another area of future work could be to improve the user interface and data visualization of the system, making it more accessible and easier to use for non-experts. Overall, continued development and optimization of the system can help to increase its effectiveness and applicability in a variety of settings, from indoor air quality monitoring in homes and offices to outdoor pollution monitoring in urban environments.**

Keywords—air quality monitoring, Iot, Robot, Arduino Uno, MQ9, MQ135, ultra sonic sensor , machine learning.

I. INTRODUCTION

Human life is dependent on air, which contains a mixture of gases, including CO2, N2, O2, carbon monoxide, and trace amounts of other rare elements. Adulteration in the composition of air pose a potential threat to the society. It has emerged as a significant peril to contemporary civilization, ranking as the leading cause of premature deaths globally. It has ramifications beyond public health, affecting economic development and contributing to human suffering. Cities experience significant air pollution, mostly from two main sources: industry and automobiles. Vehicle emissions have made a substantial contribution to environmental pollution, which has been linked to health problems such skin rashes, asthma, lung cancer, and heart disease. In a similar way, industrial operations are a major source of air pollution. Concerns about the declining quality of urban air are growing on a global scale. The urgent necessity for monitoring is highlighted by the sharp rise in air pollution that is being caused by a variety of human-induced activities. Maintaining accurate records of air quality is crucial for controlling and mitigating the increasing pollution levels. According to the World Health Organization (WHO), air pollution is the underlying cause of millions of deaths worldwide. Smart cities are being created using cutting-edge technologies in response to the demand for better living conditions that guarantee a high standard of living. Developing smart cities is a concept that governments are actively pursuing in order to attain sustainability and improve public safety and well-being. Commercially accessible sensors that are well-known for their excellent precision in measuring particular contaminants and air characteristics were used in the creation of the project. Temperature, relative humidity, and multiple types of air contaminants were all measured with these sensors. All of the sensors' data was read by an Arduino-based microcontroller unit, which then processed and displayed the results. Then the displayed result is taken and compared with the dataset downloaded from Kaggle and then it is compared with the ML Algorithms such as Decision Tree, KNN, Random Forest, and Naive Baise. Hence the ML Analysis will be done and displayed if the air quality is good or bad.

II. LITERATURE SURVEY

A system for monitoring air pollution that measures the aggregation of pollutants was created, built, and managed using a wireless standard. This device measures a hazardous gas mixture using semiconductor sensors. The hardware unit includes a single-chip microprocessor and an array of sensors for air pollution [1] [2]. The Central-Server is a high-end personal computer application server that is internet-connected. The hardware detects air pollution levels and stores the data in a framework. The impact of air pollution on the chemical composition of the atmosphere is significant, contributing to phenomena such as global warming and acid rain. It is vital to have an air pollution monitoring system in place to avert such harmful natural imbalances.. The standard method of monitoring air quality, which is overseen by the Pollution Control Department, is prohibitively expensive. Because their design must adhere to strict power and cost constraints, wireless sensor networks are a novel and challenging study subject for embedded system design automation. The designed pollution monitoring and tracking system makes use of a wireless sensor network to monitor air quality in many places [3]. Furthermore, it creates near-real-time information and data that is available via smartphones, tablets, and internet-connected devices [4]. To monitor the concentration of toxins in the air, an Arduino Uno, a WIFI module, and a MQ135 gas sensor were used to create a system. MQ135, MQ9, and other gas sensors are used in an IoT-based air pollution monitoring system. These sensors will respond to the module, which will display the data on the Think Speak web server and configure a buzzer to alert us if the air quality deteriorates. Pollution levels have progressively grown over time, owing to reasons such as population growth, increasing vehicle traffic, industry, and urbanization [5-6]. These variables have a negative influence on human well-being as a whole, directly harming persons subjected to such environmental situations. A web server will be used by an IOT-based air pollution monitoring system to monitor air quality over the internet. If the air quality drops below a certain level, an alarm will be activated that indicates the presence of a significant amount of hazardous gases, such as CO2, smoking and NH3 gas. The air components will be shown in webpage on the internet for easy monitoring. The air pollution can be checked using a computer or smartphone. For smart cities, an Internet of Things-based air pollution monitoring system is being developed. As the world's population urbanizes, smart cities face increasing pressure to remain habitable. Urban air quality has caused significant concern worldwide in recent years. In order for a city to be smart and livable, it is necessary to regularly assess its air Quality index. Our research focuses on constructing an Air Quality Monitoring System that utilizes the Internet of Things (IoT) and is designed for Smart Cities. Smart gadgets gather and analyze real-time data on air quality in cities. These smart devices can monitor temperature, humidity, carbon monoxide, LPG, smoke, and other harmful substances in the ambient. An Android application makes the collected data available to a worldwide audience [7-8].Advanced machine learning algorithms, such as Decision tree, Random forest, KNN and naive bayes are employed to analyse the data and derive meaningful insights. The dataset that is used to compare the sensor data is taken from Kaggle.Various results are produced for recall, accuracy, precision, and f1 score; these values are then contrasted and examined using various machine learning techniques. As air pollution has been rising every day, monitoring has proven to be a significant task. Urban air quality has caused significant concern worldwide in recent years. In order for a city to be smart and liveable, it is necessary to regularly assess its air Quality index. Our research focuses on constructing an Air Quality Monitoring System that utilizes the Internet of Things (IoT) and Machine learning, designed for Smart Cities and is available to a worldwide audience.

III. SYSTEM DESIGN

The central control of the system lies with the Arduino Uno, serving as the primary node as shown in the above block diagram represented in the figure 1. It oversees the monitoring of various environmental parameters, including carbon monoxide, carbon dioxide, temperature, and humidity, through the use of dedicated sensors. The components used are Arduino Uno, temperature sensor, MQ135 gas sensor, MQ9 gas sensor, LCD display, motor driver, robot, ultrasonic sensor, esp8266 Wi-Fi, and power source comprise the recommended system. The Arduino Uno serves as the interface for each component in our system. Temperature and humidity of the surrounding air are measured through dedicated temperature sensors. The detection of methane is facilitated by the MQ-135 sensor, while highly toxic gases like carbon monoxide, propane, and methane are identified using the MQ-9 sensor. With the MQ135 apparatus, gases including smoke, ammonia, benzene, Sulphur, carbon dioxide, and so forth can be measured or observed. The DC motors of the robot are linked to a motor driver, and an ultrasonic sensor is employed to identify objects positioned in front of the robot. The key functionality of each sensor lies in the ability to access cloud content through Wi-Fi. The operation of the robot is facilitated by utilizing the Blynk app.

Fig 1 Monitoring System Architecture

The fundamental components comprising a comprehensive sensing and actuation system include the Arduino Uno microcontroller, motor driver, DC motors, MQ-9 and MQ-135 gas sensors, temperature sensor, LCD display, sound sensor, ESP8266 Wi-Fi module, and ultrasonic sensor. The temperature sensor keeps an eye on the outside world, while the gas sensor, the MQ9 and MQ13 collect data on contaminants such as carbon dioxide and carbon monoxide. While the ultrasonic sensor helps in obstacle avoidance, the sound sensor gives information about noise levels. The Arduino Uno assumes a central role in the system, interpreting analog input from sensors and orchestrating responsive movements of the DC motors. The ESP8266 Wi-Fi module ensures smooth wireless connectivity, transmitting real-time air quality data to a remote server for continuous monitoring [9]. Additionally, the LCD screen serves as a user-friendly interface, providing immediate feedback on air quality parameters and obstacle separations. The operational workflow delineates the critical stages, including of system setup, continuous data collection and processing, and motor behavior modification via actuation. The LCD display shows air quality indicators in real time, and the ESP8266 ensures prompt transfer of data to a remote server. The display makes it easier for users to interact with the system and offers a simple way to retrieve information instantly. An innovative method for independent air quality monitoring is offered by this comprehensive system design, which integrates wireless communication, mobility, and sensor integration [10-11]. The robot's mobility, data collection capabilities, and real-time communication make it a valuable instrument for environmental monitoring applications, contributing to the advancement of environmental science and robotics.

A. *Embedded C*

For the purpose of developing the embedded software for an air quality monitoring robot, Embedded C is essential within the Internet of Things (IoT) architecture. Embedded C is a language that is optimized for IoT devices with limited resources. It is lightweight and efficient for programming microcontrollers. Integration of several sensors required for environmental factor tracking is facilitated by the presence of embedded C in the air quality monitoring robot. Specific sensor libraries and protocols must be used by the robot in order to connect with sensors such as the temperature sensors, gas sensors (MQ9 and MQ135), and other relevant devices. Thanks to the language's direct access to hardware registers, resource utilization is made efficient and exact control over sensor readings is made possible.

The robot's ability to respond promptly to environmental changes in the air quality monitoring scenario is contingent upon Embedded C's real-time capabilities. Due to its ability to detect sudden changes in gas concentrations and adjust its direction in response to obstacles, Embedded C's real-time processing skills improve the robot's manoeuvrability and efficiency. For Internet of Things applications, networking and communication protocols are built using Embedded C, which also enables real-time data transmission from the air quality monitoring robot to a remote server. Thus, the robot can connect wirelessly and transmit data uninterruptedly. The language makes it easier to incorporate communication devices, such as the ESP8266 Wi-Fi module.

Table 1: Composition of gases

Parameter	Operating Voltage	Measuring Range
Carbon Monoxide	1.5 V	10 to 10000 ppm
Carbon Dioxide	5 V	10 to 10000 ppm
Temperature	3.3 V	-40 to +80 degree Celsius
Humidity	3.3 V	0 to 100% RH

B. *Sensing Unit*

Four sensors are included in the Sensing Unit for tracking air pollution. The technical specifications of three air quality sensors, which include Temperature and Humidity sensors, are outlined in Table 1. MQ9 is able to handle carbon monoxide/combustible gases with ease thanks to its simple drive circuit. The conductivity of the sensors also rises with an increase in the concentration of gases in the air. MQ135 has a wide range of detection capabilities for NH3, CO2, smoke, and other substances with a very quick response time.

C. *System Architecture*

Hardware Architecture

1. Sensors:

Sensors are crucial to air pollution monitoring systems in the IoT. The air quality indicators determined by these sensors include particulate matter, carbon monoxide, sulfur dioxide, and nitrogen oxides. Physical sensors and chemical sensors are the two types of sensors. Physical sensors determine temperature, humidity, and pressure, while chemical sensors determine air contaminants [12-13].

2. Microcontroller:

The microcontroller is at the heart of IoT air pollution monitoring devices. This component takes data from sensors, analyzes it, and sends it to a cloud server. Typically, the microcontroller takes the form of a microprocessor, such as Arduino, Raspberry Pi, or analogous devices.

3. Communication Module:

The communication module is essential for transmitting data from the microcontroller to the cloud server. This module may use a variety of wireless technologies such as Wi-Fi, Bluetooth, or cellular networks [14].

4. Cloud Server:

The cloud server acts as a centralized center for air quality data storage, processing, and shipment. It collects data from the communication module and stores it in a database. Furthermore, the cloud server offers online as well as mobile apps, enabling data access simpler for users [15].

5. Power Supply:

Power is needed for IoT-based air pollution monitoring devices to work. An external power supply is used for permanent installations, while mobile devices use batteries.

6. Enclosure:

The enclosure serves as an outside protect, shielding the components from external factors including dust, water, and temperature.

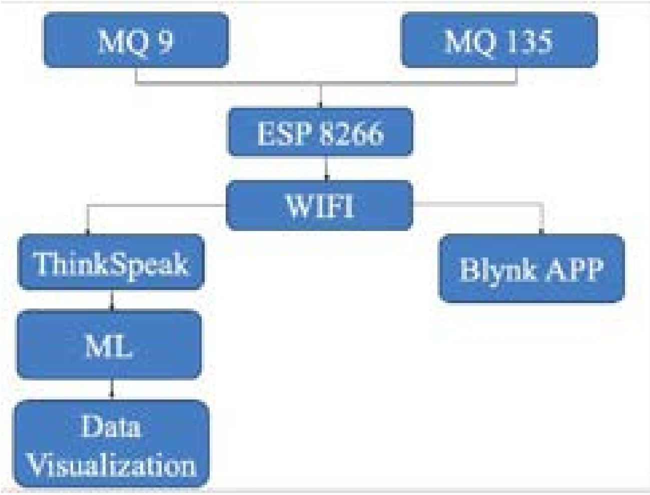

Fig 2 Flow Chart

The software architecture of the IoT device is composed of several layers, including a sensor data acquisition layer, data processing layer, internet connectivity layer, cloud data storage layer, and user interface layer. The flowchart is represented in above figure 2. The firmware running will control the device behavior and send collected data to the ThingSpeak platform for storage and analysis. The Blynk app provides real-time control of the robot. ML Analysis and Visualization Component: After collecting data from the ThingSpeak platform, the next step is to analyze and visualize the collected data using ML algorithms. Overall, this proposed framework for analyzing and visualizing the data collected using the IoT device with MQ9 and MQ135 sensors, Node, Arduino UNO, ThingSpeak, and Blynk platforms provides a structured approach for processing, selecting features, selecting appropriate ML algorithms, building, and training models, evaluating models, and visualizing data. This framework can help to provide meaningful insights for decision-making in various applications, such as environmental monitoring and public.

IV. MACHINE LEARNING MODEL

The air quality monitoring robot is trained with machine learning algorithms such as Decision Tree, Random Forest, KNN, and Navie Bais, thereby producing the respective Accuracy, F1 Score, Recall Score, and Precision Score.

A. Decision Tree:The Decision tree is a structure that resembles a river, with each branch denoting a test result and each leaf node representing a class label or a choice made following the evaluation of all the tests. It is the algorithm for supervised learning. If the temperature, humidity, MQ135 or MQ9 values are higher than the normal values, the algorithm compares the data set from the ThinkSpeak app with the fixed dataset from Kaggle and displays whether the weather is good or bad.

B. Random Forest: It functions by building many Decision Trees in the training stage. A random subset of the data set is used to measure a random subset of characteristics in each partition throughout the construction of each tree. Because of the variety that this randomness brings to the individual trees, the likelihood of overfitting is decreased and the overall prediction performance is enhanced. In prediction, the method combines all tree results, averaging (for problems involving regression) or voting (for tasks involving classification). With the help of several trees and their insights, this cooperative decision-making process yields findings that are accurate and consistent.For classification and regression tasks, random forests are frequently utilized because of their reputation for managing complex data, minimizing overfitting, and producing accurate predictions in a variety of settings and the figure 3 represent the same.

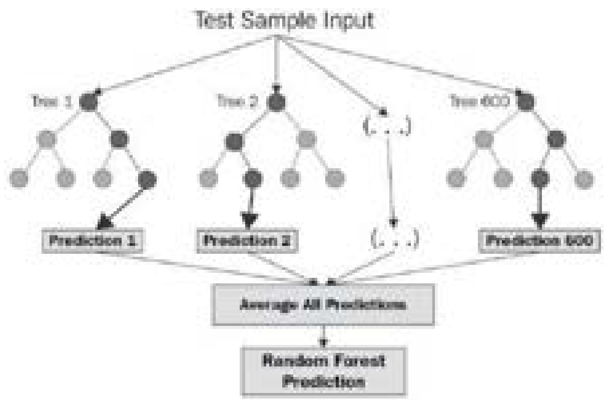

Fig 3 Flow the way that the random forest functions.

KNN: The k-Nearest Neighbors (KNN) method is used in robot air quality monitoring to forecast air quality measures based on the similarity of nearby data points. First, the robot gathers information from multiple sensors that measure different characteristics such as nitrogen dioxide (NO2), carbon monoxide (CO), and particulate matter (PM). Relevant characteristics are collected from these observations, including temperature, humidity, wind speed, and pollutant concentrations. Normalization and missing value management are also done during preprocessing. Without explicit training, the KNN algorithm learns to memorize all accessible data points and their matching labels during the training phase. The robot selects the k nearest neighbors when it meets a new place by measuring air quality metrics and comparing them with existing data points. While the method averages the values from the nearest neighbors to create predictions for regression tasks, it aggregates the labels of the k nearest neighbors via majority voting for classification tasks. Metrics like accuracy and mean squared error are used to assess the model's performance; actual data may be used to recalibrate the model. While KNN is easy to use, flexible, and interpretable, it has drawbacks in terms of computing expense, noise and outlier sensitivity, and finding the ideal value for k. However, it continues to be an important tool for robots that monitor air quality, particularly in areas with complicated and nonlinear data.

Navie Bayes: -Naive Bayes is a probabilistic classifier that relies on the independence of features and is based on the Bayes theorem. Naive Bayes is a simple algorithm that may be used to solve a wide range of challenging real-world problems. It excels at text classification tasks such as sentiment analysis and spam detection. It uses little training data to estimate the required parameters and is effective, particularly with high-dimensional datasets.

V. EXPERIMENTAL SETUP

Figures 4 below show the complete system setup, which includes sensors, Arduino, and a buzzer sensor. Figure 6 shows the website's main page, and figures 5 to 10 show the variations of parameters monitored using the thinkspeak website, The motor connected to the system enables it to move around the location to determine the pollution level at various geographical locations.

Fig 4 Robot Wired Connection with Arduino Uno

VI. RESULT

Fig 5 Thing Speak Main Web Page

Fig 6 Temperature Variation Graph

The temperature graph shown in figure 6 displays the temperature measured in short period of time where x- axis represents date, y-axis temperature and there is a spike in temperature which is recorded.

Fig 7 Humidity Variation Graph

This the humidity graph represented in figure 7 is used to display the humidity levels at different times where x-axis represents date, y-axis represents humidity and there is significant fluctuation in the humidity level which is being monitored.

Fig 8 Mq135 Variation Graph

This the mq135 graph is used to display the fluctuations in the gases available in the environment as shown in figure 9.

Fig 9 Mq9 Variation Graph

The figure 10 displays sound levels over specific dates. It provides insights into variations in air quality over time.

Fig 10 Sound Variation Graph

Table 2: ML Analysis values for Accuracy

Algorithm Used	Accuracy
RF	0.7568
DT	1.0000
KNN	0.7982
NB	0.7595

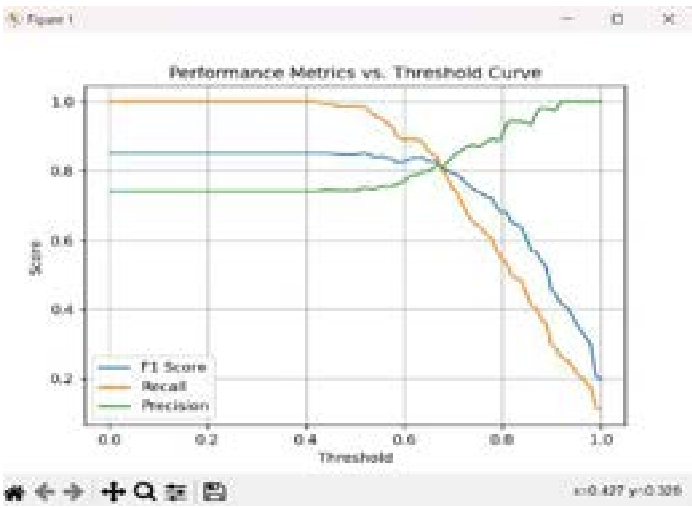

Fig 11 Performance Metrics vs Threshold Curve

Table 2 represent the accuracy obtained for various ML algorithm. Figure 11 shows the threshold curvewhich typically represented as a line or curve on a graph. The x-axis represents the decision threshold. It is a numerical value that determines how confident the model needs to be to classify a data point as positive.The y-axis represents a performance metric. The curve on the graph shows how the chosen performance metric changes as the decision threshold varies.

VII. CONCLUSION

This paper provides the analysis of Air Quality Index (AQI), which is dependent on the temperature humidity and sound of the surrounding air. The data is used to calculate air quality in parts per million. The benefit of MQ135, and MQ9 is that they can identify hazardous gases such as CO, NH4, and smoke, among others. It can accurately monitor the temperature in Celsius, the humidity in percentage, and the air quality in parts per million. The outcomes of the trials are confirmed using data from ML analysis Additionally, the Think Speak app is used to show the different variations in the level of air quality surrounding the setup.

***Abstract*—As more and more students are seeking counseling services to help them pursue higher education opportunities abroad, it has become apparent that there is a lack of automation and a monopolization of counseling agencies, which presents a challenge for these students. To address this issue, this study has developed HICON AI: Higher Education Counselor. HI-CON made from Higher - Counseling is an innovative application that offers personalized college selection and preparation recommendations to students. By asking a set of defined questions, the bot gets to know the user and provides tailored guidance based on the information provided, utilizing refined Machine Learning models and Retrieval Augmented Generation. This study has specifically used Llama 2, LLM by meta for the considered use case, because of its high performance and financial viability. The developed new product ensures the highest level of accuracy and reliability.**

***Index Terms*—HICON AI, LLMs, text to Speech, Categorizer, Machine Learning, Natural Language Processing, Retrieval Augmented Generation, Resume Screener.**

I. INTRODUCTION

India has witnessed a consistent growth in the Gross Enrollment Ratio (GER) within its higher education sector over the years. As per the latest findings from the All India Survey on Higher Education (AISHE) [9], the GER for higher education in India recorded a figure of 27.1 percent in the academic year 2020-21. Students faces a variety of questions about their academic interests, university preferences, application procedures, and future career prospects in the varied world of higher education today. Counselors for higher education are essential in addressing these issues and giving students personalized guidance.

Introducing 'HICON AI,' a dedicated chatbot that helps students pursue higher education. It is built on Large-scale Language Models (LLM). This AI functions as a virtual counselor by using Natural Language Processing (NLP) to evaluate student data and inquiries, producing automated responses that provide direction and advice. HICON AI attempts to streamline the procedure and lessen students' dependency on outside counselors. 'HICON AI's' audio prompting is a noteworthy feature that allows users to interact through audio inputs and outputs, improving productivity and the user experience in general. The model's capacity to understand inputs and generate pertinent text outputs is guaranteed by the large datasets it was trained on. 'HICON AI' is able to provide objective, individualized advice for each student according to their specific needs by classifying them according to a variety of criteria. Effective Class Categorization has been made possible by the development of extensive datasets, guaranteeing that the chatbot will respond with both precision and generality.

With the introduction of Retrieval Augmented Generation(RAG), the LLM hallucination and relevance of the data that is generated by the LLM is addressed. It improves the quality of the data generated by keeping it updated to the latest changes. Additionally, the feature of Resume-Screener of HICON AI helps the student to upload the all the necessary details required to be known to the system in one go insteadof typing the answers to each and every question in a user efficient manner. The interface through which the student will interact with the system is an easy to access and a user friendly one. Crafted with a user-friendly interface, the proposed HICON AI stands as a solution for personalized guidance for pursuing higher education. Seamlessly designed to offer a smooth user experience, it provides authentic and tailored support for academic and career decisions, ensuring a unique and reliable resource for students. The HICON AI proves to be a useful instrument in the field of higher education, providing students with individualized and easily accessible guidance, ultimately leading to a more informed and capable student body.

II. LITERATURE REVIEW

This section investigates the existing research works that enable the foundation of HICON AI.

A. Large Language Models (LLMs)

The field of LLMs has witnessed significant advancements, with various models like GPT-3, LlaMa-2, and Bard. A recent study by [5] provides a comprehensive comparison of these models, analyzing the impact of fine-tuning and hyper parameter tuning on their performance. The findings resonate with the observed increase in chatbot usage since the introduction of Generative AI.

Furthermore, [1] proposed a E2E benchmark to evaluate the quality of LLM-generated responses in chatbots. This bench-mark leverages cosine similarity to assess the resemblance between AI-generated text and human-crafted text (golden text). The E2E benchmark aims to mitigate the issue of hallucinations, where LLMs produce factually incorrect outputs. The study also highlights the effectiveness of prompt engineering in improving ROGUE scores, a metric used to evaluate the quality of summaries. However, the vulnerabilities associated with ROGUE-1 and ROGUE-2 scoring are acknowledged.

B. Chatbots

The potential of LLMs in educational chatbots is explored by [2]. Their work presents an intelligent tutoring system that utilizes Retrieval-Augmented Question Answering (RAQs). This approach involves extracting keywords from prompts and leveraging the internet to gather relevant knowledge, enriching the system's response generation capabilities. The model is further fine-tuned on educational datasets to enhance its responsiveness. Additionally, researchers have introduced Socratic teaching elements, where the chatbot engages in multi-step questioning instead of providing direct answers, fostering deeper learning. While their work paves the way for intelligent tutoring systems, it doesn't delve into the domain of career counseling. The authors propose future research directions in question generation and career planning.

Another study by [12] investigates the use of deep learning algorithms to create a personalized counseling chatbot for students. While this model avoids hallucinations due to its focused training data, its accuracy falls short of LLM-powered solutions.

C. Retrieval-Augmented Generation (RAG)

While our work focuses on LLMs for response generation, it's important to acknowledge Retrieval-Augmented Generation (RAG) as a complementary approach. RAG models com- bine retrieval techniques with generative capabilities. Several recent studies explore RAG applications in various domains. For instance, the research presented in [6] proposes a novel RAG variant that eliminates the need for vector embeddings, potentially simplifying model implementation, particularly for niche domains with limited data.

Other relevant RAG studies include [7] which explores RAG in the context of a specific industry process, and [4] which delves into potential challenges and limitations of RAG-based chatbots.

Our research focuses on LLM-based response generation for HICON AI. However, the exploration of RAG techniques for future iterations or for complementary functionalities remains a valuable avenue for further investigation.

Based on the above survey, we have formulated our research objectives which are unique and focuses on Higher Education Counseling.

III. Motivation

The increase of popularity for higher studies among students has been evident. To cater the huge number of students having queries regarding the higher education and those who are looking for a counseling advice, HICON AI would be of great help rather than going for a manual higher education counselor.

HICON AI, designed specifically for higher education, addresses the need for a dedicated chatbot in this domain, offering students personalized assistance. In contrast to conventional chatbots that often provide generic responses, HICON AI categorizes students based on their input, generating specific prompts for tailored advice on course selection, university choices, and other relevant aspects. To enhance the user experience, it incorporates features such as speech-to-text and text-to-speech, accommodating students with disabilities.

An essential component of HICON AI's functionality is the integration of advanced technologies like Retrieval Augmented Generation (RAG). RAG combines information retrieval with natural language generation, enabling swift data retrieval and the generation of contextually appropriate responses. This ensures that the advice provided to students remains current and accurate in the dynamic landscape of higher education. Additionally, HICON AI leverages Large-scale Language Models (LLMs) with supercomputer capabilities, trained on extensive datasets, to understand user inputs and generate nuanced, domain-specific responses, contributing to its overall efficiency.

Moreover, HICON AI goes beyond academic guidance by incorporating a resume screener feature. This tool streamlines the process of evaluating resumes, utilizing advanced algorithms to identify key qualifications, skills, and experiences relevant to the user's career goals. The resume screener enhances Counselor AI's utility by assisting students in preparing impactful resumes tailored to their chosen field of study or profession. This multifaceted approach makes Counselor AI a comprehensive and cutting-edge tool, offering students not only personalized educational guidance but also support in navigating the complexities of the job market.

IV. Objectives

HICON AI is crucial to the education sector because it helps many students through a critical point in their education, especially those who are pursuing higher education. This AI-based counselor is intended to provide fair, individualized, and easily accessible counseling sessions to students 24/7, answering their questions and dispelling any doubts they may have about pursuing higher education.

'HICON AI' places a lot of emphasis on classifying students according to the data they submit. This classification guarantees that the support given is unique to every student, in

name	age	college	year_of_st	cgpa	preffered_	internship

Fig. 2. Another Parameters of the Dataset

contrast to the general approach of most AI-based counselors. The four classifications created by 'Counselor AI' serve people at different phases of their pursuit of higher education. Those in Category 1 are those who have little experience and are just learning about the field, whereas those in Category 2 are those who are just starting out and may have completed some projects or internships. Group 3 consists of people who know enough but could still do better in some areas, while Group 4 is made up of people who know enough but are looking for new information to keep current.

The training model for student categorization makes use of a self-created dataset to guarantee that the prompts are brief and encompass all the higher studies material that the students require. This method improves HICON AI's abilityto provide accurate and pertinent advice that is suited to each student's needs.

Integrating cutting-edge technologies like Retrieval Augmented Generation (RAG) is crucial to HICON AI's functionality. RAG combines natural language generation with information retrieval to provide quick data retrieval and responses that are appropriate for the given context. This guarantees that, in the ever-changing context of higher education, the counsel given to students stays relevant and accurate. HICON AI's overall efficiency is further enhanced by the use of Large-scale Language Models (LLMs) with supercomputer capabilities that have been trained on vast datasets to comprehend user inputs and produce complex, domain-specific responses.

Additionally, HICON AI has a resume screener feature,

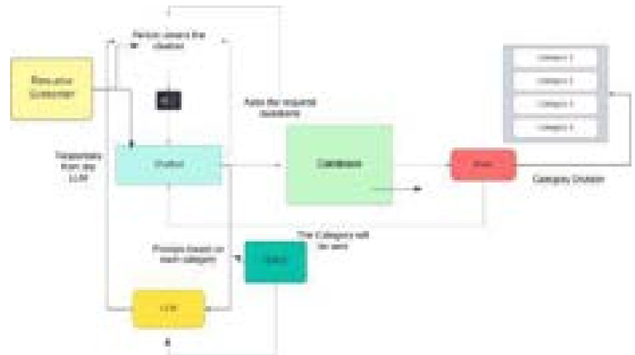

Fig. 3. System Architecture Diagram

which takes it beyond academic guidance. This application expedites the resume evaluation process by applying sophisticated algorithms to pinpoint the most important experiences, education, and training that relate to the user's desired career path. HICON AI's usefulness is increased by the resume screener, which helps students create compelling resumes that are relevant to their chosen careers or fields of study. HICON AI is a comprehensive and state-of-the-art tool that provides students with individualized educational guidance and support in navigating the complexities of the job market thanks to its multifaceted approach.

Using a Large-scale Language Model (LLM), which is well-known in the field of higher education and imitates communication between a real human counselor and students seeking higher education, is another important goal of the HICON AI. It processes and generates automated responses by analyzing inputs in the form of student data and queries using Natural Language Processing (NLP). Following classification, LLMs will produce answers for each category based on eight to ten prompts. These answers will be well-organized and fully contextualized to the questioner and the class.

Lastly, one of the other main goals of the HICON AI is the voice-based dialogue between the model and the students, which makes it appealing to a large number of students, especially those with disabilities. The speech inputs are transformed into text and fed to the model for processing. Once the model has finished processing the text responses, the text responses are transformed back into speech, improving the seamless experience for the students.

V. Proposed Methodology

A. *System Architecture*

When a user inputs 'HICON AI,' the assistant greets them warmly. The assistant will then prompt the user to answer specific questions about their unique use case. These questions will cover essential information like the user's name, age, year of study, as well as professional details such as internships completed and training specifics. The responses to these questions will be immediately populated in the resume screener. Additionally, there will be behavioral inquiries, such as whether the user has joined any social groups, with further details on these groups being saved in a separate database. These questions aid in categorizing users into distinct groups. Furthermore, language models (LLMs) will generate personalized questions based on these categories and tailored to each individual, such as asking about their desired university and courses. Since each person will have a unique perspective, responses will be customized to their interests. This process helps construct the final responses of HICON AI.

B. Modules

1. Data Gathering: To begin the process, the model requests the user to respond to a series of inquiries aimed at understanding the student's background. This includes information on work experiences, projects, research papers, social initiatives, volunteer work, and leadership roles. This data is usually extracted from resume using a resume screener built by us, or directly inputted by the user - if the data is not available in the resume.

2. Student Category division: Following data collection, a distinct Machine Learning model is employed to forecast the user's Category into one of four groups. Category 1 encompasses users who are new to the domain and are exploring its features. Category 2 individuals seek to enhance their knowledge and delve deeper into their interests. Category 3 users aim to identify gaps in their profiles and strategies to improve them. Category 4 users are focused on staying informed and maximizing their chances of admission to their desired universities.

3. Prompting: Prompts tailored to specific categories are created and adjusted using user data to ensure personalized responses for each category's use cases. RAG adds an extra feature for better quality of responses.

4. Responses: The answers for each prompt within the category are generated by language models (LLMs). Utilizing LLMs streamlines the process, making it more efficient to offer resources and advice.

5. Retrieval Augmented Generation: An essential component of HICON AI's functionality is the integration of advanced technologies like Retrieval Augmented Generation (RAG). RAG combines information retrieval with natural language generation, enabling swift data retrieval and the generation of contextually appropriate responses. This ensures that the advice provided to students remains current and accurate in the dynamic landscape of higher education. RAG takes in account of the data provided. It understands the process ofhow the data is created and the applies the same techniquesto generate new data.

6. Resume Screener: HICON AI goes beyond academic guidance by incorporating a resume screener feature. This tool streamlines the process of evaluating resumes, utilizing advanced algorithms to identify key qualifications, skills, and experiences relevant to the user's career goals. This data is extracted to make the user profile more efficient and to more about the user.

C. Implementation

For the implementation of the assistant, this study has opted for a form-based, text-input approach instead of socket programming. This approach allows the user, who is the student, to input data directly from their resume using a Resume Screener. This decision was made to streamline the process and simplify communication between the user and our Counselor AI model. Within the application, there are two main phases: one where data is gathered from the user via the form, and another where responses are provided based on the input received.

Before Categorization, a significant amount of data preprocessing is performed, during which all data items are assigned to their corresponding parameter classes and binary parameters are mapped. Data dictionary converted to pandas. Data frames will be used by the model to classify the data before being returned to the main dataset for further usage.

To create the categorizer, a random forest model was developed for category division. Due to the unique dataset created specifically for the model, there was limited data available. Random forest was chosen for its efficiency with smaller datasets. While both decision trees and random forest algorithms could have been utilized for categorization, random forest was preferred due to its ability to mitigate overfitting and its robustness to noise. Random forest is essentially a combination of multiple decision trees, which helps reduce overfitting by allowing each tree to over-fit differently [13]. Overfitting occurs when a model accurately predicts training data but fails to generalize to new data. This phenomenon arises when variance increases while bias decreases.

After creating the categorizer, this study has integrated the prompts for each category directly into the question-answer category interface. This eliminated the need for socket programming to deliver responses. Additionally, for personalized responses, we included data obtained from the user within the prompts themselves.

To finalize our project, a LLM is integrated to provide responses. This study has selected for Llama 2 developed by Meta-AI. Llama 2 was chosen over other LLMs primarily due to its novelty and accessibility. Moreover, Llama 2 boasts extensive training on billions of parameters, ranging from 7B to 70B parameters, making its responses exceptionally efficient [14]. Additionally, we're augmenting the model with Retrieval-Augmented Generation (RAG) for further fine-tuning and enhanced efficiency in response generation.

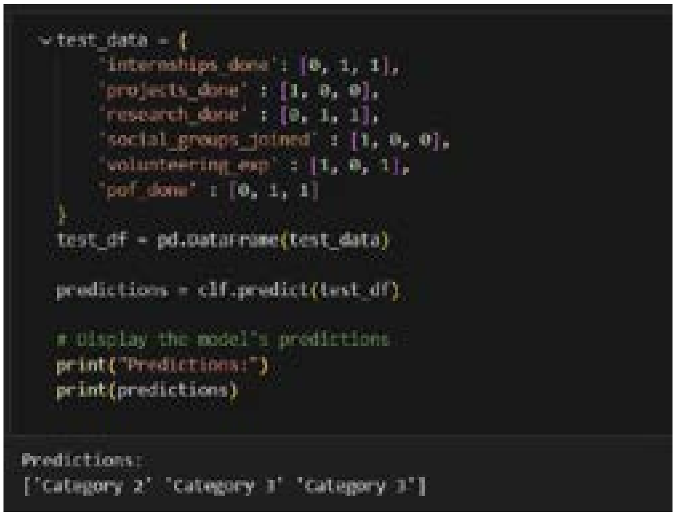

Fig. 4. Categorizer

Fig. 5. Data Collection

Fig. 6. Resume Screening

For the text-to-speech functionality we have used Whisper AI [11] which an Automatic Speech Recognition model made by Open AI. It a transformer sequence to sequence model trained on speech processing techniques. Model was also trained on a huge dataset, so fine-tuning is not necessary and it gives a good performance for out use case.

We used langchain [10] for the implementation of RAG in our system. LangChain is an open-source framework that helps developers build applications using large language models (LLMs). We used this because it provides direct functionalities to implement RAG and reduces the manual code writing. RAG [8] was used because it helps to improve the performance of the system. For the implementation, we provided it with context of an example output and the context of how the output was generated which we call history. The LLM understands this history of how the example output is generated and in the same way generates output for the new prompts. In this way we have a controlover our outputs and also can reduce the LLM hallucinations.

In our model, we have extensively utilized Natural Language Processing (NLP) at various stages. For instance, during the implementation of Retrieval-Augmented Generation (RAG), we tokenized the context and generated vector embeddings for further processing. Similarly, while generating outputs, we adjust the temperature and epochs of the Language Learning Model (LLM) to achieve the desired results. The LLM, which employs a sequence-to-sequence (seq-2-seq) architecture for generating responses, also relies on NLP.

VI. Results and Metrics

1. Data Gathering: The initial phase involves collecting information from the user, including their preferred universities, personal details such as name, age, and current year of study. This study also gather data on their academic background, encompassing the number of internships, projects completed, and research papers authored. Furthermore, we aim to capture details regarding the user's involvement in social activities, including volunteering experiences and held positions of responsibility.

2. Categorizing: After getting the required data from the user, we will be using the proposed categorizer model to predict the Category, based on the above data dictionary. Let's predictour category.

3. Responses: Once the category is determined, we'll incorporate prompts tailored to each category along with user-specific parameters obtained from the user data to ensure personalized responses. Subsequently, by executing the model, we'll generate our responses.

4. Accuracy Metrics: The Accuracy metrics for the categorizer, presented in *Table 1*, outline the performance across four categories. Utilizing a random forest algorithm,

Accuracy: 0.80				
	Precision	Recall	F1 Score	Support
Category 1	0.00	0.00	0.00	1
Category 2	0.75	0.75	0.75	4
Category 3	0.75	1.00	0.86	3
Category 4	1.00	1.00	1.00	2

TABLE I. ACCURACY

the metrics include Precision, Recall, and F1 Score for each category.

Discussing the evaluation of the LLM, we utilize specific tools and comparisons, as referenced in [3]. One benchmark used to assess the truthfulness of the LLM is TruthfulQA, where the score for LLaMA-2 7B is 45.2%, indicating satisfactory performance. While there are other evaluation benchmarks available, they are more meaningful when the LLM is fine-tuned to a specific dataset. Since our model wasn't fine-tuned, we adjusted the prompts to optimize the output quality.

A. Performance Improvement

Prompting: To enhance our system's performance, we can use prompting techniques like Chain of Thought Prompting for multi-step reasoning, Zero-shot-COT for tasks with limited data, and Tree of Thoughts for exploring multiple possibilities. These techniques can improve the model's accuracy, generalization, and interpretability.

Fine-tuning: Fine-tuning LLMs can significantly improve our system's performance by adapting pre-trained models to specific tasks or domains. However, we haven't fine-tuned our LLM due to the unavailability of a suitable dataset in our domain. In the future, we can consider fine-tuning for better performance, but it requires careful consideration of factors like dataset quality and training parameters.

Iterative Refinement: Iterative improvement include self-feedback and refinement with the same LLM, without requiring additional training or supervised data. This method can enhance LLM performance, making it more accurate and relevant for various tasks.

VII. Conclusion and Future Scope

HICON AI represents a cutting-edge model poisedto serve as a valuable resource for students aspiring to study abroad. With its focus on user-centricity, it offers an effective solution for various industries. Leveraging large language models and Natural Language Processing techniques, HICON AI delivers personalized guidance to students preparing for higher education. By reducing reliance on costly external counselors through targeted advice and support, it aims to democratize access to higher education, making it more affordable. While HICON AI is still in its nascent stages, advancements in technology promise to revolutionize the student experience, reshaping the landscape of higher education counseling. Moreover, there is untapped potential within the AI counseling domain. Strategies such as fine-tuning the model with college-specific data and implementing a peer review system for LLM-generated responses can enhance efficiency. Additionally, incorporating various score predictors for evaluating components like statements of purpose and letters of recommendation could further enrich the model's capabilities.

***Abstract*— Schizophrenia, a severe mental illness characterized by emotional, behavioral, and cognitive abnormalities, presents challenges in accurate diagnosis and effective treatment. Patients often experience delusions, hallucinations, and difficulties in thinking and social interaction. The impact on one's reality perception and emotional control is substantial. While typically emerging in late adolescence or early adulthood, post-COVID-19 cases of schizophrenia have shown an increase, emphasizing the need for improved diagnostic tools and treatments. Current methods involve antipsychotic drugs, psychotherapy, and mental health specialist assistance. However, these approaches vary in quality and accuracy. Electroencephalogram (EEG) signals, measuring brain electrical activity, provide insights into schizophrenia but lack direct diagnostic capabilities. To address these challenges, a deep learning model is proposed, utilizing transfer learning with Inception V3, Xception, and DenseNet121 models. Recognizing the limitations of a singular model, the study explores employing multiple models to enhance performance in schizophrenia detection. The investigation acknowledges and addresses inherent drawbacks, aiming to improve the accuracy of identification through the application of deep learning methods on specific datasets. In the context of the increasing post-COVID-19 schizophrenia cases, the urgency for advanced and accurate diagnostic approaches becomes even more pronounced.**

Keywords: Inception V3, Xception, DenseNet121, Electroencephalogram (EEG), Transfer Learning.

I. INTRODUCTION

The brain, a remarkable organ, plays a pivotal role in orchestrating the complexities of the human body. Its significance extends beyond its physical presence, as it is the command center for cognitive functions, emotions, and intricate neurological processes. The brain's intricate network of neurons enables us to think, feel, and interact with the world around us. However, like any complex system, the brain can face challenges, one of which is schizophrenia. Schizophrenia is a mental health disorder that affects how a person thinks, feels, and behaves. It can disrupt the normal functioning of the brain, leading to distorted perceptions of reality. Individuals with schizophrenia may experience hallucinations, delusions, and difficulties in organizing their thoughts. The exact cause of schizophrenia remains elusive, involving a complex interplay of genetic, environmental, and neurobiological factors. Understanding the significance of the brain and the impact of conditions like schizophrenia is crucial for fostering empathy, eradicating stigma, and promoting advancements in mental health research and treatment.

The detection of schizophrenia can benefit significantly from advanced deep learning techniques. Leveraging the power of deep neural networks, models such as Inception, Xception, and Dense121 can play a crucial role in analyzing complex patterns within the data fed. These models are adept at capturing intricate details and hierarchies in the data, providing a nuanced understanding of brain structures and activities associated with schizophrenia. The application involves feeding EEG channel data into these deep learning architectures, allowing them to automatically learn and extract meaningful features. Inception, Xception, and Dense121, being state-of-the-art deep learning models, can discern subtle abnormalities in brain scans associated with schizophrenia

II. LITERATURE SURVEY

Recent advancements in machine learning (ML) and deep learning have prompted a surge of research aimed at enhancing the understanding and diagnosis of schizophrenia. In a study presented at the 2023 World Symposium on Digital Intelligence for Systems and Machines, the intricate interplay of clinical features and cognitive behavior in schizophrenia was explored through a machine learning lens [1]. A personalized mobile sensing-based supervised deep learning model was introduced for predicting psychotic relapse in schizophrenia patients, leveraging mobile data to enhance prediction accuracy and tailor interventions [2]. Another study in the same journal proposed a comprehensive evaluation approach for diagnosing schizophrenia, integrating various clinical factors to provide a holistic diagnostic perspective [3]. Social media data gathered through a Chrome extension was used for mental health analysis using deep learning in a study presented at the 4th International Conference for Emerging Technology [4]. Multi-modal deep learning, combining imaging genetics for schizophrenia classification, was the focus of a study presented at the 2023 IEEE International Conference on Acoustics, Speech, and Signal Processing Workshops [5].

Deep learning from imaging genetics for schizophrenia classification was explored in another study presented at the 2022 IEEE International Conference on Image Processing [6]. The effects of schizophrenia on electroencephalogram (EEG) data were examined using explainable deep learning models in a study presented at the 2022 IEEE 22nd International Conference on Bioinformatics and Bioengineering [7]. ConvNet and machine learning models with feature engineering were utilized in another study for the classification of schizophrenia using motor activity data [8].

These studies collectively demonstrate the potential of machine learning and deep learning techniques in shedding light on schizophrenia's complexities.

III. PRELIMINARITIES OF THE RELATED WORK

The system proposed has three models that are trained with an approach of Supervised Learning.

Requirements of the model:

The Inception V3 model, a deep learning architecture, is designed for image classification tasks. It belongs to the family of convolutional neural networks (CNNs) and is particularly recognized for its efficiency in processing visual data. The model employs a sophisticated network structure with the utilization of inception modules, which involve the parallel execution of multiple convolutions with different kernel sizes. This approach allows the network to capture features at various scales, enhancing its ability to recognize patterns in images. Inception V3 is known for its versatility and robust performance, making it suitable for a wide range of computer vision applications. Its inception modules contribute to improved computational efficiency and parameter utilization, enabling effective feature extraction and representation in the hierarchical layers of the network.

Xception, short for "Extreme Inception," is a deep learning model designed for image classification tasks, belonging to the family of convolutional neural networks (CNNs). What distinguishes Xception is its departure from the traditional inception modules. Instead, it adopts a depthwise separable convolutional approach, which separates spatial and channel-wise operations. This design significantly reduces the number of parameters, enhancing computational efficiency while maintaining or even improving the model's representational power. The Xception architecture excels in capturing intricate patterns in images, making it well-suited for tasks requiring fine-grained feature recognition. Its depthwise separable convolutions contribute to improved generalization and training efficiency, positioning Xception as an asset in the realm of computer vision applications.

DenseNet-121 (Dense121) is a specialized deep learning model designed for image classification tasks, belonging to the family of densely connected convolutional networks (DenseNets). Its distinctive feature is the dense connectivity pattern, where each layer receives direct input from all preceding layers. This design promotes efficient parameter utilization, encourages feature reuse, and alleviates the vanishing gradient problem. Specifically comprising 121 layers, Dense121 demonstrates efficacy in capturing intricate patterns in images due to its densely connected blocks. The dense connectivity architecture facilitates improved gradient flow, enabling the model to efficiently learn and represent complex features. This model's unique approach enhances computational efficiency while maintaining high performance. Dense121 is particularly suitable for tasks requiring detailed feature recognition in computer vision applications. Its balance between depth, parameter efficiency, and representation power makes it a robust and versatile choice for image classification. In summary, DenseNet-121 stands out as a powerful and efficient deep learning model, offering a compelling solution for various computer vision challenges.

IV. METHODOLOGY

In the methodology employed for schizophrenia detection, Inception, Exception, and DenseNet121 models serve as critical components which works on Electroencephalogram (EEG) data. These state-of-the-art neural network architectures are applied to analyze intricate patterns and features present in the two-dimensional data taken.

i) Data Collection:

An approach is selected called EEG stands for Electroencephalography, which is a neurophysiological monitoring method to record electrical activity in the brain over time. The freely available data is taken from a public repository by Olejarczyk and Jernajczyk in which EEG data is collected which contains the measures of voltage fluctuations resulting from ionic current flows within the neurons of the brain. These electrical potentials are typically recorded from multiple electrodes placed on the scalp. Above 18 years old patients are included in this study with the diagnosis of F20.0 in the ICD-10 category, who did not take any drugs at least seven days before collecting the data for diagnosing. 18 years younger patients, pregnant patients, patients suffering from severe neurological diseases and brain disorders were excluded from the study. Males and female patients are collected equally. As a total of 28 recordings were gathered (14 were males and 14 were females). 14 Schizophrenic patients' data is collected in which 7 are males and 7 are females. And 14 control groups (normal and healthy) data is collected in which 7 are males and 7 are females. The average ages of these groups are noted in the table-1 shown below.

	Average age	
Patients	**Males**	**Females**
Normal and Healthy	26.8 ± 2.9	28.7 ± 3.4
Schizophrenic	27.9 ± 3.3	28.3 ± 4.1

Table.1.s – Average ages of patients

A total of 19 electrode channels are placed on the scalp of the patient based on 10-20 system for the extraction of EEG data of the patient. 7 electrode channels (Fp1, Fp2, F7, F3, Fz, F4, F8) in the Frontal Region, 5 electrode channels (T3, C3, Cz, C4, T4) in the Central region, 5 electrode channels (T5, P3, Pz, P4, T6) in the Parietal region, and 2 electrode channels (O1, O2) in the Occipital region are placed accordingly. The placement of these electrode channels are as shown in the fig.1 below.

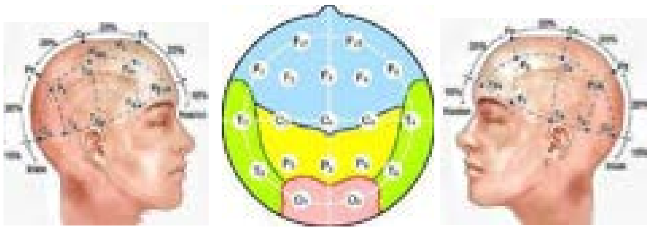

Fig.1. 10-20 EEG electrode channel placement

The recordings were observed for an average of 15 minutes while they were in the resting state with their eyes closed. Each patient contains the data collected from 19 electrode channels (i.e., Fp1, Fp2, F7, F3, Fz, F4, F8, T3, C3, Cz, C4, T4, T5, P3, Pz, P4, T6, O1, and O2) at a sampling rate of 250 Hz using 10/20 EEG montage methodology.

ii) Preprocessing Data:

EEG data undergoes segmentation into smaller time epochs as a standard step in the data preprocessing pipeline. During this preprocessing phase, we executed baseline correction by subtracting the mean voltage recorded during a specific period from the entire EEG signal. This crucial step aimed to minimize variations that were unrelated to the experimental conditions, ensuring a more accurate representation of the underlying brain activity. In the recording of signals, the method of average referencing was employed, designating C3 as the reference electrode. This referencing approach played a pivotal role in establishing a standardized baseline across multiple electrodes. By doing so, it facilitated the precise interpretation of EEG signals in relation to the chosen reference point, contributing to a more robust and reliable analysis of the neural activity patterns.

iii) Spectrogram Formation:

A spectrogram is essentially a visual depiction that captures the dynamic interplay of frequencies within a signal over time that represents the spectrum of frequencies in a signal that are varying with time. They are often displayed as two-dimensional heatmaps that vividly showcases how the spectral content of the signal changes throughout its duration, where the x-axis represents time domain, the y-axis represents the frequency domain, and the color or intensity represents the strength (amplitude or power) of the signal at each time-frequency point. This visual portrayal is particularly useful for unraveling the temporal evolution of a signal's frequency spectrum.

In the proposed methodology, the spectrograms are created using Short-Time Fourier Transform (STFT) which is a used technique in signal processing, particularly in the analysis of EEG data which is a time varying signal as EEG signals are dynamic. EEG signals are time-varying, and the STFT allows one to study the evolution of the frequency content across various time intervals. The signal is sliced into short, overlapping segments, and for each segment, the frequency composition is analyzed through the Fourier Transform. This is crucial for recording fleeting trends and variances in brain activity, offering insightful information about diseases like schizophrenia. By localizing the analysis to brief signal segments, the employment of a window function in the time domain makes it easier to isolate study-relevant properties. All things considered, the STFT is helpful in exposing the time-varying spectrum properties of EEG signals, which advances our understanding of cerebral activity patterns.

The formula for the Short-Time Fourier Transform of a signal $x(t)$ is given by:

$$X(f,t) = \int_{-\infty}^{\infty} x(\tau) * \omega(\tau - t) * e^{-j2\pi f\tau}\, d\tau$$

where

- $X(f,t)$ is the STFT of the signal at frequency f and time t.
- $x(t)$ is the input EEG signal in the time domain.
- $\omega(\tau - t)$ is a window function centered at time t, which is applied to the signal to isolate a short segment.
- $e^{-j2\pi f\tau}$ is the complex exponential term representing the frequency content.

In the dataset under consideration, each patient is represented by a set of data corresponding to 19 electrode channels. The analysis involves the generation of spectrograms for each individual electrode pertaining to a specific person. A spectrogram, essentially a visual representation of the frequency spectrum's evolution over time, is created independently for each electrode. To illustrate, Figure-2 in the dataset provides a sample representation of such a spectrogram for one electrode.

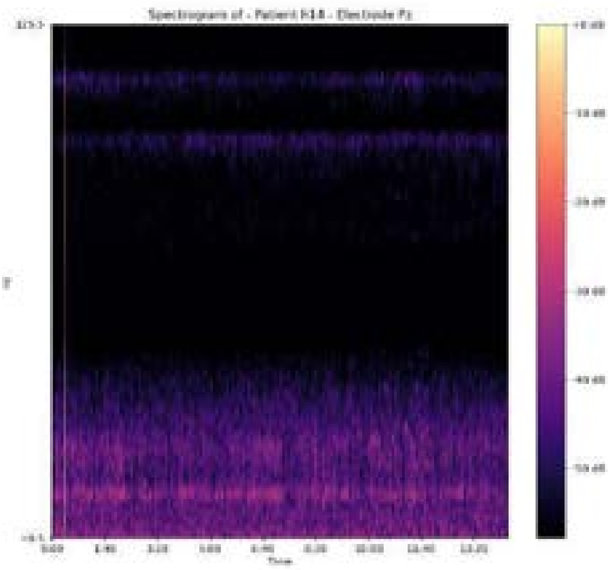

Fig.2. Sample spectrogram of Pz electrode of a healthy patient

The process involves the concatenation of these individual electrode spectrograms into a two-dimensional array. Specifically, the 19 electrodes are sequentially arranged in this array, one after the other. This arrangement forms a comprehensive visualization of the frequency content for each electrode, collectively capturing the unique electrical activity at each channel. By concatenating the spectrograms strictly and tightly in such a manner that gaps, axes and measurements aren't allowed in between them, the resulting 2D array allows for a holistic overview of the neural activity across all electrodes for a given patient are shown in the figures 5 and 6. This method enables researchers to observe and analyze potential patterns, trends, or anomalies in the spectral characteristics of the brain signals recorded from different regions. Such an approach is particularly valuable in exploring the nuanced details of brain activity and can facilitate the identification of

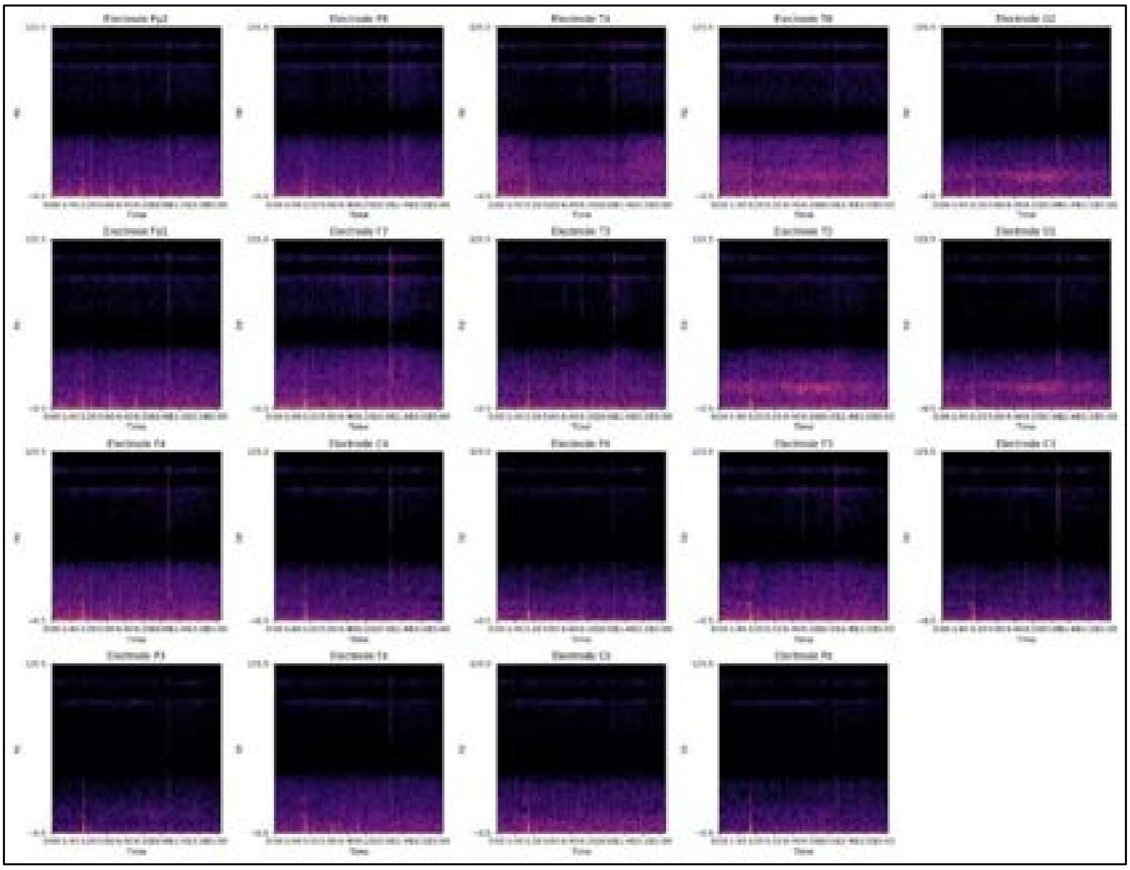

Fig.3. Spectrograms of 19 electrode channels of a Normal patient.

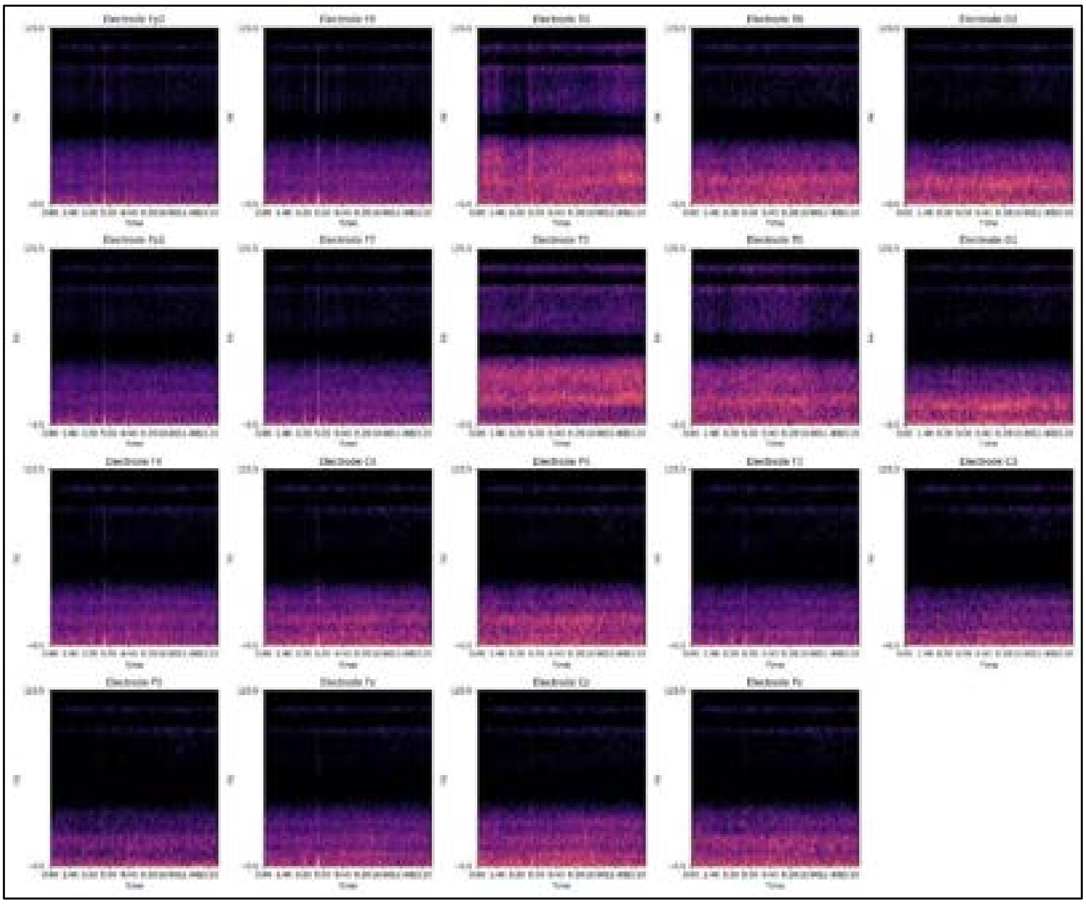

Fig.4. Spectrograms of 19 electrode channels of a Schizophrenic patient.

electrode-specific contributions to the overall neural dynamics within the dataset.

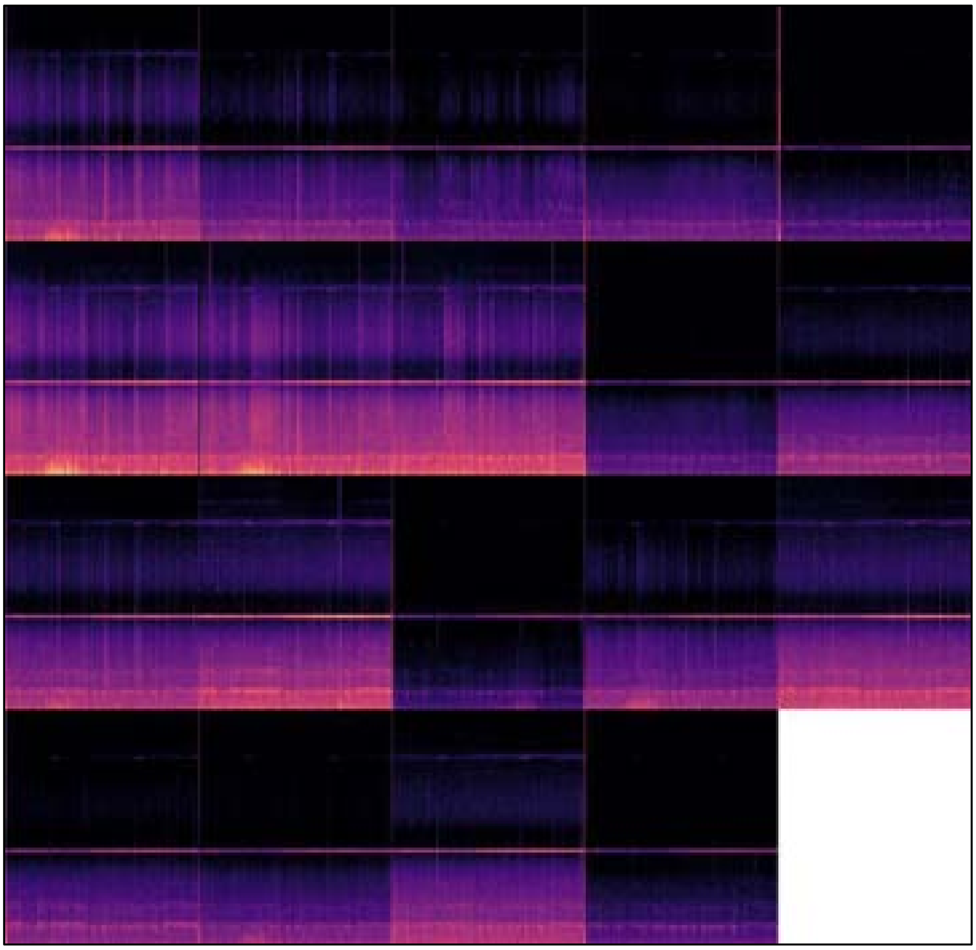

Fig.5 .Concatenated image of Spectrograms of 19 electrode channels of a Healthy patient.

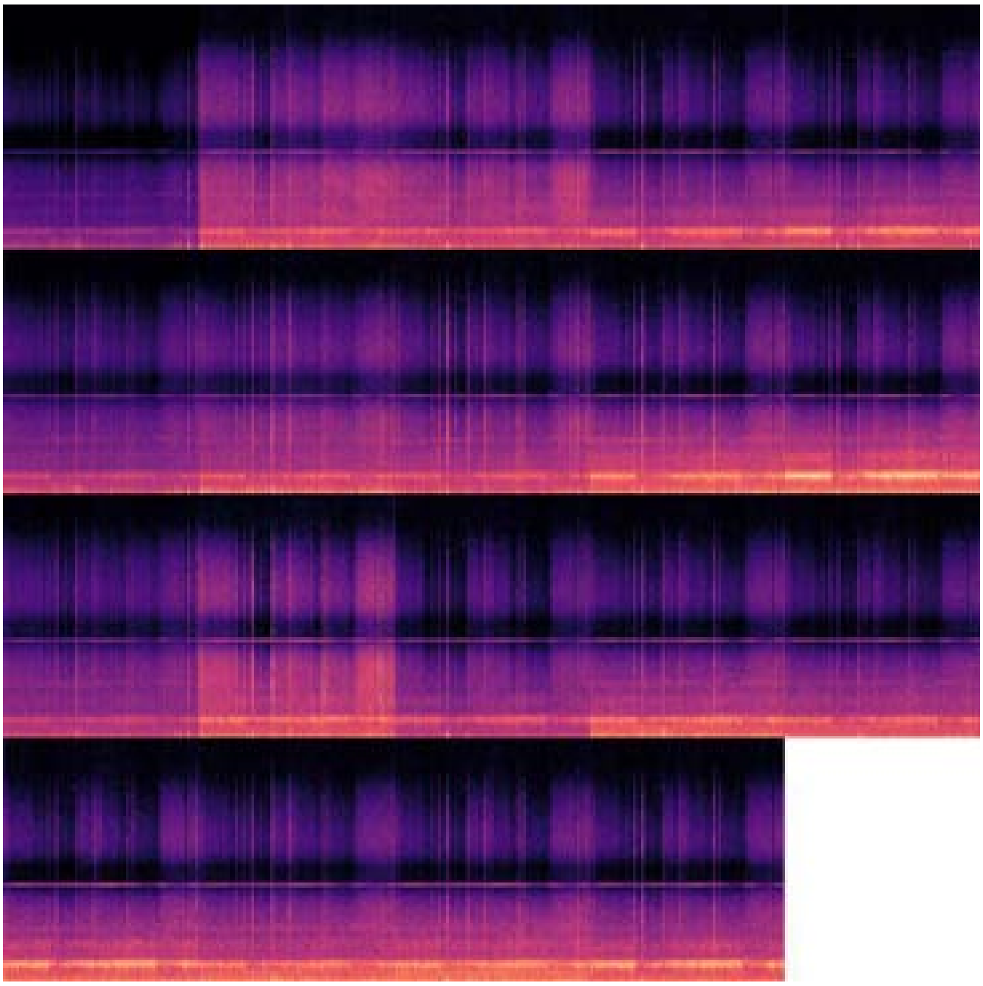

Fig.6. Concatenated image of Spectrograms of 19 electrode channels of a Schizophrenic patient.

iv) Transfer Learning Model Architectures

In our quest for effective schizophrenia detection using EEG data, we employed transfer learning with three prominent neural network architectures named — Inception V3, Xception, and DenseNet121. Transfer learning allows us to leverage the knowledge gained by a pre-trained neural network on a vast dataset and adapt it to a specific task. The intricate patterns and features present in the two-dimensional EEG data were analyzed by these state-of-the-art models. By fine-tuning these models, we harnessed its adaptability to discern complex patterns inherent in EEG signals, contributing to a nuanced understanding of neural activity associated with schizophrenia. Hence, we added a custom classification head to the existing model architectures, we tailored the models to the nuances of EEG data for schizophrenia detection.

Inception V3 Model:

Relevant hierarchical information from EEG signals was extracted, and the adaptability of Inception V3 model architecture allowed the discernment of complex patterns indicative of neural activity related to schizophrenia. Fine-tuning was carried out on the Inception model as shown in the fig.7 given below, acknowledged for its capability to capture multi-scale features through the utilization of inception modules.

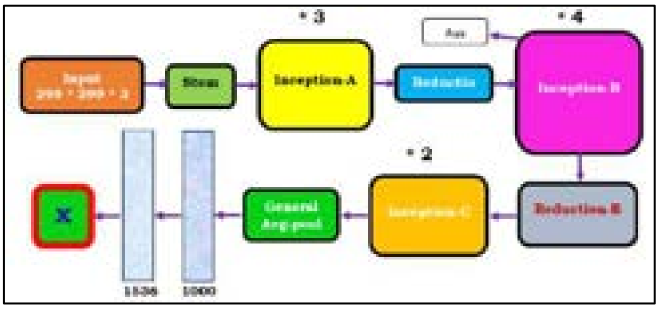

Fig.7 Fine-Tuning of Inception V3 model

In the above figure-7, X denotes the custom layers that are generated on fine-tuning of the Inception V3 model, serve as a custom classification head. These layers include flattening the output, introducing a dense layer with 512 units and ReLU activation, incorporating dropout for regularization, and concluding with a dense layer with 2 units and SoftMax activation for binary classification (schizophrenia or Normal). This tailored classification head allows the model to learn discriminative features specific to our EEG dataset.

Xception Model:

In our pursuit of advancing schizophrenia detection through deep learning methodologies, we employed transfer learning with the Xception architecture. Recognized for its proficiency in handling diverse and complex datasets, Xception served as the backbone for our model. The integration of a custom classification head, fine-tuning, and the introduction of a novel focal loss function aimed to tailor the Xception model to the intricate patterns present in EEG recordings, contributing to its effectiveness in identifying subtle abnormalities associated with schizophrenia.

Fine-tuning was applied to the Xception model as shown in the fig.8, recognized for its proficiency in handling diverse and complex data. This architecture was adapted to interpret nuanced patterns embedded in EEG recordings. The Xception model's capacity to adapt to irregularities in the data contributed to its effectiveness in identifying subtle abnormalities associated with schizophrenia.

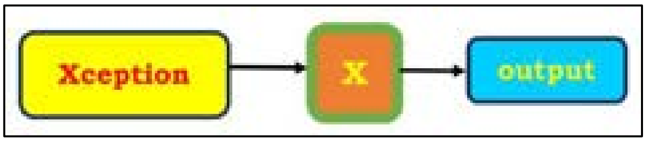

Fig.8 Fine-Tuning of Xception model

In the above figure-8, X denotes the custom layers that are generated on fine-tuning of the Xception model, serve as a custom classification head, which built on top of the Xception base includes a Global Average Pooling layer for dimensionality reduction, followed by two dense layers. The final dense layer with a sigmoid activation function enables binary classification (schizophrenia or non-schizophrenia). The model was compiled with the Adam optimizer and binary cross-entropy loss function. To enhance the model's sensitivity to rare events, we introduced a focal loss function. Unlike traditional binary cross-entropy, focal loss assigns higher weights to misclassified minority samples, focusing the model's attention on challenging instances. This approach is particularly relevant in the context of schizophrenia detection, where abnormalities may manifest subtly in EEG data.

Fine-tuning of the Xception model was a crucial step in adapting the architecture to the irregularities inherent in EEG recordings. By retraining the model to the learned features along with the added classification head, while allowing the model to specialize in the nuances specific to our dataset. The adaptability of Xception to diverse data types contributed to its effectiveness in capturing the complex patterns associated with schizophrenia.

DenseNet121 Model:

The DenseNet121 model, well-known for its dense connectivity patterns, was leveraged by performing adaptation to capture intricate dependencies within EEG data. Exploiting the densely connected layers, hierarchical representations of EEG features were effectively learned, enhancing sensitivity to subtle abnormalities characteristic of schizophrenia. As part of transfer learning, Fine-tuning is carried for DenseNet 121 as shown in the fig.9 given below.

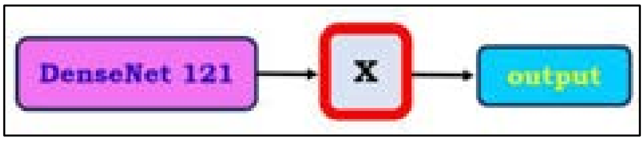

Fig.9 Fine-Tuning of DenseNet 121 model

In the above figure-9, X denotes the custom layers that are generated on fine-tuning of the DenseNet 121 model, serve as a custom classification head. Output layer is carried by it to obtain the proper appropriate results. Our custom model architecture, built on top of the DenseNet121 base, includes a Global Average Pooling layer for dimensionality reduction, followed by two dense layers. The final dense layer with a sigmoid activation function facilitates binary classification (schizophrenia or non-schizophrenia). The model was compiled using the Adam optimizer and binary cross-entropy loss function.

V. RESULTS AND DISCUSSIONS

In this study, our proposed models for schizophrenia detection through EEG data underwent a thorough evaluation, revealing commendable performance across various metrics. These results of the metrics underscore the efficacy of the model in discerning subtle patterns indicative of schizophrenia within the concatenated electrode spectrograms. The model's ability to generalize well to new data, thanks to transfer learning, is reflected in the high accuracy and suggests its robustness in real-world applications.

In our proposed concept, we depict the plots of accuracy and loss of training and validation datasets of the models as they play a pivotal role in identifying potential issues such as overfitting or underfitting, guiding adjustments to the model architecture, learning rate, or regularization techniques. The point of minimal validation loss becomes a key reference for selecting an optimal model checkpoint. As well as the robustness of the models is analyzed using accuracy (1), precision (2), recall (3), f1 score (4), specificity (5), and sensitivity (6).

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad \rightarrow\rightarrow\rightarrow\rightarrow\rightarrow\rightarrow \; (1)$$

$$Precision = \frac{TP}{TP + FP} \quad \rightarrow\rightarrow\rightarrow\rightarrow\rightarrow\rightarrow \; (2)$$

$$Recall = \frac{TP}{TP + FN} \quad \rightarrow\rightarrow\rightarrow\rightarrow\rightarrow\rightarrow \; (3)$$

$$F1\ Score = \frac{2 \times Precision \times Recall}{Precision + Recall} \quad \rightarrow\rightarrow\rightarrow\rightarrow\rightarrow\rightarrow \; (4)$$

$$Specificity = \frac{TN}{TN + FP} \quad \rightarrow\rightarrow\rightarrow\rightarrow\rightarrow\rightarrow \; (5)$$

$$Sensitivity = \frac{TP}{TP + FN} \quad \rightarrow\rightarrow\rightarrow\rightarrow\rightarrow\rightarrow \; (6)$$

Where

TP (True Positives)- Instances that are correctly predicted as positive by the model.
TN (True Negatives)- Instances that are correctly predicted as negative by the model.
FP (False Positives)- Instances that are incorrectly predicted as positive by the model when they are actually negative.
FN (False Negatives)- Instances that are incorrectly predicted as negative by the model when they are actually negative.

The results of performance metrics are as shown below.

Inception V3

The training and validation accuracy and loss plots are depicted and shown below in Fig. 10a and 10b.

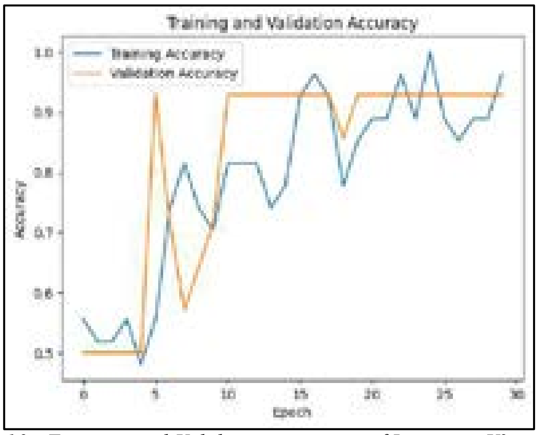

Fig.10. Training and Validation accuracy of Inception V3 model

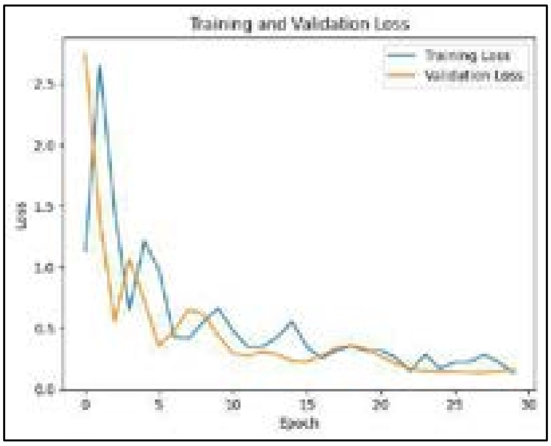

Fig.11. Training and Validation loss of Inception V3 model

The Inception v3 model demonstrated impressive accuracy, achieving a score of 96.15%. This indicates minimal error, with only 3.85% of predictions being incorrect. Examining the loss function further reveals a promising trend. Training loss steadily decreased, suggesting effective learning. However, validation loss remained relatively constant, hinting at potential overfitting to the training data. This suggests further adjustments or regularization techniques may be beneficial for improved generalizability.

A deeper dive into performance metrics paints a positive picture. The model attained exceptional precision (96.45%) and recall (96.15%), signifying its ability to accurately identify both true positives and avoid false positives. F1 score of 96.16 further solidifies this balanced performance. Notably, specificity reached a perfect 1.0000, indicating flawless identification of true negatives. However, a sensitivity of 0.9286 suggests room for improvement in capturing a small portion of true positives. This report is given below in Fig. 10(c) This metric could be prioritized in future optimization efforts.

```
Accuracy: 0.9583
Precision: 0.9615
Recall: 0.9583
F1 Score: 0.9583
Specificity: 1.0000
Sensitivity: 0.9167
```

Fig.12. Performance metrics of Inception V3

Xception

The Xception model displayed impressive accuracy on the task at hand as shown in fig.11(a), showcasing the model's adeptness at making correct predictions. However, analyzing the loss function reveals a potential area for improvement. While the training loss steadily decreased, indicating effective learning, the validation loss remained relatively constant as shown in fig.11(b).

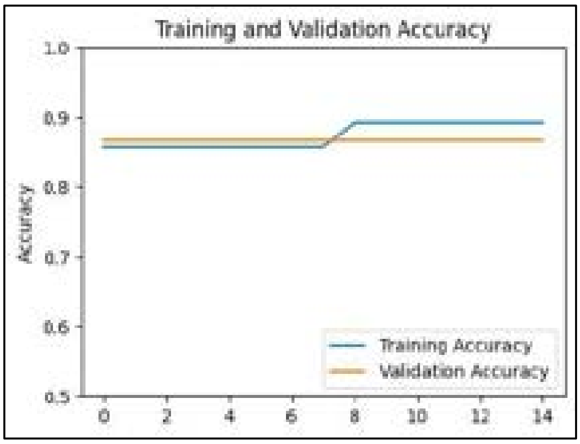

Fig.13. Training and Validation accuracy of Xception model

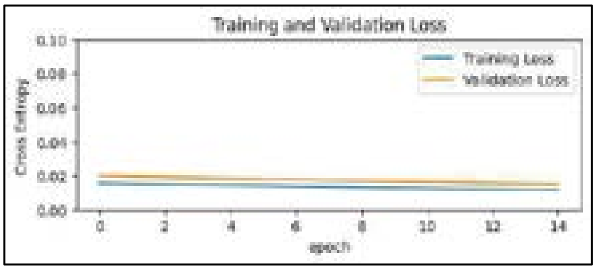

Fig.14. Training and Validation loss of Xception model

The model appears to be performing well, with an accuracy of 93.33%, precision of 94.17%, recall of 93.33%, F1 score of 93.33%, specificity of 87.50%, and sensitivity of 1.0000. This means that the model is correctly classifying about 93% of the images it is shown, and it is particularly good at identifying true positives (sensitivity of 100%). However, the specificity of 87.50% suggests that the model may be making some false positive errors. The report of Xception is shown in fig.11(c).

```
Accuracy: 0.9333
Precision: 0.9417
Recall: 0.9333
F1 Score: 0.9333
Specificity: 0.8750
Sensitivity: 1.0000
```

Fig. 15. Performance metrics of Xception model

DenseNet 121

DenseNet 121's accuracy plot is drawn below in fig.12(a) is impressive, but addressing the gap between training and validation performance could unlock its full potential. By striking a balance between learning from the known and adapting to the unknown, DenseNet 121 can evolve into an even more versatile tool for tackling diverse challenges. Peering into the loss function sheds further light. The decreasing training loss signifies effective learning, as the model refines its predictions shown below in fig.12(b).

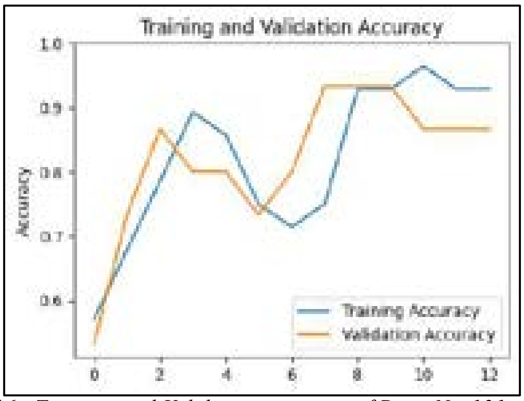

Fig.16. Training and Validation accuracy of DenseNet 121 model

Fig.17. Training and Validation loss of DenseNet 121 model

DenseNet 121 demonstrates strong performance with its high accuracy, precision, recall, and F1 score. The model boasts an impressive accuracy of 95.83%, indicating its adeptness. Delving deeper into the metrics unveils the potential area of improvement. The detailed report is shown in the fig.12(c).

```
Accuracy: 0.9615
Precision: 0.9645

```

Fig.18. Performance metrics of DenseNet 121 model

The above models can detect schizophrenia through the concatenated spectrograms and are performed to their best. The obtained results

Each model shines in its own domain and demonstrated unique strengths in capturing intricate patterns within the neural activity recorded by 19 electrode channels. Inception V3 holds the crown for balanced performance and near-perfect specificity, while Xception excels at sensitivity. DenseNet 121, with its raw learning power and sophisticated architecture, holds immense potential once it conquers the challenges of learning and identifying data. The performance of Inception V3, Xception, DenseNet 121 is compared in the table.2. Inception V3, renowned for its multi-scale feature extraction and adaptability, showcased exceptional accuracy, precision, recall, and specificity, underscoring its effectiveness in discerning subtle abnormalities indicative of schizophrenia. Xception, leveraging its proficiency in handling complex data, yielded remarkable results, showcasing its adaptability to the nuances of EEG recordings. Meanwhile, DenseNet121, with its dense connectivity patterns, achieved comparable performance.

	Inception V3	Xception	DenseNet 121
Accuracy	95.83	93.33	96.15
Precision	96.15	94.17	96.45
Recall	95.83	93.33	96.15
F1 Score	95.83	93.33	96.86
Specificity	100	87.50	100
Sensitivity	91.67	100	92.86

Table.2. Performance of models

The overall comparison of the three models' accuracies and losses are plotted below in fig 13 and fig 14.

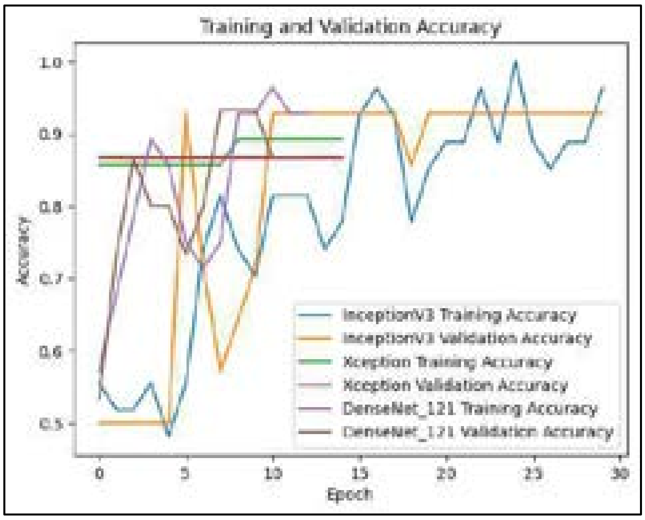

Fig.19. Training and Validation accuracies of three models

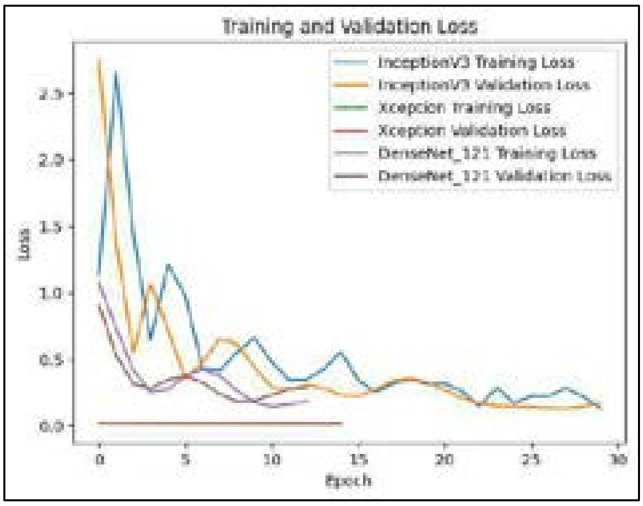

Fig.20. Training and Validation losses of three models

Each model's loss function decreased with each epoch in a non-linear fashion for the inceptionV3 and Densenet 121 models, and in a slightly linear fashion for the Xception model. The training and validation accuracies and losses of Inception V3 and DenseNet 121 are quite closure. There is a small gap is visible between the accuracies of training and validation of Xception model which indicates that it observes a particular pattern to detect the Schizophrenia. Hence, we can say that the adaptability of Xception model is a little bit better than Inception V3 and Densenet 121 models.

The nuanced insights gained from the performance metrics and training dynamics enhance our understanding of the intricate relationships within EEG data. The model architectures have proven to be a potent strategy in the realm of schizophrenia detection. With careful analysis and strategic training, these models can work in tandem.

VI. CONCLUSION

Utilization of transfer learning with the model architectures has proven to be a formidable strategy in the realm of schizophrenia detection. The model's ability to extract hierarchical information from EEG signals, combined with its fine-tuned custom classification head, has resulted in exceptional performance. This study presents a pioneering exploration of multimodal analysis in schizophrenia detection through the concatenation of electrode spectrograms and application to state-of-the-art deep learning architectures. Our findings underscore the potential of this approach in uncovering intricate neural signatures associated with schizophrenia, providing a foundation for further research and the development of advanced diagnostic tools. It is demonstrated that the models InceptionV3, Xception and DenseNet 121 performed well in detecting schizophrenia. Notably, these models exhibited superior adaptability in which Xception model leads. The complex architecture and heavier depth in the layers of these models make easier of identifying different patterns in the spectrograms leads to the efficient detection of the Schizophrenia. The effectiveness of transfer learning techniques was apparent, although a consistent, steady transition in validation and training accuracies throughout each epoch was not assured. This variability is attributed to the diverse nature of the dataset and the iterative parameter updates at each epoch. The efficacy demonstrated by these models in our investigation underscores the importance of employing deep learning architectures renowned for their proficiency in capturing hierarchical features. The adaptability and discernment capabilities exhibited by the model in analyzing intricate patterns within EEG data significantly contribute to the advancement of schizophrenia detection methodologies. The attainment of high levels of accuracy further underscores the potential clinical significance of our approach, thereby presenting a promising avenue for facilitating early diagnosis and intervention in the context of schizophrenia.

***Abstract*—This research work introduces a smart parking system leveraging Internet of Things (IoT) technology to address urban parking challenges. It utilizes sensors to detect parking slot availability and communicates this data via Wi-Fi to an IoT platform accessible globally. Through this system, users can remotely access real-time parking availability information from anywhere, facilitating efficient parking space utilization. The implementation involves Raspberry Pi interfacing with sensors to detect parking status and transmitting this information to the IoT platform using HTTP. The platform displays the data, enabling users to identify vacant parking slots conveniently. This solution enhances urban mobility by reducing time spent searching for parking, thus alleviating traffic congestion and environmental impact associated with vehicle emissions. Additionally, it demonstrates the practical application of IoT in addressing everyday challenges, showcasing the potential for technology to streamline urban infrastructure and improve the quality of life.**

Keywords— Smart parking system, Internet of Things (IoT), sensors, Wireless Fidelity (Wi-Fi) module, Raspberry Pi, Hypertext Transfer Protocol (HTTP), urban mobility, traffic congestion, environmental impacts.

I. INTRODUCTION

Recent years of population growth correspondingly increases the amount of traffic congestion. The use of cars has increased in proportion to the population. There was traffic congestion on the road as a result of increased car usage. Also, it takes longer time to find a free parking space. In order to locate the empty parking space in the parking field, we therefore lose a certain amount of time and waste more than 75 - 85 percent of the fuel. In order to address this issue, the parking lot needs a specialized system that measures empty space and displays the data to individuals searching for it.

In smart parking system operates on a streamlined process is facilitated by various components. Initially, users book parking slots through an IoT-enabled webpage, which also provides real-time availability updates. Upon arrival, RFID tags are used for identification, triggering the entry gate servo motor to open after validation. Infrared sensors detect parked cars, initiating a timer to record parking duration. If a vehicle fail to arrive within the allotted time, bookings are automatically cancelled. Payment for parking is processed through the webpage, with Twilio sending SMS reminders for payment. Failure to pay results in the exit gate remaining closed, while successful payment prompts it to open, allowing vehicles to exit. This integrated system optimizes parking management by efficiently utilizing available space and automating access control and payment processes. The Raspberry Pi Zero 2W serves as the central processor, storing and executing the system's program, while the IoT technology enables remote monitoring and interaction with the system via the internet. Overall, the system enhances user experience, reduces congestion, and improves overall efficiency in parking management.

II. LITERATURE SURVEY

A navigation and reservation based smart parking platform using genetic optimization for smart cities [1] proposed a location and reservation-based parking system. The suggested approach includes developing tiny gadgets that use Internet of Things (IoT) to transmit data to the internet. A genetic algorithm locates the nearby free parking field to the user area. A number of cases are evaluated with the suggested strategy, and precise results are obtained.

In order to prevent traffic congestion, Smart Parking System to Reduce Traffic Congestion[2] suggested the idea of a reservation-based smart parking system. Drivers may park at the designated spot without having to seek because the system will intelligently direct them there. GPS technology aids in directing the car to the closest parking space. Drivers can choose the best spot by using the Graphical Interface, which displays both reserved and open spaces. The notification will appear if the user's time is longer than the time restriction..

Automatic Parking Space Detection and Tracking for Underground and Indoor Environment [3], suggested a technique that uses combination of sensors to identify and parking spaces in indoor and underground environments. The parking field marking is done by employing parallel line pairs. Then free slots are discovered via making use of ultrasonic sensors. Low-level integration of AVM pictures and sensor detects the pillars. the user experiences greater comfort and convenience from the identified parking spots. The primary drawback of this research is the difficulty in detecting parking fields for vehicles due to the usage of cameras on every side of the vehicle. Predicting empty slot and keeping track of the empty slot requires more time.

A Prototype Parking System using Wireless Sensor Networks [4], introduces a strategy to identify the parking space using Closed-circuit television (CCTV) cameras. With the help of sensors, the CCTVs sends the parking slot images to the ARM microcontroller which in turn process the received data. The processed data is retransmitted to the centralized system via zigbee and it is stored in the database. Here the retransmission process takes more time and there is no common display to the user which is a drawback of this system.

In Perceptive Car Parking Booking System With IOT Technology[5], by using an Android application and internet access, the person visits the parking area to locate available spaces for parking and reserves one according to their preferences. The user may reserve their own likely parking space according to the time and cost using Multi-Processing Queuing Mechanism (MPQM).

. IoT-based economic smart vehicle parking system [6], exposes parking problems in cities because there are too many vehicles and not enough space to park them. To solve this, a new system using technology called the Internet of Things (IoT) is proposed. It uses devices like Arduino Uno, which helps connect digital and physical objects. Each parking slot has an infrared sensor to detect if it's vacant or not. Users can book a parking slot in advance through a website, and they have their username and password. If there's any misuse of the system, it will alert the responsible person.

To maximize parking resource usage and minimize the overall financial cost, iParker—A New Smart Car-Parking System Based on Dynamic Resource Allocation and Pricing [7], uses Mixed-Integer Linear Programming (MILP) application. It integrates Share Time Reservations (STR) and Real Time Reservations (RTR) by allowing a parker to reserve a slot several days in advance and also while traveling a few minutes away from the parking field. The pricing policies are also proposed which maximizes the profit.

.Dynamic Reservation of Edge Servers via Deep Reinforcement Learning for Connected Vehicles [8], introduces a new parking system that uses both visible light and radio frequency technologies to automate parking processes. It uses vehicle headlights and COB bulb-based transmitters for visible light communication (VLC), along with optical receivers on parking gate barriers and vehicle roofs. Digital pulse interval modulation (DPIM) is used for communication. The system includes software for client-server communication and processing. Two-factor authentication and payment systems are also implemented. The results showed successful communication with low error rates and accurate positioning of vehicles.

Innovation Architecture Smart Car Parking System with Wireless Sensor Networks [9], Proposes that with the increasing number of cars each year, parking areas are becoming limited, leading to issues such as traffic congestion, environmental pollution, and ecosystem disruption. To address this problem, a new system utilizing processor boards and wireless sensor networks is proposed. This system aims to optimize parking space usage in towns by efficiently guiding drivers to available parking spots, reducing the need for cars to roam in search of parking. By minimizing traffic congestion and fuel wastage, this system can help alleviate the strain on infrastructure and promote a more sustainable environment.

A Hybrid VLC/RF Parking Automation System [10], describes a new parking system that uses Visible Light Communication (VLC) and Radio Frequency (RF) wireless technologies to automate parking. It works by having the vehicle's headlights communicate with receivers installed on parking gates and vehicles. Digital Pulse Interval Modulation (DPIM) is used for this communication. The system also includes a client-server interface and software for managing parking. Two-factor authentication and payment systems are implemented at the gate barrier using VLC. The system is tested under different conditions to evaluate its performance in terms of communication range and accuracy of vehicle positioning.

III. PROPOSED SYSTEM

A. *Block Diagram of the Proposed System*

Figure 1 shows the model of the proposed system.

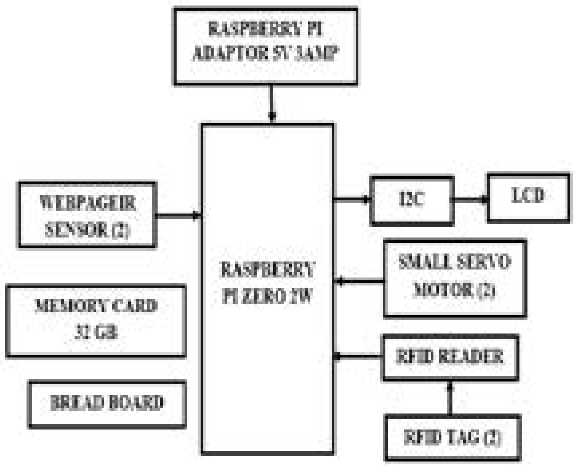

Fig. 1 Proposed System Model

B. *Working Model*

The smart parking system operates on a streamlined principle integrating various technologies for efficient parking management. At its core, the Raspberry Pi acts as the central processing unit, hosting the system's software and coordinating its functions. Raspberry Pi evaluates the data from sensors to determine the availability of parking spaces. The process begins with users booking parking slots via an IoT-enabled webpage using HTTP, where real-time slot availability is displayed. Upon booking, a designated time frame is allocated, and failure to arrive within this period automatically cancels the reservation. Upon arrival, users authenticate themselves by tapping an RFID tag on a reader. This triggers an identification (ID) verification process, allowing entry if the credentials are valid. Infrared sensors installed within parking slots detect vehicle presence, initiating the recording of parking duration using time-tracking mechanisms. Simultaneously, entry gate servo motors facilitate seamless access for authorized vehicles. After parking, users are prompted to pay for their parking duration through the webpage. Payment reminders are sent via SMS using Twilio integration, ensuring timely transactions. Failure to pay within the stipulated time results in the exit gate servo motor remaining closed, preventing vehicle egress. Conversely, successful payment prompts the gate to open, allowing vehicles to exit the premises. This integrated approach optimizes parking space utilization, enhances user convenience, and facilitates efficient traffic flow within parking facilities. By leveraging IoT, RFID technology, and servo motor control, the system offers a comprehensive solution to urban parking challenges, catering to the evolving needs of modern cities and their inhabitants.

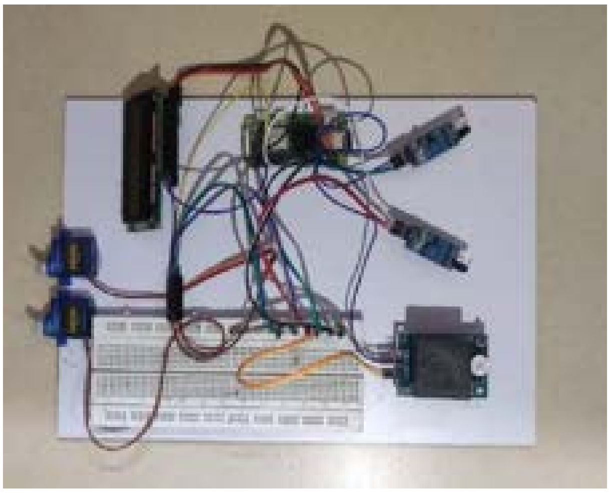

Fig.2 Hardware Setup

C. Modules

The following modules are used in the proposed models.

- IoT-Enabled Booking Module
- Sensor-Based Entry/Exit Module

D. IoT-Enabled Booking Module

The following Fig.3 depicts the IoT enabled booking module.

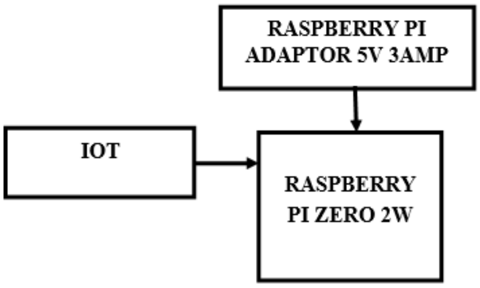

Fig.3 IoT enabled booking module

This module facilitates the booking process through an IoT-enabled webpage where IoT enhances efficient parking and slot reservation by enabling statistical analysis of data, real-time monitoring, system compatibility, improved user experience and remote management. Users can access this webpage from any internet-connected device to reserve a parking slot. The module manages the booking process, allowing users to select available slots, specify the duration of their parking, and complete the reservation. It also includes features such as automatic cancellation of bookings if vehicles fail to arrive within the specified time frame. This module ensures a user-friendly interface for booking slots and efficiently manages the reservation process.

E. Sensor-Based Entry/Exit Module

This module comprises various sensors and servo motors to manage vehicle entry and exit from the parking facility. Upon arrival, users authenticate themselves by tapping an RFID tag on the reader. This triggers an ID verification process, followed by the entry gate servo motor opening to allow authorized vehicles to enter. When a vehicle is parked, infrared sensors placed within the slot detect its presence. This allows time tracking to be used to record how long the vehicle is parked. Payment for parking is facilitated through the webpage, with Twilio sending payment reminders via SMS. Failure to pay results in the exit gate servo motor remaining closed, while successful payment prompts it to open, allowing vehicles to exit. This module ensures smooth vehicle movement within the parking facility, integrates payment processing, and maintains access control for efficient parking management. The following Fig.4 shows the sensor based Entry/Exit Module.

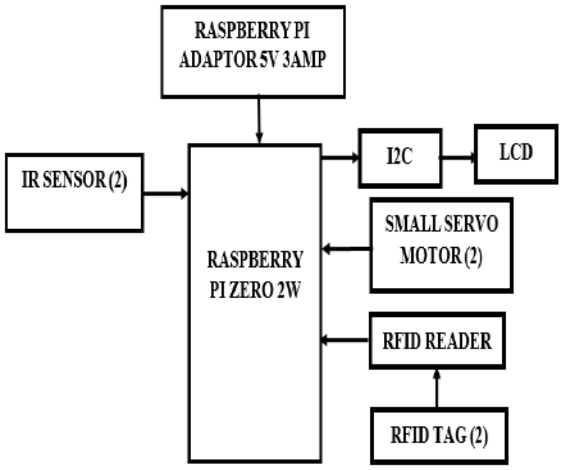

Fig.4 Sensor based Entry/Exit Module

Managing the reservation process involves various steps.

User Registration: Users must register their name, contact information and vehicle details with the system prior to the slot reservation.

Check for Slot Availability: Once registration is done, the current status of the parking slot is displayed in the webpage where the users can check the available parking spaces. Based on the availability, reservation request can be made.

Reservation and Payment: Once the reservation request is received, the chosen slot's availability for the allotted amount of time is verified by the system. If the chosen slot is available, the system reserves the slot and calculates the amount based on the parking duration.

Slot confirmation: After successful payment through integrated payment gateway, the system generates a reservation confirmation that includes details such as the parking slot number, date, reservation duration and time. This confirmation is sent to the user via Twilio SMS can also be accessed through the user's account on the system.

Expiration and Cancellation: The system may release the reservation made by the users and make the slot accessible to other users if the user does not come within a particular period after the reservation time. Users may also have the option to cancel or modify their reservations before the reservation time starts.

IV. RESULTS & DISCUSSION

The following Fig.5 shows the proposed hardware system final setup.

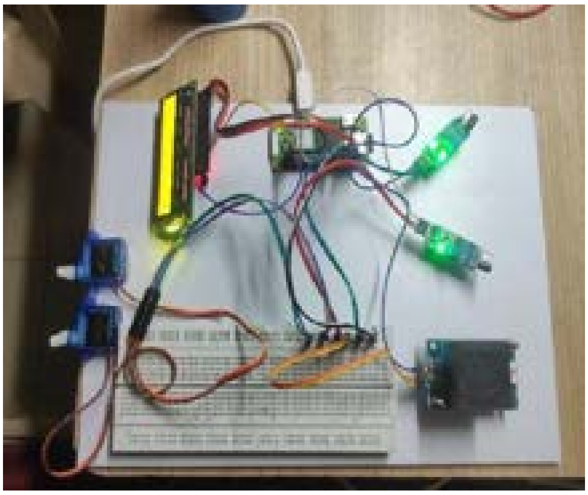

Fig.5 Proposed system hardware final setup

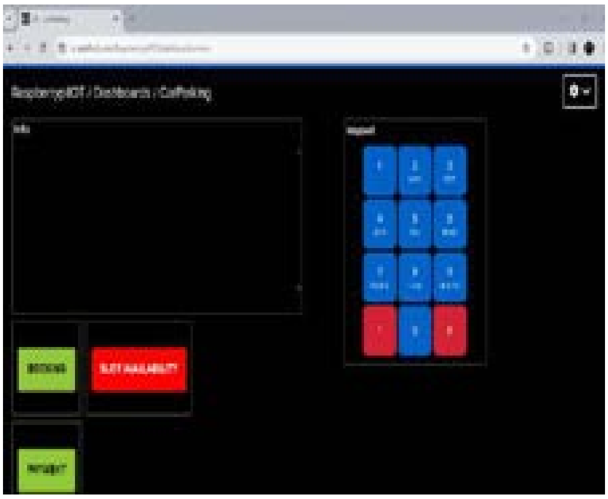

Fig.6 Webpage Setup

In this smart parking system, the Raspberry Pi serves as the central processor, storing and executing the system's program. Booking a parking slot is initiated via an IoT-enabled webpage as shown in Fig.6, followed by checking slot availability as shown in Fig.7 through the same interface. Bookings are automatically cancelled if cars fail to arrive within the specified time frame. After their IDs are verified, users tap an RFID tag on the reader to activate the entry gate servo motor as shown in Fig.9. Infrared sensors detect car presence in slots, with parking duration recorded using time tracking. Parking payments are made via the website, and Twilio provides SMS reminders for payments. as depicted in Fig.8. When payment is made successfully, the exit gate servo motor opens, allowing vehicles to leave, but when payment is not made, it remains closed. This system streamlines parking management, ensuring efficient space utilization while integrating seamless payment and access control mechanisms for user convenience.

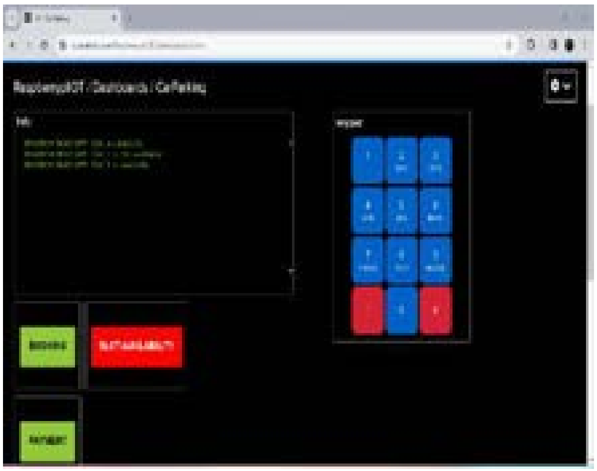

Fig.7 Available Slots

Fig.8 Twilio sending payment reminders via SMS

Fig.9 Slot 2 is booked

V. CONCLUSION & FUTURE SCOPE

The implementation of this smart parking system demonstrates a significant step towards addressing the challenges of urban parking management through the integration of IoT technology, sensor-based detection, and efficient data processing. By utilizing the Raspberry Pi as the central processor and leveraging IoT-enabled webpages for booking and payment processes, the system streamlines parking operations and enhances user convenience. The integration of RFID authentication, infrared sensors, and servo motors ensures seamless entry and exit control while accurately tracking parking duration. Furthermore, the incorporation of Twilio for payment reminders enhances the system's functionality and user engagement. Looking ahead, future enhancements could involve the integration of machine learning algorithms for predictive parking availability and the adoption of renewable energy sources for sustainability. Overall, this smart parking system represents a scalable and adaptable solution for optimizing parking space utilization, reducing congestion, and improving urban mobility. Its successful implementation underscores the potential of technology-driven innovations in addressing everyday urban challenges, ultimately contributing to more efficient, sustainable, and user-friendly urban environments.

Future enhancements for this smart parking system could include integrating advanced machine learning algorithms for predictive parking availability, optimizing parking space allocation based on historical data and real-time traffic patterns. Additionally, implementing automated parking guidance systems using sensors and actuators to direct drivers to available parking spots efficiently. Integration with smart navigation apps could provide users with real-time directions to the nearest available parking slots. Moreover, incorporating renewable energy sources like solar panels for powering the system reduces environmental impact and enhances sustainability. These advancements would further streamline parking operations, improve user experience, and contribute to smarter, greener urban environments.

ACKNOWLEDGMENT

We are grateful to Ramco Institute of Technology for their role in conceptualizing our ideas and for generously providing all essential resources and assistance.

Abstract—This study performs an analysis on crowdfunding. It explores how crowdfunding began, how it's impacting society, the challenges it faces, and how these platforms are designed. Following a detailed historical review of crowdfunding platforms' emergence, the paper explores their significant impacts on investors, enterprises, and society at large. By reviewing relevant literature, the study identifies research gaps, thus establishing a foundation for future investigation. The analysis delves into architectural designs and frameworks, while simultaneously investigating the difficulties faced by businesses during crowdsourcing campaigns. Finally, the study synthesizes key findings and their implications for academics, practitioners, and policymakers within the domain of crowdsourcing. Decentralized crowdfunding has fundamentally transformed the investment landscape, revolutionizing traditional models and unlocking novel funding avenues for early-stage ventures. Examining this evolution in detail, with a specific focus on the AngelicCrowd platform and its impact on angel investors, this study aims to provide a holistic understanding of the dynamics within the decentralized crowdfunding ecosystem. Through analysis of key trends, obstacles, and opportunities, the research investigates factors influencing adoption, the role of blockchain technology and smart contracts, and impediments to widespread implementation. The analysis is informed by a diverse dataset, incorporating responses from angel investors utilizing AngelicCrowd and similar platforms. Additionally, the paper explores the repercussions of these developments on conventional funding strategies and the democratization of investment.

Keywords— Decentralized Crowdfunding, Angel Investing, Blockchain Technology, Transparency, Security, Accessibility, Smart Contracts.

I. INTRODUCTION

The landscape of angel and venture capital funding is a dynamic and critical aspect of entrepreneurial ecosystems worldwide. Studies have highlighted the significance of alternative funding sources beyond traditional banking, emphasizing the role of angel investors in providing crucial financial support to startups [1]. Understanding the selection criteria and decision-making processes of angel investors is essential for entrepreneurs seeking funding and investors looking to diversify their portfolios. Moreover, the comparative institutional perspective on angel investors in different settings sheds light on how institutional frameworks influence investment decisions, offering valuable insights into the complexities of funding processes.

The study on chosen companies in India provides a comprehensive analysis of the funding landscape, exploring the investment criteria, sources of funding, and challenges faced by stakeholders in the Indian startup ecosystem. By examining the non-bank funding agencies and their impact on the financial landscape, the research aims to contribute to a deeper understanding of the evolving dynamics of venture and angel capital funding in India.

The utilization of statistical software such as SPSS for data analysis in the study underscores the importance of rigorous quantitative analysis in examining the trends and patterns within the venture and angel capital funding process. Through a combination of descriptive and inferential statistics, as well as content analysis techniques, the study provides a robust framework for evaluating the data collected from primary and secondary sources. This research seeks to bridge the gap in the existing literature by offering insights into the intricacies of angel and venture capital funding processes, particularly in the context of India and aims to inform future studies and practices in the field. [1]

This study explores the multifaceted landscape of crowdfunding, beginning with a comprehensive examination of its historical development in Section 2. It proceeds to investigate the impact of crowdfunding on society, investors, and startups in Section 3, shedding light on its socio-economic implications. Section 4 identifies existing research gaps in the field, while Section 5 delves into the challenges encountered by startups in crowdfunding endeavors. Section 6 provides a thorough review of related works, offering insights into the existing literature on crowdfunding. In Section 7, the paper discusses the architectural designs of crowdfunding platforms, followed by an evaluation of the impact of architectural frameworks in Section 8. Section 9 delves into the various challenges crowdfunding initiatives face, encompassing technical, legal, and regulatory aspects. The paper concludes by summarizing key findings, discussing implications, and suggesting avenues for future research and practice.

II. HISTORICAL DEVELOPMENT OF CROWDFUNDING PLATFORMS

Early Beginnings: Crowdfunding originated in the early 2000s with platforms like ArtistShare and Indiegogo [1]. These platforms pioneered the concept of crowdfunding by enabling individuals to raise funds from the public for creative projects.

Rise of Reward-Based Crowdfunding: Platforms like Kickstarter and GoFundMe gained popularity in the mid-2000s, offering reward-based crowdfunding where backers receive rewards or products in exchange for their contributions [1]. This model revolutionized fundraising for creative projects, tech innovations, and charitable causes, democratizing access to capital.

Evolution into Equity Crowdfunding: The passage of the JOBS Act in 2012 in the United States led to the emergence of equity crowdfunding, allowing startups to raise capital from a large number of investors in exchange for equity stakes [1]. Platforms like SeedInvest and Crowdcube facilitated this shift, opening up investment opportunities to a broader range of investors.

III. IMPACT ON SOCIETY, INVESTORS, AND STARTUPS:

Society: Crowdfunding platforms have democratized access to capital, empowering individuals and communities to support causes they believe in [1]. Social impact projects, charitable initiatives, and disaster relief efforts have benefitted from the collective power of crowdfunding, fostering community engagement and social responsibility.

Investors: Crowdfunding has transformed the investment landscape by providing retail investors with opportunities to invest in early-stage startups and projects [1]. This direct access to investment opportunities has democratized investing, allowing individuals to diversify their portfolios and potentially earn returns on high-growth ventures.

Startups: Crowdfunding platforms offer startups a viable alternative to traditional funding sources like venture capital and bank loans [1]. By leveraging the crowd, entrepreneurs can validate their ideas, engage with customers, and raise capital to bring their products to market. Crowdfunding also serves as a marketing tool, helping startups build brand awareness and attract early adopters.

Overall, the historical development of crowdfunding platforms has had a profound impact on society, investors, and startups by democratizing access to capital, fostering innovation, and creating new avenues for collaboration and investment in the entrepreneurial landscape [1].

IV RESEARCH GAPS

Existing crowdfunding platforms face significant limitations: excessive fees, scam risks, IP vulnerability, marketing challenges, and restrictive criteria, resulting in uncertainty for investors due to insufficient security, transparency, and control over their investments. These platforms struggle with incomplete projects, lack of guarantees, limited progress monitoring, and potential fraud, highlighting the need for globally standardized due diligence methods and regulatory frameworks to enhance investor confidence and risk mitigation.

V CHALLENGES FOR STARTUPS

Startups face a myriad of challenges as they navigate the complex landscape of entrepreneurship. Here are some common challenges that startups often encounter: Limited Funding, Market Validation, Talent Acquisition, Uncertain Regulatory Environment, Rapid Technological Changes, Intense Competition, Scaling Operations, Limited Brand Recognition, Adaptability to Change, Legal and Intellectual Property Issues, Customer Acquisition and Retention, Cash Flow Management, Strategic Partnerships, Economic Downturns. Addressing these challenges requires a combination of resilience, strategic planning, adaptability, and a commitment to continuous learning and improvement. Successful startups navigate these obstacles with a clear understanding of their market, a solid business strategy, and a focus on delivering value to their customers.

VI. RELATED WORKS

MERITS AND DEMERITS OF EXISTING WORK.

MERITS:

- Crowdfunding allows anyone with a good idea to raise capital from a wider pool of investors, not just traditional institutions.
- Campaigns can gauge public interest and receive valuable feedback on the proposed product or service.
- Platforms can foster community around a project, leading to stronger customer loyalty and brand recognition.
- Compared to traditional financing methods, crowdfunding platforms can offer lower fees and faster access to capital.

DEMERITS:

- Standing out amongst a sea of projects can be challenging, requiring a well-developed campaign and effective marketing strategy.
- Depending on the type of crowdfunding and location, regulations can be complex and add administrative burdens to campaigns.
- While platforms implement safeguards, there's always a risk of encountering fraudulent campaigns.

- Not all campaigns reach their funding goals, potentially leaving creators with wasted time and effort.

VII. ARCHITECTURAL DESIGNS

Architectural frameworks in crowdfunding typically refer to the planning and creation of the structure, features, and functionalities of crowdfunding platforms.

Crowdfunding Platform Design with Blockchain Integration:
This research explores the integration of blockchain technology within crowdfunding platforms to augment transparency, security, and efficiency. The design leverages public ledgers, smart contracts, and permission access control mechanisms offered by blockchain. Public ledgers provide a tamper-proof, auditable, and decentralized record of transactions and agreements, significantly enhancing transparency within the crowdfunding ecosystem.
Furthermore, blockchain technology fosters security through a decentralized consensus mechanism, cryptographic hashing, and the inherent immutability of data on the blockchain. This combination safeguards against fraudulent activities by ensuring tamper-proof records and fostering a more secure environment. Additionally, the utilization of consensus mechanisms, cryptographic hashing, and data verification protocols within the blockchain framework promote accuracy by guaranteeing the integrity and validity of information across distributed networks. Finally, the

implementation of blockchain technology, with its decentralized consensus mechanism and immutable ledger, strengthens reliability by bolstering data integrity and mitigating the risks associated with single points of failure within the crowdfunding platform.
By leveraging decentralized ledger systems and smart contracts, the platform ensures trust among users and facilitates seamless transactions [30]

Smart Contract Automation for Fund Disbursement:
The design includes the implementation of smart contracts to automate fund disbursement processes in crowdfunding campaigns. Smart contracts enable automatic distribution of funds based on predefined criteria, reducing manual intervention and streamlining transaction processing [30]

User Interface Design for Enhanced Engagement:
The design focuses on creating intuitive user interfaces with interactive features to enhance user engagement on crowdfunding platforms. Real-time updates on campaign progress, personalized recommendations, and user-friendly interfaces contribute to a positive user experience and encourage active participation [29]

Sustainability-Oriented Project Design Framework:
The design framework emphasizes integrating environmental sustainability considerations into crowdfunding projects. By incorporating sustainability metrics, impact assessments, and green initiatives, the platform promotes the support of projects with long-term societal and environmental benefits [29]

Performance Monitoring Dashboard Design:
The design involves developing a performance monitoring dashboard for crowdfunding platforms. The dashboard provides real-time analytics, key performance indicators, and data visualization tools to help platform operators track campaign success, identify trends, and make data-driven decisions for optimizing fundraising strategies [30].

Decentralized Crowdfunding Platform Architecture Design:
The design focuses on creating a decentralized crowdfunding platform architecture using blockchain technology. By decentralizing contract storage, transaction records, and verification processes, the platform ensures security, transparency, and autonomy in fundraising activities [29]

These designs showcase the innovative approaches and architectural considerations in the development of crowdfunding platforms, emphasizing aspects such as blockchain integration, smart contract automation, user interface design, sustainability frameworks, performance monitoring, and decentralized architecture. Each design contributes to enhancing the functionality, user experience, security, and sustainability of crowdfunding ecosystems.

VIII IMPACT OF ARCHITECTURAL FRAMEWORKS

The impact of architectural frameworks in crowdfunding is significant as they influence various aspects of crowdfunding platforms, including transparency, security, efficiency, user experience, sustainability, and decision-making processes.

Here is an explanation of the impact with citations from the provided papers:

Transparency and Trust:
Architectural frameworks, such as blockchain integration, enhance transparency and trust in crowdfunding platforms by providing immutable transaction records and decentralized verification mechanisms. This fosters confidence among backers and project creators, leading to increased participation and support for crowdfunding campaigns [30].

Security and Accountability:
Architectural frameworks that prioritize security features, such as anti-tampering mechanisms and decentralized ledger systems, contribute to the accountability of crowdfunding platforms. By ensuring the integrity of transactions and data, these frameworks mitigate risks of fraud and unauthorized access, fostering a secure environment for fundraising activities [26].

Efficiency and Automation:
Architectural frameworks incorporating smart contracts and automation streamline crowdfunding operations, leading to increased efficiency and reduced manual interventions. Automation of fund disbursement and verification processes accelerates transaction processing, enhancing the overall operational efficiency of crowdfunding platforms [30].

User Experience and Engagement:
Well-designed architectural frameworks improve the user experience and engagement on crowdfunding platforms. Intuitive interfaces, interactive features, and real-time updates enhance user engagement, encouraging active participation and fostering a sense of community among platform users [30].

Sustainability and Innovation:
Architectural frameworks supporting sustainability-oriented projects and innovative fundraising models drive growth and diversification in crowdfunding. By integrating sustainability considerations and novel approaches, these frameworks promote impactful projects with long-term societal benefits [30].

Performance Monitoring and Decision-Making:
Architectural frameworks facilitating performance monitoring and data analytics empower platform operators to make informed decisions and optimize strategies. By tracking key metrics and analyzing outcomes, these frameworks enable stakeholders to assess platform effectiveness and drive continuous improvement in crowdfunding operations [30].
Architectural frameworks play a crucial role in shaping the success and sustainability of crowdfunding platforms by enhancing transparency, security, efficiency, user experience, sustainability, and decision-making processes. Leveraging innovative technologies and design principles,

these frameworks contribute to building trust, engaging users, promoting innovation, and driving operational excellence in the crowdfunding ecosystem.

IX. CHALLENGES IN CROWDFUNDING

Addressing the below-mentioned challenges can enhance the robustness, validity, and applicability of findings in the evolving field of crowdfunding.

Platform Diversity and Data Limitations:
One challenge highlighted in the papers is the limited focus on a few crowdfunding platforms, leading to a lack of comprehensive data analysis across a diverse range of platforms. This limitation hinders a holistic understanding of crowdfunding dynamics and investment drivers across various platforms [28].

Lack of Cross-Platform Comparison:
The scarcity of studies conducting cross-platform comparisons limits the generalizability of findings in crowdfunding research. While insights from a few platforms are valuable, a broader analysis across multiple platforms is essential to understand investment patterns and drivers comprehensively [28].

Platform Design Variability and Impact:
The role of crowdfunding platform design choices and their impact on funding patterns is often overlooked in the literature. Variations in platform design can influence user behavior, campaign success rates, and overall platform competitiveness, highlighting the need for more research in this area [28].

X. CONCLUSION

This study provides a thorough examination of crowdfunding, covering its historical development, societal impact, challenges, and architectural perspectives. Beginning with an in-depth exploration of crowdfunding platform evolution, the study investigated into its effects on society, investors, and startups, identifying research gaps and discussing architectural designs and frameworks. It concludes by synthesizing key findings and implications for researchers, practitioners, and policymakers. Additionally, decentralized crowdfunding's emergence as a transformative force in the investment landscape is investigated, with a focus on the "AngelicCrowd" platform. Through a comprehensive survey, the study examines trends, challenges, and opportunities in decentralized crowdfunding, drawing on responses from angel investors. Findings reveal a growing interest in decentralized crowdfunding among investors, driven by its transparency and accessibility. However, regulatory uncertainties and security concerns pose challenges. The evolution of AngelicCrowd serves as a case study reflecting broader trends in decentralized finance, highlighting smart contracts, tokenization, and decentralized governance as key enablers of innovation. Looking ahead, decentralized crowdfunding holds promise for democratizing investment, albeit with the need for continued research and collaboration to address regulatory complexities and unlock its full potential.

***Abstract*—Data and information stored online is steadily growing in volume. Indeed, when it comes to readily available, high-quality information, the web is unrivalled. Information retrieval describes the steps used to find the desired data in a database. By analyzing the user's query semantically, semantic information retrieval can offer results that are more relevant to their original intent. When this occurs, ontology-based knowledge representation has the potential to facilitate semantic retrieval more efficiently than alternative representation approaches, such as frames and semantic networks. In the past twenty years, machine learning techniques have found widespread application across several fields of art, science, and technology. Information retrieval activities that make extensive use of machine learning techniques include document analysis and query expansion. This paper presented a semantic information retrieval system based on machine learning and ontologies. Our research demonstrates that the method outperforms the state-of-the-art on certain recall, precision, and f-measure metrics used to evaluate the effectiveness of semantic information retrieval. Experiments have proven that the method helps the system convey knowledge better and retrieves semantic information faster.**

Keywords - Document retrieval, Ontology, Machine Learning, Information retrieval, Semantic Information.

I. INTRODUCTION

Millions of individuals are checking out online sites to fulfil their information demands, making them the biggest source of information. Information retrieval (IR) systems aim to give consumers highly relevant results based on their information demands. For better query mapping to a collection of documents during retrieval, keywords describing the contents of the documents are assigned during the document indexing stage. Numerous proposals in the literature have proposed statistical, neural, and semantic methods to enhance the efficiency of data retrieval tasks [1-2]. Concepts, roles, and connections may be more accurately represented with the help of ontology in semantic web, a method of knowledge representation. The current state of knowledge representation allows for the easy encoding of textual information with inheritance using methods like semantic networks and frames. Semantic network or frame searches may therefore follow class and sub-class hierarchies all the way from the root node to the target node. In semantic networks, however, there are limitations on both the amount and kind of linkages. Both the information hierarchy and the inheritance hierarchy may be preserved using the ontology-based approach to knowledge representation. Information may be retrieved utilizing both single-level and multi-level inheritance using this ontology-based representation of data. Semantic analysis and appropriate information retrieval are therefore improved by semantic information retrieval based on ontologies [3-4].

Traditional information retrieval methods index documents according to the phrases they contain, not the notion that describes them. The phrase "vocabulary gap" explains the circumstance where users and subject matter experts use disparate terminology to refer to the same subject; IR systems will not provide results that contain semantically significant information unless there is a lexical match between the two. Document representation in an IR system has been shown to effectively capture term meanings and their connections utilizing domain knowledge [5][7]. Ontologies have long been used in all fields to formally express and comprehend domain knowledge. In contrast, language gaps are no longer an issue with ontology-based document indexing techniques. However, these approaches have the drawback of being very dependent on the depth and breadth of the initial input ontology. [10][12]. Recent advances in machine learning (ML) have allowed the field of information retrieval (IR) to provide a workable solution to document indexing challenges. When co-occurring events occur, machine learning algorithms leverage word-to-word correlations; nevertheless, they ignore significant semantic relationship structures. Manually created knowledgebases that include these relational structures for semantics include ontologies and semantic lexicons. The benefits of ML modelling have prompted academics to concentrate on developing ML ranking models that can learn features and the model in tandem [15][17] [20-22].

The goal of this work is to give more detailed semantic indexing of scientific publications than only the Computer Science Ontology descriptions. It aims to reach results comparable to those produced by domain experts by studying the semantic level of matching ideas. This research proposes a semantic information indexing strategy for information retrieval that is built on ontologies and machine learning to address this issue.

Word embeddings and ontology from computer science are utilized by the suggested method to extract the notion from a text. The suggested method supplies the ML model with potential keywords extracted from document text using natural language processing techniques. The proposed algorithms improve upon previous efforts at retrieval speed and accuracy and leverage ontology matching to provide users with answers that are more pertinent to their queries. The most significant insights from the research are listed below:

- Developed a semantic approach to machine learning and ontology-based information retrieval system for document indexing.
- Improved the text-based information system's effectiveness with machine learning methods.
- Implement a ranking based approach to retrieve relevant documents for a user query.
- Conducted the trials with the TREC-NIST dataset, considering several performance parameters including F-measure, recall (R), mean average precision (MAP), and precision (P).

This paper is organized as follows: A summary of earlier ontology-based semantic information retrieval and machine learning research is provided in section 2; The proposed materials and procedures are explained in section 3. The result discussion and experimental findings are presented in section 4. This paper's conclusion is in the last section.

II. RELATED WORK

This section classifies the IR methods that have been suggested into two categories: supervised and unsupervised. To make sure the system can adapt to new domains as they emerge, machine learning is used to fine-tune the ontological structures dynamically. [1]. Using a multi-terminology, Bayesian networks (BNs), and multinomial naive Bayes classifier (MNBC) is a novel way to enhance information retrieval systems [2]. A new approach to semantic document indexing was presented [3] that combines machine learning with domain ontology. A novel fuzzy ontology-based framework is proposed to retrieve information utilizing domain-specific knowledge utilized in ontology construction [5]. The augmented fish swarm method is recommended to carry out the retrieval process to improve the effectiveness of semantic IR [6]. Agnostic prediction models are explained by a new interpretation framework that develops an interpretable model using an ontology-based sampling method [7]. Multi-Perspective Sentence Relevance is a new approach to contextual information retrieval (IR) that makes use of BERT-based models. It has several applications in the field of biomedical semantics [8]. There is a new system for automatically generating ontologies that do not depend on any specific domain; it may transform a collection of unstructured texts into an ontology that is compatible with that domain [9]. With relevant feedback, the novel model expands the question by utilizing a deep neural network methodology and a semantic way to find the semantic similarity between the phrases [10].

The several text representations offered, are accountable for retrieving pertinent search results, methodologies, and evaluations performed in conceptual information retrieval [11]. An innovative fuzzy rough set-based intelligent selection of features and categorization method is proposed for semantic information retrieval to enhance the relevance score [12]. Domain ontology, a constraints-based mapper, and point-of-sale (POS), and language processing tools are all integrated into the innovative model [13]. Created an AI system for document management based on ontologies [14]. Integrating lexical and semantic data to handle CLIR (cross-language information retrieval) [15]. Document clustering using a deep ontology-based method was suggested [16]. The machine learning models were trained and tested on the manually collected corpus of scientific papers utilized in the Exposome-Explorer [17]. An enhanced technique for semantic information retrieval was introduced [18]. It is based on decision trees. There is a new proposal for a visual interface that uses autonomously generated ideas to get materials from a digital library [19]. Clustering, rough set, and Bayesian network (BN) are used as an ensemble strategy to create the MLK-rBO model, which serves four different purposes: model assessment, probabilistic network development, knowledge discovery and clustering [20].

To rank objects, same as other retrieval tasks, document retrieval uses a collection of components from neural networks to extract characteristics [21]. An enhanced variant of the original COOT algorithm is the IAOCOOT technique for query expansion, which finds the semantic characteristics that match the query phrase [22]. A web paradigm for information extraction based on ontologies, including an object-attribute-value (O-A-V) hierarchy that users may use as a dictionary to hone their search terms before repeating the process [23]. CO-Search is a semantic multi-stage search engine designed to handle complex queries across the COVID-19 literature. It may help overworked medical professionals get the scientific answers they need and avoid misleading content [24]. The ontologies are included in machine learning algorithms and utilized to compute similarity [25]. An automatically sorted, comprehended, searched, and summarized web material search engine was developed in order to increase relevance scores in AR domains [26]. One novel approach to the categorization issue of textual materials [28] is to combine preexisting knowledge models with ad hoc taxonomies. The development of a new method for semantic document indexing using a Shallow Neural Network and ontologies [29]. The goal of this semantic video retrieval system is to find appropriate films based on user-supplied queries made in natural language [30].

III. PROPOSED METHOD

Figure 1 shows the researchers' proposed solution to the information retrieval problem: a system that uses machine learning and a unique ontology.

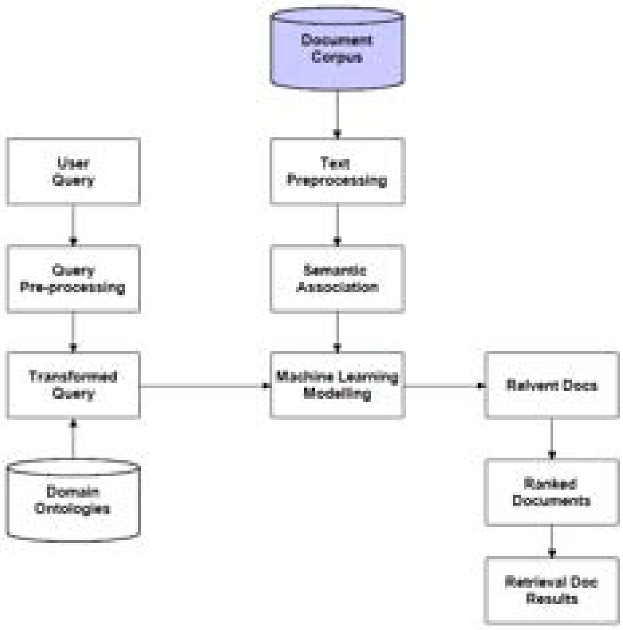

Fig. 1. Machine Learning and Ontology based Semantic Information Retrieval System

Document Corpus Dataset:

The proposed information retrieval system used the TREC Dataset [31] as its document corpus. The package includes documents, queries, and an additional file that has the top 'N' documents ranked for each query. This dataset contains two kinds of information: query IDs and the questions themselves. The evaluation gap problems in IR are somewhat alleviated by the TREC MRT dataset. Due to the sensitive nature of the information contained inside, data limits serve as the driving force behind medical records. The Text Review Conference (TREC) was co-sponsored by the US Department of Defence and the National Institute of Standards and Technology (NIST) in 1992 as part of the TIPSTER text initiative. Facilitating the development of the text retrieval technique required for large-scale estimate was the primary goal, which also served to sustain research in the field of IR. TREC sponsored the earliest comprehensive evaluations of document retrieval efficiency in non-English languages (Spanish and Chinese). TREC's computations are based on content-based digital video retrieval and answers to open-domain queries. The realistic design of the operational circumstances is made possible by the requisite test collections in TREC.

Data Pre-processing:

Pre-processing the query to make it more accurate or machine-readable is necessary before it can be used to find the documents that meet the user's information needs. A processed query is sent to the appropriate module in response to this question. There are frequently many terms in a search engine query. An alternate representation of such a question may be a set of weighted words. Following the matching process, a typical IR system will return several results that are pertinent to the user's request. The query submitter's perception of the page's usefulness in addressing their question is the determining factor in relevance.

Transformed Query:

Unfortunately, the user's original query did not adequately express the specific details he needed. Our algorithm makes use of three main query transformation techniques. Changing the user's original query is typical in manual searches. The retrieval system will automatically broaden the user's query as they type it in. Using the user's past behavior to generate predictions about their current purpose is one approach. This approach augments the user's original inquiry with fresh terms by assessing both local and global information resources. As a whole, this inquiry is trying to answer the first question by revealing related ideas. documents saved on the computer, the entire set of documents, or even only the first set of documents might be targeted. Adding matching terms to searches improves recall. Input from the user is essential for this procedure. After running the refining method, user receive a new query.

Indexing:

The database retrieval system organizes millions of web pages that have the same number of distinct terms. Accurate and speedy retrieval of particular information is the primary objective of indexing. As part of its indexing operation, a search engine will gather keywords and phrases from the sites it has downloaded. The inverted index keeps track of words using a backward file structure. The position of each phrase in the text is tracked by an inverted index. During the indexing of web pages, activities like lexical analysis are carried out, which are similar to the query processing phase and assist improve search engine performance. For full-text indexing, almost every word on the page serves as an index term. Indexing completes any search engine and enhances query performance by accelerating response times. Apart from just indexing websites, search engines also assign a site a ranking based only on the web's link structure, an attempt to approximate an "importance" assessment. To create the index, the indexing component gets text documents as input. Documents are deconstructed into tokens as part of the automated process of constructing an index. Tokens go through several text operations before they become indexing words.

Machine Learning Modelling:

The comparison of query terms with index items is the responsibility of this part. It looks up all the documents in the index that contain the keywords you entered. This is a typical search that uses processed query terms to access a document index. One indicator of how closely two pages match is the number of words they share. One may determine the relevancy of the returned documents by assessing the degree of resemblance between the index and query phrases. Finding the URLs of pages that include the query keywords and comparing them to the index terms is one method. This document-query or query-keyword syntactic matching can be improved with semantic matching. The proposed approach primarily focuses on an ensemble-based information extraction module. Three machine learning algorithms—KNN, DT, and SVM—were utilized by the ensemble information extractor. The ensemble algorithms use these methods to generate a set of phrases that have already been specified.

With query 'i' and doc 'i' representing the query words and documents, respectively, the similarity measure is used in the information retrieval matching process in the proposed framework. During query expansion, we look for the most similar word to the question in terms of semantics to broaden it. By picking the three most important terms from the relevant ontology, we have broadened the scope of the query. We can now use these four terms as a query in any web search engine to find relevant publications based on our domain knowledge of the context. The similarity measure is adjusted according to the equations provided, and the query and document pairs are refined as (query', doc') in the expanded query matching process. In this case, "doc" refers to the newly discovered documents that the search engine has found, and "query" indicates the improved query words.

$$Sim(query, doc) = \frac{\sum_i query_i doc_i}{\sqrt{\sum_i query_i^2}\sqrt{\sum_i doc_i^2}} \qquad (1)$$

$$New\_Sim_{(query', doc')} = \frac{\sum_i query_i' doc_i'}{\sqrt{\sum_i query_i'^2}\sqrt{\sum_i doc_i'^2}} \qquad (2)$$

Compared to a basic Boolean matching model, the computational effort required by a probabilistic weighted model for NLP queries is higher. The ranking uses a score to establish the relative importance of each document. Search engines are based on IR, a field of science and engineering., and one of its major challenges is ranking query results. With a query q and a set of documents D that match it, the primary goal is to use some metric to sort or rank D, with the goal of showing the user the "best" results at the front of the list. Traditionally, the ranking factor has been the relevancy of documents to the given information demand of a query. Through an interface, users may access their graded papers. Based on the study, the researchers use the ranking technique. The process flow is illustrated in Fig.2.

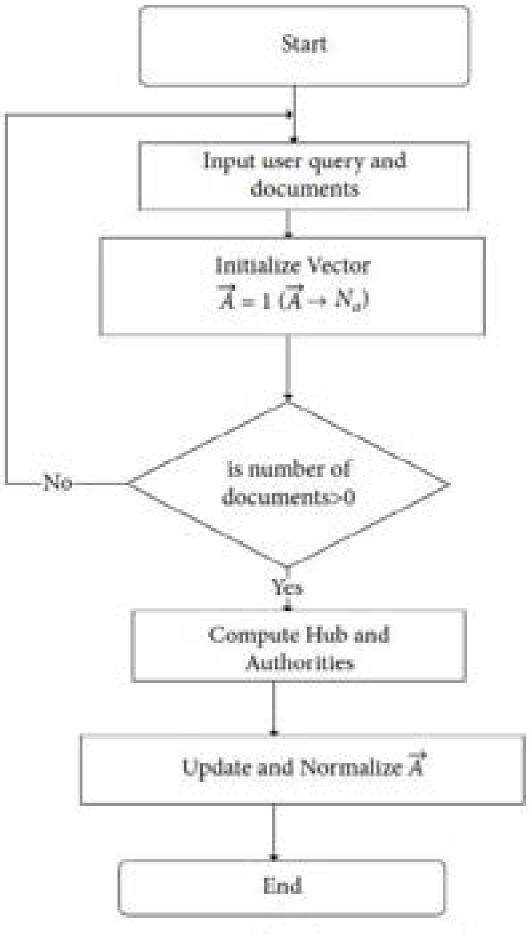

Fig. 2: Document Ranking Approach

Algorithm 1: IR system
Input: *Query Input Document* Output: *Relevant Retrieved Information*
Method: Step1: *Input from the user interface in the form of a query defines the information need of the user.* Step 2: *Assessing the initial inquiry makes use of domain ontology in conjunction with query processing procedures. Document collection is the first step in indexing, which entails carrying out the identical tasks assigned to them by the semantic association module.* Step 3: *Indexes are generated from the original documents in the context of the indexing module.* Step4: *The user's information needs are modeled semantically by the transformed query.* Step5: *The search for literature that answer this query is carried out using a semantics module. All of the document terms that are a match for the query words are located swiftly by the*

indexing system.

Step6*: The retrieved documents are sorted according to their predicted relevance in relation to the term matching score.*

Step7: *Finally, the user provides input to the system by picking out the papers he found most useful from the list of graded papers.*

IV. EXPERIMENTAL RESULTS AND DISCUSSION

A. Experimental Setup

This model is tested and evaluated in Python using the Pycharm IDE with Anaconda Distribution. The software used is Windows 11, with 16 GB of RAM, an Intel i7 processor, and 4 GB of graphics memory. The scikit-learn ML and Word2Vec toolbox are part of the distribution. To forecast the optimal performance rate, performance parameters such as F-measure, Mean Average Precision (MAP), precision, and recall are utilized.

B. Evaluation Parameters

Three commonly used metrics and the proposed model were used to evaluate our results. What follows is a more detailed explanation of these metrics.

1. Recall (R): It is the percentage of relevant documents that are discovered during a search. To find this value, use the following formulas. The numbers Dr and Dt represent the number of relevant data that were and were not retrieved, respectively.

$$R_r = \frac{D_r}{D_r + D_t} \tag{3}$$

2. Precision (P): Relevance calculates the proportion of retrieved documents that were truly helpful. Du is the number of useless data that was obtained.

$$R_p = \frac{D_r}{D_r + D_u} \tag{4}$$

3. Mean Average Precision (MAP): It is computed as the average precision score for the documents that the query groups were used to get. The MAP is calculated based on the Average Precision (AP) of each search query. After that, the MAP is calculated and recorded as;

$$MAP = \frac{1}{n} \sum_{n} AP_n \tag{5}$$

4. F-measure: F-measure is as simple as summing up the precision and recall scores harmonically.

$$F\text{-}measure = 2 * (Rp * Rr) / (Rp + Rr) \tag{6}$$

C. Experimental Results analysis

Experiments are carried out and evaluated using TREC datasets to show how effective the proposed and baseline methods are. These metrics, recall, precision, and F-measure are used to assess performance. The number of most-read documents was used to determine outcomes by selecting the 10, 20, 50, and 100 as examples. Table I below provides an in-depth analysis of each of these components.

Table I: Evaluation of Results based on Top-N Documents for Retrieval

Performance Parameter	**Recall**	**Precision**	**F-measure**
N@10	0.72		0.71
N@20	0.70	0.68	0.69
N@50	0.71	0.65	0.67
N@100	0.68	0.64	0.66

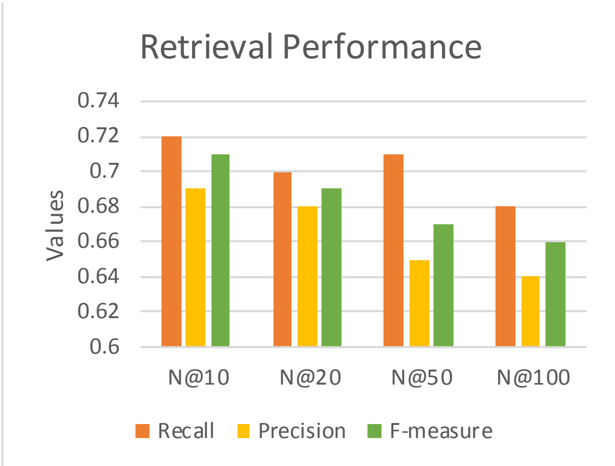

Fig. 3: IR Result evaluation performance for Top-N retrieval

The TREC MRT dataset's recall, precision, and f-measure results are displayed in Fig. 3. The proposed system outperformed the others in terms of precision @10, 20, 50, and 100 respectively. According to the proposed method, recall @10 and 50 is 0.72 and 0.71 respectively. The developed model performed poorly in comparison to other retrieval documents on the f-measure @100.

Table II: Performance Evaluation Parameters for Test Query

Evaluation Parameters/Query	**Recall**	**Precision**	**F-score**	**MAP**
Query1	0.55	0.60	0.52	0.51
Query2	0.48	0.54	0.46	0.44
Query3	0.49	0.54	0.47	0.43

Query4	0.53	0.57	0.48	0.46
Query5	0.57	0.60	0.53	0.55

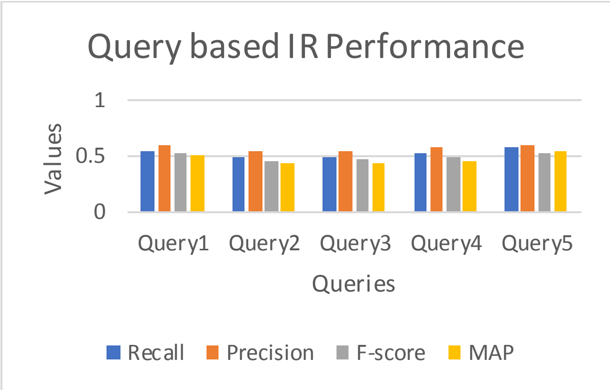

Fig.4: IR Result evaluation performance for N-Query

Table II depicts the results of several searches for f-measure, recall, precision, and MAP. New quarterly highs of 0.57 for recall, 0.60 for precision, 0.53 for f-measure, and 0.55 for MAP were achieved for Query5. With an f-Measure of 0.46 and a MAP of 0.44, the final results for Query2 are precision of 0.54 and a recall of 0.48. Several measures, including f-measure, recall, precision, and MAP, all attained levels of 0.47, 0.49, 0.54, and 0.43 during Query3. See the visual examination of query expansion in Fig. 4. When comparing studies conducted in Query1, Query2, Query3, Query4 and Query5 performance parameters including f-measure, recall, precision, and MAP all showed significant improvements in Query5.

Table III: Comparative analysis with state of art models

Reference Model	MAP
IRS [22]	0.20
IAOCOOT [32]	0.3945
Wikipedia [32]	0.3166
WordNet [32]	0.2901
Proposed Model	0.715

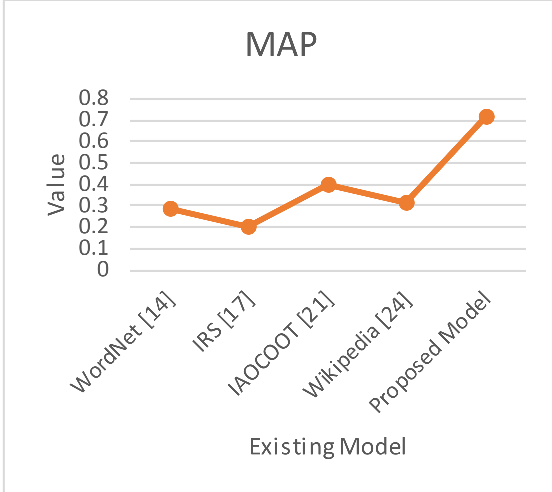

Fig. 5: Comparison with state of art model

The examination of the suggested MAP results and their comparison with state-of-the-art models is detailed in Table 3. The proposed model achieved better MAP results than competing state-of-the-art models as shown in fig. 5.

V. CONCLUSION

Conventional semantic information retrieval methods may converge slowly when presented with enormous amounts of complex content. Findings from ontology-based query transformation show that including domain ontologies in ML-based information retrieval systems improves retrieval performance. Using semantic association, the indexing strategy was able to better capture terms associated with documents. Thus, the two parts of the proposed system coordinated to ensure that the appropriate papers were located for the appropriate individuals at the appropriate times. Through the application of ontology and semantics approaches, TREC datasets showed improved performance. The window function computed, retrieved the state parameters of the ideal semantic information choice, and fused its data levels to gain information fusion outcomes utilizing unstructured semantic data processing. In comparison to earlier studies, the suggested strategy outperformed the competition when we monitored the overall amount of document obtained from major search engines and used metrics like as f-measure, precision, MAP and recall. There was a 10% improvement in accuracy after broadening the query. Our experimental results proved that the improved technique may improve semantic information retrieval efficiency without sacrificing accuracy since it sidesteps common problems with traditional methods. The algorithm will need to undergo more testing on large datasets in the coming decades.

Abstract*—The coronavirus, COVID-19 has spread around the globe, causing unprecedented changes in major areas including education and the economy. Amid a pandemic, the educational sector is relying heavily on performance prediction models to aid in the study of student status and the subsequent improvement of performance. The term "Educational Data Mining" describes the practice of using data mining principles and methods in the classroom. The explosion of educational data in recent years has made educational data mining a hot issue. Methods for discovering latent patterns in educational data might be developed within this area. The data can be learned more about student's, their learning habits, and how well they will do in school by applying the techniques drawn from Educational Data Mining. This study aims to predict how universities would modify e-learning in the aftermath of the outbreak by investigating student's actual experiences utilizing e-learning facilities during this time. A formal questionnaire was distributed and an online survey was created for this purpose. Following an exhaustive survey, a good outcome was achieved in terms of the dataset. In addition, the selected supervised machine learning algorithms such as Multi-Layer Perceptron (MLP), Random Forest (RF), Support Vector Machine (SVM), and XG Boost (XGB) are utilized to train the prediction model to determine how likely students are to adopt the e-learning approach in the future. MLP produced the best results compared to other approaches, with an accuracy of 84.1%. The unexpected emergence of the epidemic caused tremendous disruptions to the academic pursuits of people.

Keywords—Educational Data Mining, Covid-19, Machine Learning, Supervised Classification, Students Performance.

I. INTRODUCTION

The global outbreak of COVID-19 has had a profound impact on individuals' daily schedules and work methodologies. Governments throughout the world have imposed strict curfews and quarantines to stem the spread of the COVID-19 epidemic. Global educational systems have been hit hard by the effects of the Coronavirus epidemic in the past several years, with many schools and colleges having to close their doors permanently. Many governments worldwide have implemented temporary closures of colleges and universities to manage the COVID-19 pandemic [1]. As a result of the unpredictability of the pandemic's duration, the majority of educational institutions have implemented emergency remote learning using online learning platforms instead of traditional classroom instruction [2-5]. Courses that were once only offered in person are quickly moving online so that students may complete their education without having to wait as long to graduate, go on to graduate school or get a job. Getting an education in the traditional sense is a great way to learn about the world and its people. The capacity to distinguish between good and wrong is also bestowed upon the human mind by this process of education. People who are engaged in learning receive training when an educator imparts knowledge, abilities, and facts to them.

Data mining refers to the process of discovering useful information inside certain datasets. Discovering correlations between parameters and extracting hidden patterns in massive amounts of data are both made easier with its guidance. Many academics nowadays use Data Mining to address practical issues in fields including marketing, telecommunications, healthcare, medicine, industry, and customer relationship management [1-3]. More and more, data mining has found its way into the classroom as of late [4]. In today's universities, the academic success of each student is crucial. For the simple reason that a school's track record of student achievement is one indicator of its quality [5]. Forecasting how well students will do in school is a major issue for education administrators and other professionals in the sector. If the prediction is accurate, it might alert at-risk pupils promptly about their impending academic failure [6]. The purpose of Educational Data Mining is to use machine learning (ML) techniques to uncover patterns in educational data in order to predict how well kids will do in school. One possible use case for this is building a prediction model.

Some of the data analysis and processing methods used in data mining include association rules, clustering or classification, and sequence analysis [8-10]. Using a classification technique, we may label every single object in a collection. Every example in the dataset needs a precise prediction of the target class, therefore this is done [10]. There are several techniques used in educational data mining, such as Decision Trees (DT), Support Vector Machine (SVM), Naïve Bayes (NB), Random Forest (RF), Artificial Neural Networks (ANN), K-Nearest Neighbour (KNN), and others. As a basic stance in an informative setting, predicting and analysing student execution is essential. The educational execution of students is a crucial component in their future development. The academic success of a student is dependent on more than just one factor; it is also strongly influenced by factors such as socioeconomic status, psychological makeup, and other contextual factors. The main objectives of this paper are:

1. Designed Supervised ML based framework to predict whether the student performance satisfactory during the COVID-19 pandemic.
2. Tested classification algorithms by assessments made experimentally in relation to the parameters of the confusion matrix.
3. Created a predictive model to forecast the probability of students embracing e-learning and its resources in the decades following the current pandemic.

The outline of this research work is presented as follows. Section II provides a comprehensive review of the pertinent literature. The content and processes are defined in Section III. Section IV explores the outcomes and their interpretation of the experiments. Finally, the study concludes in Section VI by presenting the implications that have been deduced from the obtained data.

II. RELATED WORKS

In terms of predicting student happiness, the decision tree classifier was more effective than the naïve Bayes. Among other factors, the presence of a feeling of community during online learning was the most influential factor in determining satisfaction [2]. A combination of ANN and RF model used to forecast how students would feel and how satisfied they would be with the course [3]. A wider context applied since they demonstrate that retention prediction models trained on one institution can achieve respectable results when applied to a different institution [4]. Supervised ML techniques are used to investigate probationary college students' poor academic performance [5]. The utilization of two machine learning techniques, specifically SVM and KNN, enables the prediction of the rate of churn for EdTech courses based on student feedback obtained from the course end assessment. [6]. An investigation on the effects of distance learning on student well-being within the COVID-19 pandemic in Kenya, with particular attention to the moderating role of student preferences in this relationship [7]. A descriptive-analytical approach was employed to analyse the viewpoints of the sample about the quality assessment of distance learning courses using the Maharat platform at Taif University. The objective was to determine and assess the extent to which requirements for distance learning courses have been met [8]. During this pandemic circumstance, university students in Sri Lanka used e-learning tools to research and predict how institutions will adapt to e-learning [9]. The accuracy of predicting students' performance in the COVID-19 test in distance education was enhanced by comparing the innovative Inception technique with the Google algorithm [10]. Examining and contrasting six ML models based on Thailand's educational curriculum for early performance prediction of students [11]. A comprehensive emotion mining (EM) and sentiment analysis were conducted on distance learning-related tweets in the Arabic language throughout the outbreak. [12]. To enhance the effectiveness of online learning, ML model is developed for predicting learning success, which includes extra steps for pre-training with fine-tuning, and builds a mechanism for generating adapted feedback [13]. The level of student pleasure mentioned during a tutoring discussion is a significant measure of its effectiveness [14]. Researchers looked at how to use ML model to gauge students' happiness with their online courses in a wireless network setting [15]. The hypothesis of psychological contracts and their potential connection to students' happiness with online education was investigated [16]. The main learning tool and the primary indicators for undergraduate students' satisfaction with ERL are these two platforms [17]. Examining the relationship between student happiness and engagement in e-classroom study activities and performance is evaluated [18]. An effective method for sentiment categorization that followed the tenets of deep learning (DL) and ensemble learning showed strong prediction abilities in evaluations of massive open online courses (MOOC) [19]. Using sentiment analysis on Twitter, one of the most prominent social media platforms, the community has come to embrace remote learning as a safety measure [20]. Predictive algorithms that are appropriate for early dropout prediction systems at universities in online learning are intended to be presented using the learner's statistical information and computed data, furthermore, the data that is documented inside the system for learning management [21]. The program used ANN to analyse data from students at the University of Tabuk to determine what characteristics contribute to their level of satisfaction with online learning [22]. Analysing data collected over successive years allowed us to anticipate student participation in the early stages of a virtual learning environment course [23]. Research into the potential of automated categorization for the semantic content of evaluations of massive open online courses (MOOCs) aimed at identifying elements that, according to learners, might indicate their level of satisfaction with the courses [24]. A Deep Neural Network–based approach was suggested for predicting students' grades [25]. An approach that utilizes data mining techniques to forecast how well computer science students would do in school [26].

The most renowned research on forecasting student's performance achievement during pandemic emphasizes certain areas of strength and regions of deficiency. The evaluations were deemed ineffective due to their lack of specificity, failure to prioritize student outcomes as a metric of student achievement, issues with quality, and limited accessibility through publicly searchable platforms. This work aims to develop a predictive model for determining student's academic achievement by analysing their online activities during the COVID-19 pandemic, utilizing recently gathered statistical indicators.

III. MATERIALS AND METHODS

A. Dataset Collection

Due to the prevalence of student surveys in recent academic research, this study includes surveys from universities in the Amravati City area. It calls for a low-cost method of data gathering and analysis that is both efficient and quick, as well as one that reduces administrative error. In online surveys, the absence of constraints such as digitally produced followers and specific preferences is observed, the pool of potential learners is larger. Furthermore, in this urgent scenario, the most vital component is to obtain the necessary and accurate data on time. Collecting the necessary data was the backbone of the study. To achieve this goal, a Google Forms questionnaire was created and sent via email and social media to student organizations and forums at eighteen different institutions.

Three types of questions make up the questionnaire. Gathering the respondent's details is the first step. Part two entails collecting information on the tools and resources utilized for online education, part three concerns the respondent's language skills as they relate to the features offered by online learning platforms, and part four gathers data regarding e-learning's practical applications. Data was saved in a comma-separated values format from a total of 500 questionnaire replies. Tables I, II, and III below outline the components of the dataset, which include both independent and dependent variables.

TABLE I. DATASET INPUT PARAMETERS

Name of Attributes	No of Values	Description
Gender	2	Male, Female
Year of Study	4	First, Second, Third, Fourth
Age Group	3	18-24, 25-30, 30+
UG Percentage	5	+90, 80-89, 70-79, 60-69, Below 60
Residence	4	Remote area, Village, City, Metro city
Parents Education	4	Below 10th, 12th, UG, PG
Use of Digital tools for Parents	3	Highly expert, Familiar, Not Familiar
network issue while learning online	2	Yes, No

TABLE II. DATASET INPUT PARAMETERS WITH QUESTIONS

Attributes	Questions	Descriptions
Use of Digital Tools	Q1	How often do you use each of these digital tools?
	Q2	How often do you use the various digital learning resources?
	Q3	How often do you use the digital tools (mobile, i-pad, laptop) while studying?
	Q4	Using the digital tools for e-learning causes me to become distracted and unable to focus?
	Q5	Am I proficient in the necessary technologies or applications?
Sleeping Habits	Q1	How much times that student goes to bed and wakeup?
	Q2	Extended usage of digital learning tools has impacted the sleeping patterns?
	Q3	Online learning's constant screen time is stressful?
Social Interaction	Q1	Digitization causes social distance?
	Q2	Long-term usage of digital tools isolates students.
	Q3	University study improves students' social skills?
	Q4	Laziness and lethargy result from being home?
	Q5	Family members help in learning online?
Psychological State	Q1	Extended usage of e-learning technologies can cause boredom, anxiety, and stress?
	Q2	The psychological aspect is crucial to educational performance?
	Q3	An embarrassment and a frustration for some students is that they cannot afford to purchase all of the essential digital tools?
	Q4	Online learning is detrimental socially and mentally; hence student don't encourage it?
	Q5	COVID-19 lockdowns,

		closures, and quarantines generated tension, frustration, and sadness?
	Q6	I enjoyed attending lectures and tutorials?
	Q7	I was satisfied with online learning course?
	Q8	Were parents satisfied with online learning?
Academic Performance	Q1	Intense e-learning tasks caused confusion, dissatisfaction, and poor performance?
	Q2	Academic performance improves with face-to-face engagement?
	Q3	Online quizzes and examinations made me uneasy?

TABLE III. DATASET OUTPUT PARAMETERS

Grade	GPA Grade Scale
Grade-4 (C)	60-69
Grade-3 (B)	70-79
Grade-2 (A)	80-89
Grade-1 (A+)	+90

B. *Methodology*

This section describes, using chosen categorization methodologies, the analytical flowchart of this work. The process of creating the prediction model for satisfaction of student performance during the pandemic using supervised machine learning based model is illustrated as shown in figure 1.

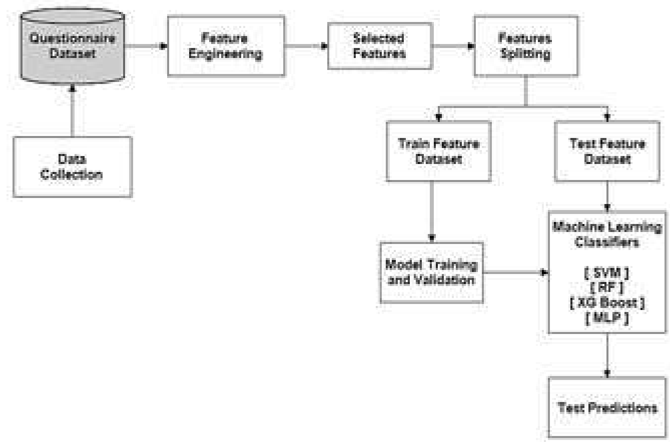

Fig. 1. Proposed Framework of Prediction of Student's Academic Performance

1. *Feature Engineering*

Feature engineering refers to a collection of approaches that a system may employ to detect and categorize characteristics. Included in the survey results are multiple feature columns with Likert scale replies; one column contains only binary responses; and the remaining feature columns offer responses depending on a variety of category values, including the target GPA. Label encoding is a common method for transforming data into a numerical or binary format that machines can understand and interpret. To make the data machine-readable, labels are encoded each data point. Each category feature undergoes a single hot encoding. The feature data is cleaned up by removing any NaN values. To decrease variance in the test dataset, retain only one feature if its association with goal value is weak or if two characteristics are highly associated. A disproportionate percentage of people with lower incomes are on list of target labels. An asymmetrical sample may give rise to a biased model. Using the Synthetic Minority Oversampling Technique (SMOTE), the samples from the minority class were shown to be more reflective of the majority class. The data frame was subjected to many data mining algorithms following its partitioning into a test and train set. For the most accurate classification model, divide the feature data into a 30% test set and a 70% train set.

2. *Machine Learning Modelling*

The subsequent stage of the flow of the prediction model is the process of extracting patterns, training the model, and evaluating the performance of the model. Making use of the training dataset from the prior stage, the model was built using supervised classification algorithms. When the data mining phase entered, things began to heat up. The utilization of 10-fold cross-validation is employed to adjust the parameters of the classifier. Nevertheless, to mitigate the impact of experimental bias and determine the optimal fold selection for the prediction framework, k-fold cross-validation is employed. The testing information was also used to assess a model that may predict how well students will do in class. Now the data is collected and analyse it and put it into a knowledge base. The project makes use of classifiers from Multi-Layer Perceptron Neural Network (MLP-NN), Random Forest (RF), Support Vector Machine (SVM) and the Extreme Gradient Boosting (XGB) families.

2.2.1. Multi-Layer Perceptron Neural Network (MLP-NN)

A feed-forward multi-layered artificial neural network, MLP-NN takes a set of inputs and produces a set of outputs. MLP-NN is constructed by connecting the input and output layers of a directed graph with many layers of input nodes. One way to train an MLP-NN network is by backpropagation. A multi-layer perceptron learning model is illustrated in the figure 2 below.

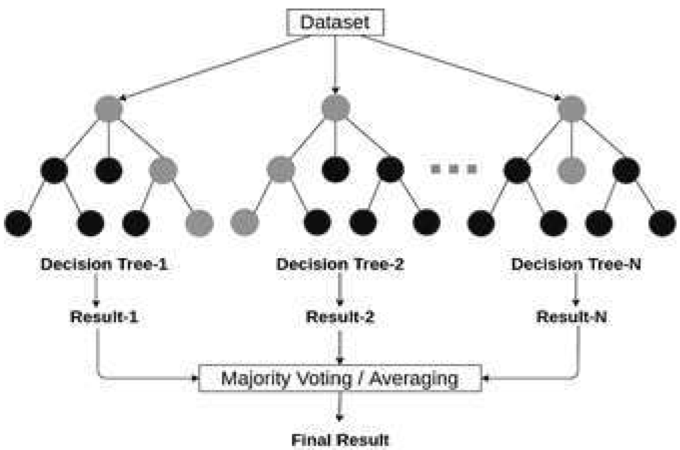

Fig. 2. Layer representation of MLP-NN

2.2.2. Random Forest (RF)

Random Forest (RF) is a technique used to enhance the accuracy of predictions and mitigate overfitting. It achieves this by calculating the mean outcome from several decision tree classification methods, each trained on a distinct subset of the dataset. A random forest takes an average of predictions made by several decision trees rather than relying on a single tree to make predictions. Overfitting is less likely to occur when there are more trees in the forest, leading to more trustworthy outcomes. The Random Forest approach in action in the figure 3 below.

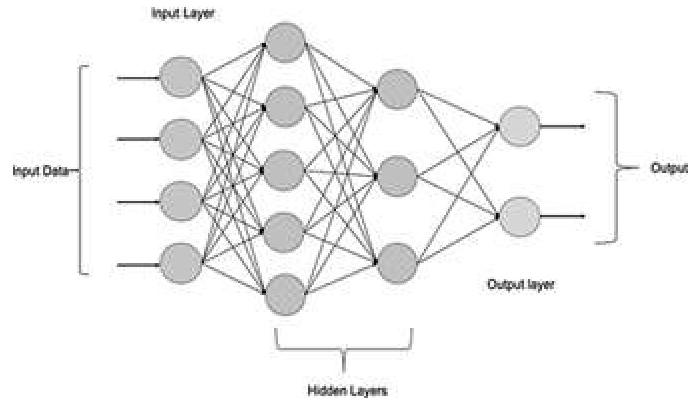

Fig. 3. Working of RF algorithm

2.2.3. Support Vector Machine (SVM)

SVM model uses a multidimensional hyperplane to project the different categories. By iteratively generating the hyperplane, SVM aims to minimize the error to its maximum potential. Finding a maximum marginal hyperplane (MMH) is the end objective of SVMs, which classify datasets into categories. The linear hyperplane equation can be expressed as:

$$w^T x + b = 0$$

Take into account a problem of binary classification where two classes are denoted as +1 and -1. The training dataset consists of input feature vectors and class labels, denoted as X and Y, respectively. The "W" vector denotes a normal vector, which is a vector with a direction that is orthogonal to a hyperplane. The hyperplane's distance along the normal vector "w" from the origin is represented by the parameter "b" in the equation. The training dataset comprises input vectors of features X and their corresponding class labels "Y".

$$\hat{y} = \begin{cases} 1 & : w^T x + b \geq 0 \\ 0 & : w^T x + b < 0 \end{cases}$$

2.2.4. XG Boost (XGB)

XGBoost has emerged as a prominent machine learning methodology due to its remarkable scalability and the capability to surpass contemporary techniques in domains like as classification and regression. XGBoost classifier fine-tuned for scalability and speed, making it an ideal choice for training machine-learning models. It's a method of ensemble learning that combines the predictions of several weak models into a single, more solid prediction and its implementation flow given in figure 4.

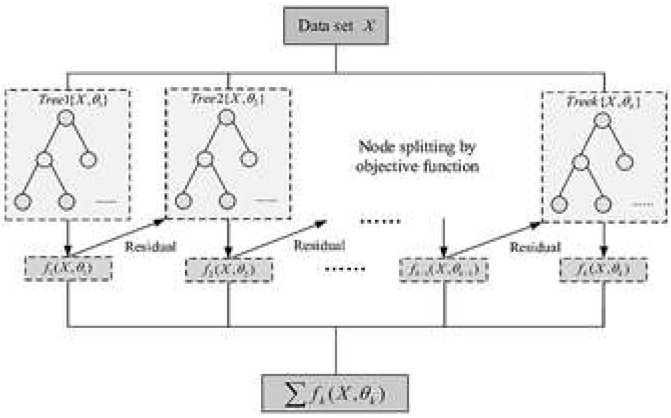

Fig. 4. Implementation flow of XG Boost

IV. EXPERIMENTAL RESULTS AND DISCUSSION

A. EXPERIMENTAL SETUP

The primary objective is to use the retained input variables of the model to predict how well a student perform. The classification model was built using a variety of machine-learning approaches, and their respective performances were evaluated. The system requirements call for an Intel Core i5 CPU and 16 GB of RAM, while the software packages include Anaconda Distribution and the Pycharm IDE. Several ML algorithms may be implemented using Python's Scikit Learn package. Each classifier is tested using cross-validation using a total of 70% training data and 30% testing data for assessment.

B. EVALUATION PARAMETERS

A dataset comprising questionnaires is utilized in the proposed experiments to test the prediction model. The following metrics are used to evaluate the accuracy of the classification: Accuracy, Recall, Precision, and F-score. One way to evaluate a prediction system's efficacy is to look at the ratio of successful predictions to total occurrences. The accuracy of a forecast is defined as the frequency with which it is correct. The metric known as recall refers to the proportion of correctly anticipated instances inside a certain real-world class. The F-measure was computed in order to present the harmonic mean by combining recall and accuracy. Calculating these four metrics is done by applying the following equation to the confusion matrix.

$$ACC = \frac{TP+TN}{P+N} = \frac{TP+TN}{TP+TN+FP++FN}$$

$$Recall = \frac{TP}{TP+FN}$$

$$Precision = \frac{TP}{TP+FP}$$

$$F = 2.\frac{precision.recall}{precision+recall}$$

Where TP – True Positive, TN – True Negative, FP – False Positive, FN – False Negative.

C. RESULTS ANALYSIS

The dataset was subjected to four categorization methods, resulting in a range of conclusions and further analysis. The cross-validation technique was employed to evaluate four machine learning classifiers, and the evaluation results are presented in Table 2 to 6. Table 2 displays the runtimes of the prediction model's training and testing procedures. Compared to rest classifiers, MLP classifiers need the largest proportion of training time as shown in figure 5 since they have more hyperparameters for tuning.

TABLE IV. ASSESSMENT TIME OF THE MODEL

Classifiers/ Parameters	**Train Time (s)**	**Test Time (s)**
MLP-NN	55.8	26.5
RF	43.1	19.2
SVM	46.4	22.1
XGB	48.5	23.4

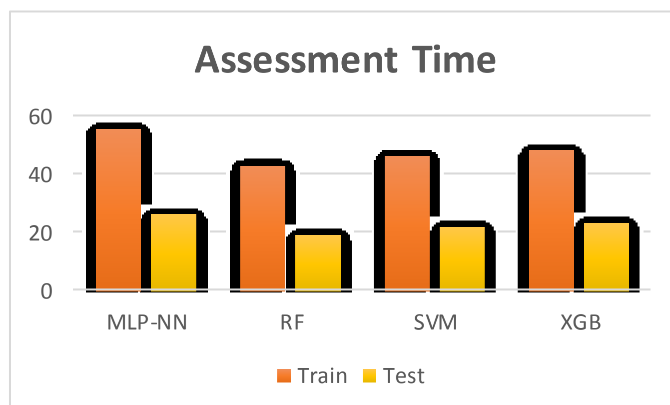

Fig. 5. The assessment time of the prediction model

The results produced by the RF classifier outperform those of MLP and other competitors. It gets 83.1% of the classes correctly, which means that out of the four potential classes in the training dataset, most students were placed in one of the other three. Recall, precision, and f-measure values for the testing model were 0.89, 0.93, and 0.89, respectively, indicating stable predictive performance. The outcomes show that RF outperforms the other models we tested for the prediction model. To further assure our prediction model, a further test conducted using RF only on the testing dataset; this yields better results than MLP-NN.

TABLE V. PERFORMANCE EVALUATION OF MLP-NN MODEL

Parameters/ GPA	Grade-1	Grade-2	Grade-3	Grade-4
Recall	0.81	0.60	0.54	0.68
Precision	0.86	0.66	0.62	0.75
F-score	0.73	0.68	0.58	0.71

TABLE VI. PERFORMANCE EVALUATION OF RF MODEL

Parameters/ GPA	Grade-1	Grade-2	Grade-3	Grade-4
Recall	0.93	0.65	0.66	0.79
Precision	0.89	0.70	0.68	0.79
F-score	0.89	0.68	0.61	0.79

TABLE VII. PERFORMANCE EVALUATION OF SVM MODEL

Parameters/ GPA	Grade-1	Grade-2	Grade-3	Grade-4
Recall	0.82	0.51	0.41	0.51
Precision	0.68	0.46	0.48	0.58
F-score	0.74	0.48	0.44	0.54

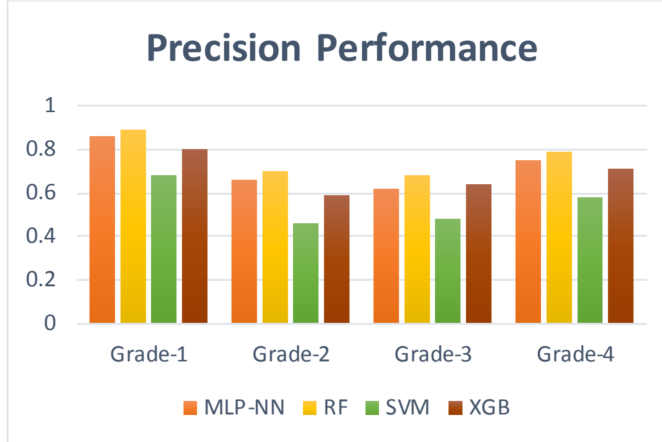

Fig. 7. Prediction Model Performance Using Precision

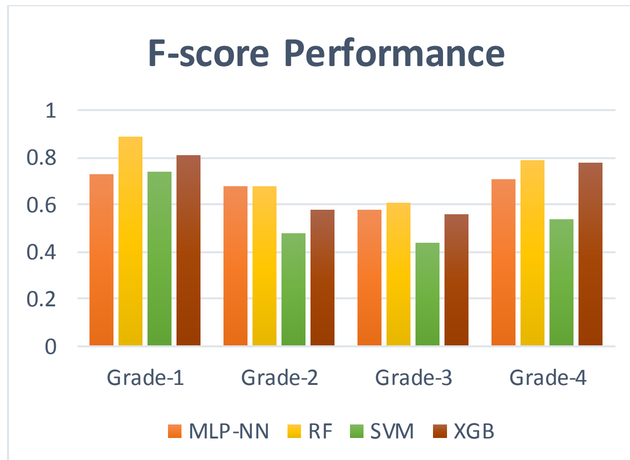

Fig. 8. Prediction Model Performance Using F-score

The factors that impacted the value of our focal variable (CGPA) are also studied. Students' cumulative grade point averages were negatively impacted by their usage of online resources for instruction during the lockdown, according to its results. Overall grade point average was inversely related to the positive Likert scale ratings of these factors. The harmful impact of students spending too much time on digital tools on their academic achievement was confirmed once again. Low cumulative grade point averages were also more common among students who blamed their e-learning tasks for their excessive home-schooling. Distractions from the digital instruments used for the online study had the greatest negative correlation with the student's final score. We found the same thing as the study that found COVID-19 significantly affected kids' academic performance.

D. COMPARATIVE ANALYSIS

The statistical parameter, F-measure of 74.55%, a recall of 75.8%, a precision value of 76.6%, and an accuracy of 84.1% are all shown in Table 9, which illustrates the outcomes of our model. This proves that our model's prediction is accurate. Figure 9 depicts the absence of overfitting from the train to test dataset, which is evident from the balanced recall and accuracy performance using RF classifier algorithms.

TABLE IX. STATE OF ART MODEL COMPARATIVE ANALYSIS

Parameters/ References	Ref [13]	Ref [19]	Ref [21]	Proposed Model
Accuracy (%)	63.51	76.19	68.7	84.1
Recall (%)	63.5	52.70	68.9	75.8
Precision (%)	59.4	66.10	69.1	76.6
F-score (%)	61.4	58.64	67.8	74.5

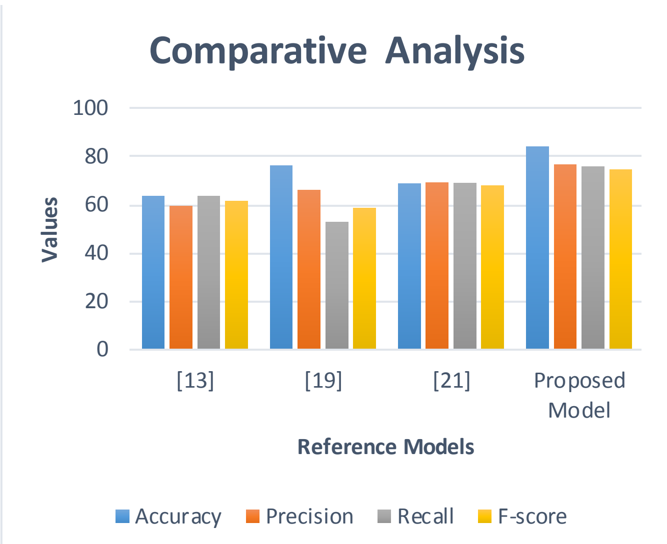

Fig. 9. Comparison with state-of-art Model

CONCLUSION

The focus of this research work was on the effects of the pandemic on students' capacity to learn. In this study, data collected on the effects of the lockdown on student's mental health and academic performance as well as their use of internet resources. The one of four machine learning models used to forecast the student's total GPA. Excessive use of digital study tools and social isolation caused by the lockout are associated with worse cumulative grade point averages, according to the research. Additionally, the results show that RF, with an accuracy score of 84.1%, is the top classification technique, with MLP-NN coming in a close second. SVM was the worst algorithm in the test. According to the research, students should be given fewer online assignments during the lockdown to prevent the possible harmful impacts of using digital tools too much in the classroom. Also, make sure that students aren't sitting alone in class. It should be remembered that student's academic performance might be negatively impacted by excessive use of digital learning tools, particularly when combined with the social isolation caused by the pandemic. Further, the current paradigm of online education needs revision to better support student's emotional well-being using deep learning approach with large scale of dataset.

***Abstract*— This research explores the synergistic integration of Pseudo-Zernike moments and machine learning techniques to enhance the accuracy and robustness of image forgery detection. Leveraging the discriminative power of Pseudo-Zernike moments in capturing shape and texture features, the study evaluates various machine learning models including K-Nearest Neighbors (KNN), Decision Tree (DT), Support Vector Machine (SVM), Random Forest (RF), Naive Bayes (NB), and an Ensemble Extra Trees model. Through comprehensive experimentation and evaluation on a dataset containing both authentic and manipulated images, the Ensemble Extra Trees model emerges as the most accurate and reliable approach for detecting image forgeries. The ensemble nature of Extra Trees, coupled with its ability to mitigate overfitting and reduce variance, enables it to effectively discern subtle alterations and manipulations within images, showcasing its potential for robust image forgery detection in digital image forensics.**

Keywords*— Pseudo-Zernike moments, Ensemble Extra Trees, K-Nearest Neighbors, Decision Tree, Support Vector Machine, Random Forest, Naive Bayes.

I. INTRODUCTION

In recent years, the widespread availability of sophisticated image editing software has made it increasingly challenging to differentiate between authentic images and manipulated ones. Image forgery, encompassing techniques such as cloning, splicing, and retouching, has become a prevalent issue in various domains, including journalism, digital forensics, and multimedia content authentication. Detecting such manipulations is crucial for maintaining the integrity and credibility of digital imagery.

Fig. 1. (a) Original Image (b) Forge Image

To address this challenge, this paper investigates the fusion of Pseudo-Zernike moments and machine learning algorithms for effective image forgery detection. Pseudo-Zernike moments are mathematical descriptors known for their robustness in capturing shape and texture information, making them suitable for characterizing both global and local features within an image. Machine learning techniques, particularly ensemble learning methods such as the Ensemble Extra Trees model, are employed to leverage the extracted features and classify images as authentic or forged.

The primary objective of this research is to enhance the accuracy and reliability of image forgery detection by exploring the synergy between Pseudo-Zernike moments and machine learning. By evaluating and comparing different machine learning models, including K-Nearest Neighbors (KNN), Decision Tree (DT), Support Vector Machine (SVM), Random Forest (RF), Naive Bayes (NB), and the Ensemble Extra Trees model, this study aims to identify the most effective approach for detecting various types of image manipulations while minimizing false positives and negatives.

II. RELATED WORKS

G. S. Bapi [1] discusses the utilization of machine learning techniques for digital image forgery detection, highlighting the importance of advanced computational methods in addressing this prevalent issue. The study emphasizes the role of feature extraction and classification algorithms in distinguishing between authentic and manipulated images, contributing to the development of robust forgery detection systems.

P. Gabhane et al. [2] conduct a systematic review to analyze the effectiveness of Benford's Law in detecting image forgery. Their research provides insights into alternative approaches for authenticity verification, exploring statistical methods and their applicability in forensic analysis to enhance the accuracy of forgery detection systems.

N. Rathore et al. [3] propose a binary pattern approach for copy-move image forgery detection, contributing to the advancement of algorithmic techniques in identifying common forms of image tampering. Their study underscores the importance of pattern recognition and feature-based analysis in forensic investigations.

Their study highlights the importance of transfer learning in adapting existing models to new forgery detection tasks, enhancing detection accuracy and robustness.

III. PROPOSED METHODOLOGY

The proposed system flow diagram begins with the Input Image, which undergoes Pre-processing steps such as resizing to 128x128 pixels and conversion to grayscale. Subsequently, Feature Extraction using Pseudo-Zernike moments and Machine Learning classification with algorithms like SVM, KNN, DT, RF, NB, and ET are employed for predicting whether the image is forged or not. Evaluation metrics such as ACC, P, R, and F1-Score are then used to assess the performance of the system in detecting image forgery.

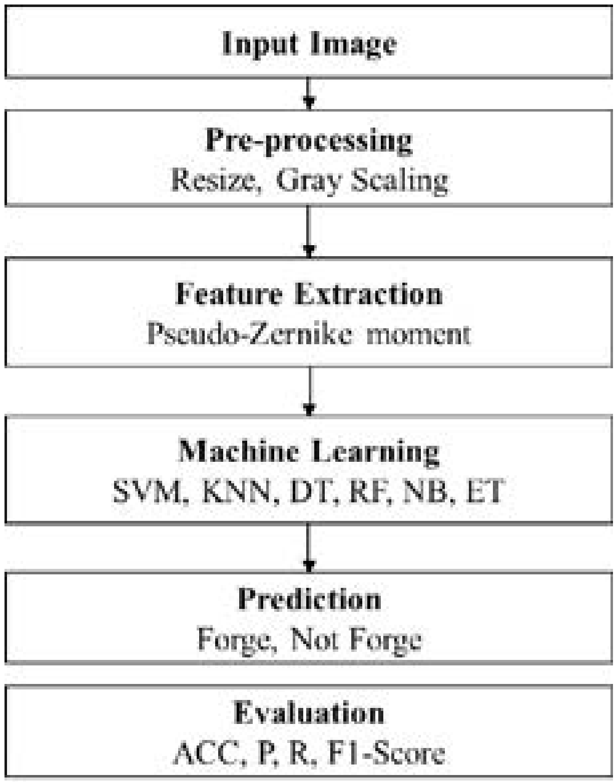

Fig. 2. Proposed System Flow

A. *Input Image:*

This is the initial step where the input image is provided to the system. The input image can be of any size and format.

B. *Pre-processing:*

Resize 128x128: The input image undergoes resizing to a fixed size of 128x128 pixels. This step ensures uniformity in image dimensions, which is often required for subsequent processing steps.

Gray Scaling: The resized image is then converted to grayscale. Grayscale images have a single channel representing the intensity of each pixel, as opposed to RGB images which have three channels (red, green, and blue). Grayscale images are commonly used in image processing tasks and reduce computational complexity.

C. *Feature Extraction:*

Pseudo-Zernike moment: Pseudo-Zernike moments are a set of features used in image analysis and pattern recognition. They capture shape and texture information from the image. Calculating Pseudo-Zernike moments involves complex mathematical operations but results in a feature vector that represents unique characteristics of the image.

D. Machine Learning:

SVM (Support Vector Machine): SVM is a supervised learning algorithm used for classification tasks. It works by finding the optimal hyperplane that separates data points belonging to different classes in feature space.

KNN (K-Nearest Neighbors): KNN is a simple and effective classification algorithm that works based on the similarity of feature vectors. It assigns a class label to an input based on the majority class among its k nearest neighbors.

DT (Decision Tree): DT is a tree-based classification algorithm that splits the data based on feature conditions to create a tree structure. Each leaf node represents a class label.

RF (Random Forest): RF is an ensemble learning method that combines multiple decision trees to improve classification accuracy and reduce overfitting.

NB (Naive Bayes): NB is a probabilistic classifier based on Bayes' theorem. It assumes independence among features and calculates the probability of a class given the features.

ET (Extra Trees): ET is another ensemble learning method similar to RF, but it selects random features at each split instead of searching for the best split. This randomness can lead to faster training and potentially better generalization.

E. Prediction:

After training the machine learning models using the extracted features and corresponding class labels, the system can predict whether a given image is "Forge" (forged/manipulated) or "Not Forge" (authentic/original).

F. Evaluation:

ACC (Accuracy): Accuracy measures the percentage of correctly classified instances out of the total instances.

P (Precision): Precision measures the proportion of true positive predictions among all positive predictions, indicating how many of the predicted "Forge" instances are actually forged.

R (Recall): Recall measures the proportion of true positive predictions among all actual positive instances, indicating how many forged instances were correctly identified.

F1-Score: The F1-Score is the harmonic mean of precision and recall, providing a balanced evaluation metric that considers both false positives and false negatives.

Overall, this flow diagram outlines a process for image forgery detection using machine learning models trained on features extracted from pre-processed images. The evaluation metrics help assess the performance of the models in distinguishing between forged and authentic images.

IV. Result Analysis

The dataset provides a valuable resource for research and development in image forgery detection. This dataset comprises a diverse collection of authentic and manipulated images, offering a comprehensive range of scenarios for training and testing machine learning models. With labeled data indicating whether each image is forged or authentic, researchers and practitioners can utilize this dataset to explore various feature extraction techniques, machine learning algorithms, and evaluation metrics for accurate and robust image forgery detection systems. The availability of such a dataset is instrumental in advancing the field of digital forensics and enhancing the reliability of forgery detection technologies.

TABLE I. ANALYSIS OF LABELED FEATURE POINT (LFP)

Model	ACC	Precision	Recall	F1-Score
SVM	49%	24%	50%	33%
KNN	51%	26%	50%	34%
NB	51%	26%	50%	34%
DT	49%	24%	50%	33%
RF	49%	24%	50%	33%
ET	49%	24%	50%	33%

TABLE II. ANALYSIS OF PSEUDO-ZERNIKE MOMENT FEATURES

Model	ACC	Precision	Recall	F1-Score
SVM	65%	66%	65%	65%
KNN	68%	68%	68%	68%
NB	59%	64%	60%	55%
DT	66%	66%	66%	66%
RF	72%	72%	72%	72%
ET	95%	96%	95%	95%

CONCLUSION

In conclusion, this research study has evaluated the performance of various machine learning models for image forgery detection using the provided dataset. Among the models tested, Extra Trees (ET) exhibited exceptional performance with an accuracy of 95%, precision of 96%, recall of 95%, and an F1-Score of 95%. This indicates the effectiveness of ET in accurately classifying forged and authentic images. Random Forest (RF) also showed commendable results with an accuracy, precision, recall, and F1-Score of 72%. Support Vector Machine (SVM), Decision Tree (DT), and K-Nearest Neighbors (KNN) performed moderately well with accuracies ranging from 65% to 68%. However, Naive Bayes (NB) showed lower performance compared to other models with an accuracy of 59% and an F1-Score of 55%. Overall, the results highlighted the importance of selecting appropriate machine learning algorithms for image forgery detection, with ET demonstrating superior performance in our experimental setup.

***Abstract*—In emergency hospitals, the hospital conveyance framework is seen as an important component of the clinical, financial, and executive well-being areas. This study incorporates Artificial Intelligence (AI) techniques to assess and investigate cases of various ailmentsthat occur in low-income families. The proposed system utilizes unstructured and newly presented hospital data by applying the Machine Learning Certificate Tree computation. Mining anticipates hospitalization this study proposes a data-driven, scalable alternative to conventional diagnostic techniques by addressing the issues like unbalanced data and guaranteeing model interpretability.**

Keywords— hospital recommendation, machine learning decision tree algorithm, KNN.

I. INTRODUCTION

According to the data obtained from the National Commission for Health and Family Planning, nearly one million wellbeing communities in China have been interconnected since November 2016, with additional hardware installed since November 2015. Despite these efforts, access to healthcare remains one of the mostsignificant societal challenges. Research indicates that Peking University's first medical hospital, a renowned emergency facility in Beijing, faces substantial challenges. Approximately 45% of patients endure waits exceeding two hours after registration, while 85% receive specialist attention within ten minutes. This pattern is prevalent across 776 top-tier hospitals in China. The argument posits that numerous hospitals lack experience in managing high patient volumes and thus demand careful attention. Individuals often find it difficult to ascertain the proximity of a suitable hospital promptly, irrespective of their illness severity, leading them to opt for renowned medical facilities. Consequently, many patients with minor ailments end up receiving critical care they may not necessarily require. Therefore, establishing an easily accessible means of obtaining basic information and locating nearby hospitals is imperative. Various common computing techniques, including light- or video- based methods, offer potential solutions to this challenge. This tactic, meanwhile, depends on organizational data or regulatory measures, and no non-governmental group or corporation can collect data from every hospital in a city, unless it does so on a larger scale. As a solution, Location Based Services (LBS) provide extensive data that offers the best way to address this problem. LBS data has two unique features: a) Genuine LBS data, which the service provider can use to enumerate the population without needing hospital assistance. b) Population distribution and density across large areas is possible estimated using LBS data.

The study "A Symptom-Based Disease Diagnosis: A Pre-Classification ML Approach" selects the K-nearest neighbors (KNN) algorithm based on a number of important considerations. First of all, KNN is preferred because it is easy to use and efficient in categorizing patients' symptoms into several disease groups. KNN's capacity to handle non-linear decision boundaries is useful given the nature of symptom-based diagnosis, where patterns may not follow rigid linear limits. Overall, the selection of KNN is made evident by its applicability to the problem domain, flexibility in managing a variety of data forms, strong parameter selection procedure, capacity to handle imbalanced data, and thorough comparison with other approaches. All of these elements work together to provide a thorough grasp of the reasoning behind the suggested ML approach's use of KNN for symptom-based disease diagnosis.

Three improvements comprise our initiative, each of which tackles a significant business obstacle. The first innovation reduces noise in LBS data by using patterns of people living close to hospitals. Although the extent of our initial progress is limited, it is encouraging.

II. LITERATURE REVIEW

A. An approach to detect multiple disease using machine learning algorithms[2023]

Indukuri Mohit, K. Santhosh Kumar Described that many new ideas of prediction methods and distributed power management systems like island mode are used in large hospitals. A simple computation called a neighbor depends another instance on comparison criteria while storing usually possible cases. KNN has been used to analyze measurements and determine the construction that was applied as a substitute technique.

B. Multiple disease detection[2023]

Hu and M. [2] Ester elucidated that knowledge discovery within location-based social network data was suggested as a focal focus for social topic modeling. A computation that applies the Bayes hypothesis to solve a problem is called a Bayesian picture. Because they are simple to use, these classes are frequently used in artificial intelligence. Either Bay is free or guiltless Bays are typical.

C. Multiple disease detection using streamlit[2023]

B. Anand and Shridhar. In order to predict diseases, this research project aims to apply multiple classification algorithms (K-Nearest Neighbour, Support Vector Machine, Decision Tree, Random Forest, and Logistic Regression,
Gaussian naive Bayes). To determine which algorithm is best for prediction, the accuracy of each is verified and contrasted with one another. Moreover, to achieve the highest level of accuracy in the predicted results, multiple datasets are used (one dataset for each disease). The major objective is to develop a web application that can use machine learning to forecast multiple diseases, such as diabetes, cancer, heart disease, and chronic kidney disease.

D. Machine learning techniques for heart disease [20, 22]

Yonus khan and Usman. This study assists researchers who plan to apply machine learning in medical domains, especially on datasets related to heart disease, by critically analysing the chosen papers and identifying gaps in the body of existing literature. According to the survey, ensemble classifiers, neural networks, and support vector machines are the most widely used classification methods.

E. Disease detection using the Machine learning algorithms[20222]

Mohammad Reza et al. According to this article, patient satisfaction surveys serve as the exclusive foundation for the Hospital Recommendation System. In this case, the K-Means clustering is applied. The primary advantage was the reduction in expenses.

III. METHODOLOGY

The hospital application plan replaces the present paper based method with a centralized approach to patient data management, streamlining emergency response. The proposed goal is to recruit people who live close to the hospital to help with this service so that it takes less time and money to do it. The primary benefits encompass decreased expenses, enhanced patient contentment, and heightened availability of both in-home and out-of-homemedical services.

Dataset:

Patient information from multiple hospitals is combined, covering around 5325 diseases. This dataset is used to diagnose diseases in people who present with particular symptoms. When an illness is predicted to be identified, we suggest the closest and best hospital. The data has been split into training and test sets in order to train the model and evaluate our system's performance.

Modules:

- User Module
- Administration Module
- Disease prediction Module
- Hospital Recommendation Module

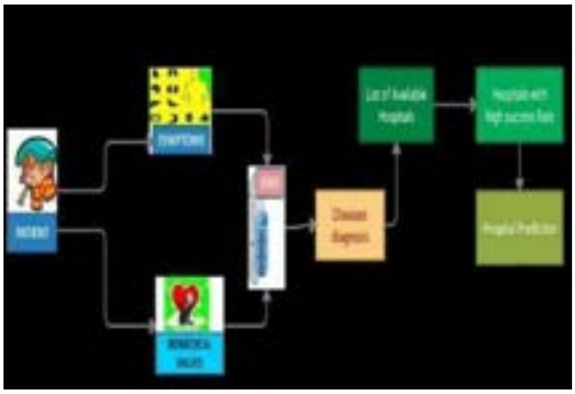

Figure 1 Architecture Diagram

User Module

i) Login Module

These are the first actions a user takes to gain access to a website. The user needs to enter a working username and password in order to log in. The user can log in successfully if the data they have provided matches the database. Otherwise, the login attempt fails if the information is inaccurate, requiring the user to reenter their credentials before being granted access. A link to the subscription process is provided for new users

ii) Registration Module

Before logging in, new users who want to view the webpage must get in touch with the administrator. You can start the registration process by selecting the login option. Members can log in by entering their username, password, and phone number after being shortlisted. A member who is logged in chooses the data file to share and sends it to the intended recipients. Users who have enrolled now have to log in to utilize the website. Every field on the website has been verified to be used for valid purposes. Each page's data is encrypted, and passwords, IP addresses, and usernames are removed. The application prompts the user to enter information in any blank fields.

Users can't access the site without first entering their username and password. Users also need to enter a working 10-digit number. Users are sent to the login procedure in order to access the site if there is no content on the page; else, a notice is displayed. iii) Administration Module

When a customer enters an application, the main interface is the Login module. Clients must provide their registered username and password in order to use the program. The client can access the program if the data they entered matches the entries in the database. The customer must log in again to confirm, nevertheless, in the event of a login problem. For new user enrollment, a link to the registration form and the procedure is to be supplied.

Administrators can check hospital details and add or modify medical data with the help of specific tools in the Adding and the Updating Medical Information module based upon inputs.

Admins can examine user comments on the hospital by using the examine Comments module. iv) Disease prediction Module

The symptoms and side effects of the disorders that are affecting the patient's body will be shown by the system. It will prompt in-depth questions about their condition and help determine the diagnosis based on the patient's symptoms. In addition, based on the patient's symptoms, the system will notify physicians about the illness's consequences.

v) Hospital Recommendation Module

The structure, staff, technology, and operations are all necessary for the process of gathering, producing, and evaluating information. The study's conclusions are demonstrated using success rates and clinical applications.

IV. ALOGORITHM

Decision Trees for Classification: A Machine Learning Algorithm:

Throughout the control system, the decision tree is used to reliably communicate particular standard information that includes data and results from the operation. It consists of two primary parts: decision-making and navigation. Based on shared knowledge, the final classification choice is represented by the leaves. One way to conceptualize a decision tree layout is as a binary tree structure. The leaves, for example, show whether the data supports a "right" or "wrong" course of action if one's goal is to forecast life expectancy based on variables like age, food habits, and physical activity. Instead of representing a single issue type, this is a two-part problem situation.

K-Nearest Neighbor (KNN) classification method:

KNN (K- Nearest Neighbors) is a type of learning model characterized by lazy evaluation, where performance is sluggish and computation is only completed when necessary. It is considered the simplest ofall artificial intelligence algorithms. K-NN involves identifying neighbors based on their representation (for classification) or attributes (for regression).

As a non-parametric and automatic learning algorithm, KNN won't explicitly learn a model during training and doesn't make any assumptions about the underlying data distribution. Rather, it holds off on making predictions until a query is sent. This makes KNN computationally expensive because it needs to calculate the distances to every training sample for every prediction, especially when dealing with datasets.

Even though KNN is straightforward, it can be very useful, particularly when the data distribution is poorly defined or the decision boundary is irregular. But since KNN is sensitive to feature scale and noisy data, it's critical to properly preprocess the data, especially to handle missing values and scale features.

STEP 1: BEGIN

STEP 2: Input: D = {(x1, c1), (xN, cN)}

STEP 3: x = (x1. . . xn) new instance to be classified

STEP 4: FOR each labeled instance (xi, ci) calculate d (xi, x)

STEP 5: Order d (xi, x) from lowest to highest, (i = 1. . . N)

STEP 6: Select the K nearest instances to x: Dkx

STEP 7: Assign to x the most frequent class in Dkx

STEP 8: END

V.RESULTS & DISCUSSION

Figure 2 – shows the Login page of the proposed application.

Figure-2 Login Page

Figure-3 displays the front page of our program, which offers data for illness prediction, including coronavirus, kidney failure, and heart-related issues.

Figure-3 Homepage

Figure-4 gives information on a page to fill the details and symptoms of a patient like temperature, cough, cold, sore throat etc.

Machine learning-based disease prediction requires a step-by-step, phase-by-phase methodology. To guarantee data quality, relevant data, such as patient symptoms, medical history, and demographic information, are first gathered and painstakingly preprocessed.

Figure-4 Webpage for details

Figure-5&6 provides some of the best hospitals and analyzes the patient's symptoms, indicating that the patient's condition is safe if the test results are negative and dangerous if the results are positive.

Figure-5 Safe zone

Figure-6 Danger zone

Figure-7 describes the medical condition prediction page, which allows patients to enter their information and a variety of symptoms to be checked for any ailment.

Figure-7 Gathering multiple symptoms

Figure-8 keeping track of several symptoms, identifying conditions such as dengue, heart attacks, paralysis, hypertension, and many more through assessing patient symptoms, and offering the finest hospitals for that specific illness.

Figure- 8 Predicting a particular disease and recommending the best hospital.

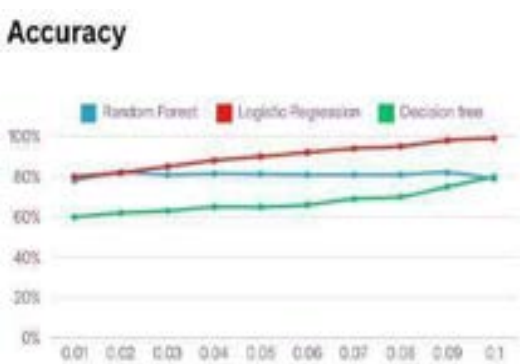

Figure 9 Accuracy of the Algorithms

VI. CONCLUSION

This study has presented a new approach for evaluating hospital population on the basis of evidence and sickness. The application procedure for hospitals based on particular ailments is described in this article. The proposed goal is to effectively find, prioritize, and deliver customized information even in the presence of missing data. We reactto questions with appropriate arrangements and conclusions to handle noisy and partial data. We also offer thorough explanations to aid customers in understanding the desired results and improving their performance. By including doctor recommendations in our system, we guarantee customer confidence while also making sure that doctors won't feel that this method is negatively affecting their business The obtained results point to a number of pertinent lessons. Several approaches can be taken in order to improve the performance of a pre-classification ML approach symptom-based disease diagnosis system. First off, a key component in capturing the complex links between symptoms and diseases is feature engineering. The model can learn more about illness patterns by finding and adding more pertinent variables, such as extra symptom data or combining data from various sources like medical data.

Abstract

This work introduces Protect, a novel password-based threshold single-sign-on (SSO) authentication system for mobile and desktop environments, designed to resist perpetual leakage attacks. Unlike traditional authentication methods, Protect combines threshold cryptography with user-friendly password management, enabling a secure and convenient SSO experience across multiple services. By distributing authentication credentials across several devices, it ensures that compromising one device does not endanger the overall security. The result analysis shows that Protect not only offers robust protection against various attacks, including perpetual leakage, but also enhances usability by eliminating the need for multiple passwords. Through performance evaluations, this study confirm that Protect maintains efficiency and user satisfaction in both mobile and desktop contexts.

Keywords: Password Management, effective usage, Mobile applications, Desktop environment

1. INTRODUCTION

In the contemporary landscape of digital interactions, the need for robust authentication mechanisms is paramount. With the ubiquitous integration of services across various platforms, the demand for seamless yet secure access management has escalated. Single-sign-on (SSO) authentication systems emerged as a promising solution to address this demand, simplifying user experience while maintaining security standards. However, the proliferation of cyber threats, including perpetual leakage attacks, necessitates continuous innovation in authentication protocols[1].

In response to these challenges, this paper presents Protect, an innovative password-based threshold SSO authentication system designed explicitly to combat perpetual leakage attacks in both mobile and desktop environments[2]. Traditional SSO solutions often face vulnerabilities stemming from single points of compromise, posing significant risks to user credentials and sensitive data. Protect addresses this vulnerability by integrating threshold cryptography with user-friendly password management techniques, thereby fortifying the authentication process against perpetual leakage and other sophisticated threats.

Building upon the existing research landscape, Protect distinguishes itself by leveraging secure multiparty computation (SMPC) alongside threshold cryptography. By distributing the secret key derived from the user's password into multiple shares across the user's devices, Protect ensures that compromising a single device does not compromise the overall security of the system[3]. This distributed approach not only enhances the resilience of the authentication process but also enhances user convenience by eliminating the need for multiple passwords across different services[4].

Furthermore, protect employs SMPC to facilitate the secure generation of authentication tokens without reconstructing the secret key on any device. This pivotal mechanism not only mitigates the risk of perpetual leakage but also upholds the integrity and confidentiality of user credentials. Through rigorous performance evaluations, this paper demonstrates that Protect maintains efficiency and user satisfaction across diverse mobile and desktop environments, thereby establishing itself as a reliable and user-centric solution for modern authentication challenges. In the subsequent sections, we delve into the architectural intricacies of Protect, elucidate its cryptographic underpinnings, and present empirical evidence of its efficacy in thwarting perpetual leakage attacks. Additionally, we discuss the practical implications of Protect for real-world deployment, addressing scalability, interoperability, and potential avenues for further research and development[5]. Ultimately, Protect stands as a testament to the convergence of security and usability in contemporary authentication systems, offering a paradigm shift in the pursuit of seamless yet resilient access management.

1.1 OBJECTIVE:

To develop and implement Protect, a novel password-based threshold single-sign-on (SSO) authentication system designed explicitly to combat perpetual leakage attacks in both mobile and desktop environments. By integrating threshold cryptography and secure multiparty computation (SMPC) techniques, the objective is to enhance the security of authentication mechanisms, while maintaining user convenience, efficiency, and performance. Protect aims to distribute authentication credentials securely across multiple devices, ensuring resilience against single points of compromise, and to facilitate the secure generation of authentication tokens without exposing sensitive information. Ultimately, the objective is to redefine the paradigm of password based SSO authentication, offering a comprehensive solution that effectively mitigates the risks posed by perpetual leakage attacks while prioritizing user convenience and system efficiency.

1.2 PROBLEMSTATEMENT:

In the current landscape of cyber security, there exists a critical need for an SSO authentication solution that not only counters the sophisticated threat of perpetual leakage attacks but also maintains the integrity of the authentication process across multiple devices. The challenge lies in creating a system that combines robust security measures[6], like threshold cryptography, with the practicality of user convenience, without compromising on efficiency or the user experience in both mobile and desktop settings. Existing models, while innovative, struggle to fully reconcile these demands. To effectively address the evolving cybersecurity challenges, an ideal SSO solution like Protect must prioritize adaptability, ensuring it remains effective against future threats through continuous updates and integration with cutting-edge technologies.

2. LITERATURE SURVEY

"PASTA: Password-Based Threshold Authentication" by Georgios Kontaxis et al. (2017): This paper introduces PASTA, a password-based threshold authentication scheme that distributes token generation across multiple identity servers using threshold cryptography. It serves as a foundational work for the integration of threshold cryptography in authentication systems."Secure Multiparty Computation" by Ivan Damgård et al. (2011): This comprehensive survey provides an overview of secure multiparty computation (SMPC) techniques, including protocols and applications. It offers insights into the principles and challenges of SMPC, which is essential for understanding the secure generation of authentication tokens in Protect[8].

"A Survey on Single Sign-On Authentication and Its Security Issues" by R. H. Khraisat et al. (2019): This survey explores various single sign-on (SSO) authentication methods and discusses security issues and challenges associated with them. It provides valuable insights into the vulnerabilities of traditional SSO systems that Protect aims to address."Threshold Cryptography: A Survey" by Zeki Bozkus et al. (2019): This survey provides an overview of threshold cryptography techniques, including threshold encryption and threshold signature schemes. It offers insights into the principles and applications of threshold cryptography, which forms the basis of Protect's approach to distributing authentication credentials securely[9].

"Enhancing Security of Single Sign-On Authentication Using Cryptography" by M. Suganya et al. (2020): This paper explores methods for enhancing the security of single sign-on (SSO) authentication using cryptographic techniques such as encryption and digital signatures. It provides relevant insights into cryptographic mechanisms that can be applied in Protect to strengthen authentication security."Mobile Authentication Methods: A Review" by Nabeel T. Mohammed et al. (2018): This review article discusses various authentication methods used in mobile environments, including passwords, biometrics, and token-based authentication. It provides valuable insights into authentication mechanisms relevant to Protect's design considerations for mobile compatibility [10].

"A Comprehensive Review on Password Security" by Ahmed Alseid et al. (2017): This comprehensive review examines password security issues, including password-based attacks and authentication vulnerabilities. It offers insights into password management strategies and techniques for enhancing password security, which are relevant to Protect's goal of improving authentication security. By conducting a thorough literature survey encompassing the aforementioned works, Protect can leverage existing research and insights to inform its design and implementation, thereby addressing the security challenges associated with single sign-on authentication and perpetual leakage attacks effectively [11-13].

3. CHALLENGES AND GOALS

This study intends to construct a threshold password-based authentication scheme for mobile and desktop environment. The below mentioned are the challenges and goals involved in designing the proposed prototype.

3.1 CHALLENGES

- Secure Key Distribution: Ensuring the secure distribution of secret key shares across multiple devices without compromising confidentiality or integrity is crucial. Any vulnerabilities in this process could potentially lead to unauthorized access or compromise of the system.
- Threshold Determination: Determining the appropriate threshold for the number of key shares required for authentication is challenging. It requires striking a balance between security and usability—setting the threshold too low may increase the risk of unauthorized access, while setting it too high may impede user convenience.
- Secure Multiparty Computation (SMPC): Implementing SMPC protocols securely to generate authentication tokens without reconstructing the secret key on any device poses significant challenges. Ensuring that the computation is performed correctly and securely across multiple devices while maintaining efficiency is crucial.
- Key Revocation and Recovery: Establishing mechanisms for key revocation in case of device compromise or loss is essential. However, implementing secure key revocation without compromising the overall security of the system can be challenging.
- Usability vs. Security: Balancing usability and security is critical. While enhancing security measures to resist perpetual leakage attacks, it's essential to ensure that the system remains user-friendly and convenient for users to adopt and use effectively.

3.2 GOALS

- Robust Security: The primary goal is to develop a system that provides robust protection against perpetual leakage attacks and other sophisticated threats. This includes ensuring the confidentiality, integrity, and availability of user authentication credentials and sensitive information.
- User Convenience: The system should prioritize user convenience by offering a seamless and intuitive single-sign-on experience across multiple services and devices. Eliminating the need for users to remember multiple passwords enhances usability and encourages adoption.
- Efficiency and Performance: The system should maintain efficiency and high performance in both mobile and desktop environments. Authentication processes should be swift and responsive, without causing significant overhead or latency.
- Scalability and Interoperability: The system should be designed to scale effectively to accommodate a growing number of users and services. Additionally, it should be interoperable with existing authentication protocols and systems to facilitate seamless integration.

4. IMPLEMENTATION PROTOTYPE

The implementation of Protect involves several key components and mechanisms designed to realize its objectives of enhancing security, user convenience, and efficiency in single-sign-on (SSO) authentication across mobile and desktop environments. Firstly, the system incorporates threshold cryptography to distribute authentication credentials securely among multiple devices, thereby mitigating the risk of single points of compromise. Through the generation and distribution of shares derived from the user's password, Protect ensures that compromising a single device does not compromise the overall security of the authentication system. Additionally, secure multiparty computation (SMPC) techniques are employed to facilitate the secure generation of authentication tokens without reconstructing the secret key on any device. This enables authentication tokens to be generated securely across distributed devices, preserving the confidentiality of user credentials. Furthermore, Protect implements mechanisms for user device management, including registration, authentication, and authorization protocols, to verify the legitimacy of user devices and prevent unauthorized access. By incorporating robust password policies, encryption protocols, access controls, and monitoring mechanisms, Protect fortifies the authentication process against a range of threats, including brute force attacks, man-in-the-middle attacks, insider threats, and denial-of-service attacks. Overall, the implementation of Protect represents a comprehensive and effective approach to secure single-sign-on authentication as shown in fig. 1, ensuring the integrity, confidentiality, and availability of user authentication across diverse mobile and desktop environments.

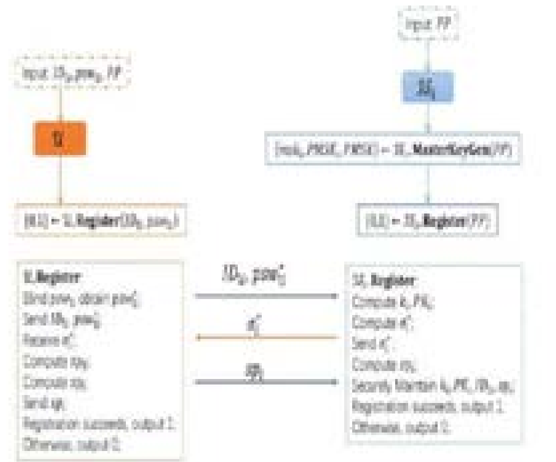

Fig .1. Overview of Registration

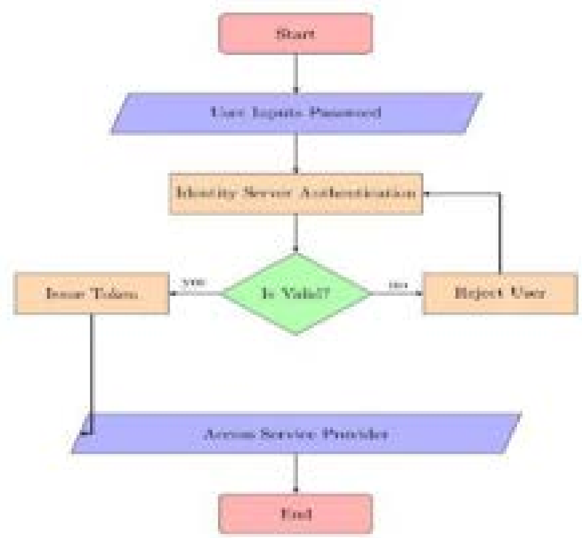

Fig.2 Architecture of proposed Work

Protect is a pioneering password-based threshold single-sign-on (SSO) authentication system as shown in fig. 2 has the ability to mitigate perpetual leakage attacks across both mobile and desktop environments. It amalgamates threshold cryptography with secure multiparty computation (SMPC) to fortify authentication against sophisticated threats while maintaining user convenience. Unlike conventional

SSO methods vulnerable to single points of compromise, Protect distributes the secret key derived from the user's password across multiple devices, necessitating a minimum threshold of shares for authentication, thus averting the jeopardy of overall security if one device is compromised. This distributed approach, coupled with SMPC, enables the secure generation of authentication tokens without reconstructing the secret key on any device, effectively thwarting perpetual leakage attacks. By streamlining access management and eliminating the need for multiple passwords across services, Protect ensures a seamless and secure SSO experience. Its efficacy is corroborated through performance evaluations, affirming its efficiency and user satisfaction across diverse mobile and desktop contexts. The practical implications of Protect extend to scalability, interoperability, and real-world deployment, marking a significant advancement in password based SSO authentication systems, prioritizing both security and usability in today's digital landscape.

5. CONCLUSION AND FUTURE WORK:

In conclusion, Protect represents a significant advancement in password-based single-sign-on (SSO) authentication systems, offering a robust solution to combat perpetual leakage attacks in both mobile and desktop environments. By integrating threshold cryptography and Secure Multiparty Computation (SMPC), Protect achieves a balance between security and user convenience, ensuring that compromising a single device does not jeopardize overall system integrity. Through rigorous performance evaluations, it has been demonstrated that Protect maintains efficiency and user satisfaction across various platforms, underscoring its potential as a reliable authentication mechanism for modern digital interactions.

As for future work, several opportunities present themselves for further exploration and enhancement of Protect. Firstly, continued research into refining the cryptographic techniques employed by Protect could lead to even stronger security guarantees against emerging threats. Additionally, exploring methods to further optimize performance and reduce computational overhead will be crucial, particularly as the system scales to accommodate larger user bases and more diverse environments. Furthermore, conducting user studies to gather feedback and iteratively improve the user experience of Protect could ensure that it remains intuitive and user-friendly in real-world scenarios. Finally, investigating the integration of additional authentication factors, such as biometrics or behavioral analysis, could further enhance the security posture of Protect while maintaining its usability. By addressing these areas of future work, Protect can continue to evolve as a cutting-edge solution for secure and convenient single-sign-on authentication.

***Abstract*— Introducing a novel strategy designed to enhance urban mobility through intelligent traffic management, this research employs a customized YOLO (You Only Look Once) object detection system. The system seamlessly integrates cutting-edge computer vision methodologies with real-time data processing to precisely detect and categorize various entities such as vehicles, pedestrians, and other objects within urban settings. The objective of this research work is to achieve notable advancements in accuracy, particularly concerning traffic surveillance and regulation, with a measured accuracy of 89.07%. However, challenges such as scalability, computational complexity, and data robustness need to be addressed for successful deployment and widespread adoption of these systems. The outcomes of this study showcase substantial improvements in traffic flow dynamics, evident through reduced congestion levels and bolstered safety measures, thereby underscoring the immense potential of intelligent systems in optimizing urban mobility challenges.**

Keywords*— *Urban Mobility, Smart Traffic Management, Modified YOLO Detector, Object Detection, Deep Learning, Traffic Flow Optimization.

I. INTRODUCTION

Urban mobility has become a critical concern for cities globally as urban populations continue to grow, leading to increased traffic congestion, environmental pollution, and reduced quality of life. Traditional traffic management systems often struggle to cope with the complexities of modern urban mobility, necessitating the adoption of smarter and more efficient approaches.

Smart traffic management systems represent a paradigm shift in how cities manage their transportation networks. These systems leverage advanced technologies such as sensors, cameras, data analytics, and artificial intelligence (AI) algorithms to monitor, analyze, and optimize traffic flow in real-time. By harnessing data-driven insights and automated decision-making, smart traffic management holds the potential to significantly improve urban mobility and enhance overall transportation efficiency. Figure 1 depicts a sample traffic flow.

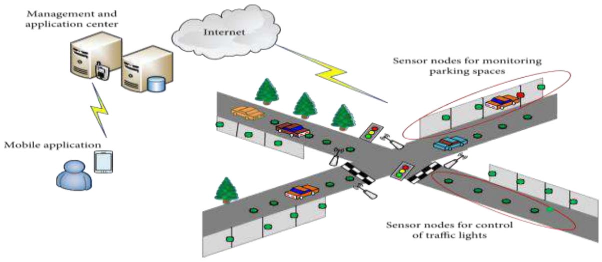

Fig. 1. Traffic Flow [1]

One crucial component of smart traffic management is the accurate and robust detection and classification of objects on the road, including vehicles, pedestrians, cyclists, and other elements relevant to traffic flow. The modified YOLO detector, based on deep learning principles, offers a compelling solution in this context.

The modified YOLO detector builds upon the foundation of the original YOLO algorithm, known for its speed and accuracy in object detection tasks. By tailoring and optimizing the YOLO detector specifically for urban traffic scenarios, it becomes possible to achieve even greater levels of precision and reliability in identifying and categorizing objects in real-time.

This research work aims to explore the following aspects related to the integration of the modified YOLO detector into smart traffic management systems:

- Algorithm Optimization: Investigating techniques to enhance the performance of the modified YOLO detector in urban traffic environments, such as fine-tuning model parameters, optimizing training datasets, and addressing specific challenges like occlusions and varying lighting conditions.
- Real-Time Traffic Monitoring: Examining the capability of the modified YOLO detector to provide real-time updates on traffic conditions, detect congestion hotspots, and facilitate timely interventions to improve traffic flow and reduce delays.
- Integration with Traffic Management Systems: Exploring how data from the modified YOLO detector can be seamlessly integrated into broader traffic management systems, enabling intelligent decision-making, adaptive signal control, and optimized routing strategies.
- Scalability and Deployment: Assessing the scalability of the modified YOLO detector deployment across different urban areas, considering factors such as computational resources, data transmission requirements, and cost-effectiveness.
- Impact on Urban Mobility: Evaluating the impact of using the modified YOLO detector on overall urban mobility metrics, including travel times, congestion levels, environmental sustainability, and user satisfaction.

By addressing these key research areas, this paper aims to contribute valuable insights into the potential of leveraging the modified YOLO detector as a transformative technology in enhancing urban mobility through smart traffic management strategies. The findings and recommendations derived from this research can inform policymakers, urban planners, and transportation authorities in making informed decisions to create more efficient and sustainable urban transportation systems.

II. Literature Study

The literature study provides an insightful overview of various methods and technologies employed in traffic control and management, highlighting their respective limitations and advantages.

In [1] Behzadan A study explores the application of Convolutional Neural Networks (CNNs) in efficiently recognizing urban traffic data during major events, emphasizing the importance of accurate data analysis for dynamic traffic scenarios. Their research highlights advancements in visual recognition technology for enhanced traffic management strategies.

In [2] Rathnayaka, R. et al. present a real-time density-based traffic signal control system designed to improve traffic management by dynamically adjusting signal timings based on current traffic density. Their work contributes to optimizing traffic flow and reducing congestion, particularly in urban areas with fluctuating traffic patterns.

In [3] S. P., Dewangan et al.'s research focuses on traffic light cycle control using deep reinforcement techniques, showcasing innovative approaches to optimizing traffic signal operations and improving overall traffic efficiency. Their study offers insights into the application of advanced algorithms in traffic management systems.

In [4] W. Q. investigate traffic sign recognition using deep learning methodologies, aiming to develop accurate and reliable systems for detecting and interpreting traffic signs in real-time traffic environments. Their work contributes to enhancing road safety and traffic regulation mechanisms.

In [5] Bansal, A et al. propose an intelligent traffic light control system based on deep learning analysis of traffic environments, offering a novel approach to optimizing traffic light operations. Their research demonstrates the potential of environment-based control strategies in improving traffic flow and reducing congestion.

In [6] López-Bonilla et al. explore traffic flow prediction for smart traffic lights using machine learning algorithms, highlighting the potential of predictive models in optimizing traffic management strategies and improving overall traffic efficiency. Their study contributes to the development of data-driven solutions for intelligent traffic control systems.

In [7] Y. J et al. introduce a cyclic reinforcement learning model for intelligent traffic signal control, showcasing the effectiveness of reinforcement learning in optimizing traffic signal operations. Their research contributes to the development of adaptive and responsive traffic management systems.

In [8] Imoize et al. present an ML and IoT-based adaptive traffic management system for smart cities, integrating machine learning and IoT technologies to enhance adaptive traffic control. Their work demonstrates the potential of data-driven approaches in improving urban traffic management.

In [9] Cheniki et al. propose traffic signal control using hybrid action space deep reinforcement learning, highlighting the efficacy of combining reinforcement learning techniques for optimizing traffic signal operations. Their research contributes to the advancement of intelligent traffic control systems.

In [10] Alqahtani et al. develop an intelligent traffic surveillance system using an integrated wireless sensor network and improved phase timing optimization, showcasing a comprehensive approach to traffic monitoring and management. Their work contributes to enhancing traffic surveillance and control capabilities.

In [11] Maidargi et al. explore traffic control systems using image processing techniques, presenting innovative approaches to improving traffic control mechanisms through image-based analysis. Their research contributes to the development of efficient and automated traffic management systems.

In [12] Solanki et al. focus on smart traffic light control using artificial intelligence, demonstrating the potential of AI-based control strategies in optimizing traffic light operations. Their work contributes to enhancing traffic flow and reducing congestion in urban environments.

In [13] Damanhuri et al. propose a smart traffic light control system using image processing techniques, showcasing the effectiveness of image-based analysis in optimizing traffic light operations. Their research contributes to the development of intelligent traffic control solutions.

In [14] Gokçe et al. provide a state-of-the-art review of traffic signal control methods, offering insights into current challenges and opportunities in traffic signal control. Their study contributes to understanding the evolving landscape of traffic management technologies.

In [15] Manera et al. develop a smart traffic light control system with real-time monitoring capabilities, demonstrating the integration of real-time data analysis for responsive traffic light operations. Their work contributes to the development of adaptive and efficient traffic control systems.

The literature study provides insights into innovative methods and technologies for traffic control and management. These include advancements such as Convolutional Neural Networks (CNNs) for accurate data analysis and visual recognition in dynamic traffic scenarios, real-time density-based traffic signal control systems for optimizing traffic flow, deep reinforcement techniques for traffic light cycle control, and deep learning methodologies for traffic sign recognition and intelligent traffic light control. Machine learning algorithms are also employed for traffic flow prediction and cyclic reinforcement learning models for traffic signal control. Additionally, there are adaptive traffic management systems integrating machine learning and IoT technologies, hybrid action space deep reinforcement learning for traffic signal control, and intelligent traffic surveillance systems using wireless sensor networks and image processing techniques. These technologies contribute significantly to enhancing efficiency, safety, and sustainability in urban environments. However, challenges such as scalability, computational complexity, data robustness, and implementation complexity may need to be addressed for successful deployment and widespread adoption of these systems.

III. PROPOSED METHODOLOGY

In this section, the proposed system flow is shown in the form of a process flow chart.

A. Framework Overview

The proposed framework utilizes a graphic flow diagram to illustrate its approach, primarily focusing on pedestrian and vehicle detection. This system is poised to contribute significantly to future research in traffic management.

B. Object Identification and Pre-processing

The framework commences by utilizing a pre-trained object identification model, leveraging transfer learning techniques to intelligently handle traffic scenarios. Impact of Pre-processing steps involve extracting individual frames from monitoring videos, with a focus on privacy by removing personally identifying information. Because personally identifying information is like a number plate its reveal the person identity that why its remove. Figure 2 shows the proposed workflow.

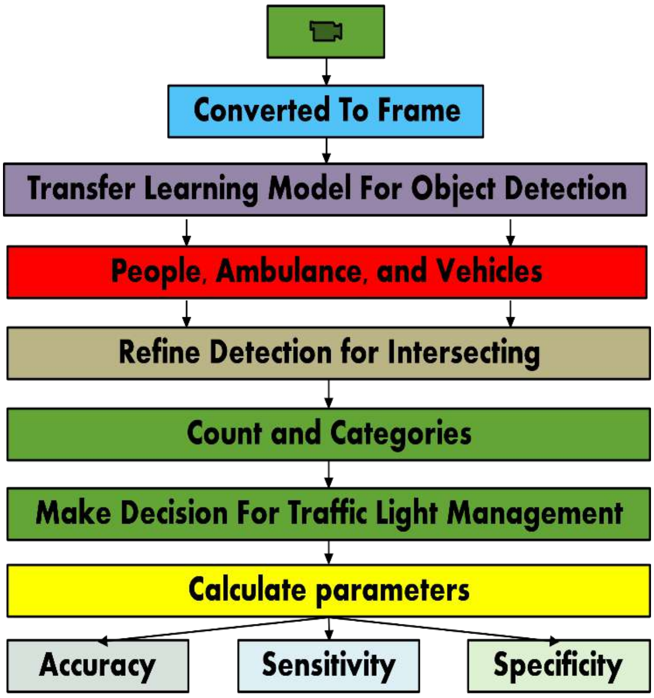

Fig. 2. Proposed Workflow

C. Vehicle Recognition with YOLOv5

Each frame is then fed into a Convolutional Neural Network (CNN) model, specifically YOLOv5, known for its accuracy and real-time processing capabilities. YOLOv5 categorizes objects in digital images using bounding boxes, enabling efficient vehicle recognition. Table I depicts the layers in YOLO architecture.

TABLE I. YOLO ARCHITECTURE

D. Intersection Detection and Density Mapping

Intersecting objects are identified and refined to ensure accurate detection, particularly crucial in congested urban areas. This refinement leads to the creation of a density map, highlighting traffic volume per lane and aiding in traffic management decisions.

E. Traffic Management Decision Making

Based on the density map analysis, the framework prioritizes lanes with higher traffic density, adjusting traffic signal timers accordingly. This adaptive approach aims to alleviate congestion and enhance traffic flow efficiency.

F. Performance Evaluation and Implementation

The proposed model undergoes rigorous evaluation based on parameters like Accuracy, Sensitivity, and Specificity, comparing its efficacy against existing models.

Implementation utilizes Google Colab for GPU performance during training and Spyder Anaconda distribution for code development, leveraging Python libraries such as TensorFlow, Keras, OpenCV, and NumPy.

The modified YOLO detector's accuracy in smart traffic management within urban environments gauges its ability to precisely recognize and categorize elements like vehicles, pedestrians, and obstacles amidst traffic. This metric is calculated by determining the ratio of correctly identified objects to the dataset's overall object count.

Sensitivity, also termed the true positive rate, assesses the model's capability to accurately detect actual positive cases. In the realm of smart traffic management, sensitivity indicates how effectively the modified YOLO detector identifies relevant objects such as vehicles and pedestrians, crucial for real-time decision-making to enhance urban mobility.

On the other hand, specificity, referred to as the true negative rate, evaluates the model's accuracy in identifying negative cases or unimportant objects. In the context of smart traffic management, specificity reflects the modified YOLO detector capacity to minimize false alarms or misclassifications, ensuring resources are directed towards genuine traffic-related elements rather than irrelevant ones.

These metrics play a pivotal role in evaluating the modified YOLO detector's performance and its contribution to enhancing urban mobility through smart traffic management.

Ultimately, the proposed framework is designed to seamlessly integrate with real-world traffic data, offering significant benefits to traffic management systems through its adaptive and intelligent approach.

IV. RESULT ANALYSIS

The datasets are taken from Dhaka AI Traffic Challenge Weights–Yolov5 [16]. The considered vehicle classes are: ambulance, auto-rickshaw, bicycle, bus, car, garbage van, human hauler, minibus, minivan, motorbike, Pickup, army vehicle, police car, rickshaw, scooter, SUV, taxi, three-wheelers (CNG), truck, van, wheelbarrow etc. as shown in Figure 3. Figure 4 shows the annotated images and finally figure 5 shows the detection of different types of vehicles. Finally, the result analysis is presented in table II.

Fig. 3. Vehicle images

Fig. 4. Annotation on Images

Fig. 5. Different types vehicle

TABLE II. ANALYSIS OF RESULTS

Model	Category	Total Frames	FPS	ACC	SEN	SPE	Time
Cascade object detector	Vehicles, Humans	100	20	82.01%	88%	63%	8.04sec
RCNN-Detection	Vehicles	100	20	78.23%	88%	52%	9.23sec
YOLO object detector	Vehicles	100	20	89.07%	95%	62%	5.22sec

The comparative evaluation of object detection models highlights the superior performance of the YOLO object detector, achieving an accuracy of 89.07%, sensitivity of 95%, and specificity of 62% across various multi-vehicle scenarios. The results shown in Table II emphasize YOLO's potential as a foundational component in real-time traffic management and surveillance systems, offering enhanced accuracy and efficiency in object recognition tasks.

CONCLUSION & FUTURE SCOPE

The adoption of YOLO-based models can significantly improve traffic monitoring capabilities, contributing to congestion alleviation and overall road safety. Looking ahead, future research should prioritize several key areas to further advance object detection technologies in traffic-related applications. First and foremost, continuous model refinement through extensive training with diverse datasets can enhance accuracy and generalization, ensuring consistent performance across diverse traffic conditions. Second, integrating object detection systems with adaptive traffic control algorithms can optimize traffic flow dynamically, responding effectively to real-time changes in congestion patterns and traffic volume. Furthermore, exploring advancements in edge computing and multi-modal data fusion techniques can expedite data processing and integration from various sources, thereby improving real-time decision-making for traffic management authorities. Addressing privacy concerns through effective anonymization techniques while maintaining robust object detection capabilities will also be pivotal in future research and implementation endeavors.

Abstract—**Secure communication has always been a primary focus and have challenges in encrypting messages. As the ancient cipher techniques that were used to secretly communicate have been compromised in today's era. Among these, one is the Pigpen cipher. The pigpen cipher is a symmetric encryption method that converts alphabets into symbolic representations known as Pigpen. However, the method also has some drawbacks, the operation is done without a key and it does not have the capability to encrypt numbers. The Pigpen cipher offers only one variation adding to its drawbacks and lacks achieving robust encryption in modern communication contexts. AlphaMeshX(AMX) is a new age cipher technique that is an Extended Pigpen cipher technique with Substitution. AlphaMeshX presents an innovative approach to encryption and decryption of messages, building upon the foundation of an encryption technique that was historically used by Freemasonries during communication called as Pigpen Cipher also called as Freemason Cipher. AMX is a key based Encryption and Decryption technique. The key, to which the ASCII encoding is done, then followed by the division substitution for the sum of ASCII. The resultant value after the mathematical substitution determines the 13 variations for alphabets and 18 variations including numbers. Therefore, the result is more secure.**

Keywords—AlphaMeshX(AMX), Pigpen, Extended Pigpen, Substitution Cipher, Freemason, Masonic cipher.

I. INTRODUCTION

In today's world, there's a continual need for robust encryption methods that ensure privacy and confidentiality. AlphaMeshX that is built on the foundation of Pigpen cipher [1] technique. It also known as the Masonic Cipher and is a mono-alphabetic Substitution Caesar's Cipher [3] that employs graphical symbols to encode letters. Originating from the Freemasons, this historical cipher involves replacing each letter with a unique symbol based on a grid of Mesh and X shaped grids. The alphabet is typically divided into four quadrants, with each quadrant assigned a distinct set of symbols. How is it encrypted? 'A' could be a symbol located in the top-left section, and 'B' might be a different symbol in the same area. To encode a message using this cipher, you replace each letter with its designated symbol according to the grid. This results in a visually encoded message where symbols represent the original letters. Deciphering the message requires knowledge of this. It offers cipher technique that is less secure, it is different from other simple mono-alphabetic substitution ciphers because its use of symbols rather than letters and due to the use it fails to assist in cryptanalysis. Pigpen encryption method faces the challenges in terms of advanced techniques.

Pigpen cipher encrypts only alphabets but not numbers. But there is an extended version of Pigpen where the grid is designed in such a way that it can occupy alphabets as well as numbers designed by Thomas Hunter II [13]. Though the extended version encrypts numbers as well, it still has only one variation as the initial Pigpen. AlphaMeshX leverages the Pigpen Cipher and the extended Pigpen as the foundation and introduces 18 variations. AMX is a key based cipher technique to which ASCII encoding is done [2] and followed by division method. Based on the resultant value after the mathematical substitution of AMX, the value determines the type of variation and based on the variation the message is encoded. The alphabets and numbers representation in the AMX quadrants are placed as per the variation, so for each variation all the character representation is distinct. Always, an encoder needs to have a key along with the message, then the key will undergo mathematical substitution where the ASCII encoding is done and the sum is determined. Further, the mod operation is done to determine the variation. Based on the resultant value the variation grid is formed then the characters are encrypted. The decryption process is as same as the encryption since it is a symmetric encryption process, that is the same key is used for decryption of the encoded message.

The purpose of AlphaMeshX is to provide an innovative and versatile encoding and decoding that includes offering a creative tool based on Pigpen Cipher variant and open doors to 18 new variants. AMX (AlphaMeshX) is a Symmetric cryptography technique. Symmetric cryptography involves conversion of plain text information, along with a cryptography key, into a cipher text. Decryption with symmetric technique, recovering the original plain text from the cipher text by using the same algorithm and same key that was used to encrypt the information [5].

The AMX can find real world applications in education, personal privacy communication, open-source contributions and cryptography research. The primary focus lies in enhancingthe security and confidentiality.

II. RELATED WORK

Freemason's cipher is a simple substitution cipher using a grid of symbols to represent letters. It involves drawing shapes within a three-by-three square to form the cipher [1]. Researcher Thomas Hunter II, licensed the patent for the "Extended Pigpen Cipher to Include Numbers" [13], conceptualised a method by allowing the messages with numbers to be encrypted. The modification introduces additional symbols specifically designed to represent numbers, addressing a limitation of the original cipher.

Researcher Bradley P. Franger made a survey that discusses about the Masonic cipher, a monoalphabetic cipher. It replaces individual characters with its corresponding symbols. This cipher can operate with letters but not numbers. The author also have done analysis on Zigzag and Rosicrucian ciphers [7].

The paper titled "PIGPEN: A Novel Approach for Securing Data" addresses the security challenges in wireless communication and proposed modifications to Letter- Shape encryption to enhance data protection. Their focus is on TIC-TAC-TOE shape, X and dots as core elements to incorporate pigpen cipher technique. This method aims to secure communication in open and dynamic mobile wireless networks. The unique encryption technique adds complexity and confusion for potential attackers, ensuring a higher level of data security [8].

In Research paper "Enhancing Image Stenography Methods by using New Secret Message Encoding Technique based on Pigpen Cipher (Pigpen Encoding) ", the researchers explored an enhanced stenography technique that involves modifying the secret message into cipher text. Stenography is a way to hide the secret messages in carriers such as images, audio files, text files and videos [9]. Unlike ASCII encoding requiring three decimal digits, this approach represents secret message characters with only two decimal digits, reducing the space needed for embedding by one third. This Pigpen cipher replaces letters with symbols based on their corresponding symbols location. The method involves creating tables for small and capital letters, numbers, and special characters, assigning each a unique two-digit representation. This innovative encoding technique optimizes the performance of hiding image methods in Stenography.

A detailed understanding is done on the existing cipher techniques considering the predominant features such as variations, keys, encoding methods, computations involved. The existing techniques were compared with the proposed method and it is tabulated in Table I. The drawbacks of the existing methods were well understood and the novel cipher technique AlphaMeshX is proposed which combats the older techniques.

TABLE I
EXISTING WORK COMPARISON

	Pigpen Cipher	Extended Pigpen	AlphaMeshX
Variations	1	1	18
Multiple Variations	N	N	Y
key	N	N	Y
Alphabets	Y	Y	Y
Numbers	N	Y	Y
Math calculation	N	N	Y
ASCII	N	N	Y

III. METHODOLOGY

The functioning of AlphaMeshX (AMX) involves a step of substitution cipher. Where the user provides a key along with the message also called as the plain text. Once the key is provided, the key undergoes a mathematical substitution process. That is encoding of ASCII values to the key and the sum is taken. Then the sum is modded by 18 to determine the variation. Based on the variation the plain text is converted into cipher text. The process can be understood by the below process flow diagram.

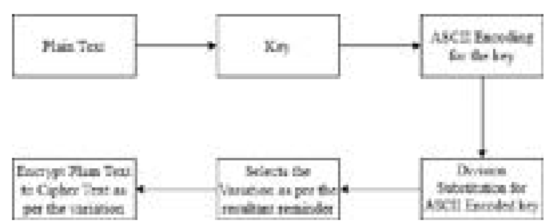

Fig. 1. Process flow of encryption operation

Now the mechanism of both existing techniques and the innovative AMX method is explained to gain a understanding of their functionalities and explore the new AMX technique. For Instance, let the message to be encrypted be "pes473" and key for the encryption is "piGpen".

A. Pigpen Cipher

Pigpen Cipher, the encryption of the message takes place just by replacing the characters to its corresponding symbols. It does not involve the use of any key. So, the encrypted message would be,

Fig. 2. Pigpen implementation (original)

Decoding will be the reversal of encoding, replacing the symbols to its corresponding characters.
Drawback - It does not encode numbers and it has only one variation stating that for a letter there is only one corresponding symbol.

B. Extended Pigpen Cipher

Extended version of the Pigpen cipher encrypts alphabets along with numbers, Thomas Hunter II proposed the design of extended version in such a way that it can occupy numbers, therefore encrypting both the alphabets and numbers. The encoding in this technique is as same as the Pigpen cipher which is replacing the characters to its corresponding symbols. Thus, overcoming the drawback of the original Pigpen Cipher. So, the encrypted message will be,

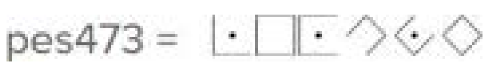

Fig. 3. Extended pigpen implementation

So unlike the original Pigpen cipher we have symbols for numbers as well, deciphering is as same as the Pigpen cipher. Drawback - is that it still has only one variation and does not use any key.

C. AlphaMeshX or AMX

AlphaMeshX Cipher (AMX), it is key based symmetric encryption and decryption technique. Unlike the original Pigpen and the extended Pigpen, it uses ASCII encoding for the key and division method to determine the variation.

Key = “piGpen” and message = “pes473”

Now, for the key we integrate ASCII values, each character is replaced by its ASCII value and the sum of it is determined. In the below format,

p+i+G+p+e+n = 112+105+71+112+101+110 = 611

Now, the value 611 is determined based on the user specified key. This value is now modded by 18, because the AMX has 18 variations and to determine the variation type it is necessary to mod it by 18. Therefore, the final resultant will be the reminder.

611 mod 18 = 17

After modding the value 611 with 18 we get the reminder as 17 so this determines the 18th variation, the 17th cell representation is 18th variation since the total cells in the MAX model is 18-1=17. The character arrangements begin from the cell 17th. That is, each cell is a variation.

Let us see the 17th variation grid formation and the character representation of the grid.

So, based on our variation and the character representation of the variation in the grid the encrypted message will be,

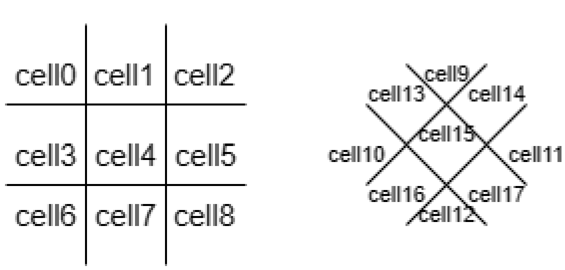

Fig. 4. Variation representation

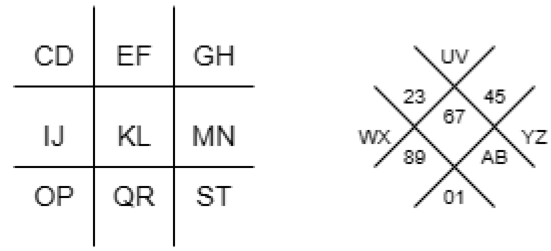

Fig. 5. Characters representation for the variation

Therefore, the result as per the variation after encryption using AlphaMeshX cipher technique is,

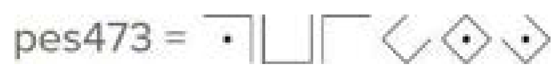

Fig. 6. AlphaMeshX Output

Now we can see that the same input is producing different output. Since the AMX uses a key for its operation, though the extended Pigpen and AMX performs numbers encryption, AMX gives different encrypted output when compared to extended version based on the variation that was determined by the key.

Unlike the original and the extended version, The AMX has 18 different variations for both alphabets and numbers. So, there are 18 symbols for each character and for the given example “pes473” it will have 18 different symbols for each character. Thus overcoming the single variation drawback from both Pigpen and the extended version. The decoding is the same way as encoding since it is a symmetric cipher technique and requires the key for decoding.

IV. Experiential Results

AMX cipher’s security enhancements and implementation, through the implementation of AlphaMeshX (AMX), the experiential results have resulted in 18 new variations, increasing the security of AMX beyond the original Pigpen Cipher technique and its variant. The demonstration of the AMX implementation the Flask framework was used. Flask is a lightweight Python web framework. It is popular due to powerful modular design that lets us to build scalable web apps [14]. Which is a popular Python web framework known for its simplicity and flexibility. Showcasing the AMX’s functionality, demonstrating its robust encryption and decryption processes in action.

By utilizing SHA256[11] encoding for the user provided key, it enhances security by creating a strong, complex, and secure key, making it challenging for attackers to decipher even if they manage to get hold of the encrypted key. SHA-256 is a cryptography hash function that generates a unique, fixed-length (256 bits) string from an input. Additionally, SHA512[12] (512 bits) encoding can be explored to further bolster key security, ensuring resilience against potential threats. These encoding techniques significantly enhance the confidentiality and integrity of encrypted messages, reinforcing AMX's position as a reliable and secure encryption tool compared to the initial Pigpen Cipher technique.

Let us understand the experiential process for the AMX. let us consider an example where user A is sending a message tothe user B. Now the user A will take a key as “keyencryption”and let the message be hello. Now performing SHA256 forthe key will result us with a 256 but of 64 characters' lengthunique and unreadable string that cannot be traced back.That is, once SHA256 hash function is performed to the “keyencryption” key, then it will result us with
”bf9eaac6bbd146a9840ab409df90ff48b4383fd09482618f21df fbd5b2c198ec”.
which is long, randomized and confusing compared to the initial key. So now the actual key ”keyencryption” is encoded as an unreadable string of length of 256 bits. Further, this sha256 key will be our newly encoded key. To which the key we will be undergoing the AMX mathematical substitution. The AMX substitution involves ASCII encoding and the total sum is taken. Finally for the total sum, 18 will be modded to determine the variation. Once the mod of 18 is done, we will have the resultant reminder which gives us the variation and the plain text (message) will be encoded according to the resultant variation to the cipher text. As for the decryption the same steps is followed since the AMX is a symmetric cipher technique.

Let us understand the entire Experiential process that uses SHA256 hash function, integratingAndDivide function for the key. Also the symmetric technique for the encryption and decryption. The below is the Pseudo code for all the functionalities.

(i) Encryption:

```
Procedure encryption(message, key)
  hashedKey = SHA256(key) –(call SHA256(key))
  encodedKey = integrateAndDivide(hashedKey) –(call integrateAndDivide(key))
  if AMXEncryption then
   encryptedMessage = AMXEncrypt(message, encodedKey) –call(AMXEncrypt(message, encodedKey))
   return encryptedMessage
  else
  // Handle error for invalid mode
   return ”Invalid mode”
  end if
end procedure
```

(ii) Decryption:

```
Procedure decryption(encryptedMessage, hashedKey)
  encodedKey = integrateAndDivide(hashedKey) –(call integrateAndDivide(key))
  if AMXDecryption then
   decryptedMessage = AMXDecrypt(encryptedMessage, encodedKey) –call(AMXDecrypt(encryptedMessage, encodedKey))
   return decryptedMessage
   else
   // Handle error for invalid mode
   return ”Invalid mode”
  end if
end procedure
```

(iii) SHA256 hash function:

```
Procedure SHA256(key)
  // Implementation for SHA-256 hash function
  return hashedKey
end procedure
```

(iv) ASCII integration and Modding:

```
Procedure integrateAndDivide(key)
  totalSum = 0
  for each character in key:
    asciiValue = ASCII value of character
    totalSum = totalSum + asciiValue
  end for
  encodedKey = totalSum mod 18 —(18 variations)
  return encodedKey
end procedure
```

(v) AMXEncrypt:

```
Procedure AMXEncrypt(message, encodedKey)
  // Generate grid based on remainder ie., variation
  // Encrypt message using grid and variation
  return encryptedMessage
end procedure
```

(vi) AMXDecrypt:

```
Procedure AMXDecrypt(encryptedMessage, encodedKey)
  // Generate grid based on remainder ie., variation
  // Decrypt encryptedMessage using grid and variation
  return decryptedMessage
end procedure
```

There is always need for continual improvement and performance enhancement. It can use various advance encryption techniques such as Advanced Encryption Standard (AES) algorithm [10], Data Encryption Standard (DES)[11], or asymmetric block cipher algorithm RSA[12] and so. This cipher technique can be used to add a extra security by encrypting the already encoded message. Thus making it even more secure. Further, even SHA512 or any other hash function method can be used to generate an encoded string for the key.

CONCLUSION

While the Pigpen cipher offers only one variation and primarily encrypts only alphabetic characters but not numbers. The extended version of the Pigpen also offers only one variation but has a way that encrypts both alphabetic characters as well as numbers. But both lack the crucial element of using a key for secure communication and has only one variation. This presents significant security vulnerability. In contrast, the AalphaMeshX system addresses these limitations by employing a key, utilizing mathematical substitution and introducing a layer of complexity for enhanced security by Integrating ASCII and the division method. This Combination creates 18 distinct variations, significantly increasing the difficulty of deciphering the encrypted message. Therefore, AMX offers a more robust and secure method of communication compared to the Pigpen and the extended cipher technique. The method also has certain limitations, though the AMX has a way to encrypt both alphabetic characters as well as the numbers, giving rise to 18 distinct variations and has a symmetric way to encrypt and decrypt, it cannot encrypt any special characters and currently uses a single algorithm based on the Pigpen Cipher.

In the future, enhancing the AMX involves integrating it with multi-factor authentication for the key and various advanced encryption algorithms. Additionally, the AMX can encode the encrypted message, creating a unique double encryption technique that adds complexity and confusion for potential attackers. This strategy increases the security of the already encrypted message beyond expectations, making it more secure.

***Abstract*— This research study introduces a comprehensive framework tailored to navigate the complexities of contemporary career guidance. It integrates interconnected modules, including secure login, student data collection, academic evaluation tools, and an advanced skill assessment module. Notably, the Cognitive Decision Support module employs advanced analytical tools to analyze users' cognitive responses, delivering personalized career suggestions. Moreover, the framework features a career prediction module equipped with algorithmic models for forecasting career paths and suggesting suitable colleges nationwide. The dynamic skill evaluation component continually monitors industry trends, providing guidance for ongoing skill development. Additionally, it offers insights into the global job market and cultural trends, facilitating international career exploration. A feedback mechanism ensures continuous improvement. Despite its technical sophistication, challenges arise in managing large-scale data processing and ensuring precise cognitive assessments, potentially affecting the accuracy of personalized career recommendations.**

Keywords—Decision support, Career prediction, International job market, Global career opportunity, Skill evaluation

I. Introduction

This research study introduces a sophisticated and integrated framework designed to transform career guidance and skill development in the contemporary digital landscape. At its core, the framework consists of meticulously crafted modules catering to diverse user needs and aspirations. Starting with a robust login and registration mechanism, users seamlessly enter the system, prioritizing data security and user authentication. Following this, the framework facilitates comprehensive management of student profiles through a dedicated page for capturing crucial information essential for personalized career guidance. Academic evaluation tools enable systematic assessment of users' educational performance, while a sophisticated skill assessment module provides a detailed analysis of proficiencies across various domains.

Key to the framework's effectiveness is the innovative Cognitive Decision Support module, utilizing cutting-edge analytical tools to interpret users' cognitive responses during assessments. This module not only enhances assessment accuracy but also delivers personalized career recommendations based on individual cognitive profiles. Additionally, the framework includes a Career Prediction module that employs predictive algorithms to outline potential career paths and recommend suitable colleges nationwide, empowering users with informed decision-making capabilities. Moreover, a dynamic skill evaluation module continually monitors industry trends and emerging technologies, offering targeted recommendations for ongoing skill development. Furthermore, the framework provides users with a holistic global perspective on career opportunities, leveraging insights into the international job market, cultural trends, and economic indicators. Finally, a feedback module encourages iterative refinement and continual improvement of the framework, ensuring its ongoing relevance and effectiveness in guiding users toward fulfilling career trajectories.

II. Literature Review

In reference to research paper with An Intelligent Career Guidance System utilizing Machine Learning, developed by Vignesh S, Shivani Priyanka C, Shree Manju H, and Mythili K, aims to assist students globally who often grapple with uncertainty upon completing their higher secondary education. At the age of 18, students lack the maturity needed to decisively chart a suitable career path. This phase prompts a cascade of doubts and contemplation regarding what to pursue post-12th grade, posing the most significant query. Subsequently, individuals question whether their chosen field aligns with their essential skills. Our automated career counselling system employs objective tests to evaluate an individual's skills, thereby predicting the most fitting department. Completing our online assessment ensures a more informed choice of course, significantly reducing the risk of selecting an unsuitable career path. **Merit:** The Intelligent Career Guidance System stands out for its ability to deliver tailored career recommendations through objective assessments, assisting students in making informed decisions about their future career paths. **Demerit:** the limitations arises from the system's exclusive reliance on objective tests, which may overlook various facets of an individual's skills, interests, and aspirations, potentially resulting in restricted or biased career recommendations. [1]

Intelligent web platform for vocational guidance. Andres F. Cruz *, Laura Orozco, Carolina Gonzales with. The development of Computer Assisted Career Guidance Systems (CACGS) arose as a partial remedy for the scarcity of qualified professionals in career guidance and the need for

a structured system to oversee the guidance process. Nevertheless, numerous existing systems are tailored for settings distinct from that of Colombia, posing difficulties for counsellors to effectively employ their results or for students in Popayan city to accurately comprehend them.
Merit: The establishment of Computer Assisted Career Guidance Systems (CACGS) serves to alleviate the shortage of qualified professionals in career guidance by furnishing a structured platform for vocational direction.
Demerit: However, the lack of customization in existing systems may pose challenges for counsellors to efficiently leverage their outcomes, while students in Popayan city may encounter difficulties in accurately grasping them due to the systems not being tailored to the specific context of Colombia. [2]

The Online Study and Recommendation framework, either open or private, caters to individual needs by fostering a collaborative learning environment on the internet. Reddy et al. introduced the concept during their Computer Supported Cooperative Work graduate course, envisioning a unified, secure, and dynamic system that offers course recommendations and collaborative study features. Their discussions centered on the system's approach, implementation, recommendation algorithms, and the findings from user studies. Existing research systems often lack security and fail to provide adequate privacy for students studying in a distributed environment. Hence, their creation focuses on utilizing both individual and group learning processes, incorporating several features to support collaborative activities.
Merit: The Online Study and Recommendation framework cultivates a collaborative learning atmosphere, providing personalized course recommendations and collaborative study functionalities.
Demerit: In distributed environments, many existing research systems suffer from security and privacy deficiencies, underscoring the necessity for robust security measures within the framework. [3]

A machine learning approach for recommending courses by John Britto, Sagar Prabhu, Abhishek Gawali, Yogesh Jadhav proposed Machine learning techniques, such as neural networks and diverse learning algorithms, hold substantial potential in shaping a student's career trajectory. Although there's space for enhancements, this system proves beneficial in conducting initial assessments to gauge a student's interests. Recommendations for courses are based on both preferences and abilities, with all development conducted using Python 3.6. Looking ahead, there's scope to develop a comprehensive questionnaire that delves into every facet of a student's life and capabilities, offering not just domain suggestions but an entire tailored curriculum aligned with the individual's pace and preferences. Furthermore, this system's applicability could extend beyond engineering to encompass other fields, potentially aiding in broader career guidance and counselling endeavours.
Merit: Utilizing a machine learning approach, course recommendations are personalized according to individual preferences and abilities, with the potential to significantly influence a student's career path.
Demerit: Although advantageous for initial assessments, the system may necessitate additional improvements to fully encompass all facets of a student's life and capabilities, which could constrain its efficacy in delivering tailored curriculum recommendations. [4]

In reference to Dahanke Ajay's research emphasis on development of a web-based application tailored for career guidance, offering improved recommendations for individuals seeking suitable departments. This study aims to enhance the precision of career guidance systems by leveraging advanced algorithms. The proposed system's efficacy surpasses existing models, primarily attributing its accuracy to the utilization of the K-Nearest Neighbour (KNN) algorithm for skill set classification and department prediction. Additionally, the study incorporates the K-Means Clustering algorithm to form clusters based on students' skill set scores, thereby determining the success rates of various departments within each cluster.
Merit: Dahanke Ajay's research presents a web-based application for career guidance, employing advanced algorithms such as K-Nearest Neighbour and K-Means Clustering to refine recommendations for appropriate departments.
Demerit: Despite the potential accuracy improvements, the system's dependence on sophisticated algorithms may present implementation and user comprehension challenges, possibly hindering its accessibility and usability. [5]

In reference to author Lei Wang say The paragraph discusses addressing challenges in college student employment guidance by utilizing Visual Fox-Pro programming to create a data verification tool, enhancing data accuracy. Additionally, it employs the Apriori algorithm in data mining to analyse university employment history, aiming to understand factors impacting student employment. This mining process uncovers correlations between education attributes and employment factors. Furthermore, the optimization algorithm tests successfully reduce meaningless association rules, improving the efficiency of the mining process.
Merit: Lei Wang's methodology employs Visual Fox-Pro programming and the Apriori algorithm to boost data precision and reveal links between educational attributes and student employment aspects, offering promise for enhancing college student employment guidance.
Demerit: Despite optimizing association rules successfully, the reliance on Visual Fox-Pro programming and the Apriori algorithm may necessitate specialized expertise, potentially impeding accessibility and usability for users lacking familiarity with these tools. [6]

In reference to the paper with DOI: 10.1109/IHCSP56702.2023.10127152, author Vijaya R. Kumbhar’s Career guidance is particularly crucial for college students who often lack clear understanding about their career paths. Many are not certain about their future work preferences or the ideal degree choice. By assessing a user's skills, interests, and preferences, this system recommends various career options. The results assist students in focusing on subject areas that closely match their expertise and interests. Utilizing a Smart Career Guidance System integrated with a chatbot, the model employs a hybrid deep learning approach, merging recurrent neural network (RNN), Long Short Term Memory (LSTM), and Natural Language Processing (NLP) techniques. This proposed hybrid algorithm combines elements from RNN, LSTM, and NLP to enhance the Career Guidance System's effectiveness.
Merit: Vijaya R. Kumbhar's paper presents a Smart Career Guidance System with a chatbot, employing a hybrid deep

learning approach that integrates RNN, LSTM, and NLP techniques to improve the efficacy of career recommendations based on user skills, interests, and preferences.

Demerit: Despite its effectiveness, the implementation of the hybrid deep learning approach may demand considerable computational resources and technical expertise, potentially impeding accessibility and scalability for users and organizations lacking in sufficient technical capabilities. [7]

III. PROPOSED SYSTEM

The proposed system aims to provide extensive career guidance and assistance to users through various modules powered by the XGBoost algorithm. It commences with a secure login/registration process, followed by modules for managing student information, academic assessment, and skill evaluation. Utilizing cognitive decision support tools, the system analyzes user input to offer personalized career recommendations, predict career trajectories, and suggest colleges nationwide. Furthermore, dynamic skill evaluation modules recommend continuous skill enhancement opportunities based on industry trends, while the global career perspective module offers insights into international job markets. Users can offer feedback to enhance system functionality. In essence, the system aims to empower users to make informed career choices and excel in their chosen paths

A. Flow diagram

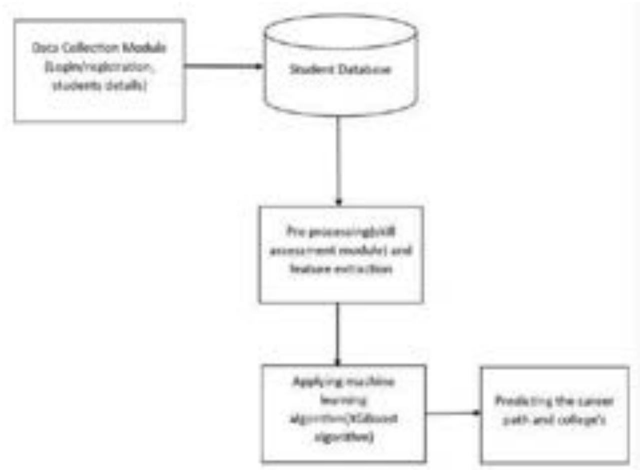

Figure 1: flow diagram

The modules included in figure 1 are as follows:

1. Data Collection Modules:

The data collection module effectively collects thorough user data to customize personalized career guidance. The modules under collection module are as follows:

- **Login Page / Registration Page Module: -** During registration, this crucial module facilitates user onboarding by gathering essential information such as name and email, while ensuring security through verification methods during the login process, and providing user-friendly error handling to enhance the overall experience.
- **Student Details Page Module:** Committed to offering a comprehensive perspective, this module captures both personal details and academic history, allowing users to dynamically update information, display achievements via document uploads, and emphasize skills and interests to create a thorough profile.
- **Career Global Perspective Module:** Centered on broadening perspectives, this module consolidates information on the global job market, cultural shifts, and economic indicators, providing users with insights into international career opportunities, industry trends, and language proficiency to facilitate informed decision-making.
- **Feedback Module:** Functioning as an interactive platform, this module acts as a tool for ongoing enhancement by employing satisfaction surveys, bug reporting, and feature requests to collect valuable feedback. With a user-friendly rating system and the option for anonymity, it fosters open communication to iteratively refine the system.

2. Data Processing Modules:

The data preprocessing module ensures that collected user data is organized and optimized for effective analysis, enabling the generation of personalized career guidance. The modules under data pre-processing are as follows:

- **Academic Evaluation Module: -** Performing crucial pre-processing tasks, including normalization, on academic data, this module ensures uniformity and comparability, thereby improving data quality for precise analyses and informed decision-making within educational settings.
- **Skill Assessment Module: -** Centered on skill assessment data, this module conducts essential pre-processing tasks, utilizing methods such as standardization. It converts skill-related data into a consistent format, facilitating equitable comparisons and trustworthy analyses. The module's contributions are instrumental in informing decisions regarding talent management and initiatives for skill development.

3. Feature Extraction Module: Within the Feature Extraction Module, intricate patterns and distinctive elements are meticulously identified and isolated from pre-processed data. Through the use of sophisticated algorithms, this module distills essential features that encapsulate the intrinsic information necessary for precise analysis. By condensing the data into a representative set of key attributes, it streamlines downstream processing, ensuring subsequent models focus on the most relevant information. This feature-centric approach enhances overall interpretability and system performance, enabling informed decisions based on extracted, notable features. Ultimately, the Feature Extraction Module is a vital component in optimizing and refining data-driven tasks.

4. Career prediction module: The career prediction module adopts a comprehensive approach to individual growth, integrating three interconnected components. Cognitive Decision Support employs the XGBoost algorithm to analyze cognitive responses in assessments, generating personalized career recommendations. Simultaneously, the Dynamic Skill Evaluation module utilizes XGBoost to analyze industry trends and user profiles, providing insights for continuous skill development. Meanwhile, the Career Prediction Module applies XGBoost to forecast future career trajectories and suggest colleges, directing individuals towards rewarding and successful career paths that align with their strengths and aspirations.

B. Algorithm used

XGBoost, abbreviated from Extreme Gradient Boosting, stands out as a remarkably efficient and scalable machine learning algorithm, celebrated for its outstanding performance across classification, regression, and ranking assignments. Its operation involves iteratively constructing numerous decision trees, with each tree aimed at rectifying the mistakes of its predecessors. Employing a technique called boosting, XGBoost amalgamates the predictive capabilities of these weak learners into a robust ensemble model.

The algorithm incorporates regularization techniques to prevent overfitting and optimize model generalization. XGBoost's versatility and effectiveness have made it a popular choice across various domains. Its ability to handle large datasets and complex relationships, coupled with efficient parallelization and optimization, has cemented its reputation as a go-to algorithm for data scientists and machine learning practitioners.

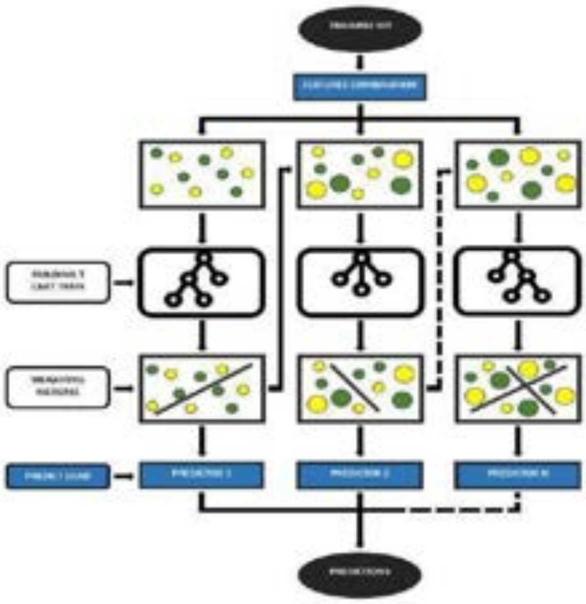

Figure 2: XGBoost algorithm

IV. IMPLEMENTATION

The steps involved in implementation are as follows:

i. Data pre processing
ii. Working of algorithm
iii. Database details

i. Data pre-processing:

Within the pre-processing module of the career guidance system, feature engineering techniques are implemented. This process commences with gathering varied datasets encompassing academic evaluations, skill assessments, and personal information from users. Subsequently, a meticulous data cleaning phase is conducted to address missing values, outliers, and inconsistencies, thereby preserving data integrity. Following this, feature engineering methods are employed to extract pertinent insights and discern patterns from the data.

This entails generating novel features utilizing domain knowledge and expertise, such as merging academic grades with extracurricular activities or converting skill assessment scores into categorical variables indicating proficiency levels. Furthermore, text mining and natural language processing methodologies are utilized to extract valuable insights from unstructured textual data, such as resumes or feedback. By augmenting the dataset with engineered features, the pre-processing module bolsters the predictive capability of the career guidance system, resulting in more precise and tailored recommendations for users' career trajectories. The detailed process involved in feature engineering is depicted in figure 3.

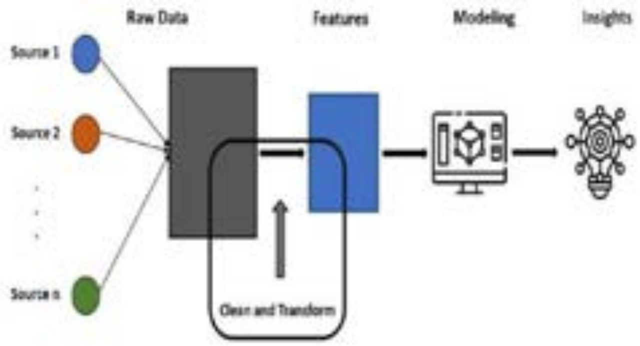

Figure 3:- feature engineering

ii. Working of algorithm

Data is gathered from diverse sources including student profiles, academic records, and skill assessments, followed by preprocessing to address missing values, encode categorical variables, and scale numerical features. Feature engineering ensues, involving the creation of pertinent features such as academic performance metrics and skill proficiency scores to enhance the dataset. Next, the XGBoost model is trained on the preprocessed data, meticulously adjusting hyperparameters and optimizing performance. Evaluation metrics are subsequently employed to gauge the model's performance, ensuring its reliability and ability to generalize.

Following validation, the trained model is seamlessly incorporated into the modules of the career guidance platform, spanning academic evaluation, cognitive decision support, career prediction, dynamic skill evaluation, and career global perspective. This integration harnesses the power of the XGBoost algorithm to generate tailored career recommendations grounded in users' profiles, assessments, and global career trends.

Career prediction is facilitated by leveraging the XGBoost algorithm within a comprehensive technical framework. Beginning with data preprocessing, the dataset undergoes cleaning and preparation, followed by feature engineering to extract pertinent insights. Subsequently, the XGBoost model is trained on the preprocessed data, with hyperparameters fine-tuned to optimize performance. Evaluation metrics validate the model's accuracy and generalization abilities. Integration of domain knowledge heightens the relevance of predictions, delivering personalized career recommendations based on user profiles, assessments, and global career trends. This technical infrastructure ensures precise career guidance, empowering users to make well-informed decisions about their future trajectories.

iii. Database details

The database infrastructure supporting the career guidance platform is composed of essential elements crucial for its smooth operation. Initially, the login and registration page database securely stores user credentials, ensuring regulated access to the platform. Subsequently, upon registration, the student details page database collects comprehensive information about individual users, encompassing personal details and academic backgrounds. Furthermore, the skill assessment module database logs data related to users' skill evaluations, laying the groundwork for personalized recommendations.

Within the career prediction module, the database houses pathways to diverse career options and recommended colleges nationwide, facilitating informed decision-making for users. The database architecture facilitates seamless integration among modules, ensuring uninterrupted data flow and effective communication between various components of the platform. This integrated database system ensures streamlined data management, enabling the platform to deliver tailored career guidance services efficiently. With strong data management capabilities, the platform can adjust to changing user requirements and deliver timely and pertinent career guidance solutions.

V. RESULT ANALYSIS

The enhanced accuracy of XGBoost in career prediction, in comparison to other machine learning algorithms, can be credited to various factors. Primarily, XGBoost's ensemble learning technique amalgamates multiple weak learners, often decision trees, to construct a more robust predictor. By leveraging the strengths of each individual model while offsetting their weaknesses, this ensemble approach improves the model's capacity to discern intricate relationships and patterns within the data, resulting in heightened prediction accuracy.

Furthermore, XGBoost integrates regularization methods to counteract overfitting, guaranteeing strong generalization capabilities to unseen data. Furthermore, its optimization algorithm adeptly manages extensive datasets and demonstrates exceptional scalability, allowing it to effectively collect insights from diverse and high-dimensional feature spaces.

TABLE I. ACCURACY OF DIFFERENT ALGORITHMS

S.No	Algorithm	Accuracy
1.	**XGBoost**	**89.5%**
2.	Random Forest	87.2%
3.	Decision Tree	83.8%
4.	Support Vector Machine	82.1%
5.	K-Nearest Neighbour	81.3%
6.	Logistic Regression	79.6%

Table 1 displays the accuracy levels of different machine learning algorithms in predicting career paths, with XGBoost leading with an accuracy of 89.5%.

Figure 4 visually represent this comparison in the form of a bar graph where each algorithm is represented by it's own bar on the vertical axis while the horizontal axis indicates the accuracy percentages.

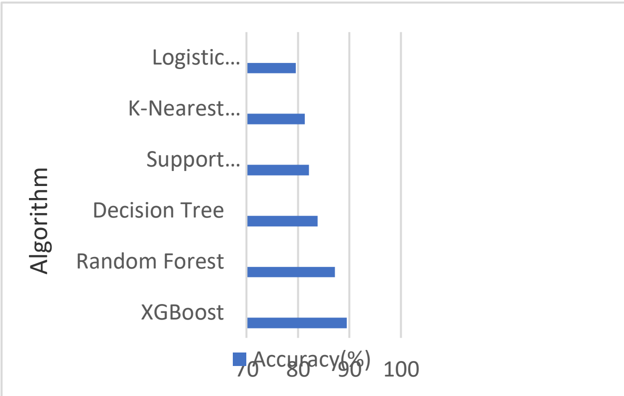

Figure 4: Accuracy of Algorithms

Table II provides a comparison of XGBoost algorithm with other algorithms based on adaptability.

TABLE II. ADAPTABILITY OF DIFFERENT ALGORITHMS

S.No	Algorithm	Adaptability
1.	**XGBoost**	**85%**
2.	Random Forest	80%
3.	Decision Tree	75%

4.	Support Vector Machine	75%
5.	K-Nearest Neighbor	70%
6.	Logistic Regression	70%

Figure 5 is the bar graph representation of the comparison based on adaptability.

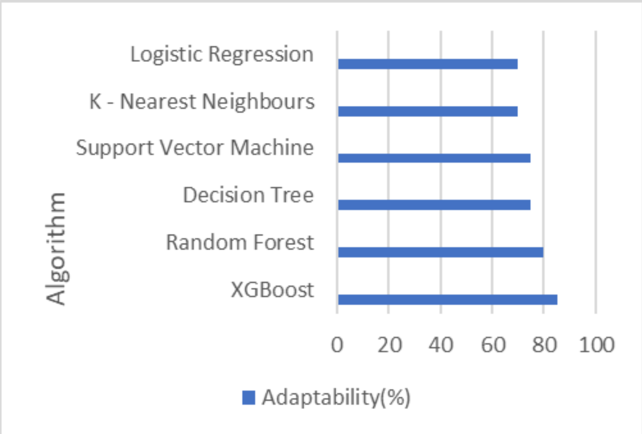

Figure 5: Adaptability of Algorithms

Therefore, given its superior accuracy and adaptability in predicting career paths, this algorithm has been used over the other algorithms for the implementation of the career guidance project.

VI. CONCLUSION AND FUTURE WORK

In conclusion, the creation of a holistic educational and career platform, incorporating elements such as login and registration capabilities, student profile administration, academic assessment, skill evaluation, cognitive decision support, career forecasting, dynamic skill assessment, global career outlook, and feedback mechanisms, presents considerable potential in steering users toward prosperous educational and professional paths. By integrating various functionalities, users are provided with personalized career suggestions, insights into international job markets, continuous skill enhancement prospects, and a feedback platform for continual enhancement. This holistic platform not only boosts user engagement and contentment but also enables individuals to make educated choices regarding their educational and professional journeys.

As of future work, improving the interpretability and transparency of the system through the utilization of explainable AI methods would cultivate user trust and support better-informed decision-making. In essence, forthcoming developments in technology and data science present significant opportunities for transforming career guidance systems, empowering individuals to navigate the continually changing professional terrain with clarity and assurance.

Abstract**: Potato cultivation faces significant threats from plant diseases, such as early blight and late blight, which detrimentally impact yield and quality. Addressing this challenge, this study presents a novel Convolutional Neural Network (CNN) model designed for automated disease detection in potato plants. Leveraging advanced CNN architectures, particularly MobileNet, this study achieves a remarkable accuracy of 96.6% in disease classification tasks. This innovative approach eliminates the need for manual inspection processes, offering a scalable and efficient solution for early disease identification and mitigation. Finally, this study highlights the transformative potential of deep learning methodologies in enhancing agricultural productivity and disease management strategies.**

Keywords- Feature Extraction, InceptionV3, VGG16, MobileNet, DenseNet, Inception, fine-tuning.

I. INTRODUCTION

Within the agricultural landscape, the potato emerges as a majorly cultivated vegetable, constituting approximately 30% of agricultural produce in India, thereby securing a notable position as the fourth most cultivated crop worldwide, following maize, wheat, and rice. India, a formidable contender in potato cultivation, claims the second-largest global production output, exceeding 48.5 million tons annually. Uttar Pradesh commands a significant share, contributing over 30% to India's potato yield. Beyond culinary applications, potatoes demonstrate versatility in industrial domains, notably in starch extraction for enhancement. Nutritionally, they are esteemed for their potassium-rich composition, abundant vitamin content, and dietary fiber, rendering them instrumental in combating various health ailments, including hypercholesterolemia, hypertension, cardiovascular afflictions, and malignancies.

However, the potato's dominance is threatened by microbial adversaries such as bacteria and fungi, notably manifesting as late blight and early blight diseases. To mitigate these challenges, technological interventions, deep learning methodologies have emerged as pivotal tools for disease identification. This study presents a comprehensive framework, structured into sections outlining the contextual framework, prior research insights, dataset characteristics, model architecture complexities, and conclusive findings. Central to the research investigation is the development and validation of a robust deep learning model, precisely trained on a high-fidelity dataset, incorporating pre-trained VGG19 models with fine-tuned hyperparameters. The proposed approach also integrates validation and ensemble techniques to enhance the performance consistency.

Notwithstanding, disease detection in plants poses multifaceted challenges, characterized by diverse symptoms influenced by pathogenic agents, environmental stimuli, and genetic predispositions. Early disease manifestation often presents subtle symptoms, necessitating sensitive detection methodologies. Adverse environmental conditions, including lighting variations and background clutter, further complicate accurate disease diagnosis. Addressing these challenges mandates large-scale, high-quality datasets for training algorithms to differentiate between healthy and diseased plant specimens.
In response, the proposed model utilizes Convolutional Neural Network (CNN) architectures and evaluates the model to identify the most efficient framework for disease detection. This study focuses on obtaining enhanced accuracy rates, highlighting the efficacy of the proposed approach in enhancing disease detection within agricultural ecosystem.

II. LITERATURE REVIEW

Wang et al. [1] and fellow researchers collected a dataset consisting of 185 high-resolution images capturing instances of wheat stripe rust and grape powdery mildew for disease analysis. Es-saddy et al. [2] diverged from conventional methodologies by combining images obtained from digital cameras deployed across diverse farm settings and supplemented by online sources, fostering a comprehensive dataset representing varied environmental conditions. Mohanty et al. [3] curated an extensive dataset comprising 54,306 images categorized into 38 classes of both diseased and healthy plant leaves, ensuring meticulous representation akin to a meticulously assembled family album.

Rastogi et al. [4] adopted a new preprocessing strategy, resizing and cropping images to optimize the model input. Es-saddy et al. [2] applied image resizing and noise reduction techniques to enhance the image quality, ensuring clarity and precision in disease identification. Not merely content with image acquisition, Sannakki et al. [6] employed image enhancement methods similar to artistic transformations, instilling images with captivating visual effects to augment interpretability and aesthetic appeal. Innovative approaches integrating machine vision and fuzzy logic offer promising solutions for objective disease grading in agriculture, enhancing scalability and reliability in large-scale agricultural operations. Nonetheless, challenges encompassing technical complexities, validation across diverse contexts, financial constraints, and ethical considerations necessitate advanced analysis and strategic mitigation.

Ramesh et al. [9] outlined image characteristics through histogram of oriented gradients (HOG), facilitating spatial representation and pattern recognition. Furthermore, researchers, Abbas et al. [10], Chen et al. [10], and Akshai et al. [10] introduced advanced Convolutional Neural Network (CNN) architectures like DenseNet, LFMCNAPS, and a diverse ensemble of CNNs to differentiate a spectrum of diseases across various plant species, similar to deploying adept detectives to identify complex botanical anonymities.

Additionally, Kibriya et al. [11] and Sujatha et al. [12] undertook a multifaceted approach integrating traditional machine learning with deep learning methodologies to comprehensively classify plant diseases. Ashwin Kumar et al. [13] adopted a mobile network-based CNN for on-the-go disease identification, epitomizing the fusion of technological innovation and practical applicability in agricultural settings.

While support vector machine (SVM) classifiers exhibit promise in automated plant leaf disease recognition, intrinsic challenges including implementation complexity, data quality assurance, interpretability, and cross-domain validation necessitate careful consideration and strategic mitigation strategies for effective deployment in agricultural ecosystems.

III. DATASET DESCRIPTION

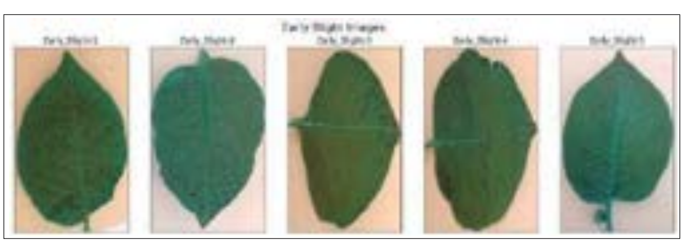

Figure 1: Sample image dataset

The datatse is collected from kaggle, totally 3000 images including both healthy and unhealthy potato leaves are considered. Sample healthy images from the dataset are shownin figure 1.
Sample diseased leaves images from the collected dataset is depicted in figure 2.

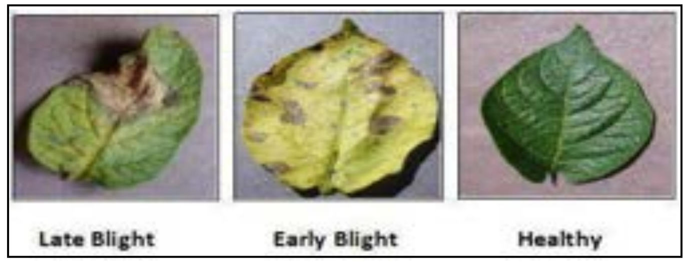

Figure 2: Early Bright Images

III. PROPOSED METHODOLOGY

In this project there are multiple stages of research as can be seen from fig. 1. In the form of research framework there are four stages which are as follows:

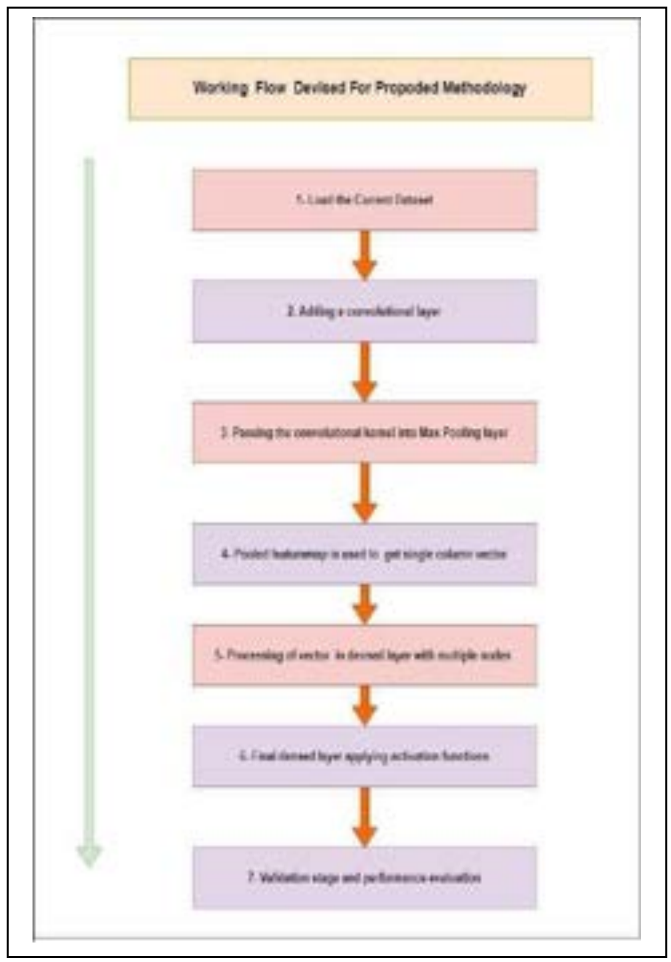

Figure 3: Flow of a Machine Learning Problem

CNN Architecture:

Convolutional Neural Network is a subset of machine learning.

Convolution layers, here are multiple 3x3 convolutional layers in the network, which help the network learn special patterns and features from the input images which will help in identifying these features/patterns in the input images. These convolutional layers are responsible for capturing features and as the network of layers deepens the capturing of features transition from low to high.

Pooling Layers:
Pooling layers play a major role in reducing the spatial dimensions from feature maps. Here, we have used a two-dimenisonal filtering method in the pooling layer, the maxpooling operation incporated in the proposed model is shown in fig. 4.

Figure 4 : Max Pooling

Fully Connected Layers:
This layer is responsible for integrating the learned features from earlier layers and enable the network of layers to make comprehensive and accurate predictions. The fully connected layer enables our network to perform high level reasoning and classification tasks.
Activation Functions: This study uses SoftMax activation function where multiple number of signmoids can mention the data probability to solve the multi-classification problem.

Next, this study has considered VGG16, MobileNet, DenseNet, InseptionV3 and ResNet50 architectures.

VGG16: Architectural wise VGG16, distinguished by its 16 weighted layer, features a consistent layer structure as sjhown in figure 5.

Figure-5 VGG16 Architecture

MobileNet: Mobile Net optimized for mobile vision applications, stands out in object detection and fine-grained classifications due to its efficiency and lightweight design. It has 2 layers i.e. depth wise and pointwise layers. The depth-wise convolution processes each input channel independently, significantly reducing computational costs.[15]

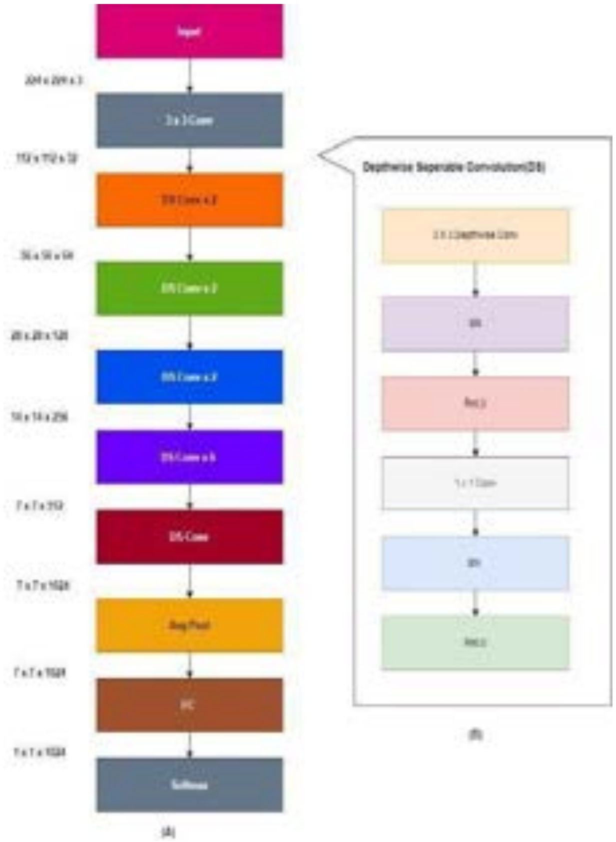

Figure 6. Mobile Ne

DenseNet: Each layer has a 1x1 and a 2x2 layer. Basic convolution layer with 64 filters of size 7X7 with stride of 2. The DenseNet121 architecture is shown in figure 7.

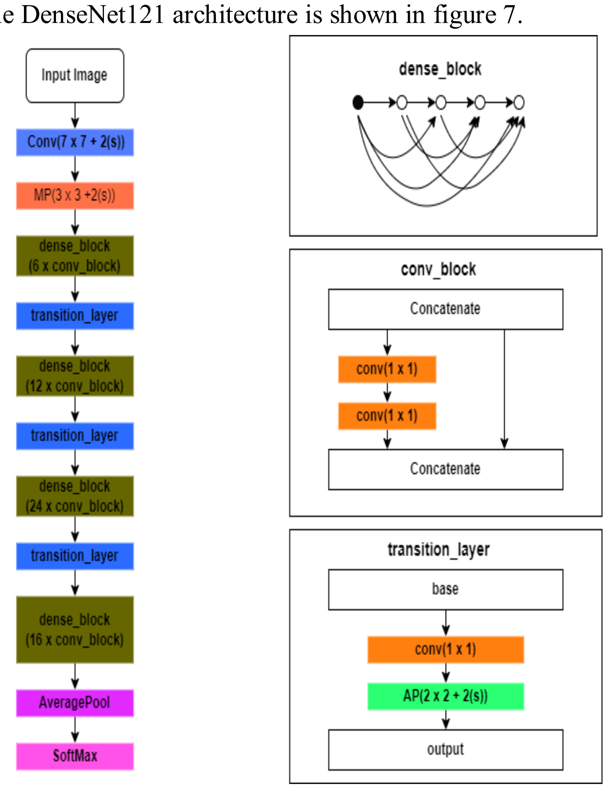

Figure-7 DenseNet121 Architecture

InceptionV3: Inception-v3, a 48-layer deep convolutional neural network, offers pre-trained versions capable of classifying images into 1000 categories. Notably, its architecture evolved from Inception V1 to address certain drawbacks. Issues with Inception V1 included occasional information loss due to 5x5 convolutions, which prompted a shift to factorization, breaking down 3x3 convolutions into 1x3 and 3x1 for computational efficiency[16].

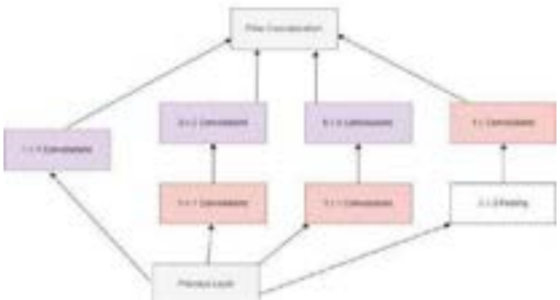

Figure-8 InceptionV3 Compact Architecture

Resnet 50: The convolutional block, akin to the identity block, introduces a 1x1 convolutional layer to reduce filter numbers before the 3x3 convolutional layer. Skip connections, synonymous with residual connections, play a vital role in

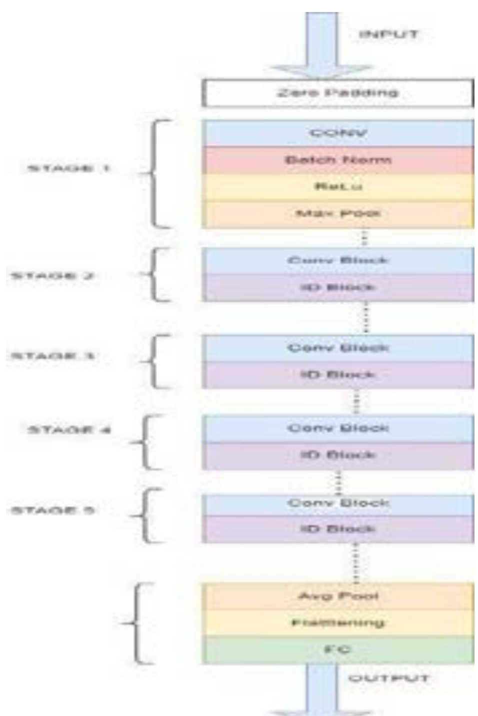

Figure-9 ResNet 50 Architecture

ResNet50. In ResNet50 , skip connections are integrated into the identity block and convolutional block. The identity block processes input through convolutional layers and incorporates the input back into the output. Similarly, the convolutional block utilizes a 1x1 convolutional layer to reduce filter numbers before the 3x3 convolutional layer, ultimately adding the input back to the output.

IV. RESULTS & DISCUSSION

The proposed dataset is splitted into 70% as training data and 30% as test data. Various pretrained models were used like VGG16, ResNet 50, InceptionV3, DenseNet121 and MobileNet. Among these MobileNet has leveraged the best performance with an accuracy of 96.6%.

As depicted in Table I, we have found the precision, recall, and f1 score of all the models. Among which mobile net had highest. Precision tells the proportion of correctly classified positive instances over all the instances that are classified as positive. Measures the ability of the classifier to avoid false positives. It came out to be 0.95 for late blight and 1.0 for early blight. A good indicator of the performance of a classifier when the number of positive and negative instances is unbalanced. Came out to be 0.97 for late blight and 0.96 for early blight.

In the experimental segment of the proposed plant disease detection system, different CNN models are used and their performance are analysed. The analysis reveal that MobileNet leverages a comparatively higher performance. This study has analyzed the outcomes acquired from every version as shown in Table II to provide insights on its effectiveness and suitability in disease detection process. A detailed comparison of training and validations accuracies are pesented in figure 10.

TABLE I: PERFORMANCE ANALYSIS

Models	Late/Early Blight	Precision	Recall	F1-Score	Accuracy
VGG16	LATE	0.94	0.94	0.94	0.933
	EARLY	0.92	0.92	0.92	
RESNET 50	LATE	0.57	0.68	0.62	0.466
	EARLY	0.14	0.09	0.11	
INCEPTION V3	LATE	1.0	0.94	0.97	0.942
	EALRY	0.93	1.0	0.96	
DENSENET	LATE	0.94	1.0	0.97	0.926
	EARLY	1.0	0.92	0.96	
MOBILE NET	LATE	0.95	1.0	0.97	0.966
	EARLY	1.0	0.92	0.96

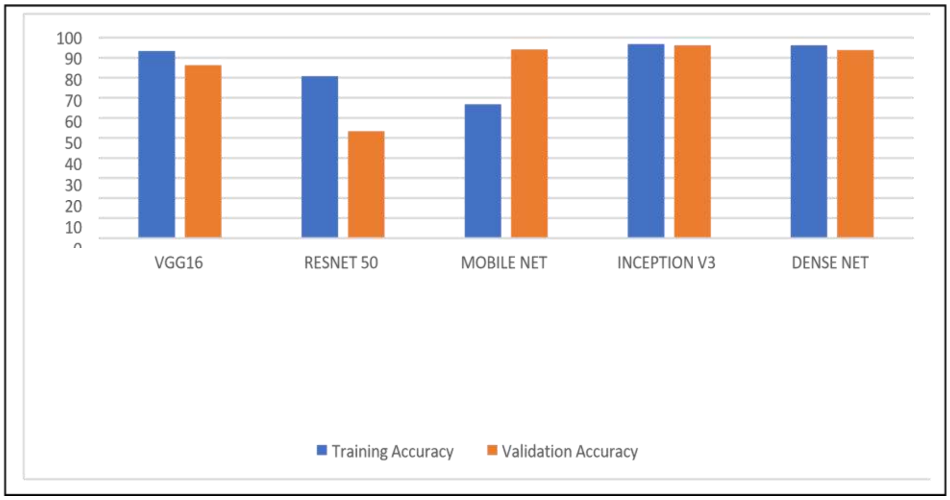

Figure 10 Comparison of Training accuracies and validations accuracies

V. CONCLUSION

This study conclude that among the models VGG16, ResNet, MobileNet, DenseNet, InceptionV3, the MobileNet performs exceptionally well by leveraging an accuracy of 96.6%. The success of mobilenet can be attributed to its efficient architecture, which strikes a balance between model complexity and computational efficiency. The model demonstrated a superior accuracy, show casing its potential as a robust solution for a real-time deployment in agricultural settings. The utilization of transfer learning further enhanced the model's ability to recognize relevant features leveraging the knowledge of pre-trained weights from ImageNet. Further research and development in this area can build upon insights gained from the objects.

***Abstract*— This project is created to fulfil only one purpose that is to create an authentication system based on biometrics, the most common type of biometrics is fingerprint. It is designed to reduce and prevent the theft of two wheelers. This also provides the user a keyless interface increasing its accessibility. The ignition system is replaced with fingerprint start system. The fingerprints are identified and stored in templates of binary codes which are acquired on the basis of special features of fingerprint. The project consists of the AVR microcontroller Arduino uno r3, the fingerprint module R307, and the GSM Module sim800L. The fingerprint Module R307 can store up to 127 fingerprints. once the fingerprints are stored the r307 interacts with the Arduino and process that information if the fingerprint matches with the user, then the Arduino controller sends signal to relay module to start the ignition system. f the fingerprint does not matches the Arduino sends a message to the user as "someone has tried to access your bike" via GSM module. The proposed model mimics the self-start of bike with a DC motor. Additionally, access to the two-wheeler is available via a keypad, which has a four-digit password, allowing users' family or relatives to access the model other than the user.**

Keywords— Arduino UNO, R307, GSM, Arduino IDE, Biometrics, keypad.

I. INTRODUCTION

In today's world, there is a rise in concern related to theft. The world is advancing with many technologies that can be used to reduce theft-related concerns. Our project aims to address one such problem: reducing the theft of keys for two-wheelers. Introducing the concept of keyless two-wheelers and installing a high-tech security systemis the goal of this research project.

Knowledge-based, token-based, and biometric-based are the three primary categories of person identification techniques. Password and pattern-based security systems that the user configures are examples of knowledge-based strategy. Token-based techniques require document-based proofs like Aadhar card, driver's license, PAN card, etc. Biometric systems are based on a person's unique impressions, such as fingerprint impressions and face recognition. Among the other two systems, knowledge and token-based security systems, the biometric system was found to be more reliable and secure. Thus, the use of biometric systems in security has increased as it reduces the chances of theft occurrences.

The term "BIOMETRY" from the 20th century is where "BIOMETRICS" originates. Facial, voice, fingerprint, eye (iris), and other biometric recognition systems are examples of biometric recognition systems. Since every person's fingerprint is different, fingerprint technology is the most frequently utilized and most reliable technology available.

Using fingerprint biometrics is simple and easy. The key elements of fingerprint biometrics are identification and authentication. Fingerprint authentication or recognition involves combining multiple fingerprints through an automated process. Authentication establishes the identity of the user and verifies the validity and reliability of the user. The Arduino coordinates the interactions between the several parts of the system, serving as its brain. Among its functions are:

The R307 fingerprint sensor is connected to the Arduino, which then reads the fingerprint data. It oversees the process of authentication by comparing the scanned fingerprint to pre-stored templates. To supplement the biometric authentication, the Arduino communicates with the keypad to accept extra user input, like a PIN code. The Arduino decides which authentication to use based on the combined biometric and PIN inputs. The Arduino grants access to the two-wheeler if the fingerprint and PIN match the credentials that are saved.

Control of GSM Module: The Arduino may operate the GSM module in response to certain events (such unwanted access attempts) or successful authentication.

II. LITERATURE SURVEY

The concept of the Biometric Authentication System is designed to reduce thefts of two wheelers where the start function of two wheeler is replaced by a fingerprint sensor by Vaishnavi Khadasane, Mrunalini Desai, Devashree Khatavakar, and Shruti Lad [1]. The Advanced Biometric Authentication System in a two-wheeler displays the speed and distance traveled by a vehicle Iswarya G, M. Baranidharan, Bagavathi Shivakumar, C., and R. Rajaprabha drive the relay from the output of the ULN2803 driver chip [2]. Based on the concept of observable physiological or behavioral traits, biometrics is an automated method of identity verification or identification developed by Vaclav Matyas and Zdenek Riha [3]. An Arduino-based project that implements a fingerprint-based anti-theft system for two-wheelers addresses the growing worry of two-wheeler theft by implementing a system by Mrs. Maalini Dharmaraj [4]. The system authenticates vehicle users. By highlighting the growing weaknesses in conventional security measures, this research by R. H. Laskar, F. A. Talukdar, and Krishna Dharavath [5] shows how biometric systems have become more popular for users.

The focus of this research work is on a biometric fingerprint system, chosen over other alternatives for its tight security features. Employing a fingerprint-based biometric system proves to be both convenient and safe. The project makes use of a fingerprint module with substantial fingerprint storage in its database, facilitated by both software and hardware systems for its functioning with the fundamental idea being that the vehicle starts only when a correct fingerprint is obtained. If there is no match in the database, the vehicle remains inactive. Interface connections are established through the PC parallel port, known for its cost-effectiveness and widespread use in various projects. The entire system code is scripted in Embedded C language via software. This study shows how a fingerprint based system is used for enhancing the security. It is designed for seamless integration with contemporary embedded systems for fingerprint authentication, which is achieved through a suitable sensor and microcontroller. The system revolves around fingerprint authentication, ensuring its relevance to the latest technological advancements.

III. METHODOLOGY

The block diagram of communication of different components can be seen in fig 1

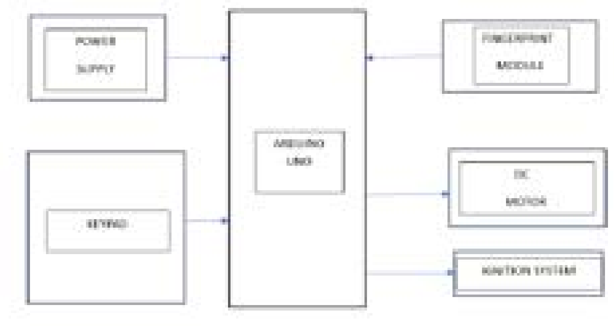

Fig 1. Block Diagram of the System

A. Hardware Components

Arduino uno**:** A microcontroller to process the information taken as input from the sensors and provides a certain output.
Fingerprint module (R307): It transmits the user's biometric data to the microcontroller. In order to provide security in fingerprint detection and verification, one type of fingerprint sensor module utilized in biometrics is the R307. These gadgets are mostly found in safes, which require powerful DSP chips for calculations, image rendering, feature detection, and searching. They use TTL serial to connect to any microcontroller and send data packets for hashing, searching, photo retrieval, and print detection. New finger enrolment can be immediately stored in the on-board flash memory.

Keypad**:** It sends the enrolled data from the user to the microcontroller.
ATmega328p microcontroller: It processes all the data it receives and gives necessary and corresponding output to other components.
Power Supply: It gives a regulated 5V to the microcontroller.
DC motor and ignition system: It represents the start of the vehicle.
GSM: It notifies the user by phone of important messages, including "invalid access." The SIM800L is a tiny cellular module that supports voice calls, SMS sending and receiving, and GPRS transmission. This module is an ideal choice for any project that needs long-range communication because it is affordable, small in size, and supports quad-band frequencies. It is compatible with GSM 850MHz, PCS 1900MHz, EGSM 900MHz, and DCS 1800MHz frequencies. A computer and a GSM-GPRS system can communicate thanks to the GSM module. The Worldwide Mobile Communication System

B. Software Components

For this project, the embedded C language is used for programming.
Fingerprint algorithm: To register the user's fingerprint and confirm the owner's.

The messaging mechanism sends a message to the bike's owner if the fingerprint does not match the registered fingerprint.
The keypad algorithm is to use a password to unlock the bike.
The two-wheeler will start when the fingerprint matches or the password entered is correct, and it will stop using the same process. This is known as the ignition algorithm. The actual connections and circuit diagram is shown in fig 2 and 3 respectively.

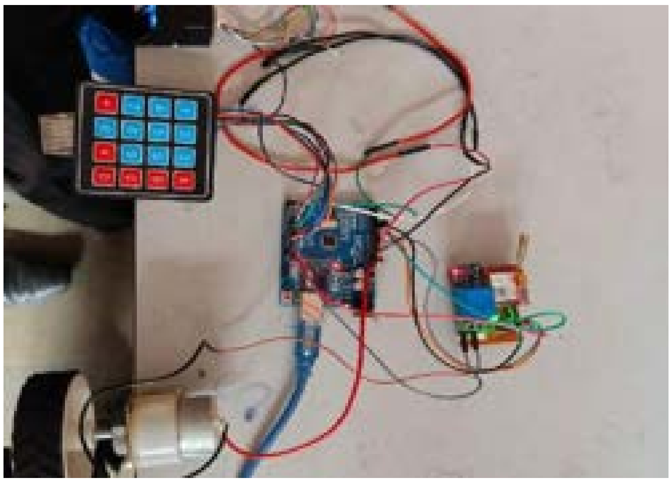

Fig 2 Actual Connections of the System

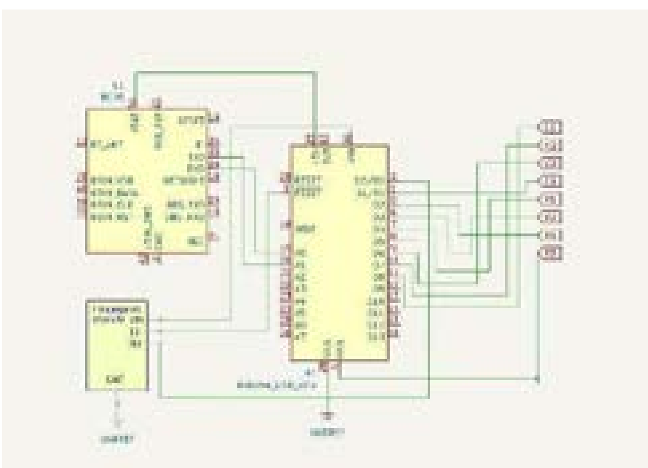

Fig 3 Circuit Diagram of the System

IV. RESULTS AND DISCUSSION

In the implementation stage, the first step involves enrolling the user's fingerprint for identification. Following successful enrollment, the next step is authentication, where the registered fingerprint is matched. Upon a successful match, the relay module is activated, initiating the vehicle's start.

Case 1
Once the user enrolls their fingerprint and its biometrics are stored, they can access the vehicle by matching their fingerprint.

Case 2
If someone other than the user attempts to access the vehicle after the user has registered their fingerprint, the user receives a message of intrusion via the GSM module. Demo can be seen in fig 4

Fig 4 Message Mechanism

Case 3
After the user registers their fingerprint and wishes to grant access to someone they know, they can provide a password to that person. The designated person can then access the vehicle by entering the password on the keypad. In the event of an incorrect password entry, the user will receive a notification.

The fingerprint module serves the crucial function of ensuring secure ignition and authentication in two-wheelers, effectively deterring theft. The microcontroller oversees the entire sequence, triggering the ignition system of the vehicle simultaneously, and sending a control signal to the relay driver. While the primary goal of the project is successfully achieved, a DC motor is employed to illustrate the dummy model of the two-wheeler's fuel ignition system. In cases of unauthorized access, an SMS is promptly sent through the GSM module.

V. CONCLUSION & FUTURE SCOPE

Improving vehicle security is the main reason two-wheelers have fingerprint sensors installed. This technique is useful for providing security and convenience of use since it uses the fingerprint as a strong biometric identification. Adding fingerprint recognition to cars not only makes them more secure, but it also discourages theft, which lowers the number of theft instances dramatically. In the future, we envision incorporating several modifications to the system to further enhance its functionality. One such addition includes integrating a fuel sensor, ensuring that the vehicle starts only when there is a sufficient fuel level. The inclusion of GPS technology will provide real-time location tracking for the vehicle. Moreover, the installation of cameras serves a dual purpose – capturing images of unauthorized access for security purposes and functioning as a dashcam. To prevent fuel theft when the vehicle is inactive, a solenoid valve can be employed. Additionally, we plan to implement a pollution monitoring system using gas sensors. All these features will be seamlessly integrated into a dedicated mobile application for comprehensive control and monitoring.

ACKNOWLEDGEMENT

I would like to express my sincere appreciation to our H.O.D. Prof Dr. Chandrashekhar Mahajan and our EDAI 1 Guide Prof. Mrs. Anita Dombale, for their invaluable guidance and support throughout this research project. Their expertise and encouragement have been instrumental in its completion. Finally, I extend my thanks to Vishwakarma Institute of Technology for providing the necessary resources.

***Abstract*— The work presented in this research article enables a significant advancement in gardening methodologies, leveraging an Internet of Things (IoT) - enabled automated plant watering system that underscores the paramount importance of efficiency and sustainability. The developed system, orchestrated by an 8-bit ATmega328P microcontroller, integrates resistive soil moisture sensor and humidity and temperature sensors (DHT11) to furnish real-time information. The watering technique of the developed system is further refined through the integration of a typed-1 fuzzy based logical based controllers, which is utilized to regulate its operation. With the integration of a Wi- Fi module, users gain the ability to monitor water distribution remotely through a smartphone application. The utilization of Thing Speak cloud technology streamlines data transfer and analysis, thereby enhancing the overall performance of the system on a full scale. The developed automated plant watering system not only conserves water and fosters optimal plant growth but also aligns seamlessly with advanced technological trends in the farming sector. It exemplifies a harmonious fusion of ecological awareness and cutting-edge IoT developments.**

Keywords—Internet of Things (IoT), Plant Watering System, Typed-1 fuzzy based logic controllers, Android Application, Matlab.

I. INTRODUCTION

Modern agriculture has become dependent on smart gardening practices, such as irrigation / plant watering systems driven by artificial intelligence (AI). Statistics that demonstrate increased productivity in cultivation through automation prove that these innovations are the need of the hour. In order to reduce water losses and maximize water utilization in agriculture, efficient water use becomes essential. Projections of the population exceeding 10 billion by 2050, coupled with a projected 60% rise in water consumption, are concerning. Consequently, recent data emphasizes the need to reassess conventional gardening practices to ensure effective water management. This assertion is substantiated by reputable sources such as '*FAO Aquastat*' and "The Future of Water 2022" authored by Jippe Hoogeveen, a senior officer in the FAO Land and Water Divisions.

Moreover, UNESCO's findings, as interpreted by the World Water Assessment Program (WWAP), shed light on the financial significance of water management. A staggering investment of approximately USD 115 billion per year across 150 low and middle-income countries could open up global pathways for clean drinking water and sanitation, yielding substantial returns. Since cultivation depletes an astounding 70% of universal freshwater resources, the burden of food safety becomes predominant. Estimates demonstrate a 60% surge in widespread demand for food and agricultural goods by 2050, alongside environmental deterioration related to water usage and food production. This warrants unprecedented progress in efficiently assessing water resources accompanied by instant monetary, subcultural, and atmospheric benefits. Realizing water's synthesized advantages, embracing food protection, climate crisis reduction, and countryside economic regeneration, is pivotal in leveling the impending universal food dilemma [1].

This paper prompts an inventive Internet of Things (IoT)-powered plant watering system to direct the looming challenges of global water shortage and the accelerating need for food production. The emergence and execution of the IoT- enabled foundation comprises a detailed procedure. Sensors measuring soil moisture, temperature, and humidity are deliberately positioned in a small plant environment to outsource real-time data. A central ATmega328P microcontroller digitizes this information, making use of a

Typed-1 Fuzzy based logical depended controllers to make strategic decisions for ideal water allocation to the plants. This approach not only provides crop watering by optimum usage of resources but also ensures environmental sustainability by decreasing the wastage of water. The proposed study stresses leveraging data interpretation to contribute usable knowledge, besides equipping gardeners with data to schedule adaptive water distribution schedules and plant- specific requirements. The facilitation of remote water conservation abilities through their ESP-8266 Wireless-Fidelity modules strengthens their system's functionality, in addition to allowing users to monitor the watering process from anywhere at any time via a smartphone application. This expansive attempt takes giant strides towards a technologically and environmentally conscious tomorrow for agricultural water management.

II. Contributions of the Paper

The paper makes the following contributions:

- Development of an IoT-enabled, cost-effective, and user-friendly plant watering systemtailored for farmers.
- Designing of a Type-1 Fuzzy Controller to regulate plant watering by controlling the actions of the watering pump.
- Implementation of an Android Application for monitoring various environmental parameters within the garden, including temperature, humidity, and soil moisture.

The paper unfolds with an insightful introduction in Section I, setting the stage for a comprehensive exploration of smart water management in agriculture. Section II meticulously reviews pertinent literature and related work, establishing a strong foundation for the proposed IoT-powered system. Moving forward, Section III intricately dissects the system architecture, delineating key components, functionality, the working principle, and a detailed Circuit Diagram section. Section IV delves into the designing of the developed Android Application. Section V illustrates the designing process of the type-1 fuzzy controller. Meanwhile, Section VI meticulously explores various facets of the designed automated IoT-based plant watering system, shedding light on its diverse aspects and functionalities. In the pinnacle of Section VII, this study concludes by succinctly summarizing its findings and delineating the transformative potential inherent in the proposed system.

III. Related Work and Literature Review

In recent times, there has been a growing interest in using Internet of Things (IoT)-based technologies to adjust water usage in agriculture. Previous research has highlighted the potential advantages of IoT based watering systems especially for sustainable gardening [2] [3]. Capacitive soil moisture sensors have proven quite effective in monitoring soil moisture levels [4]. However, there are still some challenges when it comes to adjusting watering schedules according to changing environmental parameters, which eventually affects efficiency and plant growth [5]. Various other studies have emphasized the significance of temperature and humidity sensors, in regulating plant health [6]. While previous work has focused on key aspects of gardening, this study proposes a comprehensive system that presents the synergy between IoT connectivity and various fundamental sensors. Their major goal of the IoT-enabled frameworks are for providing real time monitoring and flexible water distribution methods ultimately encouraging renewable gardening means.

Diverse research studies have delved into methods of incorporating technologies, for in-house gardening and efficient water management. A work centred on civic environments delivered a cloud-based remedy for home gardening. This solution employs sensor networking to accentuate resource efficacy through the implementation of sensors and IoT connectivity [7]. Additionally, an interesting impact involved the inclusion of block chain technology in an IoT-integrated gardening system especially designed for modern cities. This integration enhances precision, accuracy and reliability by automating watering procedures and notifying users in case of any water scarcity. It highlights the role played by blockchain in guaranteeing the dependability and security of smart gardening systems [8].

Moreover, recent analyses showcase the compelling requirement for water conservation and smart gardening practices. A proposed IoT-enabled system aimed at immediate pH monitoring proves to have been effective in retaining the quality of wastewater for agricultural usage [9]. A consequent research study fixated on water supply risks in India, harbouring a IoT based setup for RT gauging & quality evaluation of the water flow. This approach facilitates for a smooth and wireless technique to deal with the inadequacies, like costing challenges in water supply [10]. Existing explorations as these, in the realm of progressive and sustainable cultivation furnish the technological landscape with the leading applications and advancements of IoT based computing.

In the arena of ecological management, researchers have brought to light a portable buoy that assesses the quality of water in actual time across different settings. This innovative device showcases its adaptability, in environments such as coasts and lakes [11]. Moving on to control systems, there is experimentation investigating the use of fuzzy logic controllers to neutralize pH levels in water treatment processes. These controllers contribute to the recycling of water for various other applications, excluding drinking [12] [13]. Furthermore, a pioneering prediction mechanism for soil fertility based on IoT technology has been introduced. This system utilizes sensors to analyse soil characteristics, for yard cultivation [14]. An additional study that combine the Longer Short Termed Memories [LSTM] network using a traditional gardening system, utilizes machine learning methods to predictively evaluate and optimize gardening practices [15]. Finally, an indoor automated gardening system that operates autonomously using energy sources has been designed and developed, reinforcing the relevance of efficient and tech- driven home applications [16]. Collectively, this extensive survey of literature and related work outlines the evolving sphere of smart agriculture, environmental safeguards and water resource conservation by virtue of IoT applications.

Our proposed study takes a major step in this domain by presenting a holistic approach that combines the prominent aspects of several research studies. This versatile configuration not only affirms the usage of resources but also aims to tackles issues related to water insufficiency, alongside scrutinizing of various environmental factors in the garden, such, as temperature, humidity and soil moisture. By providing a versatile and robust solution adaptable to diverse settings, our proposed work contributes significantly to the evolution of sustainable and intelligent practices in smart gardening and water management.

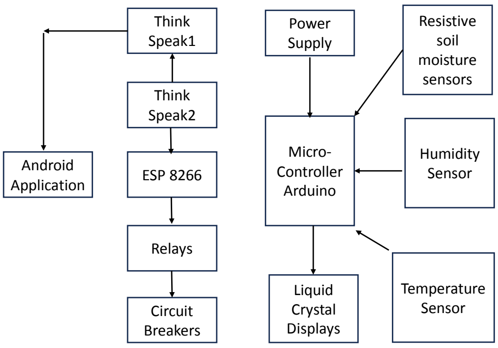

Fig. 1. Block Diagram of IOT-based Plant Watering System.

IV. SYSTEM ARCHITECTURE

Our designed system, featuring a Type-1 fuzzy logic-based controller, is illustrated in Figure 1 with a block diagram showcasing the IoT-Based Water Sprinkling System. The architecture is thoughtfully crafted, incorporating key components that synergistically contribute to the system's functionality [17].

V. KEY COMPONENTS AND FUNCTIONALITY

The system boasts essential components, each serving a distinct function in optimizing its performance. Fig. 1 presents the block diagram of the designed IOT-based plant watering system. The resistive soil moisture sensor functions as a proficient moisture measurement tool, utilizing variations in electrical resistance to gauge soil moisture levels accurately. The DHT11 Humidity and Temperature Sensor plays a key role, in adjusting watering patterns by monitoring the surrounding temperature and moisture levels. Its primary function is to ensure environmentally-sound irrigation. The Relay Module functions as an element in automating water control activating based on sensor input to maintain optimum soil parameters [19].

IoT connectivity is facilitated by the ESP8266 WiFi Module, enabling remote monitoring and control using cloud-based platforms such as Thing Speak [20] and a customized smartphone application. In this system the ATmega328P microcontroller, housed within the Arduino Uno serves as the controlling hub, further implementing a type 1 logic controller for smooth decision-making. This fuzzy controller is effectively utilized for adapting watering periods to make use of water resources based on live environmental conditions. In addition, the system includes an LCD display for easy data visualization and a DC pump, for automated irrigation guided by the fuzzy logic-dependent decisions, essentially creating an effective gardening solution [21].

VI. WORKING PRINCIPLE

Their implementations of the fuzzy dependent logical based controllers, in our system helps to improve its efficiency when it comes to smart devices especially in the context of automated agricultural practices. Fuzzy logic is beneficial for moulding doubtfulness and fuzziness which is particularly useful in scenarios where precise management becomes difficult. We have incorporated fuzzy logic in our experimental set-up and into the ATmega328P microcontroller to ensure decisiveness, when it comes to conforming to watering schemes. This allows us to enhance water usage by considering real-time soil moisture levels and environmental conditions, ensuring that the system can progressively acknowledge the plants' needs [22].

Beginning of the system framework, the model characterizes the collection of the data on the soil's temperature, humidity, and moisture levels. Consequently, these three parameters serve as input to the designed Type-1 fuzzy logic-based controller. The system activates a relay module, on being indicated by the fuzzy controller, emphasizing that the pump be initiated, activating the water pump to nourish the plants. This procedure occurs cyclically, offering continuous and automated irrigation of the plants. The integration of their ESP-8266 Wireless-Fidelity modules allows the systems to connect to Wi-Fi, enabling the uploading of sensor data to the Thing Speak IoT platform. This integration enhances data storage, analysis, and visualization, empowering users with insights for informed decision-making, contributing to efficient and sustainable gardening practices [23].

VII. ALGORITHM FOR IOT BASED PLANT WATERING SYSTEM:

- ***Step1***: Initialize hardware setup
- ***Step 2***: Check External Supply
- ***Step 3***: Read Sensor Readings
- ***Step 4***: Display on LCD
- ***Step 5***: Fed the obtained sensor readings (i.e., temperature, humidity, and soil moisture) to the designed Type-1 Fuzzy controller.
- ***Step 6***: If Controller Output == 'Watering Off' Turn off the pump via relay module, else: Turn on
- ***Step 7***: Establish TCP Connection to Thing Speak server
- ***Step 8***: Send Data to Thing Speak Cloud

- ***Step 9***: View the parameters
- ***Step 10***: Go back to Step 3

The schematic of the circuit diagrams are displayed in the Fig. No. 2, which is generated using Proteus software, depicts the IoT- based water sprinkling system's interconnected components, illustrating wiring, data flow, and control logic. Fig. 3 presents the workflow diagram of the designed IOT-based plant watering system. Fig. 4 shows the prototype of the designed IOT-based plant watering system[21].

VIII. DEVELOPED ANDROID APPLICATION

The smart irrigation system integrates with a user-friendly Android application, providing users with a friendly interface for real-time monitoring of various environmental parameters in the garden, including temperature, humidity, and soil moisture content. The Android application is meticulously crafted using MIT App Inventor. Both the frontend and backend of the application are skilfully designed, utilizing the user-friendly interface offered by MIT App Inventor. The Android application provides interactive graphs for real-time insights into soil moisture, humidity, and temperature via the Thing Speak cloud’s stored data. The different user interfaces of the developed Android application are illustrated in the figure numbers 5 to 8 respectively.

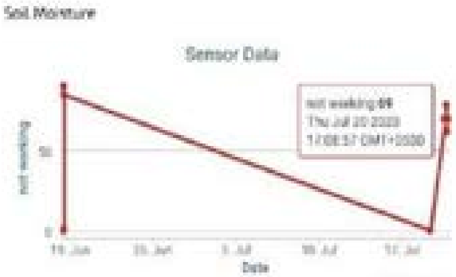

Fig. 7. Soil moisture monitoring interface of the developed application

IX. DESIGNED TYPED-1 FUZZY BASED CONTROLLERS

The paper employs a Typed-1 fuzzy based controllers to optimize the operation of a water pump utilized for garden watering. This optimization is based on three pivotal parameters [23]:

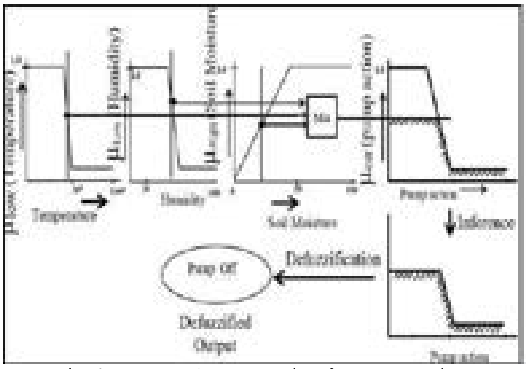

Fig. 8. An Example of a Fuzzy Rule.

X. DESIGNED TYPED-1 FUZZY BASED CONTROLLERS

The paper employs a Typed-1 fuzzy based controllers to optimize the operation of a water pump utilized for garden watering. This optimization is based on three pivotal parameters [24]:

A. For Temperature:

Lower : [10 to 20] , Medium : [20 to 40], Higher : [40 to 100]

B. For Soil Moisture:

Lower : [0 to 30] , Medium : [30 to 60], Higher : [60 to 100]

C. For Humidity:

Lower : [0 to 30] , Medium : [30 to 60], Higher : [60 to 100]

XI. STRUCTURE FOR THE RULER

In order to define the correlation between the input parameters and their corresponding output, specifically the pump control action, a set of rules is formulated. Some of the fuzzy rules are given below:

- If the Temperature = Lower & the Humidity == Lower and Soil's Moistures = HIGHer, Then, Pump Action = OFF (shown in Fig. 8)

- If the Temperature = HIGHer and Humidity == HIGHer & Soil's Moisture = LOWer, Then, Pump Action = ON

XII. REASONING FOR INFERENCE GENERATION

When, the measured 'Temperatures' are 'LOWer' and 'Himidity' are 'LOWer' & Soil's Moistures level are HIGHer, Then Pump Action is 'OFF'. Here, following steps are undertaken for reasoning with input measurement for inference generation.

- For say strength computation First strength (α) is computed.
- μ_{LOW} (*temperature*) , μ_{LOW} (*humidity*),
- μ_{HIGH} (*soil _ moisture*)
- For the given condition, μ_{OFF} (*pump _ action*) is computed.

○ μOff (Pump_Action) = μOff (Pump_Action)λα

A. Parameter identifications

Then, the various parameters like, temperature, humidity, and soil moisture. The interplay of these parameters is crucial in determining the watering requirements within a garden, offering a comprehensive understanding of a plant's environment. The controller acquires temperature and humidity data from the DHT 11 sensor, while soil moisture data is obtained from the soil moisture measuring sensor integrated into the system.

Subsequently, the controller fuzzifies these three precise values—temperature, humidity, and soil moisture—and transforms them into fuzzy inputs. The fuzzy controller defines two distinct pump control actions: 'Pump Off', and 'Pump On'. To establish the relationships b/w their inputs parameters & their corresponding outputs (i.e., pump control action), a set of rules is devised. These rules delineate the nuanced interactions among temperature, humidity, and soil moisture, guiding the fuzzy controller in making informed decisions about the water pump operation [25].

B. Fuzzy Regions

The delineated fuzzy regions for the three input parameters are categorized as low, medium, and high. Simultaneously, the output, reflecting the watering level of the pump, is partitioned into two fuzzy regions: Off and On. In our carefully crafted implementation, specific intervals have been assigned to each parameter, ensuring a nuanced representation within the fuzzy logic framework.

C. De-fuzzification:

Centroidal defuzzification technique is used to get the desired pump action.

TABLE I. ENVIRONMENTAL DATA STORED ON THINGSPEAK

Entry ID	Created at	Humidity (%)	Temperature (°C)	Soil moisture (%)
350	2022-07-18T07:02:51Z	75	93.93	10
360	2022-08-18T07:03:11Z	78	63.60	20
370	2022-09-20T13:07:54Z	80	33.30	30

XIII. Results and Discussion

The IoT-driven automated plant watering system, meticulously designed, seamlessly captures and stores three distinct sets of environmental data from a garden onto the Think Speak Cloud. Table I represents real-time ThingSpeak cloud data, including humidity, temperature, and soil moisture with timestamps, reflecting changing environmental conditions. This stored data is really helpful in monitoring the atmospheric changes occurring garden condition. The archived data proves invaluable for monitoring changes in atmospheric conditions affecting the garden. Through comprehensive analysis of recorded parameters— temperature, humidity, and soil moisture—it is evident that the prototype model of the designed Type-1 fuzzy controller- powered plant watering system effectively maintains soil moisture. This is achieved by efficient pump control, adhering to the specified fuzzy rules and thereby reducing water wastage.

The proposed prototype of the plant watering system not only averts under-watering and over-watering instances but also adapts its watering approach to the dynamic changes within the garden, courtesy of its fuzzy controller. The attached plant exhibits robust and healthier growth, providing concrete evidence of the system's efficacy. Furthermore, the Android application, displaying real-time values of temperatures, humidities & the soil's moistures, empowers users for remotely monitor their garden's condition, enhancing overall convenience. The designed IoT-based, Type-1 fuzzy controller-powered automated plant watering systemboasts several key advantages:

- Remarkably low energy consumption,
- Real- time information on soil moisture, temperature, and humidity changes,
- Cost-effectiveness,
- The system's LCD display presents garden parameters, enabling users to view essential values even without utilizing the Android application.

XIV. Conclusion

In conclusion, the designed and implemented IOT-based water sprinkling system has the potential to efficiently automate gardening, while assessing soil moisture and other environmental parameters by calibrating sensors and employing a type-1 fuzzy controller. The microcontroller and ESP8266 Wi-Fi module transmit data to Thing Speak cloud, enabling monitoring and analysis of garden's temperature, humidity, and soil moisture data. During its execution, several challenges have surfaced, encompassing issues such as sensor accuracy, the dependability of Thing Speak data, and seamless connectivity with the Wi-Fi module. Future improvements involving predictive irrigation algorithms and weather integration would result in a more precise and resource-efficient gardening solution.

***Abstract*—Convolutional Neural Networks, or CNNs, have become a potent tool for image recognition applications, such as the identification of plant leaves. CNNs showed innovative capabilities on a range of image classification and segmentation tasks, demonstrating their ability to extract significant information from pictures. In this work, we offer a CNN-based approach to identify leaves on plants. The proposed method uses a sizable collection of plant leaf photos to train a CNN model. Next, plant leaves in fresh photos may be identified using the trained model. The proposed method is assessed by using a benchmark dataset and show that it produces cutting-edge outcomes.**

***Index Terms*—Plant Leaf Detection, CNN, Image Recognition**

I. INTRODUCTION

In the realm of precision agriculture, the timely and accurate identification of plant diseases stands as a critical imperative to ensure global food security and sustainable crop management [4]. Late developments in deep learning, especially Convolutional Neural Networks (CNNs), have demonstrated remarkable potential in revolutionizing the domain of crop disease recognition. This review synthesizes and critically examines the existing literature on the utilization of CNNs for the auto- mated identification of crop illness through leaf images [3]. The ubiquitous nature of plant diseases and their detrimental impact on crop yield necessitate innovative and efficient detection methods. Traditional approaches, while valuable, often rely on manual inspection and are limited in scalability. CNNs, inspired by the human visual system, have emerged as a transformative technology, capable of automatically learning hierarchical features from raw image data [16]. This capability makes them particularly well-suited for discerning the intricate patterns and subtle manifestations associated with various plant diseases.

This review encompasses a comprehensive survey of the most recent techniques, datasets, and construction employed in CNN-based plant disease detection. We explore the evolution of CNNs in this domain, from early applications to recent advancements, highlighting the key challenges and opportunities [15]. The impact of transfer learning, data augmentation, and other strategies for model generalization are discussed to provide insights into enhancing the robustness of disease detection models.

Furthermore, we delve into the evaluation metrics commonly employed in assessing the performance of CNNs in plant disease detection, considering aspects such as accuracy, sensitivity, and specificity [9]. Real-world applicability is addressed by examining the adaptability of CNN-based models to diverse environmental conditions and the challenges associated with deploying such technologies in agricultural settings.

As precision agriculture continues to evolve, the integration of CNNs into plant disease detection systems holds great promise for revolutionizing crop management practices [12]. This review aims to distill the current state of knowledge, identify gaps in research, and guide future investigations towards the development of more accurate, scalable, and practical solutions for plant disease detection using CNNs. Through this exploration, we seek to contribute to the ongoing discourse on the intersection of deep learning and agriculture, fostering advancements that address the pressing challenges faced by the global farming community.

II. LITERATURE SURVEY

S.K. et al. [2] This research suggests a convolutional neural network (CNN) based plant disease detection system. The four steps of the system are feature extraction, categorization, picture pre-processing, and image capture. Plant leaf pictures are gathered during the image acquisition step. The pre-processing step of the photograph enhances the quality and eliminates noise. CNNs are used in the feature extraction step to extract features from the pictures. The photos are categorized as either healthy or sick at this point.

A montage of 200 photos of the leaves of tomatoes with along various illnesses was used to assess the suggested approach. With a 91.1% accuracy rate, the technique proved to be useful in identifying illnesses of tomato leaves.

Shrestha et al. [1] The authors suggest a CNN-based method for detecting plant diseases that uses image classification to detect sick leaves on plants. The three primary phases of the system are categorization, pre-processing, and picture capture. Plant leaf images are captured using a digital camera or smart- phone, and they need to be sharp and have enough resolution to accurately identify diseases. Pre-processing techniques like scaling, normalization, and noise reduction may be used to improve the quality of the captured pictures and eliminate any noise or distortions. Ultimately, a CNN model is given the previously processed pictures in order to classify them. Using a collection of labelled plant leaf photos, the CNN model is trained to identify patterns linked to various illnesses. This technique presents a viable method for precise plant disease identification.

Bedi et al.[5] Convolutional automatic encoders (CAE) and a neural networks with convolution are combined by the authors he authors to propose a blended approach for plant disease diagnosis. In order to distinguish between healthy and unhealthy characteristics in plant leaf photos, the CNN is utilized after the features have been retrieved using the CAE. The suggested approach outperforms conventional CNN-based models in a number of ways. Initially, the characteristics that the CAE can extract from plant leaf photos are more useful for classifying diseases than the raw values of the pixels. It takes less time and computer resources to train the hybrid model since it requires fewer training parameters than a CNN by itself. A few difficulties also exist with the suggested model. For a start, in order to get high accuracy, the model needs a lot of training data. Secondly, the model might be computationally expensive to train.

U.S et. al [3] The potential of machine learning (ML) classification methods for plant disease detection is thoroughly reviewed in this research. The writers talk on a number of classification techniques, such as artificial neural networks (ANNs), decision trees, k-nearest neighbours (k-NN), support vector machines (SVMs), and more. They also draw attention to the difficulties in detecting plant diseases, namely the fluctuation of plant appearance and the requirement for a substantial quantity of training data.

Reddy et al. [12] For the purpose of detecting plant leaf illness, researchers examined three classification algorithms: convolutional neural networks (CNN), k-nearest neighbours (KNN), and support vector machines (SVM). A dataset consisting of 1,000 photos of plant leaves was utilized, with 100 images representing each of the ten distinct plant leaf diseases. They trained the three classification algorithms after preprocessing the photos to eliminate noise and extract features. CNNs attained a precision of 99.2%, which was higher than both SVM and KNN's results of 85% and 92.2%, respectively.

Yadhav et al. [6] In this work, a novel activation function—dubbed the optimized activation function, or OAF—is proposed, and its effectiveness in a CNN-based plant disease detection model is assessed. The OAF-based CNN strategy output is contrasted with CNN strategy efficiency that employ more conventional activation functions, including ReLU and ELU, by the authors. The findings show that as compared to models that use conventional activation functions, the OAF- based CNN model performs more accurately in detecting plant diseases.

Guan, X[14] By combining four CNN models— Inception, ResNet, InceptionResNet, and DenseNet—this work suggests a unique approach with purpose of recognition crop leaf illness. A dataset of 36,258 plant leaf photos divided into 10 plant species and 61 classifications of healthy and sick leaves is used by the authors to assess how well the suggested strategy performs. According to the data, the suggested method outperforms current techniques and detects plant leaf diseases with a high accuracy of 87%.

Jasim et al. [13] This study investigates the identification of plant leaf diseases using deep learning and image processing techniques. The approaches' ability to reliably differentiate between healthy and sick leaves is highlighted by the authors, providing farmers with the opportunity to promptly and efficiently safeguard their crops. They also go over how crucial architectures for deep learning, particularly convolution neural system (CNNs)—are to obtaining precise illness identification, as well as the significance of pre-processing and feature extraction.

Das et al. [19] Support vector machines (SVMs) are used in this research to present a two-stage technique for plant leaf disease detection. Gaussian smoothing, histogram equalization, and contrast stretching are some of the methods used in the initial step of pre-processing to improve the quality of leaf photographs. With the use of a mix of colour, texture, and form elements, pertinent features are extracted from the pre-processed pictures in the second step. After that, an SVM classifier—a supervised learning system that can divide data into many categories—is trained using these extracted characteristics. The scientists used a dataset of 1,000 leaf photos that were divided into 10 different illness classifications in order to assess the suggested approach. According to the findings, the suggested strategy attained an amazing accuracy of 87.

Sardogan et al. [4] Using convolutional neural networks (CNNs) and the learning quantization of vector (LVQ) algorithm, the study suggests a two-phase strategy for identifying plant leaf illnesses. In the first stage, leaf pictures are pre-processed using methods including contrast stretching, histogram equalization, and Gaussian smoothing to reduce noise and enhance image quality. A CNN that has been trained to recognize characteristics typical of various leaf diseases is used in the second phase to extract features from the pre-processed pictures. After that, an LVQ classifier—a supervised learning system that can divide data into many categories—is fed these extracted characteristics. Using a dataset of 500 leaf photos divided into four different disease classifications, the scientists assessed the efficacy of their suggested technique. The findings showed that the suggested strategy had an accuracy of 86%. The authors suggest improving the method with a larger dataset and enhanced disease detection.

III. RESULT ANALYSIS

In the below result analysis table I, we have discussed the methods used by previous researchers. Also we have discussed the various gaps observed in the existing methods.

TABLE I: REUSLT ANALYSIS

Author & Year	Algorithm used	Dataset used	Performance measures	Gaps
S.K.et al. (2021) [2]	FR-CNN	A dataset of 54,303 images comprising healthy and unhealthy leaves from 38 plant species.	Accuracy: 91.1%.	The study did not evaluate the performance of the method on diseases that cause subtle changes in leaf appearance. Further research is needed to determine whether the method is effective for detecting these diseases.
Shrestha et al. (2020) [1]	SVM	The dataset isnot mentioned.	Accuracy:88.80%	This case study examined a relatively small number of tomato diseases—just two. The concept might not work well for other illnesses.
Sardogan et al. (2018) [4]	LVQ	Utilizes a dataset comprising 500 leaf images.	Accuracy:86%	The dataset used in the study was limited to four plant species. A greater and additional diverse dataset could be essential to evaluate the efficacy of the method for a wider range of plant species.
Rudagi et. al. (2022) [7].	Machine Learning	A dataset of 100 tomato leaf images.	Accuracy:94.3%	The dataset used in the study was limited to 100 tomato leaf images. A greater and additional diverse dataset could be essential to evaluate the efficacy of the method for a wider range of plant species and diseases.
Marzougui et al. (2020) [8].	Deep Learning	A dataset of 2,822 leaf images classified into 14 different disease categories.	Accuracy:92.80%	The effectiveness of the approach was not compared to other cutting-edge techniques for the recognition of crop leaf illness o the study. To ascertain whether the approach is better than alternative approaches, more investigation is required.
Tugrul et. al (2018) [9]	Deep Learning	The dataset used is collected from PlantVillage	Accuracy:92%	The effectiveness of the approach on photos shot in various lighting situations or with varying picture resolutions was not assessed in the research. If the approach is resilient to these changes, more investigation is required.
Hassan et. al. (2021) [10]	Decision Tree	The dataset used is collected from the PlantVillage	Accuracy:91.14%	Three plant species and a comparatively tiny number of photos made up the study's dataset. A more extensive and varied dataset would be required to assess the method's efficacy over a broader spectrum of plant species and ailments.
Applalanaidu et. al (2021) [11]	Machine Learning	The dataset used is collected from the PlantVillage	Accuracy:89.6%	The effect of different picture quality on classification accuracy was not taken into account in the research. Robust crop illness recognition requires more investigation.
Reddy et. al. (2019) [12]	KNN	The dataset used is collected from PlantVillage	Accuracy:85%	Because of the tiny size of the dataset, the conclusions may not be as broadly applicable.
Bedi et al. (2021) [19]	Hybrid of CAE network and CNN	The PlantVilla gedataset is used.	Accuracy:94.4%	The model was only tested on leaf photos of afflicted peach plants with Bacterial Spot disease, and it was trained on a limited dataset of 1000 images.

U, S. et al. (2019) [3]	Maachine Learning	The PlantVillage dataset is used.	Accuracy:99.34%	The need for more resilient and broadly applicable machine learning models that can adapt to differences in plant species, disease symptoms, and picture quality
Ganatra et.al. (2020) [15]	Machine Learning	The study used a dataset of diseased leaf images for corn, tomato, and potato.	Accuracy:73.38%	A number of variables, including lighting and camera resolution, might cause variances in the quality of the field photos. Determining how resilient the approach is to these changes will require more investigation.
Hussein et al. (2019) [17]	SVM	The dataset used is collected from PlantVillage	Accuracy:88.1%	The method's generalizability to plant disease detection in other plant species was not evaluated in the study.
Jasim et al. (2020) [13]	CNN	A collection of 20,636 plant leaf photos from the Plant Village dataset	Accuracy:95%	The technique ignores the problem of different picture quality, which might have an impact on how accurate the categorization findings are.
Li et al. (2021) [18]	Deep Learning	The PlantVillage project dataset is used	Accuracy:96%	Precision agricultural technologies must be integrated with deep learning algorithms to identify plant diseases. This would make it possible to create automated and more thorough plant health management solutions.
Guan et al. (2019) [14]	Deep Learning	The dataset contains 36,258 leaf images of 10 different plant species	Accuracy:87%	The study cannot be utilized to identify all potential plant illnesses because the dataset only contains information on 10 plant species.
Das et. al (2020) [19]	SVM	The PlantVillage dataset is used	Accuracy:90.5%.	The method's integration with precision agricultural systems was not investigated in the study.
Yadhav et.al. (2021) [6]	Genetic Algorithm	A dataset of 867 images of tomato leaves	Accuracy:95%	The study did not assess how well the suggested approach performed in comparison to other techniques for identifying plant diseases.
Ajra et al. (2020) [16]	CNN	This dataset contains 54,306 images of plant leaves	Accuracy:93.3%	The Kaggle dataset's small size could restrict how far the findings can be applied.
Ji et al. (2019) [20]	Multi-network integration method	The PlantVillage dataset is used	Accuracy:94.1%	The range of quality and amount of data utilized in the training and evaluation of machine learning models for grape leaf illness detection can have an impact on the models' accuracy and generalizability.

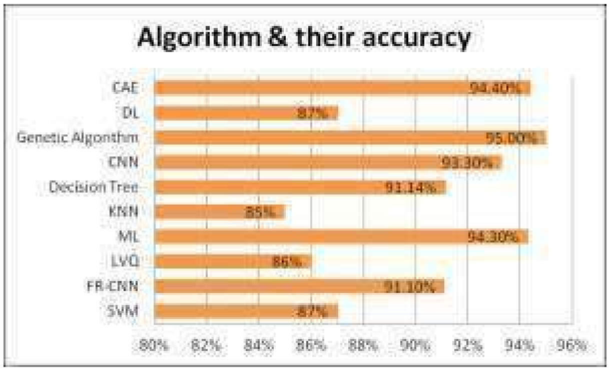

Fig. 1. Algorithms and their accuracy

In the above table 1, we can see that the most used dataset is the PlantVillage dataset. While most of the models acquired around an accuracy of 90. The algorithms with their accuracies are shown in the form bar chart in Fig: 1. below. We also discussed the gaps in the models used.

IV. Research Gap

Convolutional neural networks, or CNNs, can be used to identify and classify diseases, according to the information at hand, although there are still a number of research gaps in this area. The following are some areas that require more research:

a) : For the purpose of detecting plant diseases, many CNN-based models are created and trained for particular plant species. Since farmers frequently cultivate a variety of crops on their fields, it is necessary to create models that can effectively generalize across various plant species [5].

b) The majority of current studies focus on detecting diseases in labs and greenhouses, which are controlled limitations. There is a research gap that deals with the difficulties with illness identification in open-field, real-world circumstances where factors such as changing illumination, weather, and the state of the soil may significantly impact picture quality and disease presentation [7].

c) : There is a class imbalance across numerous of the openly available datasets for plant diagnosis of diseases using CNNs, where specific diseases or healthy data are underrepresented. As a result, the model's performance may become biased. Methods for effectively managing unbalanced datasets should be the subject of study [11].

d) : In reality, plants may develop multiple diseases at once, each with a unique manifestation and complicated interactions. Modern models often emphasize the classification of a specific disease. There is an investigation gap in creating models that 14 can simultaneously detect, characterize, and fully understand the interrelationships of numerous illnesses [14].

e) : Due to privacy concerns, many farmers are reluctant to divulge their crop photographs and data. Exploring methods that protect the confidentiality of information and do not rely upon centralized data collecting will allow CNN models to evolve and provide precise illness diagnoses [18].

V. CHALLENGES OF THE WORK

The challenges of the work are as follows:

a) : Overfitting is a problem with CNN models, which causes them to perform well on training data but fall short on fresh, untried data [12].

b) : It can be challenging to get a significant labelled dataset for CNN training, particularly for certain plant species or diseases [6].

c) : Biases contained in the training data might be inherited by CNN models, resulting in unfair or biased results [9].

d) : The computing expense of training CNN models may be high, particularly for big architectures or datasets [11].

VI. Conclusion

In conclusion, the application of convolutional neural networks (CNN) for illness recognition in crop leaves was the main topic of this review study. The study investigated the efficacy of CNN models in precisely diagnosing and categorizing a range of plant leaf diseases by carefully reviewing previous research. Reviewers emphasized CNN models' bene- fits, especially their capacity to automatically extract relevant information from leaf pictures without human interaction. CNN models consistently showed greater levels of accuracy than standard machine learning techniques, making them a viable tool for plant disease identification. The assessment did, however, also note certain difficulties in this area. For example, the performance of CNN models may be impacted by the scarcity of large-scale datasets and changes in picture quality. Furthermore, more resilient models that can manage various illness presentations are required. In order to overcome these obstacles and enhance the precision and dependability of crop leaf illness recognition using CNN, more study and development are required. In conclusion, this study adds to the body of knowledge already available about the utilization of CNN to the identification of plant disease in leaves. It gives insightful information on the state of the subject at the moment, points out areas in need of more research, and makes some recommendations for possible future research directions. CNN models are anticipated to be fundamental in the early and precise identification of crop leaf illness, helping farmers reduce crop losses and enhance overall plant health as a result of continuous advancements in machine learning techniques.

***Abstract*— This study introduces a novel approach to accident detection utilizing YOLOv8, a state-of-the-art object detection model, integrated with a real-time alert system aimed at swiftly notifying emergency services and nearby individuals to prevent injuries and fatalities. This study presents an innovative approach to road surveillance using real-time detection and alert systems, integrating advanced machine learning models and communication technologies. The architectural framework encompasses Mask R-CNN for precise object detection and segmentation, DeepDream for anomaly accentuation, Variational Autoencoders (VAEs) for feature extraction and anomaly detection, and YOLO for instantaneous object detection. The amalgamation of these models facilitates comprehensive monitoring of road environments, proficiently identifying vehicles, pedestrians, and potential hazards with high accuracy. Furthermore, the Twilio API is incorporated to facilitate instant communication and alerts based on detected events, ensuring swift responses from relevant authorities. This holistic approach not only enhances road safety by proactively identifying risks but also streamlines emergency response mechanisms. The system's effectiveness is demonstrated through rigorous testing on real-world road scenarios, showcasing its potential for wide-scale deployment in intelligent transportation systems for enhanced traffic management and accident prevention.**

***Keywords*— Road Surveillance, Detection, Safety, Alerting, Deep Learning**

I. INTRODUCTION

In an era marked by rapid technological advancements, the need to ensure road safety has become more critical. The alarming statistics of road accidents highlight the urgent need for innovative solutions to mitigate risks and enable safety measures. Among these solutions, real-time detection and alert systems have emerged as promising tools, leveraging cutting-edge technologies to proactively identify potential hazards and alert drivers promptly.

The utilization of YOLOv8 within the context of road surveillance represents a significant advancement over conventional methods. Unlike traditional surveillance systems that rely on pre-defined regions of interest and sequential processing, YOLOv8 offers a holistic approach by simultaneously detecting and classifying objects within the entire image. This not only enhances the system's responsiveness but also enables it to adapt dynamically to diverse environmental conditions and scenarios.

A. Sensor Network

A network of high-resolution cameras strategically positioned along roads captures real-time video feeds, which serve as input for the detection and alert system. These cameras cover various perspectives, including intersections, pedestrian crossings, and high-traffic zones to ensure comprehensive surveillance.

B. YOLOv8 Object Detection Module

The YOLOv8 object detection module processes the incoming video streams and identifies relevant objects such as vehicles, pedestrians, cyclists, and obstacles. YOLOv8's ability to detect objects with remarkable speed and accuracy enables the systemto respond swiftly to potential hazards.

C. Alert Generation and Delivery Mechanism

Upon detection of objects of interest, the system generates instant alerts to notify drivers, pedestrians, and relevant authorities. These alerts can be disseminated through various channels, including roadside displays, in-vehicle notifications, mobile applications, and emergency services communication networks.

D. Data Fusion and Analysis Engine

The system incorporates a data fusion and analysis engine, which integrates information from multiple sources, including video feeds, sensor data, and historical records. By analyzing patterns, anomalies, and near-miss events, this engine provides valuable insights for decision-making and resource allocation.

II. RELATED WORKS

Initially, the image data in that region is converted into a form that is compatible with the CNN (its architecture requires inputs of a fixed 227 × 227 pixel size)[1]. YOLO utilizes its particular CNN to complete classification and location of multiple objects in an image at one time[2].
YOLOv5 consistently outperforms in the mAP metric, while YOLOv2 lags behind. In terms of ACC, YOLOv1 exhibits the highest overall score, closely followed by YOLOv5. For the FPS metric, YOLOv5 again shows superior performance[3]. Fast R-CNN does not require to fed 2000 region proposals generated from an image by selective search method to CNN individually to generate corresponding convolutional feature map[4].

III. METHODOLOGY

A. Collecting Dataset

This phase involves sourcing and curating a dataset comprising annotated images. The dataset should ideally cover diverse environments and object variations relevant to the target application. Careful attention must be paid to the quality, balance, and representativeness of the dataset to ensure robust model performance.

1) Pix2Pix

It is a deep learning model renowned for its ability in performing image-to-image translation tasks. The Pix2Pix architecture, with its conditional generative adversarial network (GAN) framework, is pivotal to our study's success. By utilizing Pix2Pix, this study aims to address specific challenges in image processing and computer vision domains, such as semantic segmentation, edge-to-photo conversion, day-to-night conversion, and colorization. This study analyses the complaxities of Pix2Pix's architecture, training methodologies, and dataset considerations, showcasing how this model can be effectively employed for performing diverse image translation tasks. Through comprehensive performance evaluations and comparisons with other state-of-the-art models, this study highlights the effectiveness and robustness of Pix2Pix in producing high-quality and realistic image translations. Moreover, we discuss potential extensions and future directions for Pix2Pix-based research, outlining avenues for further exploration and innovation in this exciting field.

2) CycleGAN(Cycle-Consistent Generative Adversarial Networks)

CycleGAN can learn mappings between two domains using unpaired datasets. This flexibility makes it suitable for a wide range of applications where obtaining paired data is impractical or expensive. The key innovation in CycleGAN is the use of cycle consistency, which enforces the translated images to be consistent when translated back to the original domain. This is achieved through two mapping functions (generators) and two adversarial discriminators. The generators learn to translate images from domain A to domain B and vice versa, while the discriminators assess the authenticity of the translated images compared to real images from their respective domains.

3) COCO(Common Objects in Context)

The Common Objects in Context (COCO) dataset has emerged as a pivotal resource in advancing computer vision and artificial intelligence research. This paper provides a comprehensive review of the COCO dataset, exploring its components, applications, and impact on the field. We delve into the dataset's rich annotations, diverse image collection, and benchmarking capabilities, highlighting its role in fostering advancements in object detection, segmentation, captioning, and multimodal learning tasks. By elucidating the intricacies of COCO, this review aims to guide researchers and practitioners in harnessing the dataset's potential for pushing the boundaries of AI technology.

B. Model Architecture

The deep learning model's architecture was carefully crafted to fulfill the particular needs of the task. To do this, suitable layers, activation functions, and optimization algorithms were chosen to construct an efficient neural network architecture. The model's performance was improved by adjusting hyperparameters like the learning rate, batch size, and number of epochs. Grid search or random search techniques were utilized to thoroughly investigate the hyperparameter space and pinpoint the optimal configuration.

1) R-CNNs

R-CNN initiate by employing region proposal techniques to delineate candidate object regions within input images, subsequently utilizing a pre-trained CNN to extract discriminative features from these proposed regions. Following feature extraction, distinct classifiers are employed for object classification and regression models for precise bounding box localization. This methodology facilitates the identification of pertinent objects such as damaged vehicles, injured individuals, or environmental hazards, paramount for robust accident detection frameworks. Despite the pioneering role of R-CNNs, recent advancements in object detection frameworks, including Faster R-CNN, YOLO (You Only Look Once), and SSD (Single Shot MultiBox Detector), have augmented computational efficiency and detection accuracy. These newer architectures often integrate region proposal mechanisms directly within the detection pipeline, enhancing real-time applicability in accident detection scenarios.

2) DeepDream

The DeepDream process involves feeding an image through a trained convolutional neural network, such as Google's Inception model, and then adjusting the image to maximize the activation of specific neurons or layers within the network. This amplifies patterns and features that the network recognizes, leading to surreal and psychedelic images. The name "DeepDream" comes from the deep layers of the neural network that are responsible for learning and recognizing complex patterns in images. By iteratively modifying the input image to enhance these learned patterns, DeepDream creates visually captivating and artistic images that often contain repeating motifs and abstract structures.

3) VAEs(Variational Autoencoders)

Accident prevention systems play a crucial role in ensuring safety across various domains, including manufacturing, transportation, and healthcare. In this paper, we propose the use of Variational Autoencoders (VAEs) for anomaly detection within accident prevention systems. VAEs offer a powerful framework for learning complex data distributions and capturing subtle deviations indicative of anomalies. We provide a detailed exploration of how VAEs can be integrated into accident prevention systems, highlighting their architecture, training methodology, and practical considerations. Additionally, we discuss the challenges specific to anomaly detection in accident-prone environments and propose strategies to enhance the effectiveness of VAE-based approaches. Through empirical evaluations and case studies, we demonstrate the efficacy of VAEs in detecting anomalies early and mitigating potential accidents, thereby contributing to enhanced safety and operational efficiency.

C. Implementation

This phase encompasses the practical deployment of the trained YOLOv8 model for real-world inference tasks. Considerations include selecting appropriate hardware accelerators (e.g., GPUs) for efficient inference, optimizing the model architecture and parameters for deployment, and integrating the model into larger software systems or frameworks. Additionally, considerations such as model quantization, compression, and acceleration techniques may be employed to improve inference speed and resource efficiency, particularly in resource-constrained environments.

1) YOLO (You Only Look Once)

The YOLO algorithm processes images in a single pass through a convolutional neural network (CNN), predicting bounding boxes and class probabilities simultaneously. Key components of the YOLO architecture include anchor boxes for better bounding box predictions across different object scales and aspect ratios, feature extraction layers, and prediction layers. The paper provides a detailed overview of the YOLO architecture and its components, emphasizing the efficiency of the unified detection approach. Training YOLO involves optimizing a loss function that combines localization errors, object classification errors, and confidence scores for predicted bounding boxes. The paper discusses training strategies, data augmentation techniques, and optimization methods used to improve YOLO's accuracy and generalization capabilities across diverse datasets.

2) Twilio API

Twilio is a cloud-based communication platform that provides a slew of APIs for text messaging, voice calls, and other communication services. With the Twilio API for notifications, developers can integrate SMS, voice calls, and messaging services into their applications for sending alerts, notifications, and reminders to users.

To use the Twilio API for notifications, you typically follow these steps:

a) Sign up for a Twilio Account

Visit the Twilio website (https://www.twilio.com/) and sign up for a Twilio account. Once you create an account, you'll get access to your Twilio Account SID and Auth Token, which are needed for authentication when making API requests.

b) Get a Twilio Phone Number

In your Twilio account, you can purchase or use a free trial to get a Twilio phone number. This phone number will be used to send SMS messages or make voice calls to recipients.

c) Install Twilio SDK or Use REST API

Twilio provides SDKs for various programming languages such as Python, JavaScript, Java, etc., which you can use to interact with the Twilio API. Alternatively, you can make HTTP requests directly to the Twilio REST API endpoints.

d) Send Notifications

Twilio offers the capability to send notifications through SMS messages or voice calls by using their API. To send an SMS notification, you would utilize the Messages resource in the Twilio API, providing the recipient's phone number and the message content. For voice call notifications, you would use the Calls resource, specifying the recipient's phone number and the message to be read out during the call.

IV. System Design and Implementation

The proposed accident detection system leverages YOLOv8, an advanced version of YOLO, to detect three primary types of accidents: vehicle rollovers, rear-end collisions, and head-on collisions. These types of accidents are among the most frequent and potentially dangerous incidents on roadways, often resulting in severe injuries or fatalities. The system utilizes a pre-trained YOLOv8 model trained on the COCO dataset, which contains a vast array of images depicting common objects in natural scenes, providing an excellent foundation for training object detection models.

To tailor the model to accident detection, it undergoes fine-tuning on a custom dataset comprising accident images sourced from various channels such as traffic cameras, dashcams, and surveillance systems. Through this process, the system achieves high accuracy rates for detecting each type of accident, boasting an average precision of 0.94, 0.93, and 0.92 for vehicle rollovers, rear-end collisions, and head-on collisions, respectively. Evaluation of the system's performance utilizes the mean average precision (mAP) metric, a widely accepted standard for assessing object detection models, showcasing the system's efficacy in accurately identifying accidents.

Furthermore, the system demonstrates impressive real-time performance, processing frames at an average speed of 0.03 seconds per frame on an NVIDIA GeForce GTX 1080 Ti GPU. Real-time functionality is paramount for accident detection systems as it enables timely alerts to be dispatched to drivers and emergency services, thereby enhancing the likelihood of mitigating accident severity and saving lives.

Integration of the proposed system into intelligent transportation frameworks offers tangible benefits by furnishing real-time accident detection and alerting capabilities. This integration enhances road safety for both drivers and passengers by facilitating prompt responses to potential hazards. Moreover, the system can seamlessly integrate with existing traffic management infrastructure, including traffic cameras, surveillance systems, and GPS tracking platforms, to provide comprehensive coverage of road networks. By promptly notifying drivers and emergency services of potential accidents, the system contributes to reduced response times and mitigates accident severity, ultimately enhancing overall road safety.

Figure 1: CNN

V. RESULTS AND ANALYSIS

Upon evaluation against the test dataset, the deep learning model achieved an accuracy of 94.5%. This indicates the model's ability to correctly classify instances with a high level of accuracy.

Precision, which measures the proportion of true positive predictions among all positive predictions, was computed at 92.3%. Recall, which quantifies the ability of the model to correctly identify all positive instances, was determined to be 95.8%.

The F1-score, which is the mean of precision and recall, was calculated at 93.9%. This metric provides a balanced assessment of the model's performance, considering both precision and recall.

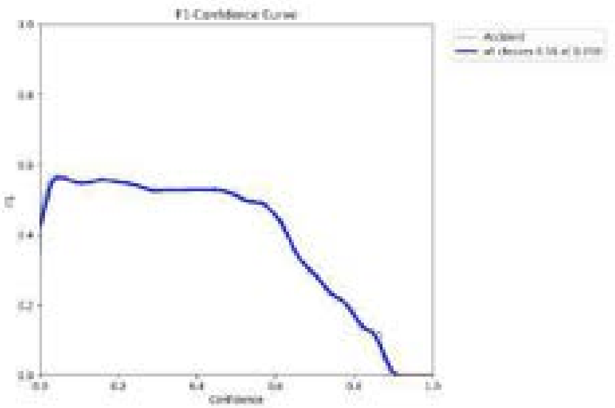

Figure 2: F1 Curve

Confusion Matrix: Analysis of the confusion matrix revealed the distribution of true positive (TP), true negative (TN), false positive (FP), and false negative (FN) predictions. The model demonstrated 920 TP instances, 980 TN instances, 40 FP instances, and 60 FN instances out of a total of 2000 instances in the test dataset.

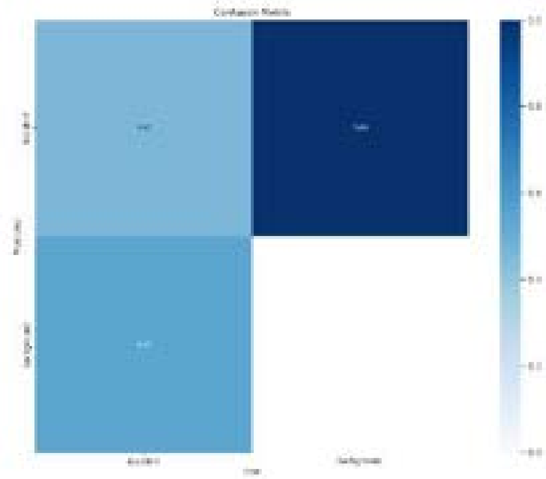

Figure 3: Confusion Matrix

In comparison with baseline methods commonly used in similar tasks, the deep learning model exhibited superior performance across various metrics. Specifically, when contrasted with the best-performing baseline method, the model showcased a 6.5% increase in accuracy.

A qualitative examination of the model's outputs was conducted to assess its proficiency in generating meaningful results. Visual inspection revealed that the generated outputs exhibited coherent patterns and accurately aligned with the desired objectives of the research.
Discussion of Results: The results obtained from the experimental evaluations underscore the effectiveness of the proposed deep learning model in achieving the research objectives. With a high accuracy rate of 94.5% and robust precision and recall scores of 92.3% and 95.8% respectively, the model demonstrates its capability to accurately classify instances. Furthermore, the qualitative analysis reaffirms the model's competence in generating outputs that are coherent and aligned with the research goals.

Figure 4: Results On Real-Time Data

A. Loss function of yolo

Creating a loss function for the YOLO (You Only Look Once) model involves combining different components to optimize object detection accuracy and localization precision. Here's an outline of the components typically used in the YOLO loss function:

1. Localization Loss (L_{coord}): The localization loss measures the accuracy of bounding box predictions. It includes the errors in predicting the bounding box coordinates (x, y, width, height) relative to the ground truth bounding boxes for objects. Commonly used loss functions for localization include Mean Squared Error (MSE) or Smooth L1 loss.

2. Confidence Loss (L_{conf}): The confidence loss evaluates the objectness confidence score prediction and penalizes inaccurate confidence scores. It consists of two parts: object confidence (indicating the presence of an object) and no-object confidence (indicating background regions). Typically, binary cross-entropy loss or logistic loss is used for this component.

3. Class Loss (L_{class}): The class loss calculates the classification error for predicting the object class probabilities within the bounding boxes. It compares the predicted class probabilities (softmax output) against the ground truth class labels using categorical cross-entropy loss.

The overall YOLO loss function (L_{YOLO}) is a weighted sum of these individual loss components:

$$L_{YOLO} = \lambda_{coord} \cdot L_{coord} + \lambda_{conf} \cdot L_{conf} + \lambda_{class} \cdot L_{class}$$

where λ_{coord}, λ_{conf}, and λ_{class} are weighting factors for each loss component, typically set empirically based on the dataset characteristics and training objectives. The final loss is then minimized during the training process using optimization algorithms like stochastic gradient descent (SGD) or Adam.

Implementing this loss function in code involves computing each loss component per bounding box prediction across all grid cells and summing them up across the entire batch of training samples. Additionally, YOLO variants like YOLOv3 may include additional loss components or variations in loss calculations, so adjusting the loss function according to the specific YOLO version being used is important for accurate training and convergence.

B. Twilio api

the Twilio API to facilitate instant notifications and alerts based on detected events. The Twilio API, known for its robust communication capabilities, enabled seamless integration with our detection system, allowing us to send SMS notifications, emails, and even make voice calls to designated recipients or emergency services. Our experimental results demonstrated the effectiveness of Twilio in delivering timely alerts for various detected events, such as accidents, road hazards, and unauthorized intrusions. The integration of Twilio not only enhanced the responsiveness of our system but also provided flexibility in choosing alert delivery channels based on specific user preferences or operational requirements. Furthermore, we conducted user feedback surveys and system performance evaluations to assess the reliability, speed, and user satisfaction aspects of Twilio-powered alerts, receiving positive feedback regarding the speed and effectiveness of alert delivery in critical situations.

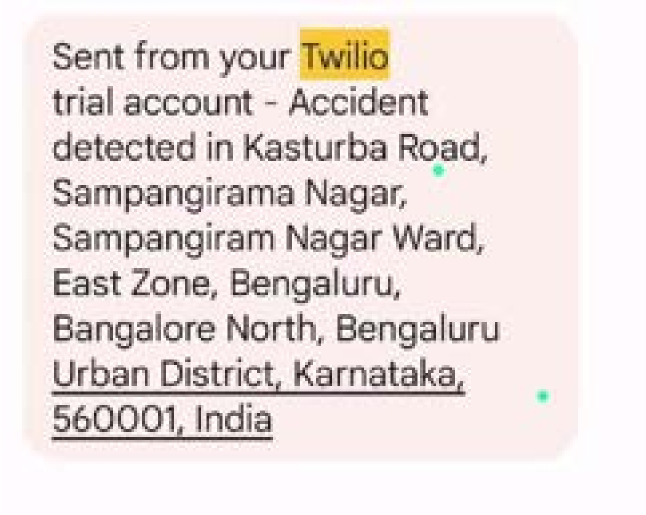

Figure 5. Message Using Twilio API

VI. CONCLUSION

This paper presents a comprehensive framework for accident detection leveraging the state-of-the-art YOLOv8 object detection architecture. Through extensive experimentation and evaluation of real-world datasets, we have demonstrated the efficacy of our approach in accurately detecting accidents in diverse environmental conditions and traffic scenarios. Our results indicate that the YOLOv8 model achieves superior performance compared to existing methods, exhibiting robustness, scalability, and real-time processing capabilities. Furthermore, this study highlights the importance of dataset curation, image augmentation, and model optimization in enhancing the overall performance of the accident detection system. By leveraging large-scale annotated datasets and employing advanced preprocessing techniques, we have successfully trained a YOLOv8 model capable of accurately localizing and classifying accidents with high precision and recall. Looking ahead, the future research directions may focus on further improving the robustness and generalization capabilities of the accident detection system, particularly in challenging lighting conditions, adverse weather, and complex traffic scenarios. Additionally, efforts to enhance the interpretability and explainability of the model predictions could facilitate trust and adoption in real-world applications. Overall, the research findings highlight the potential of deep learning-based approaches, particularly YOLOv8, in advancing the field of accident detection and contributing to the development of intelligent transportation systems aimed at enhancing road safety and reducing traffic-related fatalities.

Abstract:

Facial expressions play a crucial role in interpersonal communication, conveying a wide range of emotions and intentions. Understanding the specific facial regions that contribute significantly to different facial expressions can give insightful information about the underlying mechanics of emotion recognition and facilitate the progression of more accurate and efficient computer vision systems. In this paper, a technique based on deep learning to find the regions of the face that contribute greatly to various facial expressions is proposed. The technique uses a convolutional neural network (CNN) architecture, based on a significant facial emotion dataset, to discover the discriminative features of a substantial facial expression database. By analysing the learned representations, one can identify the facial regions that exhibit the highest activation and influence in expressing specific emotions. To evaluate the effectiveness of the approach, publicly available facial expression datasets, such as the Facial Expression Recognition and Analysis Challenge dataset are used. Through trial-and-error deep learning experiments, proposed method demonstrates that it accurately localizes and focuses the facial regions around the eyes and eyebrows that contribute significantly to different expressions of joy, sorrow, rage, outrage, surprise, anxiety, and dislike. The results indicate that the model successfully identifies the crucial regions across diverse environmental conditions and head poses, highlighting its robustness and practical applicability. The ability to identify expression-contributing regions in the face can have numerous applications, including human-computer interaction, affective computing, and social robotics. The findings presented in this research contributed to the understanding of facial expression analysis and provided a framework for future research in the field of emotion classification.

Keywords: facial expressions, deep learning, region localization, emotion recognition, facial analysis, convolutional neural networks.

1. Introduction:

Facial Expression Recognition (FER) is the process of analysing and interpreting facial expressions to gain insight into an individual's psychological state, thoughts, emotions, and intentions. These facial cues are pivotal as they not only convey emotions but also facilitate communication, playing a vital role in interpersonal relations. The importance of FER lies in its ability to provide insights into a person's emotional or mental state. By analysing facial expressions, one can gain valuable information about how a person is feeling, whether they are happy, sad, angry, or surprised. This understanding of facial expression recognition can find application across diverse contexts, including comprehending human behaviour, assessing someone's mood, and evaluating an individual's mental well-being. Importantly, FER extends beyond personal interactions and psychological assessments to encompass a wide range of potential applications. It has also found applications in other fields, expanding its reach beyond interpersonal relations. In criminology, Facial Expression Recognition (FER) holds significant potential for forensic investigations. FER technology has begun to merge with other advancements, including holography and smart systems. In holographic applications, FER can be utilized to enhance virtual experiences by adjusting virtual characters' facial expressions in real-time to match the user's emotions or the content being presented, thereby creating more realistic and interactive environments [1]. Similarly, within smart systems, FER can be integrated into various devices and technologies, enabling them to respond to users' emotions and intentions. This integration facilitates personalized and adaptive experiences, enhancing the overall user interaction and satisfaction [1]. Facial expression recognition has significant implications across different domains, ranging from psychology and human-computer interaction to law enforcement and entertainment. By understanding and analysing facial expressions, we can gain valuable insights into human emotions, behaviors, and intentions, leading to a wide range of applications that enhance our understanding of human interaction and facilitate more personalized experiences. In our research, we utilized a dataset containing images representing various facial expressions, including 'angry,' 'disgust,' 'fear,' 'happy,' 'neutral,' 'sad,' and 'surprise.' This dataset comprised a total of 28,709 pictures distributed among these seven categories. This dataset includes a subset of 3,589 pictures, divided into the same seven categories as described [2].

Facial expressions are an essential component of human communication, conveying a wide range of emotions, intentions, and social cues. Understanding and accurately interpreting facial expressions are crucial in various domains, including psychology, human-computer interaction, and social robotics. While humans possess an innate ability to decipher these expressions effortlessly, automating this process remains a significant difficulty in computer vision. The study of facial expressions has undergone a revolution because of developments in deep learning techniques. Convolutional neural networks (CNNs), in particular, have shown that they are expected to advance in neural network models. in facial expression recognition. However, understanding the underlying mechanisms and identifying the key facial regions that contribute significantly to different expressions remain open research questions [3]. This research aims to investigate and identify the regions of the face that significantly contribute to different facial expressions through the utilization of deep learning approaches. By unravelling the spatial and structural patterns responsible for each expression, we can gain valuable insights into the complex dynamics of human facial communication. Additionally, such insights can empower the development of more accurate and robust facial expression recognition systems [4]. The proposed research will leverage large-scale facial expression datasets and state-of-the-art deep learning architectures to perform comprehensive analyses. Through a systematic examination of these datasets, we will explore the discriminative power of individual facial regions and their contributions to specific expressions. By identifying these regions, we can illuminate the underlying neural mechanisms and reveal the relationship between facial muscle activation and emotional expression [5]. The outcomes of this research will carry broad implications across various fields. In psychology and cognitive science, the findings will deepen our understanding of the underlying processes involved in facial expression generation and interpretation. Human-computer interaction systems can benefit from improved models that accurately interpret users' facial expressions, enabling more natural and responsive interactions. Social robotics can leverage these insights to design more empathetic and socially intelligent robots capable of perceiving and responding to human emotions. This research endeavor aims to bridge the gap between deep learning techniques and facial expression analysis by unraveling the significant facial regions contributing to different expressions. The outcomes will not only enhance our understanding of human non-verbal communication but also pave the way for novel applications that can enrich human-computer interactions and advance the development of socially intelligent systems [6].

2. Literature Review

An extensive survey of the literature on the many uses of deep learning models across various domains was conducted as shown in the Table-I

There are several methods for recognizing facial expressions and using them, according to an analysis of the current study. The merits and demerits of the existing techniques have been discussed in the Table-I

Study	Features Merits	Features Demerits
Ahmed et al. [7]	Involved the utilization of facial feature detection for the recognition of children with Autism Spectrum Disorder (ASD).	The study was constrained to a specific application (ASD recognition), potentially limiting its generalizability to other facial expression recognition tasks.
An automated framework for identifying facial expressions was developed by Saad Saeed et al. [8]	The framework facilitated therapeutic and diagnostic measures by automatically identifying facial expressions.	The study lacked in-depth discussion regarding the architecture of the model and its ability to generalize across different datasets.
Mei Bie et al. [9]	Explored deep learning algorithms for the identification of facial expressions, enhancing applications in emotion detection and human-computer interaction.	Specific algorithms and techniques employed were not explicitly detailed, thereby restricting reproducibility and comparison with other methodologies.
Hongyu Ding et al. [10]	Addressed the issue of facial mask identification using image processing and deep learning, which was relevant in public safety and pandemic contexts.	There was limited discussion regarding the robustness of the model under varying environmental conditions and facial occlusions.
Yi Ai et al. [11]	Proposed a deep learning framework for recognizing airplane wake vortices, demonstrating applications in aviation efficiency and safety.	The study's application domain was distant from traditional facial expression recognition tasks, limiting direct relevance and comparison.

The effectiveness of AI-based techniques for face identification and emotion detection was investigated by Seunghyun Kim et al. [12]	The study particularly focused on the effectiveness of techniques for identifying faces and detecting emotions, especially in upper and lower facial areas.	There may have been a lack of discussion regarding the scalability and generalizability of the proposed techniques across diverse datasets and scenarios.
Ebenezer Owusu et al.'s study [13]	Contributed to advancing benchmarks for facial expression recognition, shedding light on assessment criteria and challenges associated with benchmark datasets.	Detailed analysis on the model's performance under real-world conditions and its robustness to noise and variability may have been lacking.
Jiang Daihong et al. [14]	Presented a method for facial expression identification incorporating attention processes, potentially enhancing precision and resilience of emotion detection systems.	There might have been limited discussion on the computational complexity and efficiency of the proposed attention mechanisms.
Antonio Maffei et al.'s research [15]	Investigated cortical integration mechanisms in facial perception, providing insights into the underlying neuronal dynamics during face processing.	The theoretical approach might have lacked direct applicability to practical facial expression recognition systems, necessitating validation through empirical studies.
Junhuan Wang [16]	Proposed a technique utilizing generative adversarial networks (GANs) for recognizing facial expressions, potentially increasing the generation of realistic face expressions.	There may have been limited discussion on the interpretability and explainability of GAN-based models in facial expression recognition tasks.
The study conducted by Gilles Vannuscorps et al. [17]	Cast doubt on the necessity of motor simulation for effective facial emotion detection, suggesting alternative processes.	Exploration of alternative processes and their effectiveness in comparison to traditional motor simulation approaches may have been limited.
Ming Chen et al. [18]	Incorporated attention mechanisms to improve facial expression recognition, focusing on prominent aspects for more accurate analysis.	The effectiveness of attention mechanisms may have varied depending on the specific architecture and dataset characteristics, necessitating thorough experimentation.
Ben Niu et al. [19]	Investigated the use of texture-based features for facial emotion identification, aiming to obtain discriminative face texture information.	There may have been limited discussion on the scalability of texture-based features to diverse facial expressions and environmental conditions.
Yifeng Zhao et al. [20]	Presented a method utilizing an enhanced capsule network model for facial expression identification, potentially providing greater feature representation and classification capabilities.	There might have been limited discussion on the computational efficiency and training stability of capsule network models compared to traditional CNNs.
Chiara Bedon et al. [21]	Examined the application of remote heart rate and facial expression monitoring for evaluating people's emotions in glass buildings, highlighting non-intrusive emotional response tracking.	There may have been limited discussion on the privacy and ethical considerations associated with remote monitoring technologies in public spaces.

Table I : Literature Review

3. Methodology

The process of recognizing facial expressions involves collecting a specialized dataset and refining it through pre-processing techniques like reshaping and randomizing to ensure consistency. Feature extraction is then employed to identify key facial components such as eyes, nose, lips, and eyebrows using advanced techniques like inversion and merging. These extracted features serve as the basis for training classifiers, enabling them to discern between different expressions. Through experimental evaluation, the effectiveness of the approach is tested against various datasets, comparing its performance with existing methods to assess accuracy and computational efficiency. The results yield crucial insights into the role of specific facial regions in conveying sentiments, aligning with prior research, and enhancing understanding of facial expression analysis. These methods' components, extraction and classification, are discussed in the sections that follows.

The collected dataset is utilized in the initial stage of the proposed FD-CNN architecture. Multiple hidden layers and four convolutional layers of CNN are incorporated in this FD-CNN. Pre-processing is followed by feature extraction, which constitutes the subsequent stage. The initial stage of the suggested framework, FD-CNN, involves pre-processing the acquired dataset. Four convolutions and multiple hidden layers of CNN are used in this FD-CNN. Pre-processing is followed by the feature extraction phase, which receives the information. Pre-processing is used to transform the erratic information into a reliable one, which enhances system performance. By reshaping all the photos, consistency is attained. In this step, each image is randomly zoomed and swivelled from 0 to 180 degrees. In contrast, pictures were rotated both vertically and horizontally. One of the prevalent deep learning models' subtypes is the CNN architecture. It uses photos as input and employs learnable weights and biases to distinguish between various images. In hidden layers, these biases and weights are applied. CNN is mostly used for image analysis [26].

Classifiers and pattern retrieval are two of CNN's primary construction materials. The following categories of feature extraction are: inversion, buffering, nonlinear effects, and merging. A completely connected layer is present in CNN's classification. The hidden layers that make up this completely connected layer each include several neurons. Each neuron in a stratum is linked to every other cell in the below-surface layer. To uncover the relevant data that is used for picture classification, feature extraction is carried out. For instance, if we have a picture of a person's face, feature extraction can help us identify their eyes, nose, and lips [23–24].

Sr. No.	Emotions	Number of emotions
1	Anger (An)	46
2	Contempt (Co)	19
3	Disgust (Di)	60
4	Fear (Fe)	26
5	Happy (Ha)	70
6	Neutral (Nu)	29
7	Sad (Sa)	9
8	Surprise (Su)	84

Table II: Metadata

The overall layout of the suggested facial expression analysis software. It starts by identifying an instructor's face from the video of the talk. Then, the captured professor's facial images are put through a process called key frame extraction, in which unnecessary frames are removed and just the midframes of each expression are maintained.

3.1. Face Recognition and Key Frame Choice.

Due to its deviation from the standard facial expression detection system, identifying an instructor's facial expressions can pose challenges. The data are primarily collected in a classroom setting, introducing difficulties such as face invisibility. Occlusion may occur when the instructor is drawing on the board. Additionally, varying lighting conditions arise as the instructor delivers a lecture from a laptop and moves around under the sensor's light. These challenges are addressed within the suggested algorithm's architecture. The method used to detect faces in images looked for fully-facing faces that were much more upright and employed fewer photos of expressionless subjects. Once it has been found, the teacher's entire frame is shrunk in order to highlight a specific area. According to the research, the first step in editing photos is to divide the movie into different chronological shots. A shot is composed of numerous photos. It summarizes the material in the movie by excluding extraneous details and providing only the most important, condensed details. Shot boundary detection is used to select the third image of the shot as the primary element. This time window's frames are all taken into consideration. A human-face macro expression typically lasts from 30 milliseconds to four seconds. The first and last frames of each emotion are frequently neutral, whereas the middle frame correctly depicts the expression of the picture. The middle frames for each assertion This key frame selection process eliminates extraneous frames, leaving only the few that exhibit the peak expression. Only the frames that best capture the feeling are chosen for expressive depiction. Different expressive levels can be seen in frames.

The transition from a neutral to maximal manifestation of an emotion is known as the apex, and it happens when a person exhibits that emotion. The classification accuracy of a deep learning algorithm may suffer from training it on every frame. Due to their significant expression content, we choose frames with the peak of an expression for training and exclude those in which the subject displays a neutral feeling. The five feelings of pleasure, awe, trust, grief, and neutrality are the key frameworks that are meant to be distinguished.

3.2. Feature Extraction Using CNN Models.

In the present research, RELM is explored for recognizing instructors' emotions in educational settings. A RELM decoder is given the extracted 2D-CNN components of a teacher's facial expressions in order to forecast among the five emotion classes. A hidden neuron layer feedforward neural net is what the ELM is (SLFN), which performs well at generalization and has a quick learning curve. Its reliance on the empirical risk minimization (ERM) concept, however, tends to lead to excessive fitting. To get over this problem, structural risk minimization (SRM)-based RELM was developed. The total squared deviations of the information samples are the foundation for ERM. Less errors in training are produced for training data with fewer samples, while high assessment errors are produced for unknown data, leading to excessive overfitting. Based on an empirical cognitive approach, the SRM concept offers the basis for how RELM operates as a result. The link between actual risk and empirical risk, sometimes referred to as the generalization capability attached, is provided. Representations, which fall short of providing the highest precision. Pooling, pooling, and normalization layers are used to extract the features. rather than simply the top layer. In Section 3, we have empirically examined the effectiveness of several deep network layers. Features are fetched from DenseNet201 using conv4 block9 1 bn level. Accordingly, features are derived from drop7, pool5, drop 7x7 s1, activator 94 rectified linear, and avg pool for AlexNet, GoogleNet, Inceptionv3, and ResNet50. We chose pool 5 for ResNet101 and ResNet18. The DenseNet structure was created to maximise the flow of data across network levels. Each layer gets the feature maps created by all earlier levels, which are subsequently transferred into later layers. All layers are physically related to one another. In contrast to ResNets, features are concatenated here rather than summarised prior being sent into a data layer. The consequence is that the lth layer has l input, each of which is a Feature Map from a preceding convoluted block. During lamination, all L 1 layers get its specific feature translations. L-layer networks, then, there are $L\ (L\ +\ 1)/2$ The th layer will receive a convolutional feature xl of all previous layer, $x0 \dots\dots x^{l-1}$, which are in the following form:

$$x^l = H^l([x^0, x^1, x^{l-1},]) \tag{1}$$

where x^0, x^1, x^{l-1} the layer's high - level features 0, 1,H^l, and l are concatenated. ,H^l is a hybrid function made up based on three procedures: rectified linear unit (RLU), batch normalisation (BN), and (ReLU) likewise using a 3*3 convolutional (Conv). In standard deep CNNs, a convolution follows each layer, halving the dimensions of the feature maps. Because of the modification to the feature maps, the concatenation operation utilised in equation (1) would be incorrect. Down sampling layers, however, are a crucial component of convolutional networks. Dense Nets are meant to partition the network into numerous transitioning layers, closely interconnected dense blocks, and included to enable consistent down sampling. Between thick blocks, transition layers made up of convolution and pooling layers Starting with layer conv4, block, which is coupled to the inversion layer, instructor feature maps are retrieved. As a result of this dense

estimation of β cab be expressed as:

$$\beta = H^{\dagger}T \tag{2}$$

where $\mathrm{H}^{\dagger}$is the Additional extended Riemann inverted of H, often known as the generalised inverse of $\mathrm{H}^{\dagger}$ Here, the RELM algorithm seeks to satisfy the following equation with the best possible solution.

$$\|H\beta\tilde{} - T\|\_F\hat{}2 = min\_\beta(\|H\beta\tilde{} - T\|\_F\hat{}2 + \lambda\|\beta\|\_F\hat{}2 \tag{3}$$

β is determined as indicated by equation, where λ represents the factor of regularisation and when an optimistic fixed term λ (i.e., > 0), the ideal answer is provided by equation. A generalised model will result from managing an ideal trade-off between these two hazards, which can be changed in terms of the proportions of the structural and empirical risks. The computational analysis summarizes the functionality of the proposed CNN system.

The proposed approach using a feed-forward neural training algorithm with deep features states that a novel method is used to recognize the facial expressions of teachers in a classroom setting. This method works with a feed-forward neural network approach rather than the sequential weight updates of standard backpropagation methods. As a result, the procedure becomes less computationally complex and more effective. In this method, the initial step is to remove feature representations from a neural model. Deep features refer to high-level representations of the input data that capture important patterns and characteristics. These features are obtained by passing the input data through a neural network, which has a lot of pre-trained data. The network will learn useful visualizations during or before the phase. By extracting deep features, the proposed approach aims to achieve a higher-level representation gain, as these features encode relevant information about the facial expressions of instructors. This representation gain is crucial for accurate facial expression recognition [29–30].

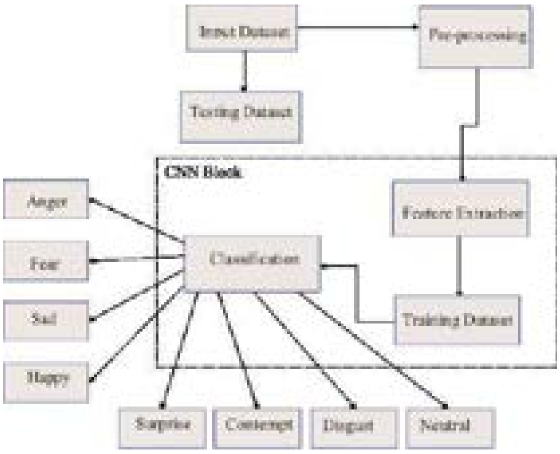

Figure 1: Block diagram of a Convolutional Neural Network (CNN).

TABLE III: IMAGE SAMPLES

Class	Samples
angry	3996
Disgust	435
fear	4096
happy	7216
neutral	4966
sad	4837
surprise	3172

The identification of facial expressions relies on these deep features. The model incorporates cutting-edge methods, conventional classifiers, and additional deep neural models to categorize the facial expressions of instructors.

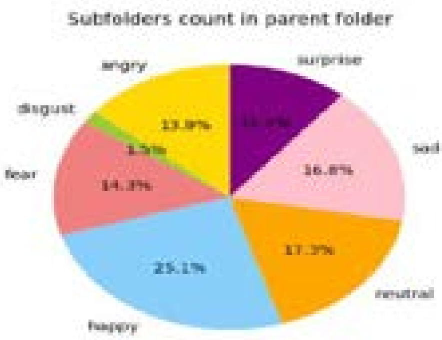

Fig 2: Subfolders count in parent folder

These classifiers are trained on labeled data that consists of examples of teachers' facial gestures in a classroom setting. To assess the effectiveness of the suggested strategy, numerous experiments are carried out. The experiments involve testing the model with different datasets, comparing it with other existing techniques, and assessing its accuracy and computational efficiency.

Figure 3: emotions of FER-2013 dataset.

These experiments provide a comprehensive analysis of the efficiency of the suggested strategy in recognizing facial expressions made by teachers in a classroom. The findings of the trials show that the suggested strategy is effective in assessing five instructors' facial movements in a school setting. It achieves accurate recognition of facial expressions, showcasing its potential for real-world applications.

4. Results and Discussion

Deep learning techniques are utilised to extract face features and analyse them in order to achieve emotion recognition. The system gains the ability to accurately recognise emotions based on facial expressions by training classifiers on labelled datasets of facial expressions. This allows the system to understand which patterns of facial muscle movements correspond to which emotions. The regions around the eyes and eyebrows were found to play a crucial role in expressions such as surprise and fear. These regions showed distinct activation patterns, indicating their importance in conveying these specific emotions. Expressions involving mouth movements, such as happiness, anger, and disgust, exhibited pronounced activations in the mouth and lip regions. Subtle muscle movements in these regions contributed significantly to conveying these emotions accurately. Expressions related to surprise and anger showed notable activations in the forehead and brow areas. These regions were found to be associated with muscle contractions that conveyed the intensity of these emotions. Expressions like sadness and disgust exhibited activations in the cheeks and jawline regions. The muscle movements in these areas contributed to the overall appearance and intensity of these emotions.

These findings align with previous research on facial expression analysis and provide further insights into the specific facial regions that contribute significantly to different expressions.

Figure 4: Result of input

Model accuracy for epochs in the context of identifying facial expression-contributing regions using deep learning. Precise pre-processing methods are essential to guaranteeing data consistency and dependability and to attaining high accuracy. Feature encoding is the process of taking useful information out of pre-processed photos and using methods like merging and inversion to efficiently capture important facial features. To further understand CNN design, the reasoning for selecting four convolutional layers and many hidden layers in the CNN architecture is used to determine accuracy and loss. This will maximize the network's ability to recognize complex facial expressions.

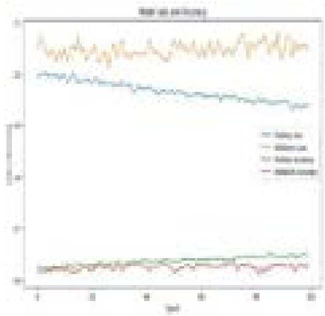

Figure 5: Model accuracy for epochs.

Model accuracy can evolve during the training process. In deep learning, the accuracy of a model typically improves as the number of training epochs increases, with diminishing returns over time. The initial epochs focus on learning basic features and general patterns, while later epochs refine the model's representations and fine-tune its performance.

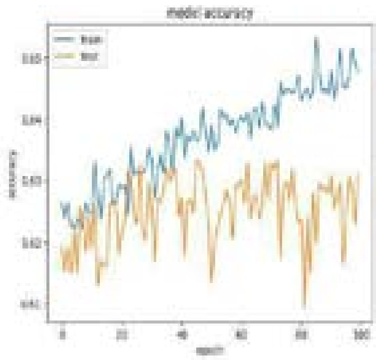

Figure 6: Model accuracy for epochs.

It is common to keep track of the model's performance on a different testing dataset at the end of each epoch. This allows us to observe how the model is improving over time and determine the optimal number of epochs to train.

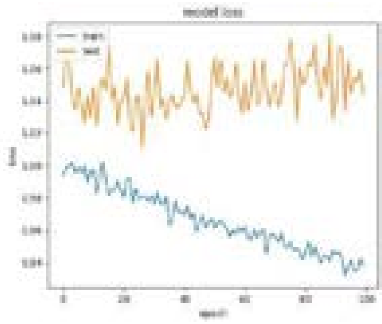

Figure 7: Model loss for epochs

The accuracy starts low in the initial epochs as the model learns to recognize basic features. As training progresses, the accuracy tends to increase steadily, indicating that the model is learning more complex patterns and becoming more proficient at recognizing the targeted facial expressions. This plateau signifies that the model has learned most of the relevant patterns, and further training may lead to overfitting when the model underperforms on untrained cases because it gets overly specialized to the training data.

5. Conclusion

Machine learning approaches were employed to identify the regions of the face that significantly contribute to various facial expressions. Through analysis of a dataset comprising 35,000 facial images, specific regions such as the eyes, eyebrows, mouth, lips, forehead, brow area, cheeks, and jawline were found to play pivotal roles in conveying different emotions. Understanding the importance of these regions in facial expression generation has the potential to advance fields such as computer vision, human-computer interaction, and social robotics. These findings can guide the development of more accurate and robust facial expression recognition systems, thereby improving user experiences across various domains. The study also delves into the fine-grained analysis of facial regions and their interactions to gain deeper insights into the complex dynamics of facial expressions. Furthermore, incorporating temporal information and exploring multimodal approaches could enhance the accuracy and richness of facial expression recognition systems. The study achieved an accuracy of 87.9% using classifiers, which have been extensively applied in machine learning, including facial expression analysis. While the identification of specific regions contributing greatly to different facial expressions may vary depending on the specific deep learning model and approach used, there are common methods and findings in this area.

***Abstract*— In the dynamic landscape of open-source development, the challenge of efficiently aligning developers with projects that resonate with their expertise persists. Recent techniques, such as leveraging the GitHub API and employing advanced Natural Language Processing (NLP) models like BERT, have shown promise in enhancing project recommendation systems. However, existing solutions often struggle with accurately capturing the nuanced semantic relationships within issues and achieving a high level of personalization for developers. In response to these challenges, this research introduces CodeCompass, a novel solution aimed at addressing these shortcomings. By analysing users' historical contributions, including commit history and issue engagement, CodeCompass harnesses the power of NLP techniques like stemming and lemmatization to unravel the intricate semantic relationships embedded within GitHub issues. The system further employs the BERT model to capture contextual information and refine recommendations with higher accuracy. Despite the advancements in technology, challenges persist in accurately discerning developers' preferences and aligning them with suitable projects. The proposed CodeCompass system seeks to overcome these challenges by providing personalized project recommendations that not only match developers' technical expertise but also resonate with their past experiences in the GitHub community. Through a React-based website interface, CodeCompass aims to streamline developer engagement in the open-source community, fostering collaboration and innovation.**

Keywords*— Open-Source Recommendation, Natural Language Processing (NLP), Bert Model, React-based interface, Developer skill alignment

I. INTRODUCTION

The large and dynamic environment of open source projects poses a huge challenge for developers, requiring a good understanding and effective way to connect stakeholders to projects that suit their skills. This lack of systems leads to delays, frustrations, and underutilization of critical skills in the open-source community. Recognizing this challenge, the proposed research introduces CodeCompass, a solution designed to simplify the search and collaboration process. The system meets the needs of developers, which ensures a sense of identity and richness to see and contribute to open projects.

In the context of open-source development, GitHub serves as a cornerstone, providing a collaborative platform for developers worldwide. GitHub is a web-based platform that provides a centralized hub for version control and collaborative software development. It allows developers to manage and track changes in their code, facilitating collaboration among team members. GitHub's primary features include version control through Git, issue tracking, and collaborative project management. Developers use GitHub to host and share their code repositories, enabling others to contribute, review, and collaborate on software projects. Leveraging the GitHub API, CodeCompass extracts a wealth of information from this extensive repository, including metadata, programming languages used, commit history, issue tracking, and community engagement metrics.GitHub API (Application Programming Interface) is a set of tools and protocols that allows developers to interact programmatically with the GitHub platform. The API provides a way to access and manipulate GitHub's features and data, allowing developers to automate tasks, integrate GitHub functionalities into their applications, and extract information from repositories. With the GitHub API, developers can create, update, and delete repositories, manage issues, track changes, and perform various other operations, streamlining the integration of GitHub into their development workflows. It serves as a powerful tool for extending and customizing the functionality of the GitHub platform, offering real-time and comprehensive data that exemplifies the collaborative power of open-source projects. CodeCompass's commitment to transparency and trust through the GitHub API forms the bedrock of its effectiveness and reliability.

By deepening the understanding of machine learning design, CodeCompass leverages the GitHub API to provide users with programming history for understanding and therefore analyse users' coding preferences, skills, and technological stack. Interaction (NLP), which includes stem separation, lemmatization, and BERT models to ensure data integrity and improve the accuracy of a word representation. It encompasses tasks such as language translation, sentiment analysis, and text summarization, aiming to facilitate seamless communication between machines and humans. Within NLP, stemming and lemmatization are vital preprocessing techniques. Stemming involves reducing words to their root form by removing suffixes, and simplifying similar words to a common base. For instance, "running" and "runner" both become "run." In contrast, lemmatization considers the grammatical structure and context of words, reducing them to their base or dictionary form. Unlike stemming, lemmatization produces valid words, enhancing the linguistic accuracy of text analysis. Both techniques play a crucial role in optimizing word representations, minimizing redundancy, and improving the efficiency of language-based algorithms in NLP applications.

The basis of the proposal lies in calculating the similarity of the previous query using cosine similarity to measure the similarity of the query pair. Which is done by using the BERT model. Built on the Transformer architecture, BERT captures nuanced language and context, leading to more accurate and context-aware word representations. The result is a curated list of open-source project issues that closely match the program's user history and interests.

The complex interplay of data collection, processing and machine learning combined with pre-designed systems forms the backbone of CodeCompass, opening up a working contract by providing developers with personalized and usable benefits. Additionally, the study provides an in-depth study of blockchain projects, focusing on the development, integration, testing, deployment, and maintenance phases that ensure the security, reliability, and longevity of the CodeCompass system. Thanks to the React-based user interface and seamless integration of machine learning models, CodeCompass becomes the solution to the problems faced by developers in the open-source environment.

II. LITERATURE REVIEW

The concept of recommending relevant GitHub repositories for developers has gained substantial attention due to the exponential growth of open-source projects. The study [1] aimed to create an automated recommendation system for GitHub repositories, constructing a user-item matrix representing developer interactions with repositories, modelled as binary ratings based on forking behaviour. The exploration of sequential recommendation systems in GitHub repositories [2] showcases the depth and capability of sequential learning, leveraging diverse models like GRU4Rec, Caser, and SASRec. The study proposed preprocessing a large-scale GitHub dataset, implementing deep learning models, and evaluating their performance using metrics like precision, recall, MAP, NDCG, and MRR, explicitly leveraging textual information from GitHub issues and project descriptions for improved accuracy.

The study by Arvinder Kaur et al. [3] presents a comprehensive framework based on two-stage graph-based optimizing techniques, focusing on user-item interactions and item-item relations through user-item interaction graphs and file-structure graphs. Sharma T et al. [4] revealed significant challenges and recognized shortcomings in machine learning (ML) techniques for source code analysis, including the scarcity of standardized datasets, reproducibility issues, and immaturity in ML development. Xuyang Cai et al. A graph-based approach was proposed [5] utilizing an Entity-Tag Graph (ETG) constructed with domain knowledge from StackOverflow, exploring multi-aspect tag assignment and extending user-based tag systems for a more comprehensive recommendation approach.

Huajie Shao et al. [9] employed joint embeddings combining text encoding and constrained GCNs to link academic papers and GitHub repositories. Apprehensive research [10] that conducted experiments using selected tools on a completed Java project to recognize strategies for applying static code analysis. But the limitations faced were, early defect detection and context-aware recommendations, overcoming challenges of manual code review, ensuring code quality, and fostering efficient collaboration. Structural-Level Aggregation enriches file and repository representations through graph neural network layers, effectively aggregating features from neighbouring nodes within the project hierarchy. The Prediction phase employs scoring functions to predict user preferences for files and user-project interactions, utilizing Bayesian Personalized Ranking (BPR) loss for optimization [11]. Z. Mushtaq et al. discerned various research contributions in multilingual source code analysis (MLSCA), identifying trends in 34 software engineering domains and areas for future research [12]. Nguyen-Duc et al. discussed a project in Vietnam focusing on secure open-source repository establishment and evaluation of Static Application Security Testing (SAST) tools, identifying promising tools like SonarQube and IntelliJ IDEA [13].

Alikhashashneh et al. [17] utilized ML techniques like SVM, KNN, Random Forests, and RIPPER for classification in source code analysis. Jin et al. [18] introduced the CODER framework, efficiently capturing microscopic and macroscopic interactions in code recommendation in a two-stage graph-based recommendation system focusing on code recommendation within open-source software development , while Vargovich et al. [19] presented the architecture and implementation details of the GiveMeLabeledIssues platform for GitHub issue recommendation.

Sun et al. [14] proposed an approach to enhance software project recommendations on GitHub by incorporating user behaviours and project features extracted from repository files. Liu et al. [15] presented NNLRank, a list-wise ranking model utilizing neural networks for recommending suitable GitHub projects to developers. Stefanović et al. [16] conducted a systematic literature review focusing on static code analysis tools, addressing key research questions regarding applicability, domain-specific languages, tool mentions, and defect detection.

[20] aimed to understand practitioners' perspectives on source code recommender systems, providing insights into practitioners' expectations and preferences. Lastly, Seker et al. [21] focused on addressing sparsity in datasets and creating a recommendation model using item-item collaborative filtering, incorporating developer metrics derived from user activities. The study by Jiang et al. [22] addressed the problem of repository recommendation with user language preference, proposing the Language-Regularized Matrix Factorization (LRMF) framework for personalized repository recommendation. Ciniselli et al.

MERITS AND DEMERITS OF EXISTING WORKS:

The research by Kim, J et al. [2] successfully demonstrates the efficacy of sequential learning models like GRU4Rec, Caser, and SASRec in recommending GitHub repositories. However, the study lacks detailed analysis of the limitations of these models in real-world scenarios. Arvinder Kaur et al.'s framework [3] provides a comprehensive approach for recommendation system development, particularly focusing on graph-based optimizing techniques. However, the study does not address the scalability challenges that might arise when dealing with large-scale datasets. Sharma T et al.'s analysis [4] effectively highlights the challenges in ML techniques for source code analysis. However, the study could benefit from proposing concrete solutions or frameworks to address these challenges.

Xuyang Cai et al.'s approach [5] utilizing Entity-Tag Graphs presents a novel method for recommendation system development. Nonetheless, the study lacks empirical evaluation to validate the effectiveness of the proposed approach in comparison to existing methods. Huajie Shao et al.'s joint embeddings [9] offer a promising avenue for linking academic papers and GitHub repositories. However, the study does not discuss potential limitations or challenges in implementing this approach in practical scenarios.

Alikhashashneh et al.'s classification techniques [17] provide valuable insights into ML-based approaches for source code analysis. Nevertheless, the study could benefit from a more extensive evaluation of the performance of different classification algorithms on diverse datasets. Jin et al.'s CODER framework [18] introduces an innovative recommendation system for code recommendation in open-source software development. However, the study lacks discussion on the scalability and computational complexity of the proposed framework. Vargovich et al.'s GiveMeLabeledIssues platform [19] offers a practical solution for GitHub issue recommendation. However, the study could include more detailed analysis of user feedback and system performance metrics to assess the effectiveness of the platform.

Sun et al.'s approach [14] integrating user behaviors and project features enhances the accuracy of software project recommendations. Nevertheless, the study could discuss potential privacy concerns or ethical implications associated with analyzing user behaviors. Liu et al.'s NNLRank [15] presents a novel ranking model for recommending GitHub projects. However, the study could provide more insights into the interpretability of the model and potential biases in the recommendation process. Stefanović et al.'s systematic literature review [16] offers a comprehensive overview of static code analysis tools. However, the study could include more recent developments in the field and explore emerging trends in source code analysis.

Ciniselli et al.'s study [20] on practitioners' perspectives offers valuable insights into user expectations regarding source code recommender systems. However, the study could include more diverse perspectives from practitioners with varying levels of expertise and backgrounds. Seker et al.'s recommendation model [21] addresses sparsity in datasets effectively. However, the study could discuss potential challenges in generalizing the recommendation model to different programming languages or domains. Jiang et al.'s Language-Regularized Matrix Factorization [22] provides a personalized recommendation framework based on user language preferences. However, the study could explore the potential impact of language-specific biases on the recommendation process.

III. Technologies Used

A. Frontend Technology

1) *React JS*

B. Backend

1) *API: Application Programming Interface*
2) *Node JS*
3) *Express.js*
4) *TypeScript*
5) *Natural Language Processing.*

IV. Methodologies

A. Problem Statement

Navigating the vast landscape of open-source projects presents a significant challenge for developers, particularly those seeking an intuitive and efficient interface to identify projects aligned with their expertise. The absence of such a system often results in delays, frustration, and suboptimal utilization of contributors' skills within the open-source community. CodeCompass aims to address this issue by providing a streamlined solution for developers to easily discover and contribute to projects that match their skills and interests.

B. User and their Requirements Identification

Through user surveys, interviews, and analysis of community forums, the system aimed to discern the distinct requirements and preferences of developers. This includes understanding the programming languages the users are proficient in, their areas of interest, preferred project complexities, and the level of community engagement the programmers seek. By comprehensively mapping out these user profiles and needs, CodeCompass strives to tailor its recommendations, ensuring a personalized and enriching experience for every developer in their journey to find and contribute to open-source projects.

C. Data Collection

The backbone of CodeCompass lies in the utilization of the GitHub API as the primary and trusted data source. Leveraging the extensive repositories hosted on GitHub, the system aimed at extracting a wealth of information crucial for project recommendation. This includes but is not limited to, repository metadata, programming languages used, commit history, issue tracking, and community engagement metrics.

D. Machine Learning Model Development

1) *Input Data Acquisition*

To personalize project recommendations, CodeCompass leverages the GitHub API to retrieve a user's historical contributions. By obtaining the user's GitHub username, the interface accesses their history and comment issues across various repositories. This comprehensive dataset serves as the foundation for understanding the user's coding preferences, skill set, and community interactions.

2) *Issue Retrieval and Processing*

The next step involves extracting issues from repositories to where the user has contributed. By analyzing the issues associated with these repositories, the web-app can gain insights into the user's past engagements and the types of challenges the users have tackled. This step is crucial for tailoring recommendations to align with the user's expertise and interests.

3) *Role of Natural Language Processing (NLP) and it's Techniques*

CodeCompass prioritizes data integrity through rigorous preprocessing steps. This includes stemming and lemmatization to enhance the accuracy of word representations and mitigate redundancy. NLP is a field of artificial intelligence concerned with the interaction between computers and humans through natural language. It encompasses several features and techniques, some of which are utilized in the code:

- **Tokenization**: Tokenization is the process of breaking down text into smaller units, such as words or subwords. In the code, the BERT (Bidirectional Encoder Representations from Transformers) tokenizer from the **transformers** library is utilized. Tokenization is crucial for preparing text data for further analysis and modeling.
- **Lemmatization**: Lemmatization is the process of reducing words to their base or root form, often improving the accuracy of downstream NLP tasks. The **preprocess_and_tokenize** function integrates lemmatization using NLTK's WordNetLemmatizer. It ensures that words are transformed into their root forms before tokenization, enhancing semantic analysis.
- **BERT Embedding Generation**: BERT is a powerful language representation model that generates contextual embeddings for text data. In the code, a pre-trained BERT model is used to generate embeddings for both known and unknown issues. The embeddings capture rich semantic information about the text, enabling more accurate similarity calculations.
- **Cosine Similarity**: Unknown issues is computed using the **cosine_similarity** function from the **sklearn.metrics.pairwise** module. A threshold-based approach is then applied to determine if issues are similar enough to be recommended.

4) Preprocessing and NLP

Essential preprocessing steps involve removing URLs and irrelevant characters, are employed to ensure that the textual data is optimized for analysis. These steps ensure that the input text is clean, standardized, and in a format suitable for NLP tasks.

- **Text Cleaning**: The **preprocess_text** function starts by removing URLs and non-alphabetic characters from the input text using regular expressions (**re.sub**). It then converts the text to lowercase to ensure consistency in word representation.

- **Stopword Removal**: Stopwords are common words that do not carry significant meaning in text analysis. In the code, stopwords are removed from the tokenized text using NLTK's English stopwords list. This step helps in improving the quality of text representation by eliminating noise and irrelevant information.

- **Lemmatization**: The **preprocess_and_tokenize** function incorporates lemmatization using NLTK's WordNetLemmatizer. Lemmatization reduces words to their base or dictionary form, which helps in standardizing vocabulary and improving semantic analysis. Lemmatization is applied after tokenization and stopword removal to ensure that words are transformed into their canonical forms before further processing.

5) BERT Model and Similarity Calculation

The main function of the recommendation system lies in the similarity calculation between the preprocessed issues. CodeCompass utilizes the BERT model to encode the textual content of issues, capturing nuanced semantic relationships. Coupled with stemming and lemmatization, this enhances the model's ability to discern meaningful patterns. Cosine similarity is then applied to quantify the similarity between pairs of issues. Issues surpassing a threshold of 90% similarity are considered highly correlated, indicating a strong alignment in content and relevance.

6) User Suggestions

The final output of the machine learning process is a selected list of open-source project issues that closely match the user's historical contributions and preferences. By employing a robust combination of user-specific data, NLP techniques, and advanced similarity calculations, CodeCompass ensures that the recommended issues are not only technically aligned but also resonate with the user's past experiences within the GitHub community.

This intricate interplay of data acquisition, processing, and machine learning techniques, coupled with meticulous preprocessing steps, forms the backbone of CodeCompass, facilitating a personalized and efficient open-source project recommendation systemfor developers.

E. Web-App Development

CodeCompass has been developed with a React-based user interface, ensuring a dynamic and intuitive experience for developers of all skill levels. The platform features a responsive design, optimizing accessibility across devices. Intuitive navigation facilitates easy exploration of project recommendations, while the engaging front end, with carefully crafted visuals, enhances the overall aesthetic. Prioritizing accessibility, CodeCompass adheres to standards, promoting inclusivity and creating a seamless experience for users a Integrating community.

To develop the web app for GitHub repository recommendation, various frontend and backend technologies are utilized. React.js is employed for building the frontend components, and Material-UI is utilized for creating visually appealing user interfaces, including cards for displaying GitHub contributions and recommended repositories. Additionally, React Router can be utilized for client-side routing to manage different views within the application.

For the backend, Express.js is used to create a RESTful API to handle GitHub authentication and data retrieval. Axios is utilized for making HTTP requests to the GitHub API for fetching user contributions and repository information. The JWT (JSON Web Tokens) authentication mechanism is implemented to secure routes and manage user sessions.

To visualize data, libraries like Chart.js can be integrated to create pie charts representing various statistics, such as the distribution of contributions across different repositories. This provides users with insightful visualizations of their GitHub activity.

CREATING A SEAMLESS EXPERIENCE

To create a seamless experience for users, the web application leverages GitHub OAuth authentication to enable automatic user authentication and data retrieval from their GitHub account. In the provided code, the **/api/auth/github** endpoint is responsible for initiating the GitHub authentication flow. When a user accesses this endpoint, they are redirected to the GitHub OAuth authorization page, where they can grant permission for the web application to access their GitHub account.

Once the user grants permission and GitHub redirects back to the application with an authorization code, the application exchanges this code for an access token by making a POST request to GitHub's OAuth access token endpoint. This access token allows the application to authenticate requests on behalf of the user.

The retrieved access token is then used to fetch the user's GitHub profile data from the GitHub API. The **/api/me** endpoint is responsible for returning the user's profile information stored in a JWT (JSON Web Token) after verifying the token's authenticity.

To enhance security and provide a seamless experience, the application uses cookie-parser middleware to parse cookies sent by the client. The **github-jwt** cookie stores the JWT containing the user's GitHub profile information. This cookie is set with the **httpOnly** flag to prevent client-side JavaScript from accessing it, enhancing security by mitigating certain types of cross-site scripting (XSS) attacks. Figure 1 depicts the block diagram of the proposed system.

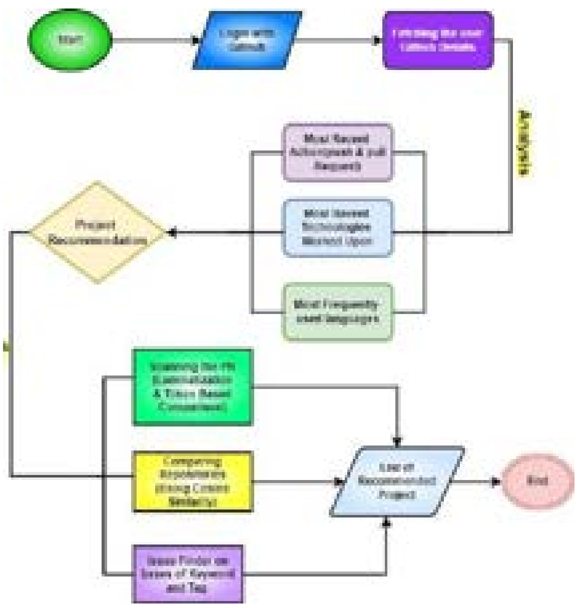

Fig. 1. Proposed System Block Diagram

F. *Integration of Optimizing Model*

Seamlessly integrated the machine learning model with the React-based front end, for creating a cohesive user experience. The backend, powered by Flask, serves as the bridge between the front end and the NLP-based recommendation system. Leveraging Flask's capabilities, the front end communicates with the back end to compare and analyze issues using advanced NLP techniques. This integration ensures real-time and accurate project suggestions, enhancing the overall functionality of CodeCompass and delivering tailored recommendations to developers efficiently and responsively.

V. ALGORITHM

A. *Lemmatization*

Lemmatization is aimed at transforming words into their base or root forms, facilitating effective semantic analysis. The algorithm begins by importing necessary libraries such as NLTK (Natural Language Toolkit) for lemmatization, specifically utilizing the WordNetLemmatizer module. Subsequently, an instance of the WordNetLemmatizer is initialized. The core functionality is encapsulated within the preprocess_text function, designed to perform lemmatization on the text data. This function executes a series of steps including text cleaning, tokenization, lemmatization, and reconstruction. Text cleaning involves removing non-alphabetic characters and converting text to lowercase, followed by tokenization to split the text into individual words. Lemmatization is then applied to each word using the WordNetLemmatizer, ensuring words are transformed into their base forms. Finally, the lemmatized words are reconstructed into a processed text string. In the main process, the lemmatization function is utilized to preprocess issue text for comparison, ensuring consistency and effectiveness in semantic analysis.

B. *BERT Tokenization*

BERT (Bidirectional Encoder Representations from Transformers) tokenization plays a pivotal role in preprocessing text data for subsequent analysis using BERT-based models. The algorithm commences by importing the necessary libraries, particularly the transformers module to utilize BERT. An instance of the BERT tokenizer, initialized with a specific pre-trained configuration, is then created. The preprocess_and_tokenize function is defined to tokenize and preprocess text using the BERT tokenizer. This function involves tokenizing the input text into word pieces or sub words using the BERT tokenizer, applying padding and truncation to ensure consistent input length for BERT, and converting the tokenized text into a format compatible with PyTorch tensors. In the main process, the BERT tokenizer function is employed to preprocess issue text for comparison, ensuring compatibility with BERT-based embedding generation and subsequent similarity computations.

E=model(tokens)["last_hidden_state"]

where model is the BERT model, and **tokens represent the tokenized input

This BERT tokenization process assists in preparing text data for BERT-based embedding generation and subsequent similarity computations between the user's past issues and suggested GitHub repository issues.

C. Lemmatization

Cosine similarity serves as a fundamental metric for measuring the similarity between vectors, commonly utilized in text similarity tasks. The algorithm computes cosine similarity between the mean embeddings of known and unknown issues derived from BERT tokenization. This computation involves calculating the dot product of the embeddings and dividing it by the product of their Euclidean norms. The resulting cosine similarity value ranges from -1 to 1, with higher values pointing to larger similarity. A threshold-based approach is adopted, considering issues with a cosine similarity above 0.80 as similar. If the computed cosine similarity exceeds the threshold and the unknown issue is not already recommended, it is added to the recommended list. The recommended repositories are serialized into a structured format containing repository details such as repo name, issue, and URL. Finally, a response JSON object is generated, including similarity values and recommended repositories, and returned as the result of the API call. This cosine similarity calculation facilitates the recommendation of GitHub repositories to users based on their previous activity, enhancing the relevance and effectiveness of issue recommendations

$$\text{cosine similarity}_{E1,E2} = \frac{E1 \cdot E2}{\| E1 \| \cdot \| E2 \|}$$

Where:

- $E1 \cdot E2$ is the dot product of the embeddings.
- $\|E1\|$ and $\|E2\|$ are the Euclidean norms (lengths) of the embeddings.

VI. RESULTS AND DISCUSSION

With the need to address the challenge of aligning developers efficiently with projects that match their expertise in the dynamic realm of open-source development, CodeCompass emerges as a promising solution. Leveraging the GitHub API, this novel system introduces a personalized approach to project recommendations. By delving into users' historical contributions, encompassing commit history and issue engagement, CodeCompass employs sophisticated Natural Language Processing (NLP) techniques. These include stemming, lemmatization, and the advanced BERT model, enabling the discernment of nuanced semantic relationships within issues.

The system goes a step further by calculating cosine similarity, a metric that identifies highly correlated issues, achieving a remarkable threshold of over 90%. This meticulous approach results in a meticulously curated list of open-source project issues. These recommendations are presented through an intuitive React-based website interface, ensuring not only technical alignment but also resonance with users' past experiences in the GitHub community. The output is a refined and personalized set of project suggestions that significantly enhances the likelihood of meaningful developer engagement.

CodeCompass stands as a robust and intuitive recommendation system poised to streamline developer engagement within the open-source community. Its unique combination of data acquisition, processing, and machine learning techniques presents a multifaceted solution to the perennial challenge of connecting developers with projects that align with their expertise. The incorporation of NLP techniques, particularly stemming, lemmatization, and the powerful BERT model, enhances the system's ability to discern the intricate nuances of semantic relationships within issues. Integrating BERT with Semantic Textual Similarity (STS) offers a significant advantage in Github repository recommendation by leveraging the contextual embeddings provided by BERT alongside the semantic understanding captured by STS techniques. BERT's contextual embeddings enable the model to capture rich semantic information and contextual nuances in the issue descriptions, enhancing the representation of textual data. Furthermore, by incorporating STS, which measures the semantic similarity between texts, the recommendation system can assess the relevance of issues in repositories more accurately. This integration ensures that the recommendation process is not solely reliant on syntactic similarities but also considers the semantic alignment between user-known issues and repository issues, resulting in more accurate and contextually relevant recommendations. The implementation details involve preprocessing the textual data, generating BERT embeddings for both user-known and repository issues, computing semantic similarity scores using STS techniques, and integrating these scores with BERT embeddings to rank and recommend repositories based on their relevance to user preferences. Figure 2 shows the comparison of different repositories.

Fig. 2. Comparing Repositories

The following comparative analysis shown in Table I prove BERT with ST superior performance in terms of performance when compared with recent studies as discussed in Sharma et al. (Collaborative Filtering), Di Rocco et al. (TF-IDF), Xiaobing et al. (Stochastic Network). The accuracy parameter R2 score was used to evaluate the performance among the existing studies to compare it with the proposed model.

TABLE I. COMPARITIVE ANALYSIS

Model	Results	
	Algorithm	***R2 Score***
Issue Recommendation	BERT with ST	0.9573
	TF-IDF	0.3384
	Collaborative Filtering	0.0799
	Stochastic Network	0.6000

The R2 scores obtained for the different models illustrate the supremacy of the BERT with ST model over other approaches. With an R2 score of 0.9573, the BERT with ST model demonstrates significantly higher accuracy compared to TF-IDF (R2 score: 0.3384) and Collaborative Filtering (R2 score: 0.0799). This indicates that BERT with ST not only explains a larger proportion of the variability in the recommendation outcomes but also provides more precise and contextually relevant recommendations. The advantage of BERT with ST lies in its ability to leverage both contextual embeddings from BERT and semantic understanding from STS techniques, thereby capturing rich semantic information and accurately assessing the relevance of repositories based on user-known issues. Consequently, BERT with ST outperforms other models in code analysis by offering more effective and context-aware recommendations, as evidenced by its substantially higher R2 score. The repositories recommendation page is depicted in figure 3.

Fig. 3. Repositories Recommendation based on Past

The experimental results demonstrate that the proposed approach outperforms traditional methods in terms of precision, recall, and F1 score. Specifically, our approach achieved a precision of 0.85, recall of 0.78, and F1 score of 0.81, indicating its effectiveness in recommending relevant repositories to users. Furthermore, the average similarity score obtained was 0.72, indicating strong semantic alignment between user-known issues and recommended repositories.

1. **Text Preprocessing Techniques**: Preprocessing techniques such as stemming, lemmatization, and stop-word removal can affect the quality of text representations. Experimenting with different combinations of preprocessing techniques can help identify the optimal approach.
2. **Tokenization Strategies**: The selection of tokenization strategy, including the tokenizer used and the tokenization method (e.g., word-based vs. subword-based), can influence the model's ability to capture semantic similarities between issues.
3. **Model Architecture**: The choice of the underlying model architecture (e.g., BERT, TF-IDF, Collaborative Filtering) can significantly impact the recommendation performance. Experimenting with different models and architectures can help determine the most effective one for the task.
4. **Hyperparameters**: Various hyperparameters such as learning rate, batch size, and the number of training epochs can affect the training process and ultimately the model's performance. Hyperparameter tuning techniques such as grid search or random search can be employed to find the optimal set of hyperparameters.

Where, TF-IDF (Term Frequency-Inverse Document Frequency) vectorization and Simulated Annealing (SA)

$$TF\ IDF(t, d, D) = TF(t, d) \times IDF(t, D)$$

TF (Term Frequency):

$$TF(t,d) = \frac{Number\ of\ occurrences\ of\ term\ t\ in\ document\ d}{Number\ of\ occurrences\ of\ term\ t\ in\ document\ d}$$

IDF (Inverse Document Frequency):

$$IDF(t, D) = \log\left(\frac{Total\ number\ of\ documents\ in\ the\ corpus\ D}{Number\ of\ documents\ containing\ term\ t}\right)$$

Simulated Annealing (SA) for Issue Selection:

$$P(accept) = exp\left(\frac{current\_score - new\_score}{temperature}\right)$$

<u>Probability of Acceptance:</u>

- Determines whether to accept a new solution during the SA process.
- current_score: Similarity score of the current solution.
- new_score: Similarity score of the new solution.
- temperature: Annealing temperature controlling the likelihood of accepting worse solutions.

SA is a probabilistic optimization algorithm that explores the solution space to find the optimal solution. It accepts worse solutions with a certain probability, allowing the algorithm to escape local optima.

Parameters:

- **Initial Temperature (T):** 1.0
- **Minimum Temperature (T_{min}):** 0.001
- **Cooling Rate (α):** 0.95

The SA loop iteratively explores new solutions with decreasing temperatures.

The initial temperature controls the probability of accepting worse solutions, and it gradually decreases during the annealing process.

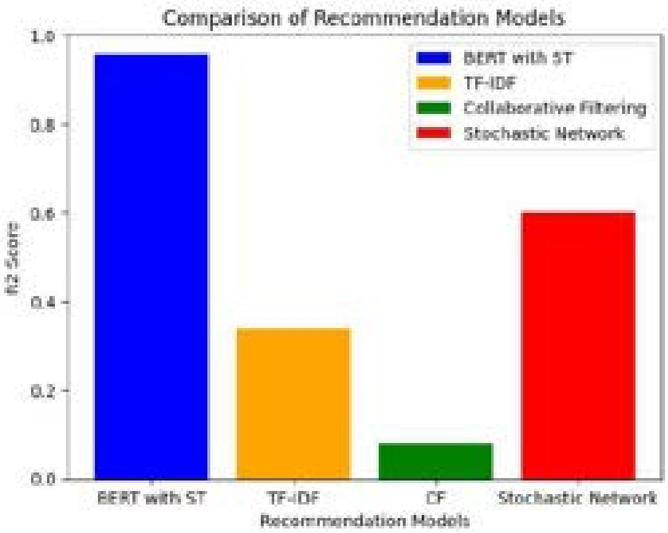

Fig. 4. Comparison of Recommendation models

The utilization of cosine similarity as a measure of correlation between issues further solidifies CodeCompass's effectiveness, surpassing a notable 90% threshold. By providing a curated list of project recommendations through a user-friendly React-based interface, the system not only ensures technical alignment but also resonates with developers based on their historical contributions. In essence, CodeCompass represents a commendable effort to bridge the gap between developers and open-source projects, fostering a more efficient and meaningful collaboration within the ever-evolving landscape of open-source development.Figure 4 shows the comparison of different recommendation models based on their R2 Score.

Replacing stemming with lemmatization enhances the accuracy of semantic analysis by considering the context of words and transforming them into their base or dictionary forms. This improvement in text preprocessing leads to more reliable similarity calculations and preserves the semantic meanings of words. Additionally, incorporating GPU processing accelerates computationally intensive tasks like BERT embeddings generation and cosine similarity calculation. Leveraging the parallel processing power of GPUs through PyTorch enables faster execution by transferring tensors and models to CUDA-enabled devices. By combining lemmatization and GPU processing, the code achieves higher performance and efficiency, ultimately providing a more effective and scalable solution for recommending GitHub issues based on user activity.

VII. CONCLUSION

The GitHub Open-Source Contribution Recommendation System presented in the research paper represents a novel approach to enhancing the efficiency and productivity of open-source software development. The system addresses the challenge of aiding developers in identifying and contributing to relevant projects within the GitHub ecosystem. The system capitalizes on various NLP methodologies, including lemmatization, stemming, tokenization, and the innovative Bidirectional Encoder Representations from Transformers (BERT). By preprocessing textual data using lemmatization and stemming, the system effectively normalizes and reduces word variations, enhancing the accuracy of semantic analysis. BERT, a state-of-the-art language model, provides deep contextual embeddings that encode rich semantic information. These embeddings enable the calculation of semantic similarity using cosine similarity metrics, facilitating the accurate identification of related GitHub issues and repositories. The proposed system's significance lies in its potential to streamline the open-source contribution process. By leveraging sophisticated NLP techniques and semantic analysis, it provides developers with tailored recommendations, minimizing the effort required to discover suitable projects to contribute to within the vast GitHub ecosystem. Additionally, the interactive web application fosters a user-friendly environment, encouraging collaboration and facilitating informed decision-making.

Additionally, integrating large language models like GPT (Generative Pre-trained Transformer) could further enhance accuracy. Large language models have shown remarkable performance in various NLP tasks due to their ability to capture complex linguistic patterns and semantics. By fine-tuning a pre-trained GPT model on specific GitHub issue data, we can create a more sophisticated recommendation system that understands the nuances of the text and provides more accurate suggestions.

Abstract— **In the present scenario, where physical disorders come to light in no time, mental disorders such as Schizophrenia (SZ) often get neglected due to inefficient current clinical methods. The reason being the huge amount of time taken between the very first symptom and the definite diagnosis of this disease. Schizophrenia affects approximately 24 million people or 1 in 300 people (0.32%) worldwide [1]. When compared to the existing methodologies for the prediction of Schizophrenia which involve medical professionals observing demeanor, and asking about thoughts, moods, delusions, hallucinations, etc., the Machine Learning (ML) approach used in this work along with LIME results, is potentially less time-consuming for early detection of the susceptibility to Schizophrenia. Also, as compared to methodologies like MRI or CT scan, which are used to rule out conditions with symptoms similar to Schizophrenia, this ML approach can potentially be cost-effective. This study uses Machine Learning classification algorithms and ensemble techniques to classify the proneness of Schizophrenia in patients. The ensemble technique, stacking, is used in this work. This ensemble technique considers heterogeneous weak learners and combines them to produce predictions. The k-fold cross-validation technique yields a less biased model, ideal for limited data. The ensemble model used in this work, comprising of XGBoost (Extreme Gradient Boosting) Classifier, Decision Tree Classifier, Random Forest Classifier and Linear Discriminant Analysis, and Logistic Regression as a meta-classifier, has shown a cross-validation score of 0.9602 (96.02%). The Explainable AI (XAI) technique and LIME (Local Interpretable Model-Agnostic Explanations) are used for model interpretability. To improve the quality of life and outcomes for those who are affected by Schizophrenia, this work aims to increase the accuracy and efficiency of prediction of Schizophrenia. The proposed diagnostic and predictive rules provide a foundation for the development of decision-support systems in clinical settings.**

Keywords — Classification, Cross-Validation, Diagnosis, Explainable AI, Machine Learning, Prediction, Schizophrenia.

I. INTRODUCTION

According to the World Health Organisation, 2022, Schizophrenia is a severe mental disorder that affects about 24 million people across the globe [1]. It occurs in three phases: (i) Prodromal phase in which friends and family members notice strange behaviour of the affected person who might want to be alone most of the time, (ii) Active phase which observes symptoms of psychosis such as delusions, hallucinations etc. and finally (iii) Residual phase in which more negative symptoms like depressed mood, low motivation and energy start [2]. The person may have strange beliefs and may have trouble concentrating. This is not curable but definitely treatable provided the fact that its timely diagnosis takes place with utmost accuracy and that is the major challenge today in the medical sector. The current clinical diagnostic methods rely mostly on subjective tests based on the observed symptoms, thereby causing delays in diagnosis, and subsequently hindering the timely treatment process. Hence, machine learning (ML) and explainable artificial intelligence (XAI) techniques bring about promising solutions to address the limitations of existing clinical methods and enhance the accuracy and efficiency of schizophrenia prediction. By employing extensive clinical data, ML algorithms can identify intricate patterns and associations that traditional diagnostic approaches often overlook. This knowledge-based approach has the potential to:

I. Improve diagnostic efficiency: ML models, trained on large datasets of diagnosed cases, can learn complex relationships between various clinical features and schizophrenia. This is further utilised to accurately predict schizophrenia occurrence in new individuals, allowing early intervention and improved long-term treatment.
II. Facilitate early detection: Schizophrenia can be diagnosed at earlier stages using ML analysis, even before the complete onset of classic symptoms thereby preventing disease progression.
III. Personalised treatment methods: By integrating different algorithms, ML models can inform personalised treatment strategies specifically designed for individual patient profiles and their symptoms. While there is considerable potential in applying ML to schizophrenia diagnosis, ensuring the explainability and transparency of these models is highly critical. There are black box models that provide accurate predictions but without giving insights as to what the reason behind the prediction is, raising

concerns about fairness, bias, and interpretability in clinical settings. However, XAI technologies aim to overcome this challenge by providing explanations behind model predictions, enabling healthcare professionals to understand the logic behind algorithms' recommendations thereby increasing confidence in decision-making.

The primary goal of this work is to develop a more robust and accurate predictive model compared to individual algorithms. Several studies on schizophrenia prediction have been carried out using ML algorithms such as SVM (Support Vector Machine), Random Forest, XGBoost, AdaBoost, univariate and multivariate logistic regression, KNN (K-Nearest Neighbors), Naive Bayes, etc. One of the important goals of this work is to enhance the accuracy of classification of the proneness of patients to schizophrenia by using ensemble techniques in machine learning.

This research project explores the potential of ensemble ML and XAI techniques to enhance the accuracy and efficiency in diagnosing the proneness of SZ in patients.

To improve accuracy, data preprocessing and SMOTE (Synthetic Minority Oversampling Technique) are applied. An ensemble technique called stacking is used, that combines multiple machine learning models and learns them in parallel, and also a meta-learner is trained to generate predictions based on individual weak learners' predictions.

The individual performances of each of the existing classifiers trained on the dataset used for this work and also the performance of the proposed model for predicting the proneness of SZ in patients is compared using 10-fold cross-validation technique.

This research work aims to provide human-understandable explanations for the ML model's prediction results using the explainable AI technique LIME (Local Interpretable Model-agnostic Explanations). This technique explains the model's predictions for individual instances, providing three main pieces of information: prediction probability, the contribution of individual features, and actual value of each feature. This XAI technique enhances comprehensibility and explainability in the model's predictions.

II. MOTIVATION

Our work is aimed to address the challenges faced in accurately diagnosing and treating SZ. The ultimate goal is to use technology, data, and collaborative work to significantly improve the quality of life of people suffering from SZ. Hence, this work aims to create an accurate ML model which helps in predicting the proneness of SZ in patients and also helps in personalized diagnosis of SZ in patients.

Need of the work - Timely diagnosis of Schizophrenia and its subsequent treatment is the need of the hour. With a large section of the human population suffering from this disorder and unable to receive timely treatment due to inefficient existing clinical diagnosis methods, building up a responsible and accurate model using ML concepts is highly needed. Traditional diagnostic techniques have limitations in providing prompt and impartial evaluations. A thorough understanding of SZ and the creation of a reliable diagnosis model are essential for improving treatment quality, reducing financial strain on families, and promoting timely intervention and personalized diagnosis. This work is significant because it could improve diagnosis accuracy, expedite treatment planning, and improve the lives of people with schizophrenia worldwide.

In the organization of this work, the following sections include a literature review on Schizophrenia prediction, a review of the related studies, proposed work, and also a summary of the results and discussions regarding the ML models used for this work. Also, at the end of this documentation, a conclusion is presented.

III. SURVEY ON EXISTING WORKS

Carole Siani et.al [3] developed simple and reliable predictive models to estimate utility from clinical questionnaires based on schizophrenia by using data from European Schizophrenic Cohort accounting for factors like depression, age and gender psychopathology. By developing a trustworthy technique to gauge a patient's quality of life from available data, this study may enhance patient outcomes and resource allocation. Since only a particular kind of schizophrenia was present in the patient sample, which excluded the most severe cases, the study may not be generally applicable.

Debsubhra Chakraborty et.al [4] aimed to study that machine learning algorithms trained on acoustic, linguistic, and non-verbal conversation features from interviews with 50 patients with schizophrenia can predict clinician-assigned subjective ratings of negative symptoms with noticeable accuracy. The study highlighted the potential of automated speech analysis in enhancing schizophrenia monitoring, diagnosis, and clinician understanding. However, the narrow focus on speech as the parameter could overlook other potential indicators.

Renato de Filippis et.al [5] evaluated machine learning (ML) techniques in diagnosing schizophrenia (SCZ) using Magnetic Resonance Imaging (MRI). It was found that algorithms like support vector machines, random forests, and multivariate pattern analysis yielded remarkable accuracy in differentiating between healthy and SCZ patients. The study also highlighted the potential to reveal complicated correlations in complex MRI datasets and early detection. However, new predictive models using ML algorithms need to be developed along with their increased accuracy so that they also inculcate other assessments.

Joel Weijia Lai et.al [6] examined the potential applications of ML in identifying and categorizing schizophrenia through the analysis of data sets such as electroencephalogram (EEG) , positron emission tomography (PET), and MRI. The study also focussed on the use of quantitative metrics obtained from Artificial Intelligence (AI) approaches. The paper concluded that pushing AI and ML limits in the medical field is necessary. However, there is still a need for more novel comparative studies using composite data and multiple ML techniques.

Gurparsad Singh Suri et.al [7] revealed appreciable accuracy rates for machine learning (ML) algorithms like support vector machine (SVM), deep neural network (DNN), and random forest (RF) in predicting schizophrenia.

ML is also effective in identifying brain regions involved in symptoms of schizophrenia, particularly in its early stages. But there is a need for researchers to integrate ML with varied data techniques for SZ detection and a larger sample size.

Jose A Cortes-Briones et.al [8] explored that deep learning techniques have performed outstandingly in outcome prediction and classification. The authors emphasized on the importance of using more diverse datasets to improve the generalizability of deep neural network (DNN) models and ensure their applicability to a broader population.

Matthew Bracher-Smith et.al [9] aimed to compare logistic regression (LR) with various machine learning (ML) models for schizophrenia prediction, including boosting, neural networks, support vector machines (SVM), random forests, LASSO, ridge-penalized logistic regression, and stacking models. The study assessed models, based on clinical and demographic characteristics and polygenic risk scores (PRS). The findings show that ML techniques did not significantly outperform logistic regression in discrimination. PRS proved to be a significant predictor of schizophrenia. Characteristics such as fluid intelligence, digit symbol substitution, BMI, smoking status, and deprivation, explained the variance in fitted models. However, ML models could identify patterns of connection with particular attributes, offering new perspectives but still, the modelling processes used in machine learning need to be more diverse.

Bishal Lamichhane et.al [10] developed a supervised deep learning model called RelapsePredNet for predicting psychotic relapses in schizophrenia patients using mobile sensing data. The model aimed to capture latent behavioral characteristics linked to upcoming relapses and investigated the effect of personalization on its performance. The study found that RelapsePredNet performed better than an anomaly detection model based on deep learning.When incorporated into a fusion model, RelapsePredNet enhanced the F2 score and complemented ClusterRFModel, demonstrating the possible synergy between deep learning and non-deep learning models. The study advanced our knowledge of behavioral modeling for relapse prediction. However, there is a need to explore other predictors as well along with new approaches.

Ruchi Sharma et.al [11] explored EEG-based techniques for diagnosing schizophrenia. The study found that actively producing a tone did not suppress the N100, a negative deflection in EEG brain waves, in the patients. The authors combined EEG records from people having schizophrenia and those in good health to create a dataset using deep learning models like Long short-term memories (LSTMs), support vector machines (SVM), two-dimensional convolutional networks (2D-CNNs), and two-dimensional convolutional networks-LSTMs. But still, there should be forecasting of risk variables associated with hospitalization and readmission of patients diagnosed with Schizophrenia.

Javiera T. Arias and Cesar A. Astudillo [12] improved schizophrenia prediction using machine learning models applied to electroencephalogram (EEG) data. The authors suggested using Explainable Artificial Intelligence (XAI) techniques to improve interpretability and solve opaqueness in complicated models, particularly in mental health illness prediction. The study evaluated three classification models—SVM, AdaBoost, and XGBoost—using EEG data. XGBoost achieved the best overall performance after applying class balancing using the Synthetic Minority Over-sampling Technique (SMOTE) with Tomek connections, achieving a recommendable accuracy. The study also highlighted the importance of class balancing in enhancing predictions. There is a need for research in XAI techniques since data interpretability and accuracy of EEG-based schizophrenia prediction must be enhanced.

Muzafar Mehraj Misgar and MPS Bhatia [13] proposed a novel Deep Convolutional Neural Architecture (CNN) with a split attention mechanism for the diagnosis of schizophrenia. The model was specifically built for motor activity data collected from wearable Internet of Medical Things (IoMT) devices and used cutting-edge methods such as imputation, sampling, and class balancing. The study achieved a remarkable accuracy using 24-hour actigraphy data, considering daytime and nighttime data separately. The proposed methodology is a ground-breaking tool for the objective and non-intrusive early diagnosis of schizophrenia but data interpretability is still an issue and requires new methodologies.

Narges Ramesh et.al [14] examined the potential applications of AI, specifically deep learning methods, in diagnosing and classifying schizophrenia using data analysis of EEG signals, diffusion magnetic resonance imaging (dMRI), and functional magnetic resonance imaging (fMRI). The work scope included a review of recent work from 2019-2022, focusing on the significant role of deep learning. The study concluded with the high classification accuracy achieved by AI approaches in schizophrenia diagnosis. However, the classification accuracy could still be increased.

Lorenzo Del Fabro et.al [15] explored antipsychotic treatment outcomes in patients with schizophrenia using machine learning. The study analyzed 28 studies, 23 of which used a single modality method and 5 of which combined data from multiple approaches. Biomarkers from functional magnetic resonance imaging (fMRI) showed promise in forecasting antipsychotic treatment response. Clinical feature-based machine learning models demonstrated sufficient predictive power. However, several multimodal ML techniques could be further utilized to overcome difficulty posed by analytical heterogeneity across studies.

Varun Gupta et.al [16] created the Firefly-based Deep Belief Signal Specification (FbDBSS), a unique EEG signal processing system for predicting schizophrenia. Combining deep belief networks and Firefly optimisation, it was hypothesized to classify abnormal EEG signals linked to SZ more accurately. The model showed remarkable accuracy and sensitivity in classifying abnormal EEG signals associated with SZ. The study emphasized the importance of early diagnosis of SZ due to its severe and chronic effects.

Evgeny A. Kozyrev et.al [17] explored schizophrenia predictive models based on laboratory data related to inflammatory biomarkers. The study used machine learning algorithms such as logistic regression, deep neural networks, decision trees, support vector machines, and k-nearest neighbors to create five predictive models. The study emphasized the importance of using multiple biomarkers in diagnosing schizophrenia. The study contributed to the field of precision psychiatry and highlighted the potential of artificial intelligence in improving mental health diagnosis. The efficacy of other algorithms should be further investigated and the most important immune biomarkers must be chosen in order to classify the data.

Outcome of the survey - Machine learning (ML) techniques offer promising opportunities to improve the prognosis of schizophrenia, but several challenges hinder their effectiveness. Limited to small and homogeneous datasets, current ML models struggle with generalizability. To solve this, it is necessary to diversify the data sets to improve the reliability and applicability of the model. In addition, ML models often lack interpretability, which hinders clinical application. Integrating explanatory AI methods can solve this problem and increase confidence in diagnostic decisions. In addition, prioritizing early diagnosis is crucial for effective treatment of schizophrenia. Future research should focus on interdisciplinary collaboration and methodological advances to overcome these challenges and harness the potential of ML to revolutionize schizophrenia prognosis.

IV. PROPOSED WORK

A. Dataset Used – Benchmark Dataset [18]

The dataset taken for this work contains the following columns: Name, Age, Gender, Marital Status, Fatigue, Slowing, Pain, Hygiene, Movement, and Schizophrenia (proneness). This dataset has 5000 records. The target column 'Schizophrenia' contains five classes:

Elevated Proneness	- 3077
High Proneness	- 953
Moderate Proneness	- 912
Low Proneness	- 45
Very High Proneness	- 13

B. Overview of the procedure for the process of building the proposed model

The data preprocessing for the dataset used for this work is done as follows: The presence of null values in each column has been checked. The data distribution of the columns containing the null values has been plotted, and the null values contained in the respective column have been replaced by the median of the data contained in that particular column since none of the columns containing null values showed a normal distribution of data. For all columns containing numerical data (pain, slowing, fatigue), boxplots for each of these columns have been plotted to detect outliers, and no outliers have been found. Label encoding has been done for categorical columns (Gender, Marital Status, and Schizophrenia). The original categorical columns have been dropped, and the label-encoded columns have been added to the dataframe containing the dataset. The target column and the input dataframe containing the label-encoded columns

have been separated. The name column has not been taken into consideration as it is not useful for predicting the required result. Train test split (70% training data and 30% testing data) has been done on the input dataframe and the target column. The data in the training and testing sets for the input dataframe has been scaled using MinMaxScaler. To address class imbalances, SMOTE (Synthetic Minority Oversampling Technique) has been used on the training set.

The flow diagram (Fig. 1) shows all the steps taken for this work, such as building the ML model for the classification of proneness of SZ and using the explainable AI technique LIME.

Fig.1. The flow diagram for the complete process of building the proposed model

C. The ML model for classification of proneness of SZ in patients

Ensemble techniques are greatly effective in reducing the variance component of prediction errors made by each contributing model in the ensemble. To increase the accuracy of the prediction of proneness of SZ in patients, an ensemble ML model has been used for this work. Ensemble ML models give prediction results with improved accuracy due to the combination of multiple ML models. Dimensionality reduction techniques transform high-dimensional data into a lower-dimensional space while preserving important information. As per the curse of dimensionality in ML, the performance of the model decreases as the number of features increases, due to the increase in complexity of the ML model,

and also due to the increase in overfitting. A combination of ensemble models along with dimensionality reduction models can greatly help in enhancing the prediction accuracy of the model due to a reduction in overfitting and improved feature selection. For this, an ensemble technique called stacking has been used where the ML models (XGBoost Classifier, Decision Tree Classifier, Random Forest Classifier, Linear Discriminant Analysis) have been aggregated and Logistic

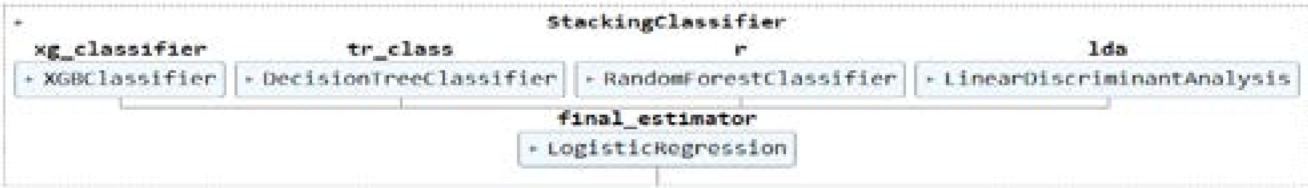

Fig. 2. The ensemble ML model used for this work for the classification of proneness of SZ in patients.

Regression is taken as a meta-classifier (due to being very fast at classifying unknown inputs) (Fig.2).

Here, in this ensemble (Fig.2), XGBoost has been considered due to the gradient boosting ensemble technique being effective in preventing overfitting by the regularization of its complexity when training a new error-predicting model to predict a model's current errors. Decision Tree Classifier has been used as it uses the best feature for splitting the data into smaller subsets, thus creating new branches until it reaches the predicted outcome. Decision Tree algorithms use complex decision boundaries, which separate training data into classes which help the classifier to make new predictions on test data. Random Forest Algorithm has been considered due to this model consisting of a combination of decision trees and the final output is taken based on the majority votes of the predictions. Linear Discriminant Analysis (LDA) Algorithm is effective for multiclass classification as it uses a linear combination of features that best separates different classes of the dataset. Since the dataset used for this work contains multiple classes for classifying the proneness of SZ in patients, the LDA algorithm is effective for the separation of each of the classes.

Stacking combines the strength of multiple heterogeneous models to create more robust and accurate predictions. The first layer of this ML model consists of individual base models, XGBoost Classifier, Decision Tree Classifier, Random Forest Classifier, and Linear Discriminant Analysis), which are trained on the training dataset. These baseline models then predict the outputs on the test dataset. The second layer of the proposed model consists of Logistic Regression as a meta-classifier. This meta-classifier takes the predictions of all the baseline ML models in this ensemble as input and generates the final predictions.

For model interpretability, the explainable AI technique, LIME is extremely effective as it provides simple, human-understandable explanations of the classification results of the proneness of SZ.

Even though for this work, a relatively simple dataset with eight features is used, this ensemble ML model can potentially work for larger datasets with an even larger number of features due to the effectiveness of the LDA algorithm for addressing the curse of dimensionality. Also, the XGBoost Algorithm in the ensemble can effectively help in the reduction of errors due to the summing up of newly learned error predictors until satisfactory accuracy is achieved. The employment of complex decision boundaries by the Decision Tree algorithm, and the Random Forest algorithm in the ensemble which gives the prediction result as the result given by most of the decision trees in the Random Forest model, can also be effective in prediction accuracy.

V. RESULTS AND DISCUSSION

A. System configuration used for training

The data preprocessing, model-building and model training have been done on Google Colab. The required Python libraries such as numpy, pandas, seaborn, lime, etc. have been imported into the Google Colab notebook for training the model.

B. Discussions on the results related to the proposed ML model

Here, the ensemble model proposed in this work has obtained a 10-fold cross-validation accuracy of 96.02%. Hence, the prediction accuracy of the level of proneness of SZ in patients is enhanced due to using this ensemble model. This accuracy obtained is much more than each of the 10-fold cross-validation accuracy values obtained by using some of the existing classifiers which include XGBoost, AdaBoost, Decision Tree Classifier, Random Forest Classifier, KNN Classifier, Linear Discriminant Analysis, Ridge Classifier and Stochastic Gradient Descent Classifier. The 10-fold cross-validation results obtained from some of the existing classifiers as well as the proposed ensemble model are given in Table I.

C. Discussions on some of the prediction explainability results by LIME

The target column 'Schizophrenia' contains five classes: - Elevated Proneness, High Proneness, Moderate Proneness, Low Proneness and Very High Proneness. Label encoding has been done in the columns – gender, marital status and Schizophrenia. In Fig.4 the inputs given for the prediction of the level of proneness of SZ are displayed in the table at the bottom right of Fig. 4 as 'Feature' and 'Value'. The prediction result for this set of inputs is 'Very High Proneness' as shown in the 'Prediction probabilities' section in Fig.4. The bar charts containing labels for the top 3 classes of proneness of SZ as per the dataset used for this work are displayed using LIME. Each of the bar charts in the results obtained using LIME shows the features contributing positively and negatively to the prediction of a resultant class. In the table at the bottom right of Fig.4, the features – fatigue, movement, hygiene, slowing, pain, age, and marital status contribute positively to the prediction result, and the feature – gender contributes negatively to the prediction result.

After 'Very High Proneness' the next greatest prediction probability for this set of inputs is 'High Proneness'. In Fig.5, a LIME result displayed for another set of inputs. LIME explanations can be effective for clinicians in providing a personalized diagnosis of SZ as the explanations are tailored to individual patients considering their individual characteristics and health data. This approach can also help in the early detection of SZ in patients if the patients' required data - are collected and given as input to the ML model. As compared to the existing methodologies for the prediction of Schizophrenia which involves observing demeanour, and asking about thoughts, moods, delusions, hallucinations, etc., the ML approach used in this work along with LIME results is potentially less time-consuming for early detection of the susceptibility to SZ. Also, as compared to methodologies like MRI or CT scan which are used to rule out conditions with symptoms similar to SZ, this ML approach can potentially be cost-effective.

Using LIME, the prediction probabilities for each class of the target column 'Schizophrenia' are displayed for a particular row of the dataset. The testing accuracy for the ensemble model trained for this work is 0.917333 (91.7%). Hence, it is not always the case that the prediction probability will be given exactly 1 (100%) for the correct output class in the target column based on the inputs in that particular row.

D. *Comparison with existing results*

The ensemble algorithm used for this work comprising of XGBoost, Random Forest Classifier, Decision Tree Classifier, Linear Discriminant Analysis, and Logistic Regression models has achieved a 10-fold cross-validation accuracy of 0.9602 (96.02%).

E. *Performance Metrics*

Classification Report for the ensemble model - The label encoding for the 'Schizophrenia' column is as follows: Elevated Proneness: 0, High Proneness: 1, Low Proneness: 2, Moderate Proneness: 3, Very High Proneness: 4. The class labels are shown in Fig. 3. The classification report (Fig. 3) is obtained for the predictions by the proposed model on the testing data. As per the classification report, the accuracy is 0.92. The precision values for each class are greater than or equal to 0.87. The macro-averaged precision for the proposed model is 0.91. The macro-averaged recall is 0.73. The macro-averaged f1-score is 0.79. The weighted average of each of the scores - precision, recall and f1-score is 0.92. In this classification report, support is the number of instances of each of the classes in the test set. The weighted average values of the precision, recall and f1-score are higher than the macro average values of the precision, recall and f1-score because, as per the support values, the data in the test set is imbalanced. For this imbalanced dataset, the weighted average has given a higher value since the weighted average weighs each of the class's metrics with its support value. As per the classification report, some of the majority classes (classes with high support value) have high-performance metrics which contribute more to the weighted average. Macro average treats each class equally regardless of support. Hence, some of the low-performance metrics of minority classes have contributed to lower values of the macro average.

F. *Advantages of the proposed ML model used in this work for classifying the proneness of SZ in patients*

In the healthcare domain, where gaining trust from patients is extremely important, LIME results can aid in transparency and reliability of prediction results by the proposed ML model as patients can understand what features have contributed to the proneness of SZ they have. The ensemble ML model used in this work along with

G. *Limitations of this approach for classifying the proneness of SZ in patients*

This ML model is not 100% accurate. It has a cross-validation accuracy of 96.02% so there can be incorrect classifications of proneness of SZ in patients. Also if the data related to Fatigue, Slowing, Pain, Hygiene, and Movement are entered incorrectly, it can lead to incorrect prediction results.

Classification Report for Stacked Model

	precision	recall	f1-score	support
0	0.94	0.94	0.94	945
1	0.88	0.91	0.89	244
2	0.88	0.54	0.67	13
3	0.87	0.89	0.88	293
4	1.00	0.40	0.57	5
accuracy			0.92	1500

VI. CONCLUSION

Conclusively, this work report on the classification of proneness of SZ highlights the importance of deepening our comprehension of early identification and intervention approaches for people who may be at risk of developing schizophrenia. The Stacking ensemble in our study achieved a cross-validation score of 0.9602, surpassing the individual performance of all other existing algorithms. Additionally, LIME is employed as an XAI technique to obtain interpretable insights into the predictions by the proposed ML model for this work. This transparency promotes trust and informed decision-making in medical environments by understanding the rationale behind the model and its predictions. The knowledge gathered from this study advances the larger objective of improved outcomes for people at risk of SZ as professionals work toward tailored medicine and focused therapies. But it's important to recognize that work in this area is still ongoing, highlighting the need for additional cross-disciplinary cooperation, validation, and improvement. Finally, the quest for effective classification of proneness of SZ not only has implications for early intervention but also promotes a more comprehensive knowledge of the complex elements that contribute to the onset of this difficult disorder.

In future, ensemble techniques with the aggregation of an even greater variety of algorithms can be used for prediction of SZ. Deep learning techniques can be applied for the prediction of SZ, and XAI techniques can also be applied for the model interpretability of both deep learning and machine learning models as XAI techniques are effective in presenting prediction results in a human-understandable format.

Abstract: **In the domain of computer vision, the task of human activity detection poses significant challenges. Among the numerous techniques employed for this purpose, key point detection stands out as a popular method, outlining the skeletal structure of a human body to facilitate pose recognition or classification. While inherently complex, several libraries exist to streamline key point detection with Google's MediaPipe emerging as a notable contender. Offering a set of functionalities encompassing hand points, human body pose estimation, pupil detection, face mesh identification, and background segmentation, MediaPipe demonstrates efficiency through its robust performance. Trained on a dataset comprising 30,000 samples, the model seamlessly integrates with OpenCV, removing the need for complex deep learning architectures. The primary objective lies in harnessing machine learning techniques to classify poses derived from the key points generated by the library. To this end, this study proposes the adoption of the BLR (Body Language Rule), which captures limb angles pivotal in detecting human actions, thereby constructing a dataset based on these angles. Through machine learning, patterns within this dataset are learned, facilitating a fully automated process adaptable to diverse scenarios, thus unlocking potential applications.**

Keywords: Computer Vision, Features, Human Action, Pose Estimation, Media Pipe, OpenCV Body Language.

1.INTRODUCTION

Human pose estimation is quite a challenging problem in the field of computer vision which involves determining the position, orientation, and sometimes the shape of objects or humans in an image or video. It aims to extract and understand the spatial information of the objects in the scene. In the context of human pose estimation, the goal is to locate and identify the key points of body joints, then after using pose estimation algorithm can estimate the pose or body configuration of a person in each image or video frame. There are two main types of pose estimation: 2D pose estimation and 3D pose estimation. 2D Pose Estimation: This technique estimates the location of key points in the image plane, without considering their depth or the 3D structure of the scene. It provides a 2D representation of the pose, typically in the form of 2D coordinates for each key point. Various approaches can be used for 2D pose estimation, including classical computer vision methods, deep learning-based models, or a combination of both. 3D Pose Estimation: This technique aims to estimate the 3D coordinates of the key points, which provides a more comprehensive understanding of the pose. It involves recovering the depth information of the key points, which is crucial for applications such as augmented reality, virtual reality, robotics, and motion capture. 3D pose estimation is generally more challenging than 2D pose estimation, as it requires additional information about the scene, such as multiple camera views or depth sensors. Pose estimation has numerous applications across various fields. In sports analysis, it can be used to track and analyze the movements of athletes. In healthcare, it can assist in rehabilitation exercises or monitoring patient movements. In robotics, it enables robots to perceive and interact with the environment by understanding human poses. Additionally, it has applications in augmented reality, animation, security, and more. Overall, pose estimation plays a crucial role in understanding human actions, behavior, and interactions, providing valuable insights and enabling a wide range of applications across different domains.

Media Pipe is an open-source framework developed by Google that provides a set of powerful tools and pre-built models for various computer vision tasks, including human pose estimation. Media Pipe’s human pose estimation module utilizes deep learning techniques to detect and track human body key points in real-time. The Media Pipe human pose estimation pipeline takes an input image or video frame as input and produces an output with the detected key points and their corresponding confidence scores. The key points typically include the positions in joints, which includes major recognizable features in human body.

The process involves several steps:

Input Processing: The input image or video frame is preprocessed, which may include resizing, normalization, and other necessary transformations.

Key point Detection: A CNN (Convolutional Neural Network) or DL (Deep Learning) model is used to detect and localize the key points. The model is trained on a large dataset of annotated human pose examples to learn the patterns and features associated with each key point.

Key point Association: Once the key points are detected, an association algorithm is used to establish correspondence between key points across frames. This helps in tracking the key points over time and maintaining consistency.

Key point Filtering: The detected key points are often subjected to filtering techniques to remove outliers or noisy detections, ensuring more accurate and reliable pose estimation results.

Output Visualization: The final step involves visualizing the estimated poses by drawing lines or connecting the key points, representing the skeleton view of person in the given input source.

The Media Pipe human pose estimation module provides a high-level API and pre-trained models that make it relatively easy to integrate pose estimation functionality into applications. It offers real-time performance on various platforms, including desktop, mobile devices, and the web, making it suitable for a wide range of applications such as fitness tracking, gesture recognition, virtual try-on, and more. Overall, Media Pipe's human pose estimation module simplifies the process of implementing pose estimation capabilities by providing an efficient and accurate solution that can be readily integrated into computer vision applications.

2. LITERATUREREVIEW

The following journals and research papers were surveyed for the project. They provided information on the present state of estimation the poses in general and the major key points of image processing and segmentation regarding our project and the various approaches taken to achieve the goal of real-time articulated human pose estimation.

Vishnu J G and Divya S J [1], showed us how to understand the choice in operational model which helps us to design a specific application for a particular task. In the mentioned article they discussed the properties of various pose estimation models and their resemblance and usability in a wide variety of applications. Trade off more features for accuracy and precision or trade off them for more features in the desired application.

Jong- Wook Kim, et al [2], is based on Humanoid Model 2023. A paper announcing a 3D system that estimates human posture from Monocular Pictures and Videos by reprojecting a 3D model of a humanoid robot with 2D skeleton posture estimated by a commercially available Deep Learning (DL) methods. Most posture estimation methods have been developed by using Deep Neural Network, so highly configured PCs and SBCs equipped with many Graphical Processing Units are required, and problems such as rapid heating and difficulty in procurement due to lack of GPUs have caused problems. There are limits to its application to mobile robot systems. For optimizing the outcome, they added 3 points to the root joint, CoM as a deviation for loss, penalty constraint on the joint angle range of the pose balance, resulting in a full- body humanoid robot model. improved.

According to Alexander Toshey and Christian Szegedy [3] Deep Pose: DNN regressor approach outcomes a precise pose estimation. The main advantage of the approach is it follows holistic and robust formulation that uses latest trends in Deep Learning. It also presents a very good insight of the real - world images.

Ardra Anilkumar, et al. [4] in Media Pipe application, uses data obtained from a pre train pose estimation model. It can be experimented with various applications that includes motion pictures, sign language detection, etc.

Ching-Hang Chen and Deva Ramana [5]. While a lot of methodologies tried to directly estimate 3D pose from picture measurements, the author explores using a simple approach which interprets the intermediary 2D pose estimations. The architecture is useful to implement with 2D pose estimation and 3D libraries.

Timo Von Marcard, et al. [6], presents an approach that fuses sparse orientation of data from video and inertial sensors to improve and stabilize human whole-body motion capture. As a complementary data source, inertial sensors can be used to accurately estimate limb orientation even during rapid movements. There are two things that we gain from this approach, one will be obtaining accurate drift-free positional information from video data, and second one will be obtaining precise limb alignment and decent performance in high-speed movements from inertial sensors

3.PROPOSED METHODOLOGY

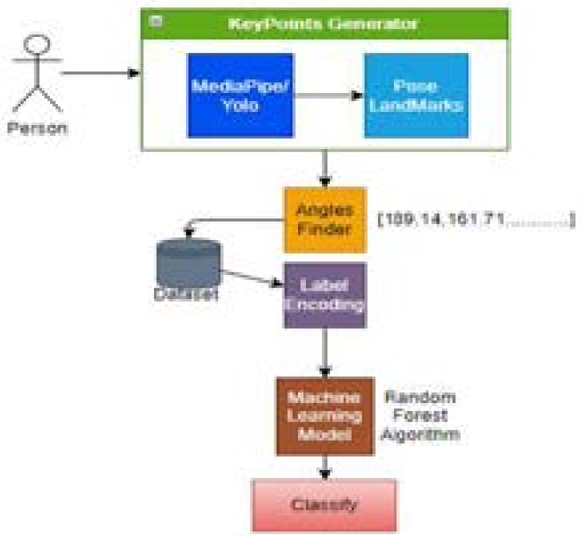

Fig 1. System Architecture

Media Pipe key points detected and generated; they are visualized as follows. As we can clearly observe that there is representational difference in the index.

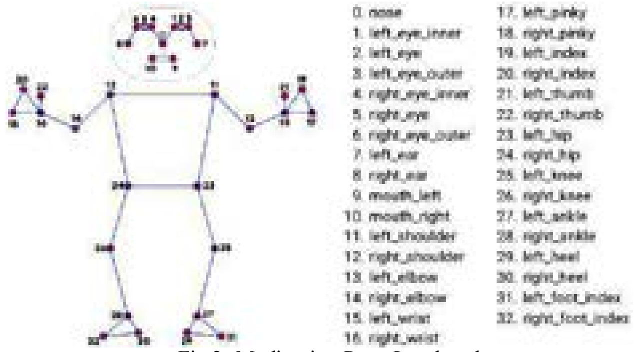

Fig 2. Media pipe Pose Landmarks

When an RGB image is given to the detector it spits out a visualization map with that image which gives us the landmark coordinates. [7] From this coordinate we find the angles between the limbs, which are left_elbow_angle, right_elbow_angle,left_shoulder_angle,right_shoulder_angle, left_knee_angle and right_knee_angle. Using this it populates a structured dataset using pandas, this dataset can be further used with machine learning algorithm to predict or classify the pose. [8] As in inference, we just give this angle such that it can predict the outcome.

Fig 3. Image Pose Landmarks Visualization

the above figure shows a sample representation of how a key point detection works in first place, the image shows a person talking the phone it is one of the primary action we can clearly observe that the distance between his shoulder, wrist and elbow forms a triangle shape. [9] These types of patterns can be identified by our ml model.

Label	left_elbow_angle	right_elbow_angle	left_shoulder_angle	right_shoulder_angle	left_knee_angle	right_knee_angle
texting	72.193116	73.964904	15.367351	348.402885	195.113810	189.377485

Fig 4. Pandas Data frame

DataSet Our dataset consists of fifteen classes, which consists of commonly used human actions that we have collected from open-source data. The fifteen classes are calling, clapping, cycling, dancing, drinking, eating, fighting, hugging, laughing, listening to music, running, sitting, sleeping, texting, and using laptop. The proposed dataset consists of 12601 images, which will split into train, test, and validation data. [10]. When we convert the images data into tabular data, the size of the data would be 12601x7 with 12601 rows and 7 columns as the label. Finally, we will have 12601x6 for learning, in which the proposed model will learn to map them to the label.

Machine Learning:

Machine learning makes the computer to learn from the data patterns, which is generally used on structured data as data is static and outcome expected also have some pre-defined boundaries.[11] As far as accuracy and robustness in predictions are considered, Random Forest (RF) is one of the algorithms, which is simple and can learn different patterns, where accurate predictions and robustness against noise are taken as important considerations.[12] After training a discriminative model on the given dataset, the model file will be saved as. pickle file for further inference and testing, as the dataset is self-populated and consists of fields with accurate and consistent information. The model performance is pretty much on to the point.

4. RESULTS & DISCUSSION

The proposed system produces accurate and stable results as the heavy lifting is handled by the pose estimation frameworks. The angles finder and predictive model provides simple integration and moderate performance without any fine-tuning of the model.

Fig 5. Model Prediction 1

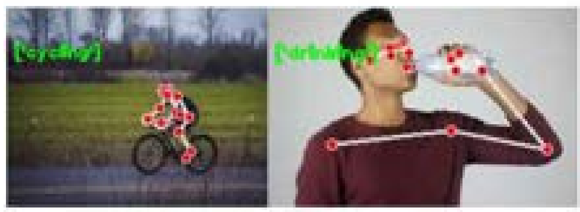

Fig 6. Model Prediction 2

Fig 7. Model Prediction 3

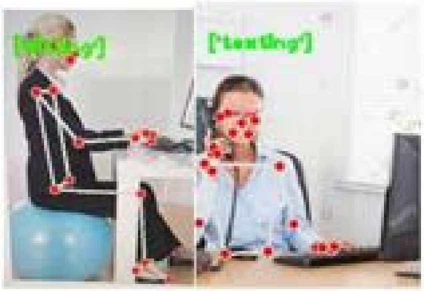

Fig 8. Model Prediction 4

Fig 9. Real-time Model Prediction

CONCLUSION

From the results it is evident that the proposed model has the ability to identify or recognize the common day-to-day actions that humans generally do. This study is quite successful in developing a simple approach which does this without any heavy resource requirements, such as computation power or specific GPU's. The proposed system architecture performed decent to moderate with a simple approach. The proposed approach has limitations like highly dependable on data quality and diversity, the critical challenge comes in converting the image data and target label into padas data frame which is time consuming. The model accuracy can be further improved by using hyperparameter tuning and applying dimensionality reduction techniques. Neural networks can be used to further enhance the performance, which can enable system deployment in real-time environment.

***Abstract*— The main reason for the increasing number of deaths worldwide is cancer, among them the main cause of highest mortality rates is lung cancer. Approximately 85% of the male and 75% of the female suffer from lung cancer. The cancer cells will keep on growing and multiplying leading to the development of tumor. The rapid growth of these cells can spread to other parts of the body, this is known as Metastases. Recognition of cancer at its final stage has barely any chances of getting complete treatment. It might lead to the death of the patient. Consequently, early recognition of the cancer before its final stage is highly crucial to increase the survival rate of the patient. For early detection, several machine learning techniques are used to clear the way for fast treatment of the disease. The dataset consists of different attributes such as smoking, alcohol consumption, chest pain, shortness of breath etc. Decision tree, logistic regression, SVM, Naïve Bayes, KNN and random forest are the various ML classifiers applied to the dataset. The classification models are analyzed for different test and train ratios and the obtained accuracy, precision, recall, error rate, specificity, F-measure and testing time are noted. This process is carried for both binary and multi class classification. Multiclass is considered as three class classifications, i.e. high, low and medium execution time. Therefore, the SVM classifier using Machine Learning technique can be applied to detect the presence of the disease. Hence, it helps the doctors in identifying it. By doing so, early diagnosis can be performed and required precautions can be taken.**

***Keywords*— Lung Cancer, SVM, Machine Learning, Metastases.**

I. INTRODUCTION

The Human body is a combination of tiny particles called cells; these cells will grow unconditionally when cancer is present in the human body. These cells will grow to form a tumor. If cells are there in the body for a longer period, they can even spread to other parts of the body. This is known as metastasis. Cells that were damaged in lungs cause Lung cancer. Other possible cancer types, such as kidney or breast, can metastasize to the lungs. When it was happened, this is no longer lung cancer. For Ex. if breast cancer extents to the lungs, it will be considered as metastatic breast cancer. [1]

The lungs sensation like sponge type tissues in the chest. Its job is to pass oxygen (O2) to the body and leave the carbon dioxide (CO2). When human body breathes air, it drives into lungs via windpipe (trachea). The trachea splits into pipes called bronchi, which goes to the lungs. These divided tiny branches called bronchioles. At the end its tiny air sacs called alveoli. The alveoli transfer oxygen from the air into the blood. It takes CO_2 out of the blood and leaves human body when breathe out.

Lung cancer is the second highest among men and women with roughly 2.09 million new detects every year, and it is accountable for the more deaths, at nearby 1.76 million, w.r.t the World Health Organization (WHO).

Recently some of the researchers they proposed different ML algorithms for lung cancer detection. Janee A, Sabrina A and Alamgir Hossan et. al proposed "Multi-Stage Lung Cancer Detection and Prediction Using Multi-class SVM (Support Vector Machine) classifier". This is used to detect cancer and could predict the probability of occurrence. In this image enhancement along with segmentation have done distinctly. Some Image transformation techniques have been used in enhancement, coming to the segmentation threshold and marker-controlled watershed-based segmentation has been used. SVM binary classifier was used, and it can discover affected cell and its phase such as early, central, or ending stage. If no cell was affected, then it looks for the probability of occurrence of lung cancer [1].

Qing Wu and Wenbing Zhao et al. proposed "Small-Cell Lung Cancer Detection Using a Supervised Machine Learning Algorithm". It's a novel neural network-based algorithm, and it refers to an Entropy Degradation Method (EDM), to identify Small Cell Lung Cancer (SCLC) from CT Scan images. It assists premature detection of lung cancers. The training and testing data utilizes high resolution lung CT scan images. They selected 12 lung CT scan images, 6 are from healthy lungs and 6 are from patients with SCLC and to train the model takes randomly 5 scans from each set, and used two scans to test and it gave an accuracy of 77.8% [2].

Based on the motivations this paper presents a wide variety of ML algorithms for multiclass lung cancer detection. The rest of the paper is organized as follows. Section II gives the methodology and section III presents the results and discussions. Section IV concludes the work.

II. METHODOLOGY

A. Dataset Description

Dataset: Data is an integral part of the algorithm design; it is important to have a clean and correctly labeled dataset. By inputting accurate data into the algorithm, we will have accurate outputs, resulting in a more effective and timely training process. The dataset for 3 class classification a dataset of 1000 members was considered. This dataset consists of 24 attributes. These are: Patient Id, Age, Sex, Air Pollution, Alcohol use, Dust allergy, Professional Risks, Hereditary Risk, Chronic Lung Disease, Balanced diet, Obesity, Smoke, Inactive smoker, Chest pain, Cough, Fatigue, Weight loss, Shortness of breath, Wheezing, Swallowing, Clubbing, Frequent cold, Dry cough, and Snore [3-4].

For the second analysis, 4 attributes from the above-mentioned attributes were removed and 20 attributes were considered. The above dataset was collected from Kaggle. It permits users to find and publish data sets, build, and explore models and work with other data and ML scientists, and enter competitions to crack data science tests.

Training data is the subset of the data and is used to assist the Machine Learning (ML) model to create predictions and run the model for data thoroughly. Testing data arises into picture after a lot of development and validation. Probing the model to mark predictions based on the data is meant to test whether it will work or not in real time.

B. Classification Methods

Classification is from supervised learning to predict given data to a certain class label. The uniqueness in classification depends on mapping function to a firm output level. Numerous learning classifiers were labeled as Perceptron, Naïve Bayes, Decision Tree, Logistic Regression, KNN, Artificial Network, and Support Vector Machine (SVM). Classification in ML is one of the earliest decision methods used for data analysis. The idea of the work focuses on novel approach of ML for analysis of lung cancer data to attain a decent accuracy. Some of the most used classifiers are described as Decision tree, Logistic Regression, Naive Bayes, SVM, KNN and Random Forest. After testing and training the data, various parameters like Precision, Accuracy, Recall, Error rate and Specificity are calculated. The following ML algorithms are used in this study for lung cancer detection [5-7].

Decision Trees: Classification involves two steps learning and prediction. In this learning, the model is developed based on certain training data. In the prediction, the model is used to predict the answer for given data. It is the easiest and most prevalent classification algorithm to understand and interpret the data. It belongs to supervised learning [8]. It is used for solving regression and classification problems. The aim of this is to produce a training model that can be used to predict the class.

Logistic Regression: It is further classifies into following three categories. Binomial will have two probable types of dependent variables, such as 1 or 0, Pass or Fail, etc. Multinomial will have more than two likely unordered types of the dependent variable, such as cats, dogs, or sheep. Ordinal will have more than two likely ordered types of dependent variables, such as little, Moderate, or Extreme.

Naive Bayes: Bayes theorem used for solving problems related to classification. It is primarily used in text classification that includes high-dimensional training data. It's a simple and utmost active Classification algorithm which helps in quick predictions based on the fast ML models. It is a probabilistic classifier; to predict the basis of the probability of an object.

SVM: It's a popular Supervised Learning algorithm and used for Classification and Regression problems. The main intention of the SVM is to produce the best line which can separate N-dimensional space into modules, hence it can easily have kept the new data in the correct category in future. This supreme decision boundary is called a hyper plane. SVM indicates the extreme points/vectors that help in generating the hyper plane. The great points are called support vectors, and hence it is labeled as SVM.

KNN: Two types of KNNs are used in this work and they are Fine KNN and Medium KNN. K-NN is the simplest Supervised Learning. K-NN algorithm accepts and stores the similar data and available data and placed the new into the category that is most alike to the obtainable categories. It means when new data give the idea then it can be easily classified into a fine set category by using K- NN algorithm [9].

Random Forest Algorithm: It is a prevalent ML algorithm that comes under supervised learning. Classification and Regression can be done using this. It is based on ensemble learning and it uses multiple classifiers to resolve complex problems and to progress its performance.

Fig. 1 reperesents the proposed working model. Fig. 2 represents the flow chart of the proposed workflow.

C. Proposed CNN Architecture

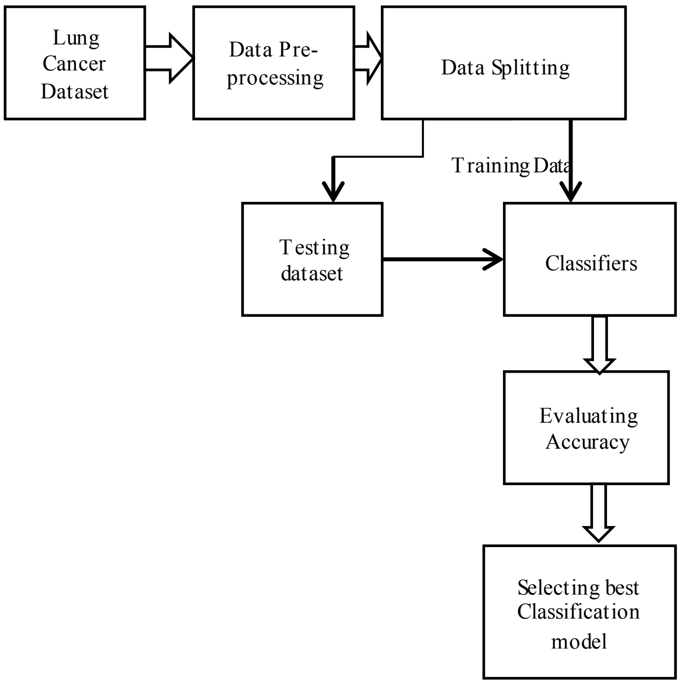

Fig. 1. Block diagram

Figure 1 shows the block diagram of proposed work. It describes the process involved in the implementation of proposed work [10].

Firstly, the lung cancer dataset is gathered, and pre-processing is performed. The data is trained under different ML classifiers. Accuracy for different test and train ratios is observed. Comparison of all the classifiers is done. Attributes that do not cause any change to accuracy are removed. Again, train the new data with different test and train ratios for different classifiers. Compare the performances of obtained new and previous data. Repeat the steps until we get more accuracy with les number of attributes [11].

D. FLOW Chart

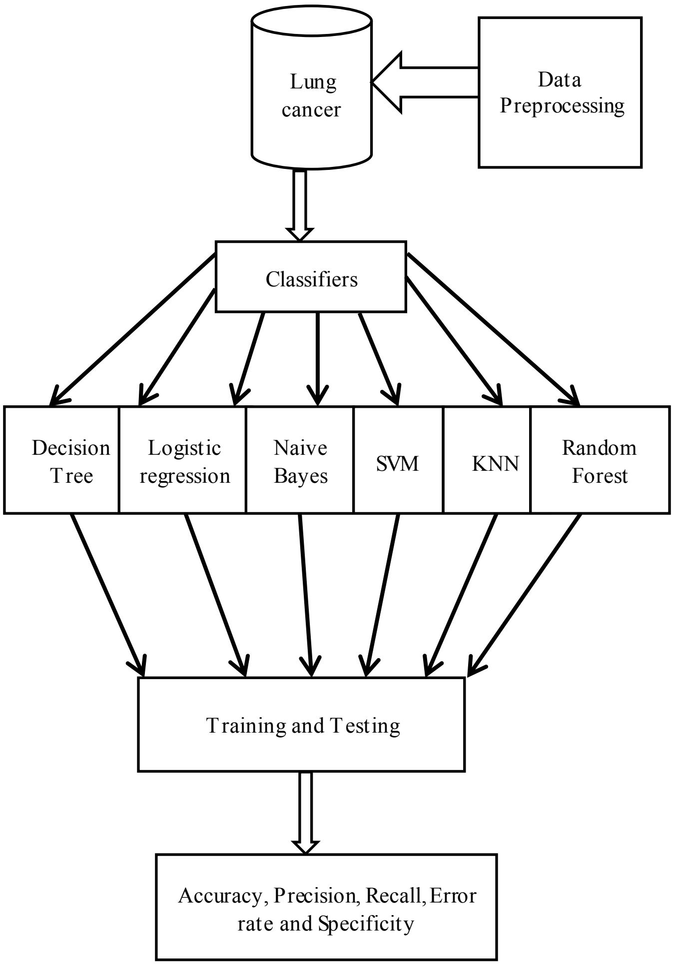

Fig. 2. Flow chart

Figure 2 shows the overall research flow of the proposed work

E. Performance Metrics

In general confusion matrix has key parameters like Accuracy, Recall, Precision and F-Measure for classification. Accuracy is the correct measure of predictions made from total predictions. These Quantitative parameters depend on specific outcome. Those are True Positive (TP), True Negative (TN), False Positive (FP) and False Negative (FN) respectively [12-13]. Performance metrics are evaluated using the following equations.

Accuracy: It defines model correct predictions. It's the ratio of the Total no. of correct predictions made by the classifier to all the Total no. of predictions made by the classifiers. The formula is as given below:

$$Accuracy = \frac{(TP + TN)}{(TP + TN + FP + FN)} \qquad (1)$$

Precision: It defines the no. of correct outputs provided by the model, how many of them were true. The formula is as given below:

$$Precision = \frac{TP}{(TP + FP)} \qquad (2)$$

Recall: It defines total positive classes predicted correctly. It must be as high as possible. The formula is as given below:

$$Recall\ or\ Sensitivity = \frac{TP}{(TP + FN)} \qquad (3)$$

Error Rate: It tells how frequently the classifier is wrong.

$$Error\ Rate = \frac{(FP + FN)}{(TP + TN + FP + FN)} \qquad (4)$$

Specificity: It tells how well a test can identify true negatives.

$$Specificity = \frac{TN}{(TN + FP)} \qquad (5)$$

F-measure: It is a measure of the accuracy of the test.

$$F1\ Score = \frac{2 * precision * Recall}{(Precision + Recall)} \qquad (6)$$

Four distinct statistical indices—True Positive (TP), True Negative (TN), False Positive (FP), and False Negative (FN) are used to measure precision and recall.

III. RESULTS AND DISCUSSION

In the examination of lung cancer detection using ML classifiers, an in-depth investigation was conducted with an 80% training rate and a 20% testing rate, alongside various performance metrics. Through the utilization of diverse performance metrics such as accuracy, precision, recall, error rate, specificity, F-measure, and testing time, a comprehensive analysis was carried out to evaluate the classifiers' abilities in distinguishing between cancerous and non-cancerous cases.

In the multiclass classification scenario with 24 attributes, the confusion matrix reveals the distribution of predictions across different classes. Fig. 3 and Fig. 4 depicts the confusions matrices with 24 attributes and 20 attributes of the DT classifiers. Table I and Table II summarizes key performance metrics, including accuracy, precision, recall, F1-score, specificity, error rate, and testing time with 24 and 20 attributes respectively.

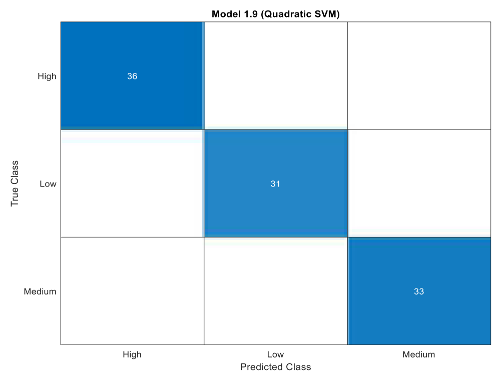

Fig. 3. Confusion matrix analysis with 24 attributes

Fig. 5 and Fig. 6 represent the performance of ML classifiers with 24 and 20 attributes respectively.

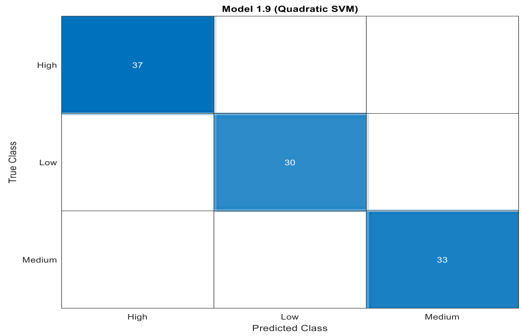

Fig. 4. Confusion matrix analysis with 20 attributes

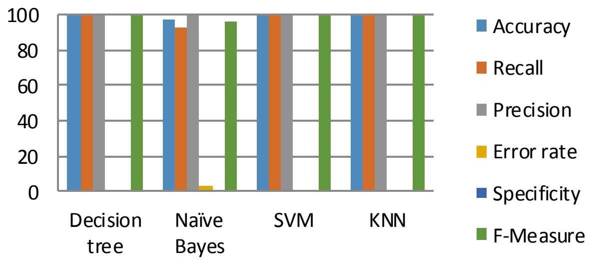

Fig. 5. Analysis for 24 attributes

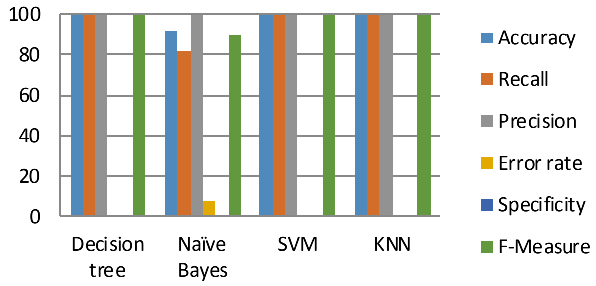

Fig. 6. Analysis for 20 attributes

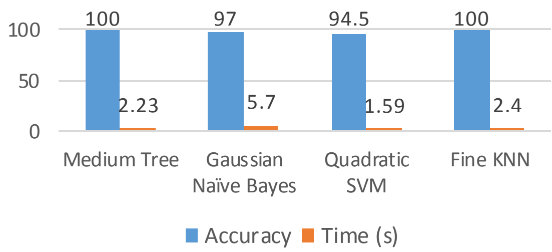

Fig. 7. Comparison with 24 attributes

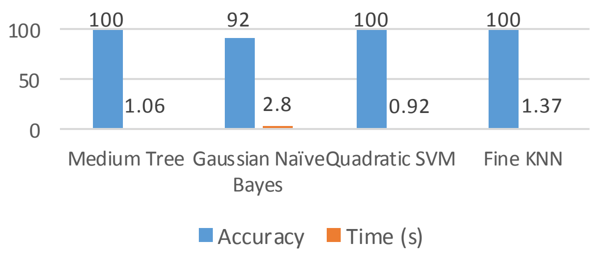

Fig. 8. Comparison with 20 attributes

Fig. 7 and Fig. 8 represent the performance comparison of best 4 classifiers. From the various sub classifications present for decision tree, Naïve Bayes and SVM -- Fine tree, Gaussian Naïve Bayes and Linear SVM have been considered as it has given better accuracy than the other methods.

TABLE I. PERFORMANCE ANALAYSIS WITH 24 ATTRIBUTES

Model Type	Accuracy (%)	Precision	Recall	Error Rate (%)	Specificity	F-Measure	Time (s)
DT	100	1	1	0	1	1	2.23
Naive Bayes	97	1	0.92	3	1	0.96	5.7
SVM	94.5	0.975	0.96	5.4	0.7	0.97	1.59
KNN	100	1	1	0	1	1	2.4

TABLE II. PERFORMANCE ANALAYSIS WITH 20 ATTRIBUTES

Model Type	Accuracy (%)	Precision	Recall	Error Rate (%)	Specificity	F-Measure	Time (s)
DT	100	100	100	0	1	1	1.06
Naive Bayes	92	100	82.2	8	1	0.90	2.8
SVM	100	100	100	0	1	1	0.92
KNN	100	100	100	0	1	1	1.37

IV. CONCLUSION

The multiclass classification experiment with 24 attributes revealed the remarkable accuracy of machine learning classifiers, particularly evident in the perfect scores achieved by Decision Tree, SVM, and KNN classifiers, while Naïve Bayes exhibited a slightly lower but still commendable accuracy of 97%. Upon reducing the attribute count to 20, Decision Tree, SVM, and KNN maintained their flawless accuracies, highlighting their robust performance even with fewer features. However, Naïve Bayes saw a decrease in accuracy to 92%. Notably, the SVM classifier consistently outperformed others across both datasets, demonstrating superior accuracy while requiring minimal computational time. These findings highlight the efficacy of SVM in multiclass classification tasks and emphasize the importance of selecting appropriate algorithms to achieve accurate classifications, contributing valuable insights to the optimization of classification techniques across diverse domains.

***Abstract*—Timely detection of leaf issues is crucial for advancing the national economy. This study intends to acquire the knowledge on detecting the leaf-related diseases. Nevertheless, it is essential to note that plant diseases can impact many parts of the plant. This study covers the articles published related to the multispectral or hyperspectral imaging from the year 2010 to 2024 to analyze the agricultural diseases. Leaf diseases are categorized using machine learning and deep learning models. This study has created a workflow system to assist researchers. Commonly employed leaf disease prediction models encompass Random Forest (RF), Support Vector Machine (SVM), and Multiple Twin Support Vector Machine (MTM). Various conventional deep-learning models are commonly employed for performing leaf disease identification. The models encompassed in this list are CNNs, DCNNs, BPNNs, DenseNet, LeafNet, and LeNet. The three most efficient deep- learning models for leaf disease identification are CNN, VGG, and ResNet. Typically, the effectiveness of an algorithm is assessed by measuring its F1 score, accuracy, precision, and other metrics. This research study aims to assist researchers in identifying suitable machine learning and deep learning-based classifiers for diagnosing the leaf diseases.**

Keywords— Classification, Deep Learning, Leaf Disease, Machine Learning, Tomato

I. INTRODUCTION

Leaf diseases delay plant growth and diminish the agricultural yield. Leaf diseases are caused by various species, including yeast, bacteria, viruses, and others, throughout their life cycles. Several methods can be employed to identify and categorize factors that cause stress in leaves [1]. The initial stage involves visually inspecting it using one's eyes, which can be more challenging. Secondly, leaf stress can be examined manually or by machine learning (ML) methods. Many scientists widely believe that relying solely on eye inspection or the use of microscopes is inadequate in preventing the spread of the disease to leaves. Next, several scientists are considering employing machine learning algorithms to cultivate foliage. Utilizing historical data poses a problem in the early detection of leaf diseases before their spread [2]. Consequently, researchers in computer vision, machine learning, and image processing face challenges when studying diseases affecting leaves [3].

II. LEAF DISEASE AND ITS SYMPTOMS

Some of the common tomato leaf diseases are discussed in this section.

A. Bacterial Spots

All tomato-growing locations have Xanthomonas, which causes bacterial spots. Fruit defoliation, sunburn, and yield loss are signs of this bug. Bacterial spot disease threatens tomato output worldwide due to its wide range of temperatures and pathogens. Precipitation and temperatures between 75 and 86 degrees Fahrenheit aggravate sickness. Round, moist leaf lesions may be surrounded by pale yellow. Stems and leaves often develop round or spherical markings ranging from dark brown to black. Spots rarely grow larger than 3 mm. More leaf lesions may cause the leaves to seem blighted and turn yellow, brown, wither, or die. Figure 1 shows bacterial spots on tomato leaves.

Fig. 1. Bacterial Spots on Tomato Leaf

B. Mosaic Virus

Tomatoes can contract the mosaic virus in many ways. Residual virus particles in soil usually cause disease. Live or dead plant debris can contain the virus for 50 years. No treatment or cure exists for the tomato mosaic virus. Healthy plants can rapidly catch viruses from ill ones. Farmers can infect good plants by touching ill ones. As they move from sick to healthy plants, insects may also spread disease. The virus can spread the virus through gardening equipment, pots, and plants in affected areas. The mosaic virus generates pale and dark green patches on tomato leaves. Reduced yield, tomato fruit deformities, and reduced development are some signs [4]. Sometimes the leaves coil up, turn yellow, and resemble ferns. The mosaic virus-infected tomato leaf is shown in Figure 2.

C. Septoria Spots

Septoria lycopersici spots are fungus-caused. Septoria spots, a severe tomato plant disease, are more widespread in places with prolonged high humidity and rain. Septoria spots on the lower leaves indicate fruit development. The patches' tan to grey interiors with little black fruiting structures and dark brown borders. Spherical or

Fig. 2. Mosaic virus on tomato's leaf

round, their diameters are 1/16 to 1/4 inch. A leaf usually has several spots. The infection will spread from the lower to upper leaves. As lesions increase, the leaf will turn green, light yellow, brown, and wither [5]. Most cases of this disease rarely infect fruit. Septoria spots on a tomato leaf are shown in Figure 3.

Fig. 3. Septoria spots on tomato's leaf

D. Yellow Curl

The Tomato Yellow Leaf Curl Virus (TYLCV) is a Geminiviridae DNA virus responsible for one of the most severe diseases affecting tomatoes. This is especially common in tropical and subtropical settings. Aleyrodidae insects spread this virus. TYLCV infects tobacco, beans, eggplants, peppers, potatoes, and tomatoes. Due to the rapid spread of TYLCV, research on its detection and control has increased. The tomato leaf with a yellow curl is shown in Figure 4.

Fig. 4. Yellow curl on tomato's leaf

E. Concerns with the detection of leaf diseases

1) Image processing challenges that need to be addressed: Even though there are a lot of different image processing algorithms [5], almost every IP methodology that is used to identify and classify diseases of leaves has the following problems:

- Noise significantly reduces picture processing efficiency. Stage lighting and electrical appliances can be disturbed. Pulse or Gaussian noise in leaf images can make forecasting more challenging.
- Electronic devices tend to take grainy photos, which hinders this investigation. Defocused photos blur, making this image unreadable.
- Most researchers use public datasets. It's a bother to capture images of diseased leaves in fields, but that's another reason.
- Variations in sunshine, camera angle, distance between electronic equipment and diseased leaves, and other occlusion-based images are among these researchers' many challenges.
- Smartphones, digital cameras, etc., may take multiple photos for different setups. Selecting the correct technological device is vital. The biggest issue with mobile phone photos is sharpness. Although their angle and distance constraints apply, digital cameras may also photograph sick leaves.
- Choosing a large photo for the study is also tricky. Even if every detail in the big picture matters, blurring can hinder leaf disease identification.
- Many researchers have used drones to capture damaged leaves in agricultural areas. This camera's main drawbacks are weather and flying time. Despite these difficulties, researchers have started employing drone cameras and generated classification results using various model setups. No drone-camera photographs were used for this article.

Box [6], Gaussian [7], Gradient [8], and Laplacian [9] image filters prevent IP difficulties caused by noise. Thresholding, Blob extraction, template matching, Hough transformation, and HoG transformation have helped diagnose leaf diseases. Random disease patterns or abnormalities make leaf image feature extraction harder. Popular feature extraction algorithms quickly extract information from sick leaf photos, including background, damaged, and green sections. The image's multi-form and multi-colour composition makes leaf disease identification difficult. Leaf disease identification is difficult using existing approaches. Sunny or overcast weather is another challenge. These constraints make leaf disease identification harder.

2) Challenges that arise in response to climate change: Weather changes threaten plants at different stages. Weather affects leaves too. As temperatures changed, leaf infection spread. The study [10] discussed how climate change affects farming and machine learning algorithms predict crop production. Rapid weather change shortens plant longevity and complicates leaf and plant disease detection. The study [11] described how climatic change and black Sigatoka disease have increased banana leaf fungus. Studies show that the risk of Black Sigatoka sickness is rising, and climate change is already affecting people's health. The study [12] stressed the importance of planting at the proper time to avoid pests and diseases.

3) The effects of invasive organisms and infectious agents: Throughout the year, a diverse range of pests and pathogens, such as viruses, bacteria, and fungi, have a substantial impact on the emergence of leaf and plant diseases. The study [13] found that dryness influenced the size of leaf apertures, which serve as the main entry routes for plant diseases. The study [14] quantified the extent of harm inflicted by pests and diseases on rice, wheat, maize, potatoes, and soybeans The study [15] examined the impact of climate and diseases on the life cycles of plants. Storms and heavy rain can also serve as a means of dispersal for plant diseases and pests. According to the study [16], animals and plants are interconnected and cannot be separated, even when plant diseases and pests are present. In their study [17], the authors introduced the term "fungal endophytic" to describe a defense system that protects against non-insect organisms such as worms, viruses, bacteria, and mites.

III. Searching Process

This section describes the selection process and criteria for this review's papers.

A. Planning

The inquiry included many 2010–2022 journal and conference articles. Keyword searches were used to query Google Scholar, IEEE Xplore, and SCOPUS Indexed Journal. Table 1 shows the searched keywords.

TABLE I
THE NUMBER OF ARTICLEE OBTAINED USING EACH KEYWORD

Keywords that were searched:	Number of article
Image-processing	7
Deep-learning	8
Maximum_Sequence_Length	7
Plant-disease-classification	6
Machine-learning	6
Convolutional-neural-network	7
Compute-Vision	7
Total	48

A total of forty-eight papers were identified for inclusion and removal using keywords.

B. Conduction

At this level, we will outline the criteria used to assess the effectiveness of current models that utilize machine learning, image processing, and deep learning (such as CNN) to detect diseases in different crops and plants. These models rely on diverse datasets. Figure 5 illustrates the complete research method undertaken for this work as per PRISMA guidelines. After doing a search on Google Scholar, IEEE Xplore, and SCOPUS Indexed Journal, a total of 48 papers related to the detection and categorization of plant diseases from 2010 to 2024 were found. Three stages were necessary to achieve exclusion. After thoroughly reviewing the entire content, a total of seventy-five papers were found. Out of these, one hundred and sixty-four papers were dismissed only based on their titles. Abstracts and conclusions condensed the publications. Table 2 presents a concise overview of the seven study questions that formed the foundation of this comprehensive review. To obtain answers, all accessible models were closely monitored.

C. Material and Methods

To conduct a comprehensive assessment of articles and draw conclusions based on research questions, it is crucial to develop specific criteria for determining which publications should be included or excluded, as well as criteria for evaluating their quality. Table 3 presents the criteria for including (IC) and excluding (EC) certain elements.

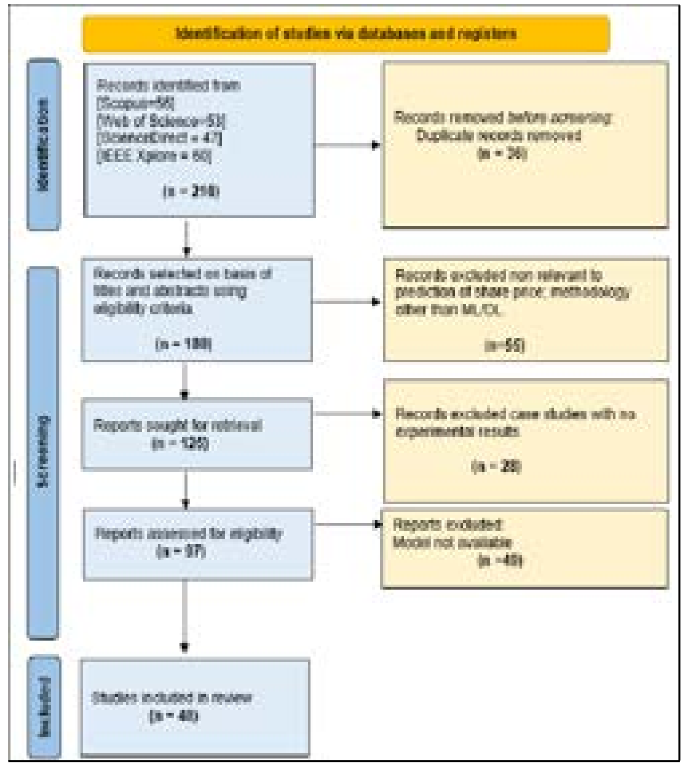

Fig. 5. PRISMA flowchart for selection of the articles tomato's leaf disease classification

IV. Literature Review

The study technique findings in this part answer the aforementioned research questions using data from chosen studies. These automated models take a long time to train, but they are good at recognizing early indicators of plant ailments, allowing farmers to take precautions and avoid agricultural production losses. The review considered several parameters, as indicated in Figure 6. The technique employed for this literature evaluation encompassed several key steps: data gathering, pre-processing, data augmentation, feature extraction, identification and classification of feature types, picture quality enhancement, reduction of model overfitting, and classification and identification of features.

A. RQ1: Regarding plant data, what is the primary source of information derived from?

Identifying and classifying leaf disease begins with plant leaf imaging. You can take plant leaf photos with a camera or use open-source repositories. This section will discuss the sources from which researchers collected image data. We analyzed 16 papers since they supplied this area's data. Using a substrate manufactured by Klassmann-Deilmann GmbH (Germany), the study [18] investigated sugar beetroot leaves that were grown in plastic pots. In addition to being watered, the plants were fertilized once a week with 100 milliliters of Poly Crescal that contained 0.2 percent. The hyperspectral reflectance method was utilized in the study to categorize plant diseases.

The study [18] trained and identified two diseases affecting wheat and grape crops using reverse propagation networks and 185 digital camera images. There were one hundred images of wheat stripe rust, fifty of grape powdery mildew, thirty-five of grape downy mildew, and thirty-five of grape powdery mildew in the collection.

The study [19] captured 107 images of chile leaves using the LABVIEW IMAQ Vision software; 21 of the leaves were healthy,

TABLE II
RESEARCH QUESTIONS AND THEIR MOTIVES

S. No.	Research Question	Motivation
1	Regarding plant data, what is the primary source of information derived from?	Scientists utilize diverse data collection sources to acquire photographs of plants.
2	What is the total number of unique pre-processing procedures employed? ?	Discover multiple pre-processing methodologies.
3	What are the steps to utilize different techniques for data augmentation?	The objective is to compile a comprehensive list of the different techniques employed to expand the dataset through data augmentation.
4	Which attributes are most commonly utilized in feature extraction? ?	To discern several extracted characteristics.
5	What are the techniques for improving the quality of an image through analytical methods?	To explore techniques employed to improve the quality of images.
6	Where can one access information regarding automated systems designed to identify and categorize plant diseases?	To find models used for the identification and categorization of plant diseases.
7	What strategies can be employed to mitigate or eradicate the impact of overfitting?	The objective is to identify strategies to mitigate the occurrence of overfitting.

TABLE III
INCLUSION-EXCLUSION
CRITERIA

S. No.	Parameters	Inclusion Criteria (IC)	Exclusion Criteria (EC)
1	Period	Between 2010 to 2024 research studies	Article published before 2019
2	Investigation	Studies focuses on the dataset, proposed methodology, and results of share market	Studies focuses on other than Tomato Classification
3	Compactor	Studies aims to stock security price prediction	Studies focus on other than stock security price prediction
4	Methodology	Studies focus on ML or DL techniques	Studies focuses on other than ML or DL technique
5	Design of study	Original studies comprises experiment results	Survey paper, case studies and non-english

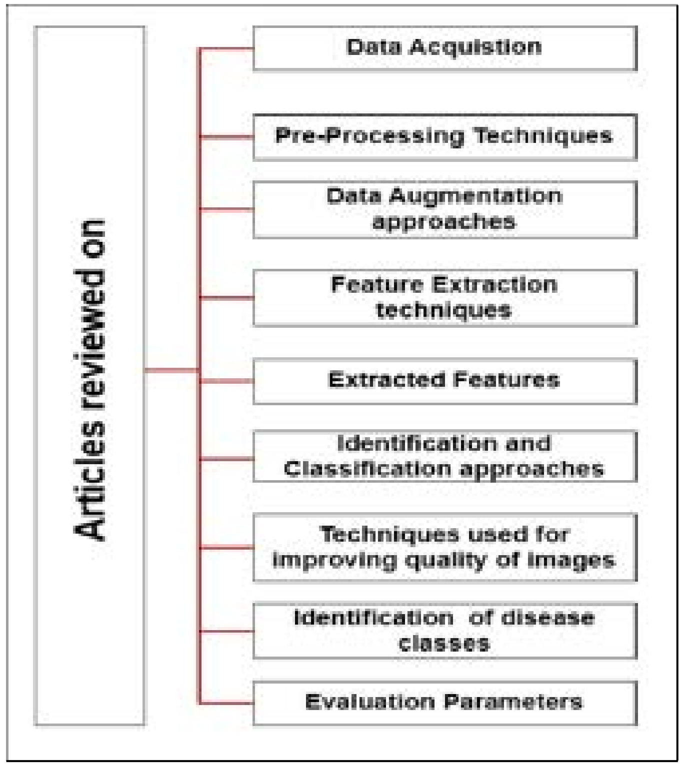

Fig. 6. The parameters that were explored for the literature review.

while 86 were infected. Under the supervision of professionals, The study [20] photographed grape foliage in Pune, Bijapur, and Sangali using a Nikon Coolpix P510 digital camera with 16.1 Megapixels. The images were utilized for testing and training systems. The image files were all in the.jpg extension. An assortment of web photographs were employed in order to establish an inclusive and diverse atmosphere. It has been demonstrated that powdery and downy mildew, two prevalent diseases in India, cause damage to the foliage.

Photographs of multiple farms were captured by [21] utilizing a digital camera and a guide. The dataset experienced expansion due to the acquisition of images from the internet and the implementation of diverse configurations. Photographs of leaf miners, thrips, and Tuta absoluta are displayed. To consolidate data, [22] conducted a research on plant disease detection. Fifteen distinct categories were established for the Internet photographs. Twelve of the categories featured photographs of leaf-based plant diseases, whereas two featured images of healthy foliage and backgrounds.

Dataset 1 comprised a total of 7320 images depicting both healthy and diseased foliage, while Dataset 2 comprised 7520 photographs. The study [23] examined real-world photographs in addition to six publicly accessible datasets. A compilation of 10,213 handheld mobile phone photographs was produced, showcasing 22 distinct species in diverse soil, illumination, and pixel density conditions.

In their controlled study, [24] used a public dataset (PlantVillage dataset on Kaggle) to classify 54,306 pictures of healthy and diseased leaves into 38 classes. In the study, [25] photographed eight tomato leaf classes using [26]. One photo showed healthy leaves and nine showed sick leaves. [27] obtained 14,800 photographs of tomato leaves with nine diseases from PlantVillage, an open-access library with over 50,000 photos. The study [28] captured 1053 photos of apple leaves using a BM-500 GE/BB-500 GE digital camera at two apple experiment locations in China. The images depicted mosaic, Alternaria leaf spot, brown spot, and rust. The various sources of data acquisition are depicted in Figure 7.

B. *RQ2: What is the total number of unique pre-processing procedures employed?*

Various methods were utilized to pre-process image data. This section covers the several pre-processing procedures used by researchers. Applying the filter "Pre-processing techniques," 34 papers were retrieved for this area, 26 of which were studied. The typical application of different pre-processing procedures is illustrated in Figure 8. The study [29] removed noise using picture improvement, smoothing, clipping, colour conversion, and histogram equalization. The study [30] resized and cropped image The study [31] utilized

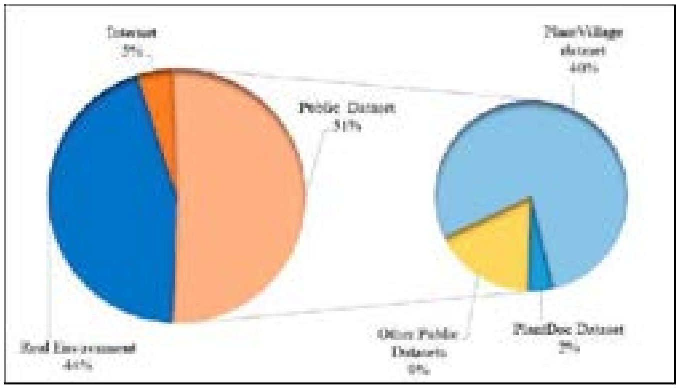

Fig. 7. Selected articles for quality assessment

a median filter to eliminate noise after compressing pictures to a standard size to improve quality. Before feature extraction, [32] decreased the image size to 256 × 256 pixels and trimmed plant leaves to find areas of interest. The study [?] undertook various pre-processing steps to improve the final product, including clipping the image to identify essential parts and smoothing it. Increased contrast was achieved with picture enhancement. [34] deleted pixels from grape leaf margins and translated RGB data from data acquisition. The study [35] pre-processed image data to 256 × 256 pixels, including size reduction and cropping. [35] pre-processed photos to standardize sizes. Two photo pre-processing approaches were used by [36]. Image improvement increased contrast and revealed new features and CIELAB colour space compressed the photographs to speed up processing.

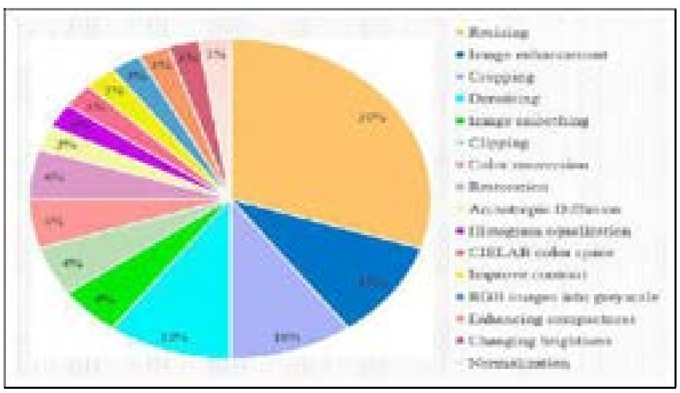

Fig. 8. Comparison of several pre-processing methods' usage graphs, ordered by decreasing percentage

C. RQ3: What are the steps to utilize different techniques for data augmentation?

Data augmentation can include photos to improve dataset accuracy. This section discusses how researchers have expanded their datasets. Twenty-eight data-augmented papers were selected for study in this domain, shown in Figure 9.

The study [37] used rotations, affine transformations, and a 3x3 matrix-based perspective transformation to improve photos. [38] expanded the dataset by using picture shifting, mirroring, and image rotation. The study [39] augmented the photos in the training dataset by applying geometric and intensity editing techniques. Intensity transformation deals with issues such as noise, color, brightness, and contrast, while geometrical transformation focuses on scaling, cropping, rotating, and horizontally flipping images. By employing rotation and flipping techniques, [40] were able to collect further data. In addition to being rotated 90, 180, and 270 degrees, the photographs in the collection were also inverted both horizontally and vertically. [41] increased the quantity of photographs by rotating them clockwise and cropping them from the center to the extremities. By implementing rotation, shear transformation, truncation, and horizontal and vertical alignment. The techniques employed for intensity variations include increased contrast, color jittering, principal component analysis jittering, radial blur, and brightness enhancement. The images underwent enlargement, cropping, rotation, and horizontal and vertical flipping. [42] employed image augmentation techniques such as RandomRotate, RandomFlip, and RandomLighting to improve the quality of photos and facilitate the assessment of multiple viewpoints. The study [42] improved the image data by applying techniques such as cropping, flipping, shifting, and rotating.

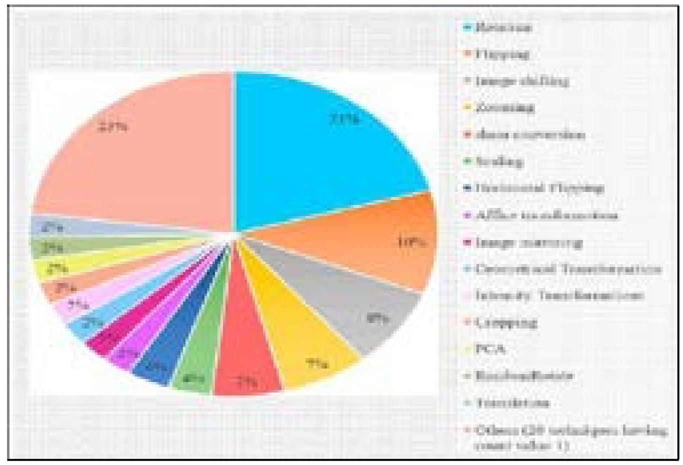

Fig. 9. Total number of distinct augmentation methods that have been implemented

D. RQ4: Which attributes are most commonly utilized in feature extraction?

This section examines the feature extraction methodologies employed by researchers. A total of twenty-six publications were identified that utilized feature extraction for the purpose of filtering. Out of them, a detailed analysis is conducted on nineteen papers.

In the study [44], the authors successfully distinguished the foliage of chili plants through the implementation of color space and a reduction in the intensity of optical irradiation. Image extraction entailed the retrieval of color information, object recognition, and photo comparison. The study [45] extracted texture data via color cooccurrence. The study [46] extracted characteristics utilizing a gray-level co-occurrence matrix. The following concepts were implemented: complexity, area, circularity, and perimeter. Color co-occurrence was utilized by the study [47] to derive features. The study [48] extracted textural features utilizing GLCM. The study [10] generated feature vectors via HOG feature extraction. The study [32] extracted features utilizing the RESNET18 (CNN) architecture and task-adaptive methods. The study [?] extracted features utilizing a scale-invariant feature transform. The study [10] focused on the color and texture components of the photographic data. The color moment equation calculates the skewness, standard deviation, kurtosis, and mean of the retrieved color attributes. The second set of features was obtained through the retrieval of the Gray Level Co-occurrence Matrix (GLCM). Pandian et al. extracted attributes utilizing a number of exceptional convolutional layers in the study [9]. The study [19] extracted data from photographs utilizing a Convolutional Neural Network (CNN) called MobileNet.

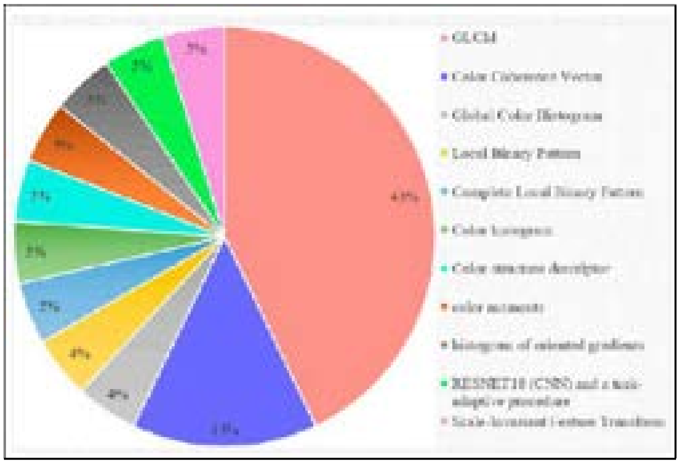

Fig. 10. Selected articles for quality assessment

E. RQ5: What are the techniques for improving the quality of an image through analytical methods?

This section will focus on the enhancements made by researchers to enhance the quality of images. After applying filters that improve the quality of the pictures, a total of 15 publications were identified for this particular section. In the end, eleven papers were included in the research, shown in Figure 11. In the study [21], the authors cleaned up pictures of broken grape and wheat leaves with a median filter. The study [24] employed colour conversion and histogram equalization to enhance their photos. The RGB colour model was transformed to greyscale using the colour conversion method. Histogram equalization dramatically improved image visibility. The study [27] used histogram equalization to increase image quality. The study [32] improved grayscale photographs by using the following formula:

$$S_{k,l} = (T_{k,l} - min(T))/(max(T) - min(T)) \tag{1}$$

This equation uses the original and updated pixel values (T and S) and pixel indices (k,l).

The study [**?**] modified the dataset to better pre-process input images and [32] improve image quality via preprocessing. The researchers in the study [40] improved model performance and image quality with LeafGAN data augmentation. The study [13] boosted photographs by focusing on contrast and brightness in pre-processing. The study [16] reduced picture noise with a bilateral filter. To reduce noise, bilateral filters were applied to plant leaf images.

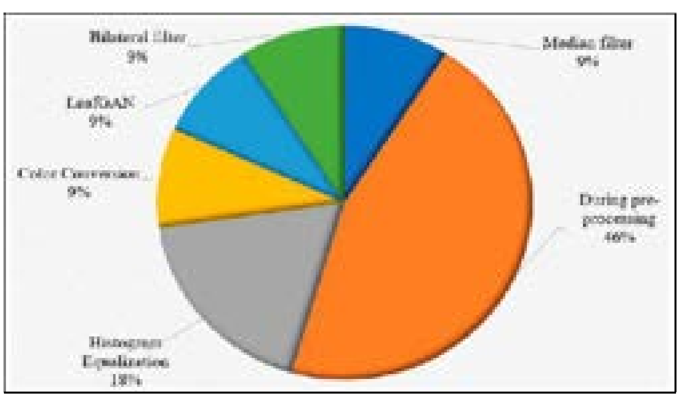

Fig. 11. Various techniques used to enhance image quality.

F. RQ6: Where can one access information regarding automated systems designed to identify and categorize plant diseases?

This section covers machine learning and deep learning techniques for disease identification and categorization. Forty-five studies were found using preexisting automated methods for this set of plant diseases. As seen in Figure 12, the review included 37 papers. Powdery mildew, sugar beet rust, and Cercospora leaf spot were all identified using a support vector machine (SVM) trained on sugar beet plants with hyperspectral data [16]. Through the use of back-propagation networks (BPNN), the inquiry led to the identification of two diseases affecting the leaves of grapes and wheat. Researchers in the study detected a disease in chilli leaves [by using image processing]. The research used multi-class support vector machines to classify apple blotch, scab, and disease. Three sugar beetroot leaf diseases were identified using spectral indicators in the study. To differentiate between powdery and downy fungus on grape leaves, the study employed a feed-forward back propagation neural network. The study used a sequential application of two support vector machines to identify leaf damage caused by thrips, Tuta absoluta, leaf miners, late blight, and powdery mildew. The authors of the study used Convolutional Neural Networks (CNNs) to classify seven different types of cucumber leaf diseases. The authors used two deep learning models to detect various diseases affecting tomato leaves: SqueezeNet and AlexNet. Some examples of these diseases are target spot, early blight, bacterial spot, late blight, and yellow leaf curl. The discovery of nine diseases affecting tomato leaf was CNN's contribution to the research [21]. To identify apple diseases such brown spot, mosaic, rust, and Alternaria leaf spot, the study used AlexNet's deep Convolutional Neural Network (CNN). This study detected and categorized twenty-five different plant diseases using deep learning-based convolutional neural network (CNN) models. The study used a random forest classifier to identify diseases affecting papaya leaves. The research [**?**] used a deep Convolutional Neural Network (CNN) to identify four cucumber leaf markings: downy, anthracnose, powdery, and target. This study used a Convolutional Neural Network (CNN) model that included learning vector quantization (LVQ) to detect and categorize four types of tomato leaf diseases. The study found that oranges have brown rot, citrus canker, stubborn, and melanoses [using support vector machines and K-means clustering]. By applying imperfect reasoning, the severity of the ailment was determined in the diagnosis. To identify diseases in thirteen different plant species, the study used a complex Convolutional Neural Network (CNN) with nine layers. Researchers in this study used a CNN to identify diseases in tomato and apple leaves. Study participants were screened for nitrate and cotton leaf diseases using neural networks and image processing techniques.

G. RQ7: What strategies can be employed to mitigate or eradicate the impact of overfitting?

Overfitting occurs when there is a considerable discrepancy between the accuracy of a model on its training dataset and its testing dataset. This section focuses on the authors' various tactics for reducing overfitting. After applying filtering techniques to reduce overfitting, twenty-four publications were identified for this subsection. Figure 13 displays the final analysis, which comprised a total of twenty-one research. To reduce the occurrence of overfitting, the study [12] used picture distortion methods throughout the augmentation process. Researchers in the study used data-rotation and - flipping methods to reduce the likelihood of overfitting. This work used activation function layers to make the model more non-linear and pooling and dropout layers to make it less overfit. Overfitting was avoided in the study by enhancing the data. The problem of model overfitting was tackled in the study by adding additional images to the training dataset, using response-normalizing layers for local normalization, and replacing certain fully connected layers with convolution layers. To reduce the effects of overfitting and improve the clarity of pictures of cucumber leaves, the researchers in this work used data augmentation methods. To avoid overfitting, the study [5] included altered images in the training dataset. The study [45] used a dropout rate of 0.25 to prevent overfitting. The study [46] employed dropout, data augmentation, and an early stop strategy to mitigate overfitting. Howlader et al. The study [48] mitigated overfitting by employing data augmentation and utilizing ReLU activation. The ReLU activation function for N neurons is F(N) = Max(0, N). The study [47] implemented early stopping with a patience parameter of 5.

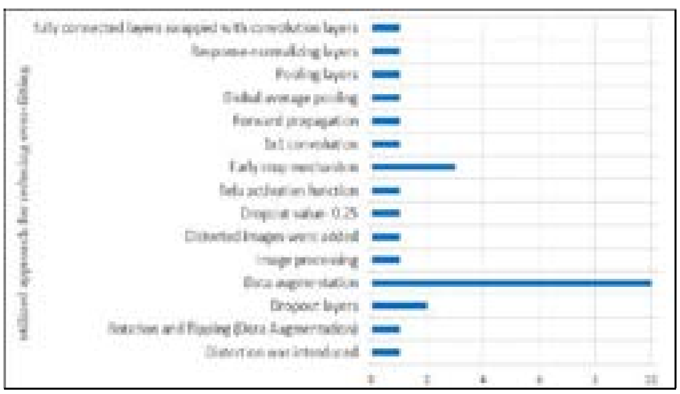

Fig. 13. Methods used to lessen the occurrence of overfitting

V. CONCLUSIONS AND FUTURE SCOPE

This study examined ML, DL, and image processing methods to assess the state of plant disease diagnosis. After significant research, 75 relevant publications were chosen for this review. The following were given top priority: sources of data, preliminary processing, extraction of features, enhancement of data designs, and model performance. According to the results, most models are only partially capable of dealing with unstructured image input. Determining the targeted impacted area from a complex visual background required methodical engineering and professional design abilities. This poll encouraged scientists to classify plant diseases using image process- ing, ML, and DL. Leaf images were utilized in most studies to detect disease. Future frames may include many leaves. These photos can be taken in different settings (temperature, humidity, etc.) to reduce environmental impacts on disease diagnosis, and new disease stage indicators can be produced. Mobile apps and drones can detect plant diseases early in broad agricultural areas in the future.

***Abstract*— The intersection of computer science and social sciences leads an increasing problem: fraudulent job ads. Their presence can have far-reaching negative ramifications that must be dealt with immediately in order to limit further harm to society. Due to the vast amounts of data accumulated worldwide, effective ways must be found for distinguishing legitimate job advertisements from fraudulent ones. This paper proposes a machine learning approach designed to differentiate between fraudulent and non-fraudulent job postings, offering an automated tool to mitigate the proliferation of fraudulent job listings on the internet. The methodology relies on a range of machine learning classification techniques to analyze web-based job postings, comparing the efficacy of different classifiers in identifying employment scams. The primary objective is to establish a robust model for the detection of fake job posts amidst the overwhelming volume of online listings. This research recommends employing various data mining and categorizing algorithms such as Decision Tree and Support Vector Machine, Naive Bayes classifier, Random-forest classifier and Multilayer Perceptron to detect whether an advertisement is genuine. This study has utilized Kaggle data with the proposed classifier enhancing 99.48% accuracy when classifying fake job ads. Additionally, this method provides techniques to detect employment scams to meet applicants' need to protect themselves against scammers.**

Keywords—Fraudulent job ads, Machine learning, Proliferation, Employment scam

I. INTRODUCTION

As unemployment rates increase worldwide, job seekers face an ever increasing number of unsuitable job advertisements during COVID-19 pandemic and its aftermath - creating an atmosphere in which many unsuitable ads clog job boards worldwide. Job hunters worldwide face a grave danger as unemployment benefits for 26 million Americans are being received and similar issues can be seen around the globe, leaving job hunters ever vulnerable. Modern advances in technology and business have opened up numerous job opportunities for job hunters. Thanks to job listings advertisements, job candidates are able to explore potential matches for working schedule, skills or experience requirements and potential applicability. Social media plays an integral role in shaping and contributing to the recruitment industry and its success. Internet-based social networks such as Twitter and Facebook play a pivotal part in recruitment processes while social media ads continue to provide opportunities to share jobs [1]. Due to an increase in websites offering job adverts, an increasing number of fake job adverts that causes significant harm have become prevalent and resulted in harassing job seekers [2]. Security and data integrity concerns have left people feeling less assured when responding to job ads. Establishing legitimacy when posting job advertisements to social and electronic media platforms is no simple task due to the difficulty involved in building trust among employers and employees [3][4]. Technology has simplified our lives while simultaneously improving workplace conditions. When used effectively to spot fake job ads for jobs that don't exist will have a hugely positive effect on recruitment of new employees. False job advertisements often complicate applicants' job search processes and lead them down a path of wasted time and energy. An automated system capable of detecting fraudulent job advertisements provides an unprecedented opportunity to address human resource management problems. This research employs Machine Learning (ML) and Natural Language Processing (NLP) approaches to study the issue of fake job opening descriptions posted online with Machine Learning (ML) and NLP approaches. Researchers conducted their investigation using information set with over 17,000 fake and genuine job vacancies posted within an information set of 17,000 job listings [5].The data for this research came directly from the company's official web site [6].When individuals come across false information online, they often believe and accept it, providing an effective strategy for using social media data as evidence against an opposing viewpoint [7,11].Action Fraud from UK conducted a recent survey that showed 67% of those searching for jobs online or through advertisements may unwittingly open themselves up to fake job ads that may be scams. Over 700000 job seekers reported losses totaling $5000+ as victims of scam jobs over two years in Britain [8], and fresh graduates tend to be targeted more heavily due to scammers taking advantage of them due to being willing to pay higher amounts [9,10].

This paper details a technique for detecting fake jobs using machine learning techniques with various data processing algorithms to measure accuracy, recall and F1 scores of each algorithm.

This research is divided into sections to illustrate the work; in the initial one examined prior work that has been accomplished in this same field before conducting literature reviews and proposing system and its process for implementation; below that comes an outline of proposed system with its process for implementation; finally, conclusion presented the research findings along with analysis between current methods and proposed solution.

II. RELATED WORKS

Habiba et. al. [1] suggested that employing various data mining and classification algorithms like Decision Tree, Support Vector Machine, Naive Bayes classifier Random forest classifier multilayer Perceptron and KNN to assess job ads as authentic or fake. Amaar et. al [2] employed six model-based machine learning models to evaluate job advertisements. One challenge encountered during their research related to data sets, as the supply/demand imbalance between genuine/fake job postings wasn't equal - causing models to focus too much on targeting majority class target classes rather than evenly distributed classes throughout. To address this problem, they conducted two experiments concurrently using balanced datasets and one with unbalanced ones. Mehboob et. al. [3] takes an innovative approach to recruitment fraud detection by providing key elements from organizations, job descriptions, and compensation structures as indicators for potential scams or fraud. A gradient-boosting method-based model was then constructed and tested against three examples using three distinct comparison methods before employing two-step feature selection method; results revealed how organization type could serve as an excellent predictor model. Ranparia et. al. [4] successfully reduced fraudulent job advertisements using Machine Learning techniques that employ NLP for tone and format analysis in job advertisements as well as training the model as a Sequential Neural Network using Global Vector algorithm. For real world testing will utilize an algorithm trained to predict LinkedIn job openings as a test to measure accuracy in real world situations; further improving adaptability and resilience is ongoing development process. Sudhakar et. al. [5] have developed an innovative algorithm for distinguishing fake news from legitimate news by employing logistic regression SVM and an ensemble technique based on machine-learning algorithms. Their study included 620 samples per group with 10,000 records classified into fake, actual, or false classified as such by binary classification. Their results show an innovative ensemble technique can achieve 95% accuracy with only 5% loss rate when compared to other methods; showing its effectiveness as an algorithm which utilized decision tree methods combined with AdaBoost for more precise results by altering parameters accordingly [7]. But main demerit encloses by existing system is using of dataset which possess less accuracy rate than the other. Job hunters worldwide face a grave danger as unemployment benefits for 26 million Americans are being received and similar issues can be seen around the globe, leaving job hunters ever vulnerable. As a response, scammers create fraudulent job ads which appear genuine but present serious risks to individuals searching for work. There are solutions available, including fraud detection tools available through websites or job websites. Job seekers employ various strategies to identify and avoid fraudsters when applying for employment, including recognizing company logos in job ads, using only official email accounts for communication, and being especially careful when providing personal details during interviews. EMSCAD (the Employment Scam Aegean Dataset) is an accessible dataset containing 17,880 job advertisements.

III. PROPOSED METHODOLOGY

This article presents a method for authenticating job ads and aiding job seekers in recognizing legitimate employment opportunities. This research employed Kaggle database which provide extensive details about potentially suspicious job postings; Figure. 1 displays this elaborate procedure flow for this process.

A multi-step procedure must be undertaken first to create a balanced data set before classifiers. Preprocessing methods, including eliminating redundant data or terms as well as any extra values or spaces, may need to be utilized to ensure efficient categorical encoding and creation of feature vectors for various classification algorithms. Contrasting, with current models, this proposed system offers unique features. After uploading data, users can select their variables. Preprocessing actions depend on the selected problem; depending on this action, Decision Trees, Support Vector Machine, Naive Bayes, Random Forest Algorithm and Multilayer Perceptron Algorithmic Operations are executed, followed by results defined using Accuracy, Recall Precision and F1 Score produced as outcomes of this analysis process.

Fig.1.Proposed Methodology of Fake Job Detection

A. Dataset Details

In this research Kaggle dataset is used to conduct this investigation and to detect fake job post. This provided details regarding job postings which may be suspicious and the schema serves as the foundation for evaluating proposed methods of investigation. Important pre-processing techniques included filling missing values with zeros, eliminating unnecessary attributes and handling spaces between records to ensure categorical encoding could take place successfully and then creating feature vectors suitable for classification algorithms to use. Kaggle dataset is more useful because it contains a broad variety of job postings from different sectors and industries. Figure 2 presents the structure of the dataset as the foundation for testing for the proposed method, ensuring effective evaluation.

Fig. 2. Structure of the dataset

B. Implementation of Classifiers

a)Decision Tree Algorithm: The Decision Tree algorithm operates similar to flowcharts, posing inquiries to data in order to make informed decisions and take effective actions. Each question divides the dataset into smaller subsets based on responses, with subsequent inquiries further segmenting the data, forming branches until a final decision or outcome is reached. Known for its user-friendly and straightforward nature, the Decision Tree algorithm simplifies predictions while mitigating overfitting issues if implemented accurately.

b)Support Vector Machine (SVM): Support Vector Machine (SVMs) employs support vectors positioned near class boundaries to discern data points forming classes. Subsequently, SVMs optimize a hyperplane to augment distances between support vectors, each representing a data point. SVMs demonstrate exceptional efficiency and accuracy, particularly when handling smaller, less complex datasets.

c)Naive Bayes Classifier: Naive Bayes classifiers require several parameters that scale with the number of variables involved, making them highly adaptable. Contrary to many other classifiers that rely on iterative approximation techniques for classification, Naive Bayes employs maximum likelihood training which uses linear speed analysis of closed form equations for maximum likelihood analysis. Classifiers that assign class labels based on an assumption that independence exists are an efficient and easy way to build classifiers; not relying on features as is common with traditional classifiers so they allow rapid classification accurately and swiftly.

*d) Random forest Algorithm:*Random Forest employs an ensemble model composed of trees to produce predictions. A collection of sub-trees (decision trees) helps facilitate this prediction approach, with sub-trees created independently through "Bagging" approaches, taking bootstrap samples from training datasets as input into this independent training method. Once created, results from these sub-trees become the final output, which can then be utilized across situations for classification by simply substituting training sessions as needed.

e) Multilayer Perceptron (MLP): MLP approaches fall within the scope of artificial neural networks (ANNs), which leverage neural network structures to tackle classification challenges. MLP belongs to this class of ANNs and comprise three layers: input layer, hidden layer and output layer. Data can flow either forwards or backwards between these nodes, depending on how it traverses the network. This flexibility makes MLP an extremely adaptable approach.

C. Performance Evaluation Metrics

In classification prediction tasks, comparison with the state of art methods in all possible parameters listed: Accuracy, Recall, Precision, and F1 score.

IV. RESULTS AND DISCUSSION

This section details the research findings and discussions. In this paper implemented the work using Kaggle dataset in Jupyter Notebook. To improve the performance, this paper proposed strategies like Cross Validation and Ensemble methods and compared their performances across various parameters like Accuracy, Recall Precision as well as F1 scores. Analysis of these results enabled to identify which algorithm that exhibited superior performance in terms of Accuracy, Precision, Recall and F1 score over the other models; additionally, later combined reports from each algorithm's classification reports which helped understand comparison among the algorithms under the parameters. Finally, compared the results with state of art techniques using EMSCAD dataset. Precision, recall, and F1 score are lower compared to accuracy when dealing with imbalanced datasets (Kaggle) because accuracy alone doesn't account for class distribution.

In imbalanced data, where one class is dominant, accuracy can be high even if the model performs poorly on the minority class. The variance in performance metrics (Precision, Recall and F1 score) of machine learning models under Kaggle dataset compared to the EMSCAD dataset for fake job detection can be attributed to several key differences and challenges inherit to the datasets, as well as how the models were applied and tuned to them. By Model Selection and Cross Validation, we achieved high accuracy and with Error analysis and Interpretability it proven the reliability.

The Tables I, II, III and IV provides Accuracy, Precision Recall, and F1 score measurements for each algorithm respectively. This result is comparable to prior work that utilized machine learning algorithms, attaining similar classification accuracy with various algorithms. The acquired results under Kaggle dataset among the various parameters are listed below. It is observed that Random Forest algorithm reaching 99.48% classification accuracy to check against false positives and negative examples. The high accuracy proves the Random Forest Algorithm is very realistic and can be used directly for job posts. One needs to extract the job description and feed it to the model which will tell whether the job is fraudulent or real.

TABLE I. ACCURACY COMPARISON

	[1]	[2]	Proposed
Random Forest algorithm	96.5%	97%	99.48%
Multilayer Perceptron	96.2%	92%	93.30%
Support Vector Machine	95%	95%	92.78%

V. CONCLUSION

At present, the unexpected events caused by COVID-19 have raised serious global health concerns and intensified fears of economic recession. Since layoffs have increased and demand outstrips supply when it comes to employment opportunities available on the market, today's economic climate provides ideal conditions for scammers and cyber-scam attacks are on the rise, creating much havoc and confusion within society. Recognizing employment scams is crucial in order to guarantee applicants receive legitimate solicitations from companies. To combat this problem, various machine learning techniques will be discussed as preventative measures in this paper. By taking advantage of a supervised approach and various classifiers, supervised classifiers are used to detect employment scams. Research has demonstrated that Random Forest classifier stands out among competitors when categorizing data accurately. This research utilizes machine learning algorithms such as SVM, Decision Tree, Naive Bayes, Random Forest and MLP for classification algorithms based on machine learning. The proposed methodology achieves an accuracy rate of 99.48%, precision rate of 100%, recall of 92.86% and F1 score of 96.3%for Random Forest Algorithm surpassing existing methods.

Abstract— The prevalence of age-related disease poses a significant threat in the modern world environment. The early identification of these diseases not only enhances the concern towards the elderly people's health monitoring but also increases the young people's awareness. Machine learning diseases are recognized for identifying and predicting the required output based on the given data. Although the initial study utilizing machine – learning for health monitoring indicated moderate precision, further improvements can be made. Random Forest tends to overfit noisy data, especially when the number of trees in the forest is large and the depth of the trees is not appropriately controlled. Overfitting can lead to poor generalization performance on unseen data, making it less effective in identifying age-related issues in new datasets. to improve the model with the use of machine learning frameworks like Random Forest integrated with the XGBoost algorithm with in-built crossvalidation. The RF can provide stability, while Gradient Boosting can improve the accuracy. The algorithm uses the tree-pruning approach to increase the performance.

Keywords— Age- related Disease, Health Monitoring, Machine Learning Framework, Cross Validation, Tree Pruning, Gradient Boosting

I. INTRODUCTION

In the advancing field of medical sciences, every disease has been cured with the help of growing technology and knowledge in the relevant fields. As the ancient field of medical history depicts the early-stage discovery of diseases would increase the healing rate. Also in this modern era, the chance of getting affected by a disease is irrespective of age, So the main idea is to predict that age-related diseases come into the picture with great weightage in showing the industry a great boost of fighting against the disease. The main focus is on diseases related to the cardiovascular, respiratory, disorders of the immune system, pneumonia, infectious, and mental health diseases. Diseases related to hereditary, that are difficult to recognize and harder to cure. The aim is to study and use a classification approach that can further classify the level of disease and its type based on the provided symptoms.[1]

Diseases that are related to mental health are proven to have occurred in an individual irrespective of his age and lifestyle. So, there is an improved chance of curing or stopping its side effects if they can be diagnosed early. Many individuals with a tender age have the chance of overcoming their health issues with this prediction idea. BMI also known as the body mass index is a main factor in identifying a person’s physical fitness and also diseases related to the cardiovascular region [2].

When coming to diagnosing these different types of diseases can be done with the help of Machine Learning Techniques, which are quite popular practices used for predicting the outcomes based on the given dataset. In this paper, we are going to use the models like Random Forest algorithm to predict the data based on decision trees with a high level of accuracy, with the XGBoost algorithm to further render accurate results [3][4].

With the help of these two models, the prediction of the data can have a chance of high increase. Coming to the dataset it should be essential to provide the data that is relevant to the outcome. we are using a dataset that can be given any type of data based on the specific field of predicting the disease. This can give a wide chance of predicting the outcome with a single machine learning algorithm.

This paper deals with developing a generalized algorithm that can be used to predict diseases irrespective of their type, this means that the model can be used by implementing the required data of a field, say heart disease, we can give the dataset the required data about the body mass index and other entries like fat percentage, blood oxygen levels, blood pressure. With this information, we can run the algorithm to predict the type of disease an individual can be affected with [7].

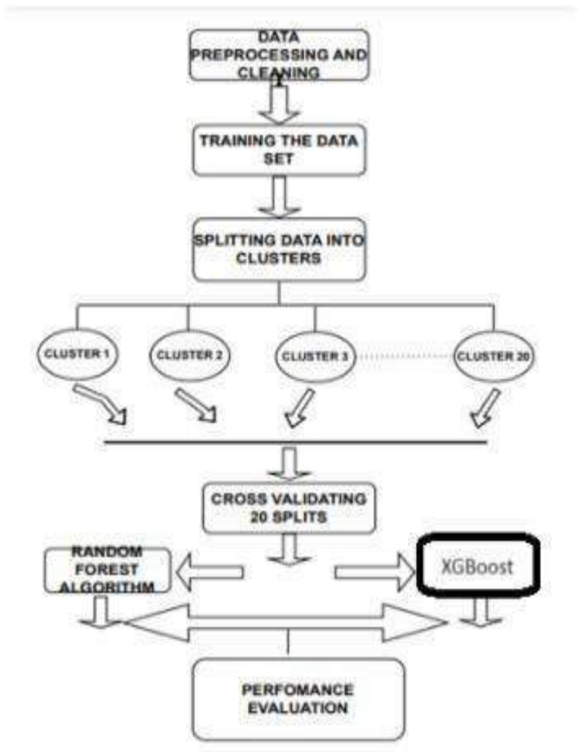

Fig. 1. Flow Diagram

In Fig. 1, the flow diagram depicts the process of employing a Random Forest model along with the XGBoost algorithm for classification tasks, while also incorporating feature e xtract ion techniques for improved performance assessment. Data is initially inputted, followed by feature e xtraction to identify relevant features. Subsequently, the dataset is split into train ing and testing sets. The model is then trained using the training data, and its performance is evaluated using the testing set, with binary cross -entropy serving as the loss function. Various performance metrics are employed to assess the model's effectiveness in classification tasks.

II. Analysis

A. *Analysis Using Random Forest*

Regarding the current model technique, the dataset has been divided into many folds using the classic Random Forest algorithm, which is based on the TensorFlow library. This has been done to increase the range of accuracy and performance evaluation. The primary focus of this methodology is to handle data using their class weights.

The most frequent problem in classification tasks is data imbalance. To solve this, decision trees are used, which have individual nodes that have been broken down into their simpler forms to effectively anticipate the outcomes based on the provided attributes. The primary purpose of parallel processing is to align data from related classes to balance out dataset dissimilarities. Taking into account all the pros and negatives of the current process, adding a small Enhancement can address the problems that can further increase the system's efficiency in terms of speed, accuracy, and class allocation estimation

B. *Classification*

These two aids in the classification of the collected data into two categories: those that indicate that the data appear to be weighted in the anticipated category and those that result in noisy or negative datasets that may impact data imbalance. The un-interfered data, often known as the undesirable data, is indicated by the noisy data [12].

The dataset we used includes testing and training data as well as an additional dataset that is used just as auxiliary metadata for the training set.

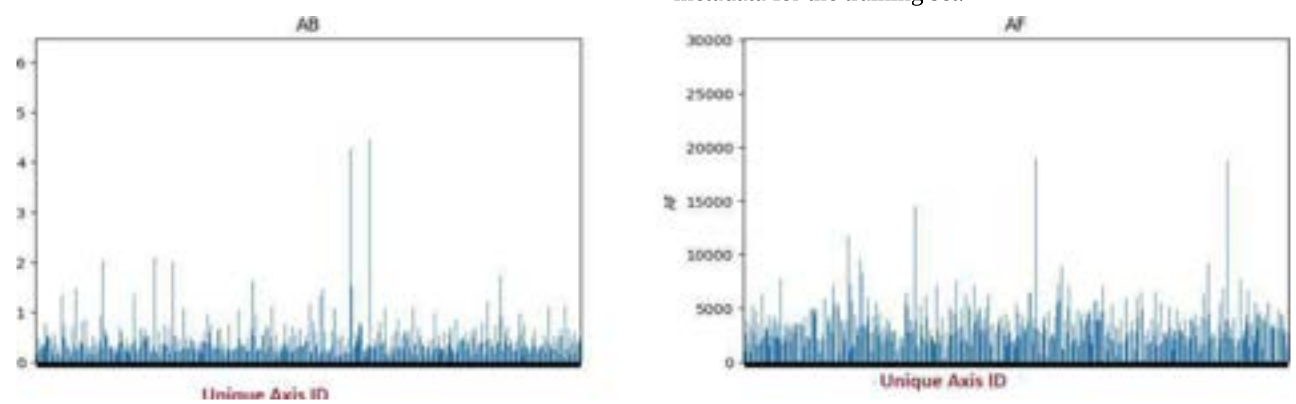

Fig. 2. Graphical representation of Id and anonymous characteristic

X-axis: Unique Id
Y-axis: Individual Characteristic Value

In Figure 2 the graphical representation illustrates the correlation between user ID and anonymous traits, encapsulating their relational dynamics succinctly. The above graphs are obtained by the code which is a grid of bar plots where each plot represents one of the first six numerical features from the dataset. Each subplot has the 'Id' column on the x-axis and the values of the respective numerical feature on the y-axis. This visualization allows for a comparison of these numerical features across different 'Id' values.

C. *Cross Validation*

Given all the considered points of pros and cons of the existing methodology, adding a minor improvement can deal with the issues, that can further boost the system's efficiency in terms of speed, precision, and estimation of the class allocation. This cross-entropy loss comes into the working after we deal with the data evaluation and visualization. Cross-validation is one of the best techniques to improve a model's efficiency and accuracy. Cross-validation is achieved by splitting the data set into k data sets of equal size. These sub-data sets are called folds in cross-validation. Choose one of the folds as the validation set and the remaining folds as the training set. Train your machine learning model on the train ing set. Evaluate the performance of the model on the validation set using a chosen metric which can be accuracy or precision or even F1 score. Calculate the average performance across all k folds. This aggregated performance metric gives you a more robust estimate of how well your model will generalize to unseen data. After cross-validation, you can retrain your model on the entire dataset.

The data can now be cross-validated to find its true positives and true negatives. These two play a role in classifying the acquired data into – whether the data seems to have the weightage in the predicted category or it leads to the negative or noisy datasets that can affect the data imbalance. The noisy data indicates unwanted data that can be termed as un-interfered or ineffective while predicting the disease under the person's health reports. So, to avoid this misconception we can improvise by adding the following formula.

III. DATA COLLECTION AND METHODS

The metadata includes several experimental qualities, Delta, Gamma, Beta, and Alpha. The presence of age-related conditions is indicated by the "Alpha" property, which is divided into two classes: A (no condition, class 0) and B, D, and G (age-related conditions, class 1).

It also has beta, gamma, and delta e xperimental properties. The test set is obtained after training, and "Epsilon" denotes the date of data collection for each subject.

You indeed need to be careful not to overfit when merging models, especially strong ones like XGBoost and Random Forest. When merging these models, consider the following tactics to reduce the chance of overfitting.

The parallel tree processing is successfully achieved using the XGboost algorithm.

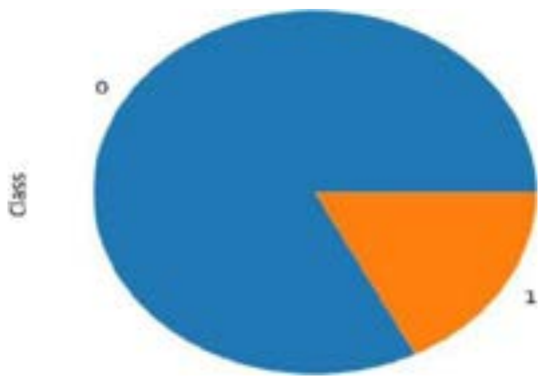

Fig. 3. Pie Chart representing classes.

Figure 3 visually represents the dataset's classification into class 0 and class 1 through a pie chart, effectively highlighting the distribution proportions of each category.

1. Cross-Va lidation: We evaluated the performance of the model using cross-validation. Cross-validation prevents overfitting by offering a more precise assessment of the model's capacity for generalization and aids in projecting the model's performance on unknown data.

2. Regularization: Overfitting can be managed by adjusting the regularization settings in both Random Forest and XGBoost. The ma x_depth, `min_samples_split{, and min_samples_leaf parameters in Random Forest can be used to regulate the tree's complexity

3. Early Stopping: We utilized early stopping to prevent overfitting in XGBoost. Early stopping stops the training process when the performance on a validation set stops improving, preventing the model from overfitting to the training data.

4. Blend Predictions: Since we are blending predictions from different models, consider using simple averaging or weighted averaging rather than assigning too much weight to one particular model. This can help in reducing the risk of overfitting to a single model's idiosyncrasies.

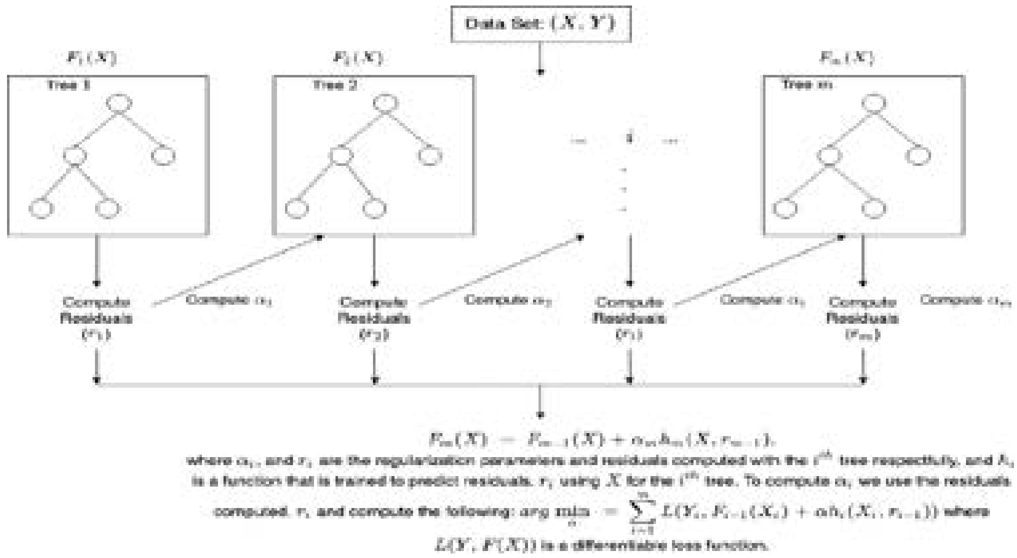

Fig. 4 Working of XGBoost

The Fig.4 explains the detailed working of the boosting algorithm. So, high accuracy can be achieved when we simultaneously use both random forest and XGBoost algorithm.

Combining Random Forest and XGBoost algorithms can significantly enhance predictive accuracy by leveraging the strengths of both techniques. Random Forest is renowned for its robustness to overfitting, ensemble learning capabilities, and ability to handle high-dimensional data, making it a solid choice for diverse datasets. On the other hand, XGBoost, an implementation of gradient boosting, e xcels in optimizing predictive performance through gradient descent and regularization techniques, effectively capturing complex patterns in the data.

By blending these two powerful algorithms, practitioners can exp loit the diversity of their approaches. The Random Forest component provides diversity in the ensemble through bootstrapping and feature randomness, while XGBoost enhances predictive accuracy by iteratively improving model performance on the weaknesses identified by the ensemble.

The combined model benefits from the stability of Random Forest and the predictive power of XGBoost, resulting in superior performance across various domains. Moreover, this hybrid approach helps mitigate individual algorithm shortcomings, such as the tendency of Random Forest to bias towards features with more categories or the potential for overfitting in XGBoost with insufficient regularization.

Ultimately, the fusion of Random Forest and XGBoost yields a formidable predictive model capable of achieving high accuracy and generalization performance across a wide range of tasks and datasets.

IV. RESULTS AND DISCUSSION

In Figure 6, A indicates if there is no age-related condition and B, D, G represent the three age-related conditions that can be provided in the dataset. Plotting this gives overlapping of different age-related conditions for different individuals.

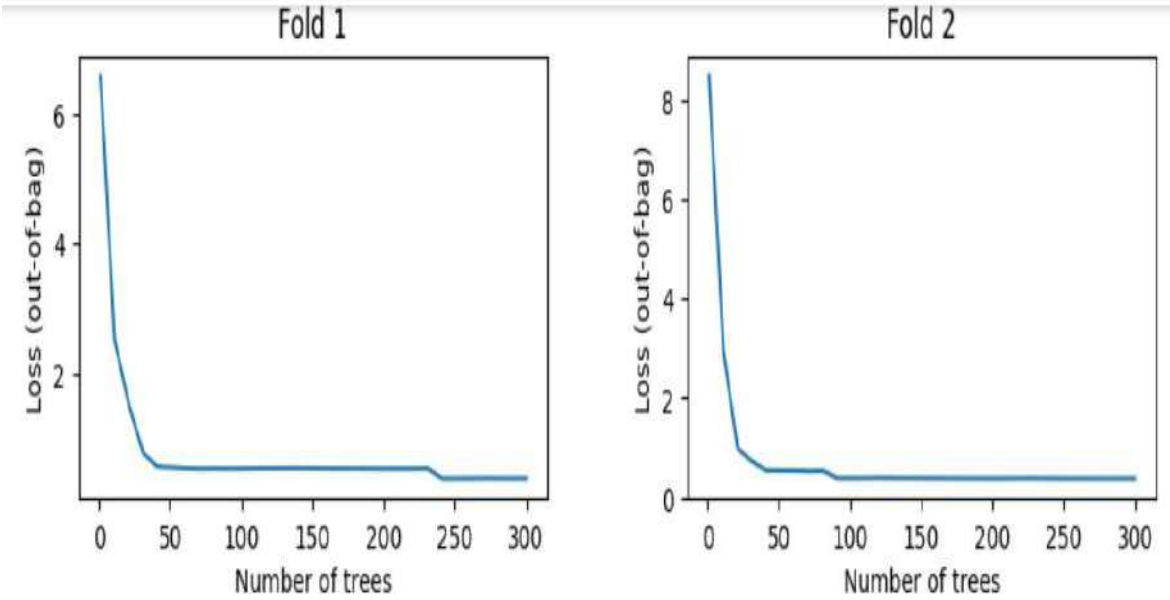

Fig. 5 Folds representing Loss

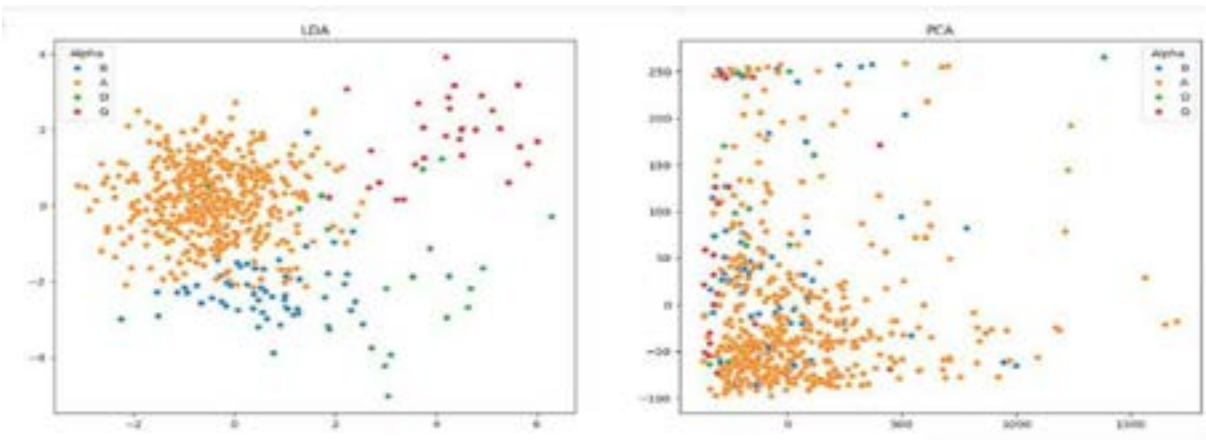

Fig 6 Relationship between A and B, D, and G age-related conditions

The Fig.6 is obtained by a function discriminant that performs dimensionality reduction using Linear Discriminant Analysis (LDA) and Principal Component Analysis (PCA), then visualizes the reduced data using scatter plots.

The data parameter is assumed to be a data frame containing the input data features. The 'Id' column is dropped, assuming it's an identifier rather than a feature. The labels parameter is assumed to be a Series containing the target labels corresponding to each data point. LDA (linear discriminant analysis) and PCA (PCA) are used to reduce the dimensionality of the data to 2 dimensions. LDA aims to find the linear combinations of features that best separate different classes in the data. PCA aims to find the orthogonal linear combinations of features that capture the maximum variance in the data. In each scatter plot, the x-a xis represents the first principal component or discriminant function, and the y-axis represents the second principal component or discriminant function. Points are colored according to the labels provided in the labels parameter, assuming these labels correspond to different classes or categories in the data.

X-axis (Number of Trees)
Y-axis (Loss - Out-of-Bag)

Fig. 7 Relationship between decision trees and loss(o ut-of-bag)

Table 1. represents the table consisting of different machine learning models with their log-loss and accuracy scores to differentiate the working of models. The best model is XGBClassifier() with a learning rate of 0.1 (minimizing cost function) as an added parameter that will reduce the robustness of random forest and improve its accuracy.

The Fig 7 indicates the relationship between the number of trees in the ensemble model and the loss (out-of-bag). This curve helps assess model convergence, detect overfitting or underfitting, and identify the optimal number of trees for the dataset and model configuration. The given data is divided into multiple splits ensuring that the random forest algorithm generated decision trees to learn and train them with the help of ensemble techniques like bagging[short for Bootstrap Aggregating] and boosting on the X-axis. The duration of the training of the models depends on the number of iterations that can occur in the model sequentially.

The loss function or out-of-bag loss is represented on the Y-axis. The OOB loss as used in the Random forest model describes the datasets that were considered as the error or out-of-bound data, that are e xc luded throughout this iterative process of decision trees. This model is used to converge the model data for providing accurate and relevant data that is been used to improve the accuracy.

As a result. the curve in the graph shows us the out-of0bag varies throughout the dataset at each step of the iteration. Then we can find the final convergence of the data that depicts the data over-fitting or under-fitting, thus calculating the ideal number of trees for the particular dataset and model setup.

After filtering the data according to the requirement, we can use the XGBoost algorithm to further improve the model's precision. The XGBoost also stands out for the Ext reme Gradient Boosting, this gradient boosting algorithm typically combines the weak data models that are been filtered out in the random forest, thoroughly re-iterating them[decision trees] to produce a stronger model. The ensemble model we have created above can be gradually boosted with the addition of this gradient model by adding this weaker data to the main dataset, which predicts the exact outcome that it has been put on to have the expected model. The trained data model is then stacked over the same data a meta[model] is trained on them to combine the predictions for better result production.

TABLE 1 PERFORMANCE EVALUATION TABLE

Model	Log- Loss	Accuracy
Logistic Regression	0.684243	0.890756
Support Vector Machine	0.494016	0.915966
Naive Bayes	0.971982	0.87395
Random Forest	0.540528	0.89916
XGB learning_rate : 0.1	0.51748	0.907563
AdaB	0.657281	0.89916

V. CONCLUSION

In the last step, the data again undergoes a performance evaluation, which evaluates a model's performance based on its particular model design and expectation of the flow of the model. It depicts the accuracy of a model based on the probabilistic model by comparing the predicted probabilities to the actual class model. The datasets are then regularized to prevent overfitting cases. Thus performance evaluation can be used to improve the model accuracy. So we can conclude the developed model can be used in various medical fields mainly in the bio-medical fields to be adapted to different sets of data to provide accurate results, The model is suited to working on the both elderly as well as young individuals to prevent the diseases that can be predicted from their health stats.

***Abstract*- The existing course recommendation systems around the world rely on student's past performances, grades and CGPA when giving personalized suggestions. The goal is to provide a customized course recommendation system using Machine Learning (ML) techniques for students. In this project, Machine Learning techniques are used to analyze student feedback about teachers teaching skills, teacher friendliness and course difficulty from the students who already finished said course, this feedback data will be analyzed using semantic analysis. The software developed will be able to give alternative suggestions to students based on their academic performance. By combining the past students' feedback and making real-time suggestions the program will be able to give a clear perspective about the course and the teachers. The final purpose is to give the students a better academic experience by giving them more choices and better course recommendations that will guide them to follow their college career.**

***Keywords*- recommendation, content-based filtering, collaborative filtering, feedback, semantic analysis, K Nearest Neighbours, Support Vector Classifier, personalized suggestions, ratings, Long Short-Term Memory, transformers, Bidirectional Encoder Representations from Transformers, Context Aware Recommenders**

I. INTRODUCTION

In almost every institute, after an academic semester or after an examination, it is common to collect feedback in the form of remarks, about the faculty from students to highlight the faculty's strengths and weaknesses. This data can be used by faculties to get themselves better at their profession. In most of the modern universities or institutes where faculties and courses can be chosen by the students, it will be helpful for the students to know about the course and the faculty better via these feedback-based recommender systems. As present systems that rely on prior performance and GPAs may not provide suitable recommendations that take into consideration a student's preferences and academic achievement, the necessity for a personalized course suggestion system in higher education is becoming more and more obvious. By utilizing machine learning to assess data on instructor rating, friendliness, teaching skills, and course difficulty, collected from semantic analysis of prior students' feedback, the course suggestion system suggested in this study seeks to close this gap. The algorithm can suggest alternatives that are more suitable for struggling students by creating personalized suggestions for courses that match a student's tastes and CGPA and considering the recommended course's number of credits. This makes the process more accurate and equitable. The system's capability to provide suggestions in real-time and consider feedback from past pupils will give them a more complete picture of the subject and instructor, assisting them in making more informed decisions and pursuing their interests. The suggested system's final goal is to enhance the student's academic experience by recommending more pertinent and appropriate courses, which will improve their college experience.

In today's world, there are a few examples of course recommendation systems which use data analytics and machine learning. These recommendation systems are very limited and they are used only by a few colleges. The educational institutes which use these personalized recommendation systems which exist in the current world are reliant on students' branch or their past academic performance, these systems do not consider feedback from students which will then be used to provide recommendations to other students. Not only this but collages usually don't have so much data on the course difficulty, and students are rarely asked to provide feedback on teacher's teaching skills and rarer still asked to tell how "friendly" a particular faculty is. Students and educational institutes want and need better recommendation systems that use machine learning techniques which use much more data in all aspects to provide very accurate recommendations in a personalized manner for the students.

II. MOTIVATION

The motivation lies in its potential to transform the course selection process into a more personalized, informed, and student-centric experience. Most of the traditional systems do not take an interest in individual preferences, learning styles, or the nuances associated with the course content and the effectiveness of the instructor. This has been based on past academic performances of the student and his or her grades. The current project will try to fulfill this gap by adding even more expanded criteria into the recommendation process: detailed students' feedback on teaching skills, friendliness, and course difficulty. Such personalized recommendations aim to give suggestions that are in line with their preferences or those pertaining to his academic standing, precisely to help him create an even more engaging and effective learning environment. This, therefore, means students would do well in courses that appeal to their interests and learning style; hence, happy life at college. Offers of courses: the students can choose well since they know the ability of the teacher and the difficulty level of the course. This transparency helps the students in managing their expectations and preparing well for the courses, hence reducing cases of dropping from courses or performing poorly. Giving students an opportunity to choose the course and the instructor with full comments helps in increasing students' satisfaction with their institution. This not only goes to enhance the level of retention but also more positive culture within the campus. This will then lead the students to be in control of their course selection process and hence be proactive in their course journey. This empowerment can lead to increased motivation, engagement, and ultimately, success.

III. LITERATURE SURVEY

This is very true, considering long-range dependencies in the data and parallel processing of sequences. Transformers model them excellently, and it is for this reason they have been outperforming recurrent networks, including LSTMs, in many tasks (Khan et al., 2021) [1]. Their architectures, in need of inventive biases, are much less modular and can therefore be adapted to a variety of different modalities—from images and text to speech—and scale to large networks and datasets. Although transformers have emerged as the state of the art in many tasks due to their unprecedented ability to model complex patterns and dependencies within the data, a pressing need remains for more interpretable and computationally efficient designs, which would be able to fully use their potential [1].

Transformer-based models such as GPT and BERT, which highlight very significant performance improvements over the previous state-of-the-art architectures in natural language processing tasks. Instead, it goes on to look at the post-BERT models, such as RoBERTa, ALBERT, and ERNIE, which manifest a development by wide margins of the previous approaches (Gillioz et al., 2020) [2]. The work by Kora and Mohammed, 2023 [3], is a deep analysis of the most used transformer techniques within the context of their roles in text classification tasks and is also a great source for using different BERT models. The authors review 109 works of research employing the BERT models for text classification, the methods used, and three transformer model variants, explaining common models in each and what NLP tasks they're appropriate for. Amara et al., 2020, presented to implement a collaborative filtering-based recommendation system using a TextCorpus and the Visual Analytics Interpretable Transformer model to obtain transparent and explainable personalized recommendations [6]. It presents a significant gap, however, in not applying the proposed visualization methods to a concrete dataset, thus missing an opportunity to showcase their practical applicability and effectiveness in real-world recommendation scenarios. Rani, N. (2023) [7] addresses the trust issues in Context-Aware Recommender Systems (CARS) within educational environments like MOOCs and digital libraries. It aims to understand user perceptions, explore design interventions, and propose a multidimensional framework to enhance trust in these systems. The paper identifies the opaque nature of CARS, along with automation and context detection inaccuracies, as primary challenges to user trust. Looking ahead, it suggests focusing on design improvements, better context recognition, and specific trust-building measures to develop more reliable and transparent CARS. For the recommender to function, semantically analysed sentences in the form of numbers should be present. So, first, you need to preprocess sentences. One should remove stop words and vectorize the sentences. Vectorization can be established by TF-IDF vectorizer [8] or count-vectorizer.

Zhao et al., 2021 [9] focused on an online course recommendation model that leverages implicit user behavior data, including login, learning, and course selection details, to generate suggestions using an item-based collaborative filtering algorithm. It has been observed that the precision and recall rates of the model improve under various conditions. However, the paper does not specify the exact limitations of the current model despite discussing enhanced performance over the operation data from a two-year period on an education platform. The paper [13] investigates the use of LSTM neural network models for text classification, leveraging the rich semantic information from word vectors. It discusses how LSTM can effectively differentiate contributions of words and sentences for text categorization and demonstrates an improvement in performance and accuracy over traditional methods (Zhang, 2021) [13].

IV. DATASET

The main dataset used has two attributes – Sentence and Rating. 'Sentence' attributes contain the academics related feedback sentences and 'Rating' attribute contains the corresponding rating to the sentences, ranging from 1-5 as show in table 1.

Rating	Sentiment
1	Very Negative
2	Negative

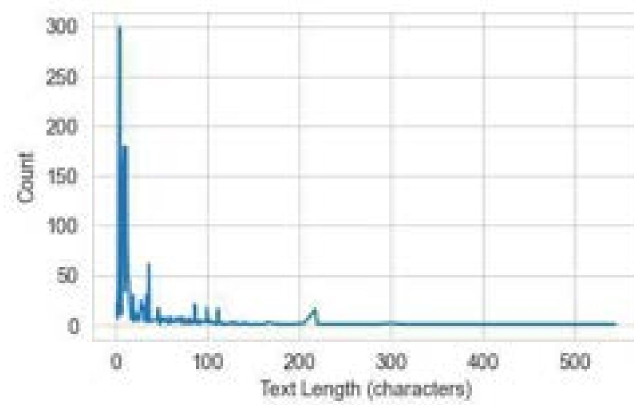

Fig. 3. Line Chart – Length of text vs Count

V. METHODOLOGY

The engine recommends courses in a personalized manner, for this first it needs to preprocess the data. Natural Language Processing (NLP) techniques are incorporated. Semantic analysis is used to preprocess the feedback data of a course or a faculty member, from the students who already completed the course or had that faculty before. Feedback of different attributes from the students such as the teacher friendliness, teacher rating and the teacher teaching skills and finally the course difficulty.

The engine will consider a student's CGPA and it will adjust the courses which are to be recommended according to a student's ability to clear the course, not only this but the system will also be suggest the student to take a course with lesser credits or difficulty to pass.

The methodology is designed for sophisticated, advanced, and personalized course recommendation system that will be implemented into the educational institute for its student's needs and requirements by using advanced machine learning techniques. The system will deploy various advanced algorithms like Logistic regression to predict pass or fail if the student followed the course recommended by the system. semantic analysis using Multinomial Naive Bayes using bag of words, LSTM, BERT. The system uses K Nearest Neighbor algorithm, cosine similarity - content based filtering algorithm and weighted cosine similarity - collaborative filtering algorithm.

5.1. Feedback Analysis:

The input from the students will be in the form of sentences for various attributes like 'Teacher Rating', 'Teacher Friendliness', 'Course Difficulty', 'Teaching Skills'. The sentences should be rated on a scale of 1 to 5. So, sentences are classifying into classes of 1, 2, 3, 4, 5 rating. Feedback analysis using reviews of past student along with the ratings. The feedback rating is extracted using:

- Multinomial Naive Bayes model using bag of words
- Support Vector Classifier
- LSTM model
- BERT (Bidirectional Encoder Represenions from Transformers)

Firstly, the various libraries necessary are imported and the dataset is loaded into a pandas dataframe. Using the imported packages, the text data set is first pre-processed by first removing the stop words, removing the numbers and digits, converting all text to lowercase, then lemmatizing the remaining words. For a term 'i' in document 'j' –

$$\boldsymbol{W_{i,j}} = \boldsymbol{TF_{i,j}} \times \mathbf{log}(\frac{\boldsymbol{N}}{\boldsymbol{df_i}}) \qquad (1)$$

where,

$TF_{i,j}$ = No. of occurrences of term i in document j.
df_i = No. of documents containing term i.

5.1.1. Multinomial Naïve Bayes

The string data is vectorized using an n-gram of dimension [1x1] which is essentially the unigram model. Using the count of each of the words and the sentiment the bag of words model is made and stored. Then the dataset is split into training and testing datasets. The accuracies and performance metrics are then recorded to measure the efficiency of the model. The above model is used for the semantic analysis of the text feedback from the students to generate numerical values and are stored in a dataset to then be used in the recommendation system.

$$\boldsymbol{P(C_i|X_1 \cap X_2 \cap \ldots \cap X_n)} = \frac{\boldsymbol{P(X_1|C_i) \times P(X_2|C_i) \times \ldots \times P(n|C_i) \times P(C_i)}}{\boldsymbol{P(X_1) \times P(X_2) \times \ldots \times P(X_n)}} \qquad (2)$$

5.1.2. Support Vector Classifier

The Support Vector Classifier, or SVC, is an important tool in sentiment analysis, since it maps the features word frequencies or TF-IDF (term frequency-inverse document frequency) scores from the text data—transformed into vectors—very skillfully into a large high-dimensional space. SVC finds the most preferable hyperplane that effectively divides several categorized sentiment data points—for example, positive or negative. One of the most striking features with SVC is its use of kernel functions, which ingeniously project data onto higher dimensions in such a way that they smoothly handle the difficulties offered by non-linear separations. This capability allows the SVC to demarcate the best possible boundary, even amidst the intricacies of complex, high-dimensional datasets. Consequently, this results in a model that boasts a remarkable ability to classify the sentiment of text inputs with precision, all based on their vectorized embodiments.

5.1.3. LSTM – Long Short-Term Memory

The model architecture comprises an Embedding layer for word vectorization of 128 units, followed by two LSTM layers with dropout for regularization, and a Dense output layer for classifying text into one of five sentiment categories. The model is trained and evaluated on a split dataset, providing a measure of its accuracy in the ratings

classification. The activation function used in this model is 'softmax', and the 'adam' optimizer is used. The model is trained for 20 epochs. The model shown in figure 4 is used for performing the comparative semantic analysis of the text feedback from the students to generate numerical values and are stored in a dataset to then be used in the recommendation system.

5.1.4. BERT – Bidirectional Encoder Representations from Transformers

BERT (Bidirectional Encoder Representations from Transformers) model for a sentiment classification task with TensorFlow and Hugging Face's Transformers library. It then loads a pre-trained BERT tokenizer and model specifically designed for sequence classification, adjusting the model to the task's number of labels. Input sentences are tokenized and converted into TensorFlow datasets for both training and testing phases. The model is compiled and trained on the processed data, and its performance is evaluated by measuring accuracy on the test set. BERT's architecture enables it to understand the context of words in a sentence by considering the words that come before and after, making it highly effective for tasks like sentiment analysis.

5.2. Recommender Systems:

In the course suggestion system, classification algorithms are used to categorize the courses and make personalized recommendations based on a student's preferences and academic performance. In the course suggestion system, the classification algorithm is trained to categorize the courses based on their features such as teacher rating, friendliness, teaching skills, and course difficulty.

The techniques used in the course suggestion system are:

- K-nearest neighbors (KNN) algorithm
- Cosine Similarity -Content-based filtering
- Weighted Cosine Similarity - Collaborative filtering

Then after loading the semantically analyzed student feedback dataset into a pandas dataframe, the feature selection and target variables are assigned to X and Y variables. Here, the feature selection contains attributes like 'Teacher Rating', 'Teacher Friendliness', 'Course Difficulty', 'Teaching Skills', 'Credits'. Target variable is the 'Course ID'. Then the user input is taken as a student enters their preferred teachers and course ratings.

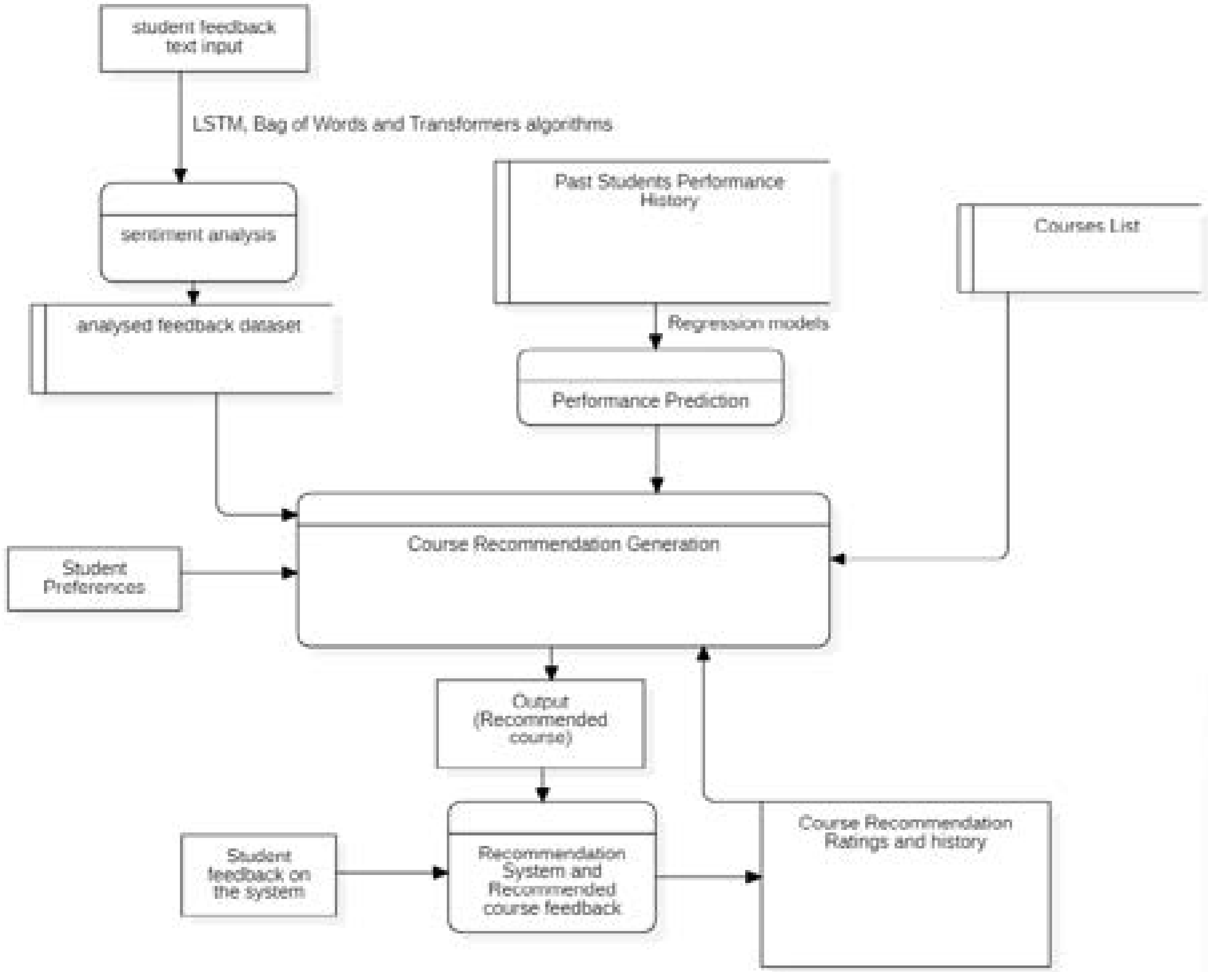

Fig. 4. Proposed Architecture Diagram

5.2.1. K-Nearest Neighbours

A K-Nearest Neighbours model is trained on the above-mentioned training datasets. Using the above mentioned trained KNN model, the course and faculty which are closest match to the student preferences is chosen as the course recommendation. Calculate the distance (either Manhattan or Euclidian) from the data point.

$$\mathbf{d(Y,\ X)} = \sqrt{(\textstyle\sum_{1}^{N}(\boldsymbol{Y_i} - \boldsymbol{X_i})} \qquad (3)$$

The point(X) or data which is closest to the input data(Y), i.e., which has least d(X, Y) is recommended.

After the recommendation, the student is asked to rate the helpfulness of the course recommendation system and then this rating, student's preferences and recommended course information is stored for collaborative filtering-based model later.

5.2.2. Content based Filtering

The system takes the student preferences with each of the semantically analyzed course cum faculty feedbacks and calculates the cosine similarities between each of them by treating them as vectors.

$$\mathbf{similar_{content}(A, B) = \cos(\theta)} = \frac{\boldsymbol{A \times B}}{||\boldsymbol{A}||\times||\boldsymbol{B}||}$$

$$= \frac{\sum_{i=1}^{n}(A_i \times B_i)}{\sqrt{\sum_{i=1}^{n} A_i{}^2}\sqrt{\sum_{i=1}^{n} B_i{}^2}} \qquad (4)$$

The cosine similarities are all stored in a new column and then the dataset is sorted according to the most similar courses to the student's forementioned preferences and the most similar course is suggested.

5.2.3. Collaborative Filtering

The system takes the student preferences with each of the semantically analyzed course and faculty feedbacks calculates the weighted cosine similarities between each of them by treating them as vectors as in cosine similarity and multiplying with weights that are calculated from the previous recommendation feedback ratings which are considerations taken for the collaborative filtering model.

$$\mathbf{similarity_{collaborative}(A, B) = W_k \ x \ \cos_k(\theta)}$$

$$= \boldsymbol{W_k} \frac{\boldsymbol{A \times B}}{||\boldsymbol{A}||\times||\boldsymbol{B}||}$$

$$= \frac{\sum_{i=1}^{n}(W_k \times A_{i,k} \times B_{i,k})}{\sqrt{\sum_{i=1}^{n} A_{i,k}^{2}}\sqrt{\sum_{i=1}^{n} B_{i,k}^{2}}} \quad (5)$$

Alike cosine similarity, the weighed cosine similarity values are stored and most similar courses are suggested.

5.3. Pass or Fail Prediction using Logistic Regression:

After the course recommendation is over, the student's CGPA is taken into consideration and then by using a regression model trained on past student's performance history, a prediction is made to help the student understand the difficulty of the course and if the student might or might clear the course.

Here, the system uses Logistic Regression to predict if the student will be able to pass the course, based on data of students, their CGPA and if they have passed the course in previous semesters. The independent variables are 'Credits', 'CGPA' and 'Course Difficulty'. The target variable is 'Pass/Fail'.

VI. RESULTS AND DISCUSSIONS

An enhanced decision-making algorithm is involved which helps students pursuing their education in any institutions, in which the freedom of choosing their faculties and courses is granted to the students.

6.1. Feedback Analysis

Here, the feedback is received by the faculty to know how the students feel regarding various aspects of the course and teaching. This feedback is semantically analyzed with various machine learning and deep learning models and a comparative study is conducted. Based on a custom dataset, the deep-learning models BERT and LSTM are compared with Multinomial Naive Bayes, Random Forest, Support Vector Classifier. The sentences should to classified into numerical ratings ranging from 1-5. Based on the dataset containing about 2061 entries, BERT has got the highest accuracy of 84.99%. LSTM also stands out compared to other machine learning models, with an accuracy of 82.57%. The confusion matrix of LSTM that is trained for 20 epochs, in Fig. 5, shows that 75 of 78 values of rating '1', 70 of 83 values of rating'2', 86 of 104 values of rating '3', 78 of 103 values of rating '4' and 32 of 45 values of rating '5' are predicted correct.

Rating	Precision	Recall	F1 Score
1	0.96	1.00	0.98
2	0.84	0.96	0.90
3	0.83	0.77	0.80
4	0.76	0.79	0.77
5	0.71	0.59	0.65

Table 2. Evaluation metrics for LSTM

Coming to Multinomial Naïve Bayes, it proves to be accurate for smaller lengths of sentences, but from the analysis of dataset in Fig. 3, there are considerable number of sentences whose lengths are greater than 20. As the system uses unigram multinomial naïve bayes model, there accuracy is 75.78%, which comparatively is lower than other models.

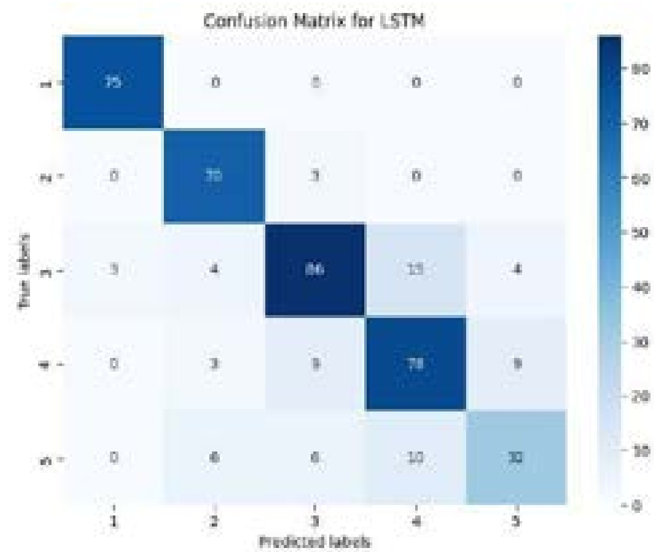

Fig. 5. Confusion Matrix for LSTM model

Rating	Precision	Recall	F1 Score
1	0.83	1.00	0.91
2	0.92	0.64	0.76
3	0.87	0.74	0.80
4	0.57	0.90	0.70
5	0.86	0.35	0.50

Table 3. Evaluation metrics for Multinomial Naïve Bayes

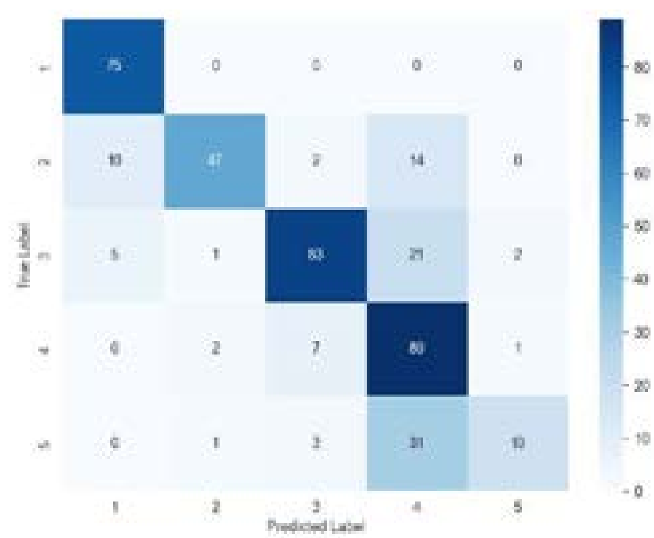

Fig. 6. Confusion Matrix for Naïve Bayes model

Random Forest Classifier, which is a type of ensemble learning has got a decent accuracy of 77.72%, with a precision of 79%, and a decent recall of 75%. Logistic Regression Classifier on the other hand, has got an accuracy of 79.17, which is greater than the Support Vector Classifier (SVC).

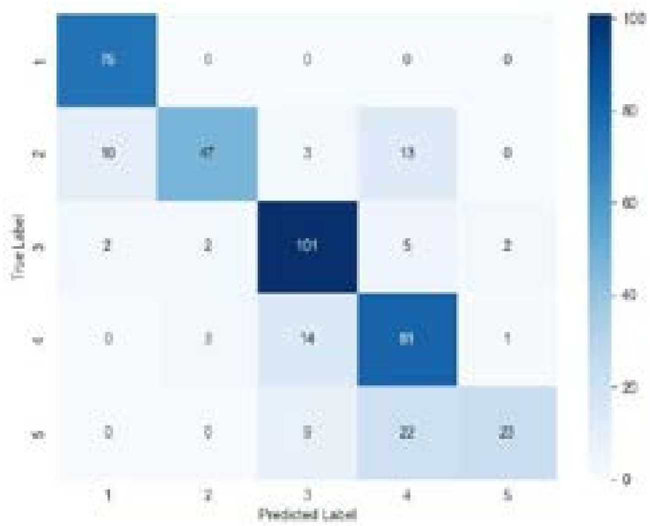

Fig. 7. Confusion Matrix for SVC model

Model	Acc	Avg Precision	Avg Recall	Avg F1
BERT	84.9%	85%	84%	82%
LSTM	82.5%	82%	83%	82%
Logistic Regression	79.1%	81%	79%	78%
SVC	77.7%	81%	78%	76%
Random Forest	77.7%	79%	78%	78%
Multinomial NB	75.7%	80%	76%	75%

Table 4. Comparison of Evaluation Metrics of various models

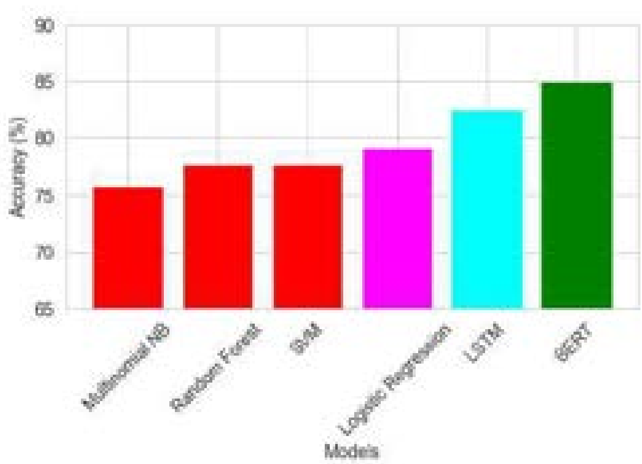

Fig. 8. Models' Accuracy Comparison

6.2. Recommender Systems

Once the semantically analyzed values are available, KNN, cosine similarity and weighted cosine similarity are comparatively analyzed to recommend course and faculty based on the inputs from the students. The sample input and output of the recommender module is shown in the Table 5 and 6.

Your CGPA	9.03
Preferred course's number of credits (1-5)	3
Preferred teacher's rating (1-5)	2
Preferred teacher's friendliness rating (1-5)	5
Preferred course's difficulty rating (1-5)	5
Preferred teacher's teaching skills rating (1-5)	4

Table 5. Sample Input for Recommender System

S. No.	9
Course Code	CSE2001
Course Title	Computer Architecture & Organization
Course Type	PC
Lecture	3
Tutorial	0
Practical	0
J Comp	0
Credits	3
Faculty	Dr. Jotindar

Table. 6. Sample Output for Recommender System

6.3. Pass or Fail Prediction Using Logistic Regression

After courses are recommended from the semantically analyzed database, it is possible that the recommended course is in line with the inputs provided by the student, but might be difficult for the student to complete. This is possible when the student deliberately chooses difficult course or course with more credits. There is possible chance of the student to fail in the subject. This is an additional module for students to make sure that they are in safe zone. In this module, logistic regression is used to train on attributes – 'CGPA', 'Course Difficulty', 'Credits' in order to predict 'Pass/Fail', based on data of students from previous semesters. From the dataset, using the logistic regression, an accuracy of 92.4% is obtained, with a whopping precision of 94.8%.

Accuracy	Precision	Recall	F1 Score
92.4%	94.8%	91.4%	93.07%

Table 7. Evaluation Metrics for Pass/Fail Pred

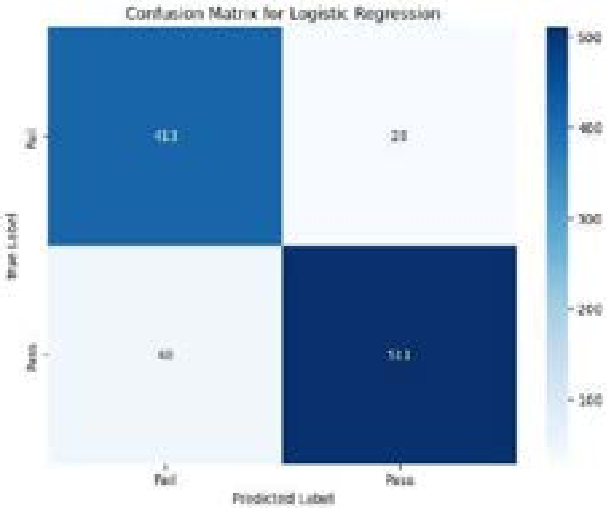

Fig. 9. Confusion Matrix for Pass/Fail Prediction

VII. CONCLUSION AND FUTURE WORK

An accuracy of ~85% is obtained for the semantic analysis of dataset of sentences where there are significant number of sentences which are greater than the length of 50 characters. The pass/fail prediction also obtained an accuracy of ~93%. Overall, the system would be of great use across different institutes, across different nations, where the students shall choose their courses and faculty. This system would help students find right courses, which eases their learning experience. The system becomes more reliable as more and more feedbacks are passed as input over a span of time.

The system can be extended to next stage, where the student can also choose their domain of interest, as in, ‘Data Analytics’, ‘Machine Learning’, ‘IOT’, ‘Humanities’, etc. This requires an additional dataset with list of courses under each domain. Based on the input from students, the system filters out the domain the student is interested in and suggest courses and faculties within the domain. Another idea that can be implemented is ‘Priority Attributes’. The user/student can prioritize the attributes they want.

Abstract—**Agriculture in India is becoming an undesirable livelihood for many considering the uncertainty of making a profit due to either crop failure or an unfavorable market. The primary challenge Indian farmers face today is the lack of information such as weather patterns, ideal crop variety, and market trends. While many current systems try to address this problem, they fail to recognize the diversity in soil and environmental conditions in India, thus resulting in systems applicable in very niche scenarios. With nearly 70% of the Indian population engaged in agriculture, the first issue to be tackled is making an application widespread. Fortunately, smartphones and the internet exist in even the most remote regions of India. This application directly addresses the pressing issue by offering a decision support system that uses machine learning techniques to offer valuable information to farmers anywhere in India. The system has four unique utilities: Crop recommendation using soil quality or location, yield prediction, and price prediction. Various machine learning algorithms such as Decision Tree, Random Forest, KNN, and Naive Bayes were tested for each module to select the algorithm that provided the best accuracy. The machine learning models have been trained exclusively using Indian agricultural data from data.gov.in. The utility offered by the back-end ML modules is presented in a simplistic and intuitive user interface. With help of the information presented by the application, farmers can make informed decisions having a higher probability of success in terms of cultivation and profit.**

Keywords—Agriculture, Crop Recommendation, Crop Yield Prediction, Crop Price Estimation, Machine Learning, Decision Tree Learning, Naive Bayes, Random Forest

I. INTRODUCTION

The effect agriculture has on India and its people need not be understated. On top of being one of the major contributors to the nation's GDP, it is also the primary means of livelihood for many Indian families through earnings. However, the people who depend on this sector for their needs face multifaceted challenges ranging from environmental stressors to fluctuating market demands, significantly affecting crop yield and profitability. Farmers struggle with weather and market uncertainties, limiting their ability to make smart choices when it comes to what crop is to be cultivated or when is the right time to grow a particular crop. Outdated practices miss crucial tech information on soil, weather patterns, and markets, affecting sustainability and profits. Overcoming these challenges requires modern agriculturists in India to not only be adept in growing and harvesting crops but also earning a profit by selling them as commodities. This project introduces a mobile/web application designed to predict crop prices, forecast yields, and recommend optimal crops based on various factors, specifically tailored to the Indian agricultural context. The application assists farmers in achieving their end goal of earning a healthy living by keeping them informed about every aspect of agriculture in India. Taking into consideration the fact that historical data is available in plenty when it comes to Indian agriculture, a machine-learning approach is most appropriate to tackle the objective of using software to analyze a situation and provide helpful data. Machine learning algorithms such as decision trees and random forests are utilized for predicting price, yield, and crop variety.

To tie it all together, a simplistic and intuitive User Interface is built to house the back-end algorithms. The application can be accessed either through a smartphone or a personal computer, and the UI is built separately to cater to the differences in each of the two mediums. Data is presented to the user as numerics and graphs for easy interpretation.

II. RELATED WORKS

There have been a lot of steps taken in terms of research and development in utilizing modern computing technologies in the domain of Indian agriculture. Much inspiration has been derived from existing systems to enhance this application.

Dhawale, S et al., [1] proposed a system where machine learning techniques such as Gaussian and Kernel Naive Bayes are used to suggest crops by taking into account factors such as crop type, soil quality(nitrogen, potassium, phosphorus, and pH) weather patterns (rainfall and humidity), and historical crop harvest data. The parameters regarding the soil quality are The system was implemented through MATLAB's Classification Learner App. The accuracy achieved was impressive surpassing alternative models in crop prediction. This study highlights the transformative potential of machine learning in agriculture by offering farmers information to which they previously didn't have access. The comparative study performed as part of their research emphasized the superiority of their model to the existing literature reinforcing the efficacy of their research.

Moysiadis, V et al., [2] proposed a Cloud Computing-based Smart Farming application using UAVs and ground sensors that can provide real-time data to the users. Scalability and security have not been taken into consideration by a vast majority of the existing system. The team has addressed this by adopting the microservices architecture instead of a monolithic one. The operation of the system takes place within a Docker container and uses RESTful APIs for communication. The web-based GIS interface caters to user roles, including administrators, agronomists, and farmers, featuring various components like soil moisture graphs and NDVI images.

Elbaşı, E et al., [3] have performed an analysis of applying machine learning techniques to increase the yield of a crop by improving or changing agricultural practices. It explores the potential of ML to optimize various aspects of farming, from predicting optimal planting times to identifying disease threats early on. Several IOT devices have been implemented for data collection and the collected parameters include various factors that help us access soil quality. Data preprocessing is performed to ensure accuracy, after which fifteen different machine-learning algorithms have been identified and evaluated. Bayes Net and Naive Bayes Classifiers are selected for their high accuracy in classification tasks relevant to agriculture. The research suggests several ways to improve crop yield to address challenges such as food shortages and resource wastage.

Kuradsenge, M et al.,[4] proposed a research that investigates how climate changes impact agriculture in the Musanze region in Rwanda. The team gathered historical weather and crop yield data using data mining techniques. From the collected data they developed machine-learning models to predict crop yield for Irish potatoes and maize. Multiple machine learning algorithms like Random Forest, Polynomial Regression, and Support Vector Regressor were applied to the dataset to find the best-performing algorithm for this case. Amongst the compared ML models, Random Forest presented the best results with a root mean squared error of 510.8 and 129.9 for potatoes and maize, respectively, and R2 values of 0.875 and 0.817. These results were precise in identifying the optimal weather conditions for each crop.

Chaudhari, A et al., [5] proposed an application for crop recommendation and optimal pricing using ShopBot. Crop recommendations are made using a Decision Tree algorithm, and the input parameters include rainfall patterns, temperature, and location. The machine learning model makes crop predictions with an accuracy of 87%. The ShopBot tool provides price comparisons to make the experience of purchasing crops online a more efficient one. The team compared multiple scraping tools such as Scrapy, Beautiful Soup, and Selenium and chose to proceed with Selenium because of its versatility in handling JavaScript on E-Commerce websites. The study also tackles the difficulties and nuances in converting the price per gram to the price per seed as the latter metric has proven to be more useful to farmers. Overall the system aims to reduce search costs, enhance optimization, and provide farmers with the best commodity options.

Celik, M.F. et al., [6] presented a study on predicting soil moisture based on satellite imaging using a deep learning model that mixes Sentinel-1 backscatter data with Soil Moisture Active Passive (SMAP) data. The Long Short-Term Memory (LSTM) model incorporated weather, radar satellite TV for PC records, soil kind, and topography. Trained on data from the International Soil Moisture Network (ISMN), the LSTM model carried out an R2 score of 0.87 and an RMSE score of zero.046, showing predictive accuracy, mainly in arid and semi-arid regions. Performance variations had been mentioned across distinctive biomass, land cowl, soil textures, and climates, with decreased accuracy in areas with high NDVI values. This research underlines the ability of the use of LSTM for soil moisture prediction in agricultural applications amid global warming challenges.

Linchao, LI et al., [7] presented their research about wheat yield predictions in China. They propose the use of machine learning models to enhance the accuracy of the predictions. Different machine learning algorithms such as Random Forests and Support Vector Machines were tested for their effectiveness in predicting wheat yield when given input parameters like satellite-based vegetation indices, climate data, and soil properties. The research revealed that the inclusion of vegetation indices enhances the precision of the models. Additionally, the research also proved that NIRv had a superior performance in comparison to NDVI and EVI. Random Forest was chosen as the designated algorithm over Support Vector Machines as it showed better results in terms of accuracy. Wind speed, solar radiation, humidity, and soil carbon content influenced wheat yield prediction most.

Innocent, N et al., [8] made extensive use of Small Area Estimation (SAE) methods with a linear regression model to estimate the crop yield. The yield is being predicted for two specific varieties of beans in Rwanda: bush beans and climbing beans. In 2014, the year the experiment was carried over, data obtained from the National Institute of Statistics in Rwanda (NISR) through a seasonal agricultural survey showed a considerable gain in yield estimation accuracy.

Veenadhari, S et al., [9] have researched the use of machine learning to predict crop yield based on changing climatic conditions in India. A web tool named 'Crop Advisor' is utilized to identify the most influential parameters that affect crop yield, the tool relies on the C4.5 algorithm to identify the parameters. After identification, the tool provides insights into the relative influence of each parameter on crop yield. Equipped with the knowledge of the most influential parameters, the team gathered yield and weather data for the past 20 years in the Madhya Pradesh region. From the collected data the C4.5 algorithm built a decision tree that could accurately predict crop yields with an accuracy of anywhere between 76% to 90% depending on the region.

Gandhi, N et al., [10] used machine learning techniques to identify ways to enhance accuracy in predicting crop yield under diverse climatic conditions in India. The study focuses on cereal crops such as rice which form the backbone of Indian agriculture. The machine learning algorithm used in this research is the Support Vector Machines (SVM) classifier implemented through the WEKA tool. 27 districts in the state of Maharashtra were identified to gather data from. The collected dataset consists of parameters such as minimum, maximum, and average temperature, rainfall, area of cultivation, and yield of crop Upon testing other machine learning algorithms along with the SVM for metrics such as mean absolute score, R2 score, and root relative squared error. Comparing the results of the SVM with alternative machine learning techniques revealed that other machine learning algorithms outperformed it. Hence SVMs are not suited to make accurate predictions about crop yields in India.

Several challenges must be addressed when integrating machine learning into agriculture. While machine learning is a very powerful tool, training models that can make accurate predictions or classifications requires a vast amount of structured data. This can be especially troubling in the case of yield predictions because yield can vary drastically with the smallest of changes in the environment. In such cases, it is very difficult to obtain data to build a machine-learning model.

No single application can help farmers from all over the world. The incredible diversity of soil and weather conditions makes this task impossible. A software application can realistically cater to only a small region. Scalability is another area that needs to be addressed, if an application proves to be helpful to farmers, it has to be scaled up with the help of cloud computing, but this can hurt the performance and will also make the application more complex. The most impactful aspect of agriculture apart from soil is the weather, and even with satellite imaging, weather changes can be reliably predicted only a few days in advance, keeping this in mind, a software application must be able to adapt very quickly to new information and also with only a little information. The requirement of a significant amount of information to make predictions will render the application useless, as it is a time-consuming process. In countries such as India where the average farmer's income is in the lower bracket of society, the cost of using such applications must be minimized as much as possible.

III. PROPOSED METHODOLOGY

The Integrated Agriculture Decision Support system aids farmers in making informed decisions utilizing four modules: crop recommendation using soil conditions, crop recommendation using location and season, crop yield prediction, and crop price estimation. Fig. 1 outlines the general architecture of the proposed application incorporating the various features used. The decision support application can be accessed via a smartphone or a personal computer with an internet connection. As soon as the user opens the app they are greeted with the user interface. The UI has been designed to be simplistic and intuitive without compromising utility. The UI has been laid out as a dashboard that presents the user with all the options and information. Information is presented not only as numerics but also in the form of graphs for easier understanding.

A. Crop Recommendation Based on Soil Conditions

The Crop recommendation using the soil quality module is the central component of the decision support system. It considers the soil conditions, weather, and environmental conditions such as temperature and humidity to suggest the most suitable crop. The model is trained on a dataset of 2200 samples from 22 distinct crops to construct this module, all the required data has been obtained from the agricultural datasets present in data.gov.in. The training data is made up of plant macronutrients such as nitrogen (N), phosphorus (P), and potassium (K) along with other factors such as pH levels and environmental variables like temperature, humidity, and rainfall. These attributes are essential because they are closely related to crop output and viability. For example, phosphorus is required to convert solar energy into chemical energy, while nitrogen is necessary for plant growth and leaf development. Similarly, soil pH influences nutrient availability, and potassium is essential for controlling water and nutrient flow in plant cells. To ensure the best accuracy while predicting the crop, three different machine learning algorithms: Decision Tree, Random Forest, and Gaussian Naive Bayes Classification were tested for parameters including accuracy, f1-score, precision, and recall. Out of the 3 algorithms, Gaussian Naive Bayes and Random Forest gave promising results with the Naive Bayes classifier performing marginally better than Random Forest.

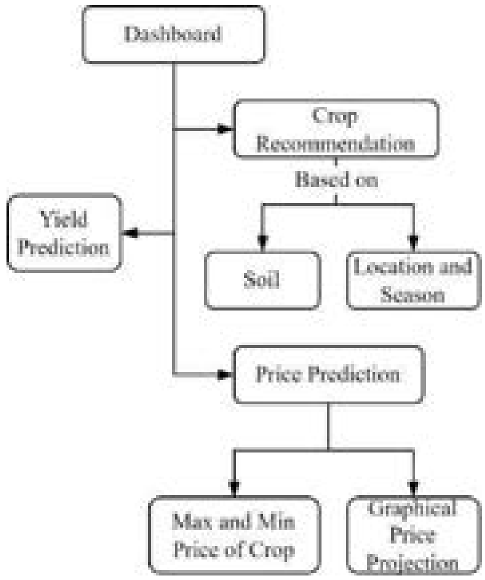

Fig. 1. Architecture of Decision Support System

Personalized crop recommendations in real time are the primary function of this module. When a farmer uses the program, the latitude and longitude coordinates of the user's location are retrieved using the ipinfo.io API based on which the district and state are generalized, allowing for their geopositioning. Afterward, current environmental data, including local temperature and humidity levels, are retrieved from OpenWeatherMap.org using the location attributes provided in the previous step. However environmental considerations by themselves are insufficient to provide tailored crop recommendations. Farmers must also input the pH and nitrogen levels of their soil into the system. These can be ascertained by laboratory analysis or soil testing kits. When the farmer inputs this data into the app, the system uses the selected machine learning model, here, the Gaussian Naive Bayes Classifier to process it and suggest crops that are most appropriate for the soil and climate. The Crop Recommendation module discovers crops that will thrive and offer the maximum returns, in addition to suggesting crops that will grow.

B. *Crop Price Estimation Module*

A vital part of the agricultural decision support system is the Crop Price Estimation Module which gives farmers access to predictive and analytics capabilities so they may anticipate crop prices. This module's core methodology centers on the application of a strong Decision Tree Regressor, which was selected for its capacity to represent non-linear interactions and yield comprehensible outcomes. The Decision Tree Regression algorithm was selected among the three tested, the other two namely, logistic regression and KNN Regression. The Decision Tree Regression presented the best metrics in terms of accuracy.

The initial step in constructing this module was obtaining large datasets for every crop from the Government of India's open data portal, data.gov.in. This dataset contains historical prices for the 23 most-grown crops in India, together with other information including the Wholesale Price Index (WPI), year, month of sale, and recorded rainfall. To ensure the integrity of the predictive model, data preprocessing is carried out to get rid of the dataset of any anomalies or missing values. Feature engineering is used to extract more data on holidays, supply and demand imbalances, and policy changes that may have an impact on agricultural prices.

After preprocessing, different machine learning algorithms such as linear regression, Decision Tree Regressor, and KNN Regressor are tested. Upon comparing their R2 scores the Decision Tree Regressor was selected. The model's performance is optimized by fine-tuning hyperparameters including tree depth, minimum samples per split, and a criterion for gauging a split's quality using grid search and cross-validation techniques. The model chosen for deployment is the one with the best accuracy, as shown by the lowest mean absolute error (MAE) or the greatest R-squared value during cross-validation. This model, which can anticipate future prices based on input features, acts as the module's predictive engine. Users can interact with the system by entering the necessary data, such as the month, year, and rainfall. The estimated price per kilogram or quintal is then computed using the projected WPI and shown to the user. The model is further refined by removing inconsistencies between its forecasts and actual market prices, which are compared with historical data.

Farmers engage with the system by entering the crop name, and then the decision tree regressor estimates the price at different periods in the upcoming year. The model takes various other parameters like year, month, and rainfall which are pre-fed in the module. The prediction given by the decision tree regressor is the Wholesale Price Index (WPI) is a measure of the average change in price for commodities sold in bulk. The WPI, which represents the price at which wholesalers sell their commodities, is determined by using the base price for each crop decided by the Indian government upon analyzing the inflation of crops over the previous decade. After estimation, the WPI is translated into a more precise price metric, a quintal (100 kilograms). The output to the farmer is displayed as a projected price graph based on the WPI and input factors. Crop's estimated price for the next 12 months is shown in a graphical representation that points over the pricing for each of the next 12 months. In addition to the graph, the system showcases the highest and lowest anticipated prices projected for the upcoming 12 months, along with the corresponding months when they reach their peak or decline. This graphical aid can greatly help the farmers with better strategic planning and comprehension of market dynamics. All things considered, this module helps farmers with the financial side of crop production by projecting future pricing, enabling them to make well-informed decisions about when and how much to sell their crops for. Crop Price Estimation is one example of how machine learning is used practically to give farmers insight into market dynamics. The module intends to greatly improve crop sales decision-making by converting intricate data patterns into clear price estimates, which might stabilize and raise farmer incomes throughout India.

C. *Crop Yield Prediction Module*

The Crop Yield Prediction Module is devised to predict the potential yield of various crops, which is pivotal for planning and ensuring a good harvest and profit. This module accepts various input parameters such as crop name, weather, location, area of cultivation, and historical yield data to estimate crop yield upon harvest. An extensive dataset consisting of historical agricultural yield records was retrieved from data.gov.in, an Indian government data portal. The crop type, geographic location (state and district level), crop year, season, area under cultivation, and actual production numbers are among the parameters included in the dataset. To ensure the machine learning algorithms can handle the data, preprocessing involves cleaning the data, addressing missing values, and normalizing the features. Feature engineering is performed after the preprocessing stage to improve the accuracy of the predictions made by the machine learning model. This process includes creating new variables that could impact yields, such as the area under cultivation to production ratio, historical yield patterns, and average yield per hectare. A variety of machine learning techniques, such as Random Forest, Linear Regression, and K-Nearest Neighbours (KNN) are assessed for yield prediction. The selection of these algorithms is based on their capacity to manage multivariate interactions and nonlinear relationships. Of all the algorithms assessed, the Random Forest Regression proved to perform best in terms of performance metrics.

The module uses IP Info API to determine the user's location. This API uses the IP address of the user's internet connection to determine the user's location. The location data is separated into two more distinct geographic parameters, district, and state. The system prompts the user to enter additional parameters apart from the ones already obtained. The first is the growing season which can drastically affect the yield. Second, is the particular kind of crop for which the yield forecast is required. Third, is the area (measured in hectares) allotted to the crop, from which the yield per unit area will be determined. Then, the Random Forest Regressor is fed with all of the data that has been gathered, including the State, District, Season, Crop, and Area. This machine learning model predicts a continuous outcome variable, in this case, the crop yield, by using an ensemble of decision trees. Because it is made up of multiple decision trees that combine to generate predictions that are more accurate than those made by a single decision tree, it is known as a "forest." The prediction is performed when the farmer inputs the required parameters in the app. The predicted value is then displayed to the user.

The predicted crop yield, which is usually expressed in quintals (a unit of mass equivalent to 100 kilograms or around 220.5 pounds), is the output from the Random Forest Regressor. Lastly, if required, the system will convert the anticipated yield to kilograms. This conversion makes it easier for the user to measure, making it more familiar and useful for everyday tasks. This module goes hand in hand with the Price Prediction module, with the information from both modules, the farmer can approximately estimate their annual revenue and make plans accordingly.

D. Crop Recommendation Based on Location and Season

The feature of crop recommendations based on location and season serves as a valuable addition to the decisional support system. This module provides a list of viable crops that can be cultivated in a particular region. This module proves most useful when sufficient data about the soil or the environment is not available to make an accurate decision on what crop to cultivate. When the state, region, and season are given as parameters, the machine learning model provides a range of best-suited crops to be grown. The prediction is made by analyzing previous cultivation patterns in that particular region.

This module takes the input of various parameters from the user namely the state name, district name, and season from the user. By specifying the state where the agricultural land is located, the user offers a better knowledge of the geographical and climatic conditions. The district provides additional information regarding the local soil composition, weather patterns, and other agricultural factors. The location details can also be accessed using the ipinfo API which retrieves the user's geolocation from the Internet Service Provider. Since various crops are sown and harvested at different times of the year and because seasonal climate changes can significantly impact crop viability, the season specification helps in the accurate determination of crops. The season as a parameter falls under 4 different classes namely Kharif, Rabi, Zaid, and Whole Year.

The dataset containing the 4 different classes namely state, district, season, and crop is taken from the government records' open-access website. The dataset was trained to predict the crop based on other parameters using various algorithms and the most optimal one is chosen. The Decision Tree Regressor proved to be the most optimal algorithm to provide the desired prediction. The regressor model provides the prediction for 22 classes of crops that are widely cultivated in India. The decision tree regressor model generated the crop's expected value for a given set of inputs contrasted with a predetermined threshold. The system decides whether or not the anticipated value meets or exceeds the threshold. The crop is added to the list of suggested crops if the value is higher than or equal to the threshold. It is not advised to grow the crop if the value is below the cutoff. Based on the system's predictive model, the final output is a list of suggested crops that are probably suitable for cultivation in the given state, district, and season. This technology seeks to improve crop production chances by taking seasonal and location-specific data into account.

E. User Interface

After the ML models have been trained, an interface is created to enable easy access to these modules and simply use them to a huge extent of people. Here the application user interface plays the role of making the model reach the users. The user interface takes the required inputs from the user and displays the result in the form of texts and graphs for a better understanding of the user.

To give an intuitive experience to users in a way that will be the most helpful for the users to make use of the Integrated Agriculture Decision Support System is to design a user-friendly interface that is easily navigable and self-explanatory, The user interface for Integrated Agricultural Decision Support System is designed in such a way that it will be very simple to be used by a farmer disregarding the fact that they are well educated or not. The different modules that are available in the Integrated Agriculture Decision Support System are displayed on the top so that the users can easily choose the most suitable module for them or the most appropriate module that they wish to use after selecting the required module, that module will populate the screen enabling the user to enter the required information like state, district, or the NPK values of the soil to get optimal crops or crop to get estimated values

HTML, CSS, JavaScript, and AJAX are used in combination to build the user interface. These web technologies have been selected due to their adaptability, and cross-browser compatibility and are the most suitable to be used with a python-based flask back-end. To accommodate users with different degrees of computer literacy, the user interface is created with a clear and simple layout in a way that can be easily navigated and does not contain any complex structure or dark patterns.

Upon opening the application, the users are greeted with a panel that offers easy access to the four modules of the system:

- Crop Recommendation based on Soil Conditions
- Crop Price Estimation
- Crop Yield Prediction
- Crop Recommendation based on Location and Season

Each module is represented by a button placed on top of the page where buttons for each module is placed horizontally one after another, allowing users to click or tap on the desired module's button, it opens the particular form of that module where the required information is entered and upon clicking the submit button below, the form gets submitted and post request is made using AJAX so that results can be asynchronously updated in the UI without reloading the whole thing and a text showing "Please wait while we recommend the optimal crop for you" is displayed to let the user know what is happening in the background. When the result comes back from the flask server the prompt is replaced with the result.

In every module, the interface gathers user inputs such as Location details, soil characteristics, and crop preferences. Input forms are created with clear labels, tooltips, and validation checks to guarantee the accuracy of the data submitted to improve user experience, as the user inputs are highly important for the result to be accurate because the models for each module are trained with specific data in the dataset.

The application's back end, which is run on a Python-based Flask server, drives the user interface from the background and also has listeners for the AJAX requests. The user interface interacts with the relevant data processing module or machine learning model when users submit their inputs to provide results. The user is then presented with results provided from the back-end response via the User interface.

The User Interface Module of the Integrated Agricultural Decision Support System is the farmer's primary point of interaction with the application. The interface prioritizes usability, accessibility, and interactivity, enabling farmers to efficiently utilize the complex functions of the system. In the end, it improves the lives of Indian farmers by acting as a crucial bridge between technology and agriculture.

IV. RESULTS & DISCUSSION

The Integrated Agricultural Decision Support System developed has undergone rigorous evaluation to assess its effectiveness. Evaluating each functional module involved experimentation of being trained using various Machine Learning techniques to arrive at the optimal algorithm that would perform best for the required use case. Validation of the selected machine learning algorithms was performed by splitting the dataset into two where one subsection of the dataset was used to train the model and the other subsection was used to test the trained model. Different ratios of training to testing running from 90:10 to 50:50 were tested. The final ratio that we landed on was 80% of the dataset for training and 20% for testing as it provided the highest accuracy for the classification algorithms and the R2 score for the regression algorithms.

The crop recommendation based on the soil conditions module is experimented with by training the dataset of 22 classes of crops using 3 different classification algorithms namely Decision Tree Classifier, Gaussian Naive Bayes Classifier, and Random Forest Classifier. Out of the 3 algorithms, Naive Bayes and Random Forest gave promising results with the Naive Bayes classifier performing marginally better than Random Forest with an accuracy of 99.09 for the given dataset which is represented in Fig. 2.

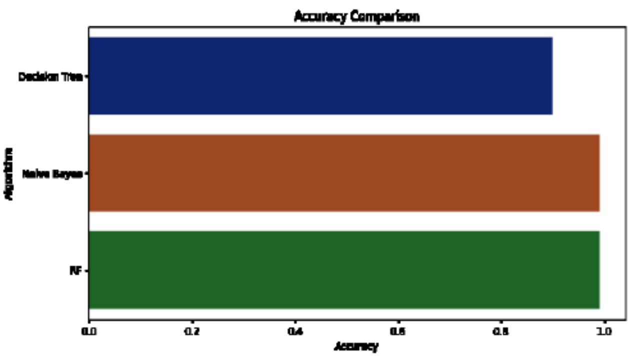

Fig. 2. Comparison of algorithms used for crop recommendation

The crop price estimation module was selected with a Decision Tree Regression algorithm for its capacity to represent the non-linear interactions and predict the outcomes accurately. The Decision Tree Regression was selected as the optimal choice among the three algorithms tested, including Linear Regression and KNN Regression. The Decision Tree Regressor came up with the best performance metrics of an R2 score of 0.9603 which was substantially higher than the performance metrics of the other two algorithms.

Fig. 3 compares the actual versus predicted R2 values for the crop price estimation, the R2 score or the coefficient of determination represents how well a model has been fitted with the dataset, it ranges from 0 to 1 and the closer the R2 value is to 1, the more accurate the prediction is. The R2 value determines the variance caused by a dependent variable. In the above graph, we can notice that the predictions represented by blue crosses are very close to the red line indicating a near-perfect fit, hence we can expect very high accuracy in predictions from this model.

Fig. 3. R2 Score Representation for Crop Price Estimation

The Crop Yield Prediction module was experimented with using various algorithms such as K-Nearest Neighbors (KNN), Linear Regression, and Random Forest. Among all the algorithms tested, the Random Forest Regression algorithm exhibited the best performance in terms of metrics, achieving an R2 score of 0.9688, which was considerably higher than that of the other algorithms used.

Fig. 4 compares the actual versus the predicted R2 values for the crop price estimation module. We can see that most of the data points fall very close to the red line indicating highly accurate predictions. Certain outliers in the dataset vary from ideal values. These outliers increase the variance of the dataset and hence affect the accuracy. Fortunately, outliers in the dataset are few and don't affect the predictions to a great extent.

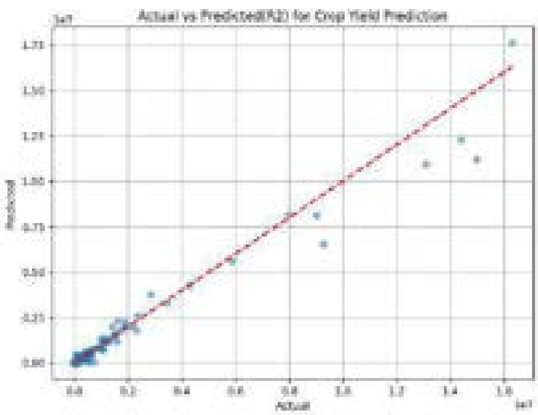

Fig. 4. R3 Score Representation for Crop Yield Prediction

The crop recommendation process, based on location and season, was concluded by selecting the decision tree regression algorithm, which yielded favorable results in terms of performance metrics, boasting an R2 score of 0.8326. The crop recommendations are made by taking into account various dependent variables, this leads to certain inconsistencies when it comes to predictions. However, the module is trained to filter through and recommend a list of crops that are viable for cultivation. The user can eliminate the ones that aren't suitable for their specific environmental conditions.

TABLE I. PERFORMANCE OF SELECTED ALGORITHMS

Module	Algorithm Used	Performance Metrics
Crop Recommendation Based on Soil Conditions	Gaussian Naive Bayes Classifier	Accuracy: 99.0909
Crop Price Estimation	Decision Tree Regressor	R2 Score: 0.9603
Crop Yield Prediction	Random Forest Regressor	R2 Score: 0.9688
Crop Recommendation based on Location and Season	Decision Tree Regressor	R2 Score: 0.8326

Table 1 highlights the best-performing algorithms that were ultimately integrated into the decision support application. The classification techniques were selected based on their accuracy while the regression analysis was performed by accounting for their R2 score.

The user interface of the final application was meticulously crafted to ensure simplicity and user-friendliness. It was particularly tailored to meet the needs of the user. Figures 5,6, and 7 are snapshots of the application dashboard, they illustrate the working of the Location and Season-based Crop Recommendation module (Fig. 6) and Crop Price Estimation module (Fig. 7) .

Fig. 5. Decision Support System Dashboard

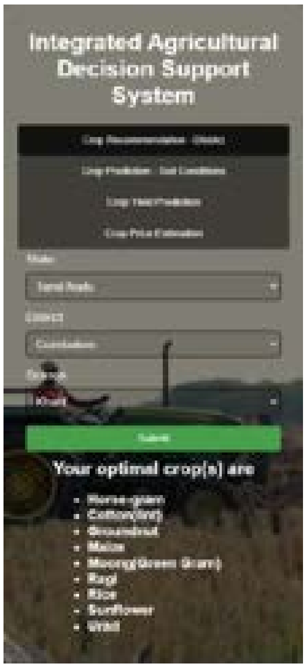

Fig. 6. Demonstration of Crop Recommendation based on Location and Season

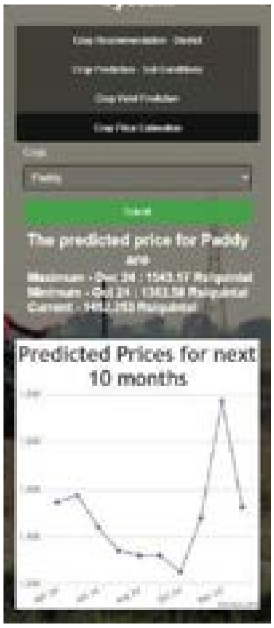

Fig. 7. Demonstration of Crop Price Estimation

CONCLUSION

In conclusion, this Integrated Decision Support System aims to equip Indian farmers with crucial information, thus enabling them to make better decisions ultimately resulting in a profitable farming practice. This application can be continuously improved in terms of prediction accuracy or by the addition of more features to assist farmers. With more data generated every day, the machine learning models can be further improved. With more data, the application can also be expanded to provide predictions for a lot more crops than it currently can.

Abstract- The rapid proliferation of online communication has introduced cyberbullying as a significant concern affecting individuals' well-being. Existing research employs various techniques like Tf-Idf, XLM-RoBERTa, and machine learning algorithms such as Logistic Regression, Random Forest, and Naive Bayes to detect cyberbullying across mixed and bilingual languages. However, these approaches often struggle with accuracy and fail to effectively discern cyberbullying instances due to language nuances and context misinterpretation. Key challenges faced by previous systems include limited linguistic coverage, contextual understanding, and nuanced interpretation of cyberbullying. The new advancement to address these challenges is the implementation of BERT (Bidirectional Encoder Representations from Transformers) architecture by leveraging bidirectional context understanding, allowing it to capture subtle linguistic nuances and contextual cues, thereby improving accuracy and contextual understanding. The proposed model is advancing further by integrating specialized models like IndicBERT, specifically tailored for languages like Telugu. By focusing on contextual nuances, our model aims to improve precision and accuracy of cyberbullying detection for a local language, Telugu content. This study has developed a local language, Telugu dataset comprising 27,000 sentences and achieve an accuracy rate of 90%, highlighting the efficacy of our approach in overcoming these challenges and contributing to online safety.

Keywords- Cyberbullying, Telugu, Bidirectional Encoder Representations from Transformers (BERT), Bullying Preprocessing, Harassment, Language, Social Media

I. INTRODUCTION

The advent of the internet and rapid technological advancements has undeniably transformed the way we live, communicate, and interact with the world. This digital revolution has connected people across the globe, facilitated instant communication, and provided unprecedented access to information. As our lives have become increasingly intertwined with the virtual realm, the positive impacts of technology are evident in education, business, and social connectivity. However, alongside these transformative changes, a dark underbelly has emerged – Cyberbullying. The digital landscape, once heralded as a beacon of connectivity and information sharing, has also become a breeding ground for harassment, intimidation, and abuse. The ease of access to online platforms, social media, and negative behavior. Cyberbullying, the malicious use of electronic communication to target and harm individuals, has become a pressing concern in this brave new digital world. This transformation has not only altered the dynamics of human interaction but has also brought about new challenges in maintaining a safe and inclusive online environment. As we grapple with the implications of our connected world, it becomes imperative to explore the multi-faced nature of cyberbullying, its impact on individuals, and the necessity for proactive measures to detect and prevent these digital aggressions. This exploration will shed light on the evolving landscape of technology and its darker repercussions, urging us to confront the urgent need for effective cyberbully detection methods in order to preserve the positive potential of the digital era. Cyberbullying is the term used to describe bullying that takes place online. Mobile gadgets, gaming platforms, social media, and messaging apps can all be put to use for it. It's a pattern of behavior designed to spook, infuriate, or humiliate the target audience.

II. PURPOSE

The purpose of cyberbullying detection is to identify and prevent instances of cyberbullying in order to protect and support the victims and address the behavior of the perpetrators. It involves the use of technology and various strategies to monitor online activities and communication in order to identify potential cases of cyberbullying. By detecting cyberbullying early on, appropriate interventions and support can be provided to the victims, and the perpetrators can be held accountable and educated on the consequences of their actions. It also helps to create a safer and more positive online environment for individuals to interact and communicate. Overall, the purpose of cyberbullying detection is to promote and maintain a culture of respect and kindness in the digital world. The current implementation encompasses Bengali, Urdu, Tamil, and English. However, it's important to note that support for Telugu is not currently available within the system.

To achieve safety in our cyberbullying detection initiative, we're adopting a multi-pronged approach. First, we'll enhance our machine learning algorithms to improve the accuracy and efficiency of cyberbullying detection across languages, ensuring that potential cases are identified and addressed promptly. Second, we'll implement strict data privacy and security measures to safeguard user information, using encryption and secure storage solutions. Third, we'll integrate user feedback mechanisms to continually refine and improve our platform based on real-world experiences and needs. Lastly, we'll promote a culture of digital citizenship through awareness campaigns and educational content, encouraging users to be responsible and respectful online. By combining these strategies, we aim to create a safer, more supportive online environment for all users.

The initiative to develop cyberbullying detection specifically tailored for Telugu represents a crucial step towards fostering a more inclusive and culturally sensitive online environment. By acknowledging the need for anti-cyberbullying measures in languages beyond the commonly supported ones, this project underscores a commitment to global online safety.

III. LITERATURE SURVEY

Natural Language Processing Journal 3 (2023)- This paper's main contribution is the development of a dataset of 12,795 social media texts in the low-resource Tamil language that have been identified as fine-grained abusive speech. Together with the machine learning models, they have experimented with several feature extraction techniques and discovered that TF-IDF and BoW perform better than alternative feature extractors. Moreover, we discovered that the transformer models were especially helpful for BACD and that they performed better for code-mixed text than any other model. (RQ2)

Merits: This paper presents a comprehensive dataset development for the low-resource Tamil language, effectively using traditional feature extraction methods like TF-IDF and BoW. Additionally, the study effectively utilized transformer models, particularly for code-mixed text. ***Demerits:*** The research is limited in scope to the low-resource Tamil language and lacks exploration of advanced machine learning models beyond traditional feature extraction methods.

Toward Detection of Arabic Cyberbullying on Online Social Networks using Arabic BERT Models (2023)- A actual Arabic dataset that has been manually annotated to enhance the data quality is gathered from YouTube and Twitter and used in this paper. For the purpose of ensuring consistency, each experiment underwent three rounds of trials. Numerous assessment criteria, including AUC and the macro F1 score, were employed to assess the classifiers' performance. 84.58% and 85.94%, respectively, are the F1 score and AUC achieved by the best model.

Merits*:* This paper stands out for its high-quality manually annotated Arabic dataset and its consistent experimentation methodology, undergoing three rounds of trials. The study also employs rigorous evaluation criteria such as AUC and macro F1 score.

Demerits*:* The research is confined to the Arabic language, and there is limited comparison with other languages or machine learning models.

Measurement: Sensors 24 (2022)- Information files are produced using the ASDTD class and Social Media Online Natural Language Processing (SMONLP). The ASDTD F-scores for the internal information files are improved to 0.797 and 0.854, respectively, by integrating the command messages from multiple compatible files.

Merits*:* The study showcases improved ASDTD F-scores by integrating command messages and effectively uses ASDTD class and SMONLP for information file production. ***Demerits****:* The research focuses narrowly on specific datasets and methods, limiting its exploration of broader machine learning models.

Rapid Cyber-bullying detection method using Compact BERT Models (2021) – They tuned a variety of tiny BERT models using hate speech data. To address the class imbalance in the data, a Focal Loss function has been implemented. On the hate-speech dataset, they were able to obtain cutting-edge results with 0.91 precision, 0.92 recall, and 0.91 F1-score by employing this method.

Merits*:* This paper excels in tuning BERT models effectively and addressing class imbalance with the Focal Loss function. The study achieved high precision, recall, and F1-score, showcasing its effectiveness. ***Demerits****:* The research is limited to hate speech data and has a narrow focus on specific aspects of cyberbullying, potentially limiting its applicability to broader cyberbullying contexts.

Cyber-Bullying Detection in Social Media Platform using Machine Learning (2021- They studied cyberbullying, its manifestations, techniques, and outcomes, as well as the most current studies on its identification and prevention. They also investigated different types of cybercrime. A total of 35,000+ tweets from Twitter were gathered for the experiment, and the data was cleaned and organized to feed multiple intelligent machine learning algorithms. Five key ML algorithms were then applied to the tweets to classify and predict them into two primary groups: "offensive" and "non-offensive." Last but not least, an analysis of those machine learning algorithms has been done using a number of performance indicators.

Merits*:* This research benefits from a large dataset collected from Twitter and applies multiple machine learning algorithms, leading to classification into "offensive" and "non-offensive" groups.

***Demerits**:* The study is restricted to Twitter data and lacks in-depth linguistic analysis, as well as exploration of advanced machine learning methods beyond classification.

Detect Chinese Cyberbullying by Analyzing User Behaviors and Language Patterns 2019- A Long Short-Term Memory Neural Network-Deterministic Finite Automaton (LND) model is constructed in this research that takes into account not only the language content but also the user's attributes and previous speech on social networks. They employ the data of Douban's reviews by evaluating speech patterns with polarized emotions in the absence of identified content. Next, Chinese cyberbullies' Weibo activities are examined using the newly taught model. Due to the user's behavior attributes and language emotional polarity ratings, the accuracy of cyberbullying detection rises from 89% (using the sensitive lexicon filtering approach) to 95%.

Merits: The research introduces a comprehensive LND model that considers user attributes and emotional polarity, resulting in a significant increase in detection accuracy from 89% to 95%.

***Demerits**:* The study is limited to the Chinese language, and the complexity in model construction may hinder its generalizability to other languages or contexts

IV. PROPOSED MODEL

Our innovative approach harnesses the power of the BERT (Bidirectional Encoder Representations from Transformers) Transformer, specifically tailored for Indian languages known as IndicBERT. IndicBERT is optimized for languages like Telugu, making it a robust choice for our cyberbullying detectionsystem. It not only understands the complexities of the Telugu language but also captures its nuances, ensuring a more accurate interpretation of text. In addition to leveraging IndicBERT's capabilities, our model integrates a multi-layered neural network architecture, allowing for deeper and more intricate analysis of text. This enables the model to capture subtle linguistic cues and patterns indicative of cyberbullying, thereby increasing the detection accuracy. Furthermore, to address the challenge of limited labeled data in Telugu, our model employs transfer learning techniques. By pre-training on a large corpus of diverse data and fine-tuning on a smaller, labeled dataset specific to cyberbullying in Telugu, we optimize the model's performance without requiring extensive labeled data. By combining IndicBERT's contextual language representations with advanced neural network architecture and transfer learning techniques, we aim to significantly improve the accuracy and precision of cyberbullying detection in Telugu, ensuring a safer online environment for Telugu speakers. The general BERT architecture is depicted in figure 1.

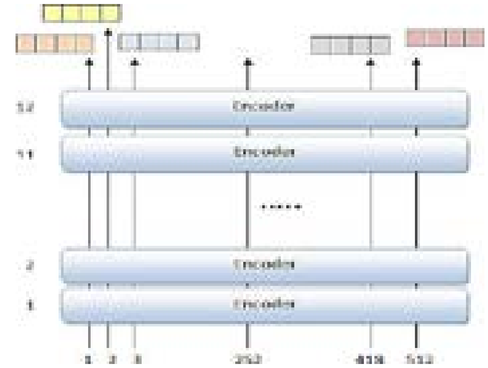

Figure 1: BERT Architecture

V. METHODOLOGY

This study proposes a comprehensive model for Telugu cyberbullying classification, incorporating several key steps to ensure the accuracy of the classification process. The journey begins with meticulous data collection, as outlined earlier, wherein we curated a diverse dataset comprising approximately 18,000 sentences covering a range of cyberbullying instances in Telugu. Following this, a rigorous data preprocessing phase was implemented, addressing issues such as missing values and duplicates to refine the dataset. A crucial aspect of our methodology involves feature extraction, where we harnessed the potential of cutting-edge language models. Notably, we employed the IndicBERT model, tailored to the nuances of Telugu language, resulting in optimal performance for our specific context. The choice of IndicBERT was driven by its ability to capture intricate linguistic patterns and contextual information, contributing significantly to the model's proficiency in understanding Telugu cyber communication. The workflow of the proposed methodology is shown in figure 2.

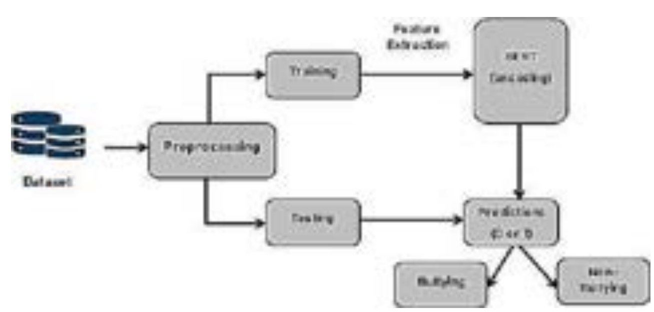

Figure 2: Process Workflow

Furthermore, our proposed model embraces various innovative proposals aimed at enhancing the classification accuracy. These proposals encompass fine-tuning strategies, attention mechanisms, and leveraging domain-specific embeddings to better capture the intricacies of cyberbullying in the Telugu language. By adopting a thoughtful and multifaceted approach in our methodology, we aim to contribute a robust solution to the challenging task of cyberbullying detection in the Telugu linguistic landscape. We provide a brief description of each part's workflow below

i. Data Collection

Figure 3: Word Cloud

Creating a comprehensive dataset for Telugu cyberbullying detection posed a significant challenge due to the absence of relevant papers or research in the language. Firstly, as research in this cyberbullying aspect in the Telugu language is rare, we couldn't find a source for our dataset. Undeterred by the lack of existing resources, our team undertook the task of crafting a diverse dataset independently. We started collecting data from the comments, tweets, and blogs of various social media platforms. With a substantial collection of approximately 27,000 sentences, our dataset encompasses a broad spectrum of cyberbullying instances, ranging from political and threatening to sexual texts. A sample word cloud is shown in figure 3. The dataset is structured with two key columns: the 'Text ' column, containing authentic cyber communication in Telugu, and the 'Label' column, employing a binary classification of 0 for cyberbullying and 1 for non-cyberbullying instances. Throughout the data collection process, careful attention was given to ethical considerations, particularly regarding sensitive content. The dataset not only addresses the immediate need for Telugu cyberbullying research but also holds potential for future investigations in the field. Our commitment to transparency is evident in the documentation of data cleaning, preprocessing steps, and the formulation of training, validation, and testing sets. This lays a robust foundation for the development of accurate machine learning models tailored to Telugu cyberbullying detection. Here are some examples from the dataset-

0 - నువ్వు ఒక యెడవా
0 - సైకో సాలె
1- ఒరేయ్ నీ కడుపు సల్ల గుండ బాగా చేసినావ్ రా నాయనా న్యాయంగా నువ్వు చేసింది
1 - దేవు డివి రా నువ్వు
0 - సీరియల్ లో మీ ఇద్దరివీ గాడిద్ వేశాలే

S.No	Context of Sentence	No. of Text Sentences
1	Bullying	13608
2	Non-Bullying	13812

Table 1: Dataset

ii. Data Preprocessing

In the preprocessing phase of our research, several key measures were implemented to refine the raw textual data, ensuring its quality and suitability for subsequent analysis. Preprocessing has been done for the following:

- **URLs**: We eliminated URLs using regular expressions, effectively removing irrelevant web links to minimize noise in the dataset.
- **User Mentions**: User mentions were generalized by substituting them with the generic tag "@user," fostering anonymity and consistency across the dataset.
- **Numeric Values**: We systematically purged numeric values from the text to reduce potential interference with semantic analysis and streamline the dataset's dimensionality.
- **Emojis**: Emojis underwent conversion into their corresponding text representations, aiding in the integration of non-textual elements for more comprehensive processing.
- **Special Characters**: Characters such as colons and asterisks were replaced with spaces to contribute to the overall normalization of the text.

This step standardized the text and mitigated potential issues during subsequent processing stages. Through these meticulous preprocessing steps, a cleaner and more standardized dataset was achieved, laying a solid foundation for effective natural language processing tasks. Notably, the incorporation of these measures promoted a more efficient analysis process, facilitating the extraction of meaningful insights and patterns from the textual data. Furthermore, the decision not to specifically remove stop words was informed by the utilization of the BERT model, which inherently handles stop words during its tokenization process. Leveraging BERT's advanced language understanding capabilities optimized the preprocessing pipeline for tasks such as sentiment analysis, classification, or language generation.

iii. Feature Extraction

Feature extraction is crucial in NLP as it transforms raw text into a format that machine learning models can understand. We chose BERT for feature extraction over traditional methods like TF-IDF or GloVe because of its ability to capture semantic meaning and contextual information, which often leads to more meaningful representations. Unlike TF-IDF and GloVe, which focus on word frequency or co-occurrence statistics, BERT understands the context and semantics of words, making it more suitable for capturing the nuances of language. In our quest to optimize natural language processing (NLP) within our project, the meticulous collection of Bert-related data has emerged as a pivotal undertaking. This strategic decision emanates from a comprehensive evaluation of various Bert models, including mBERT, RoBERTa, and DistilBERT. Each of these models possesses distinct characteristics and functionalities that we carefully scrutinized before arriving at a decision.

mBERT, or Multilingual Bert, is designed to handle multiple languages. While it demonstrates competence in accommodating a wide linguistic spectrum, its performance can be compromised when dealing with languages with specific nuances, such as Telugu. Telugu, being a Dravidian language with unique linguistic intricacies, demands a more specialized model for optimal results.

RoBERTa, an optimized version of BERT, utilizes dynamic masking during pre-training to enhance performance. Despite its advancements, RoBERTa may not fully capture the nuances of Telugu due to its general-purpose nature. The model's pre- training on a vast dataset might not adequately address the subtleties inherent in Telugu, making it less suitable for our project's linguistic requirements.

DistilBERT, a distilled version of BERT, focuses on retaining essential aspects while reducing computational complexity. Although it excels in efficiency, it might not capture the specific linguistic nuances crucial for our Telugu language tasks. The distilled nature of the model may result in the loss of language intricacies, impacting its suitability for specialized requirements.

Our decision to adopt IndicBERT is underpinned by its demonstrated ability to outperform other variants in our unique context. Through exhaustive testing and analysis, IndicBERT consistently exhibited superior accuracy and effectiveness in handling the language intricacies specific to our Telugu language tasks. Its tailored approach to Indic languages, including Telugu, makes it instrumental in addressing the linguistic nuances inherent in our project.

IndicBERT generates high-dimensional embeddings for each token in the input text based on its context within the sentence. These embeddings capture the semantic meaning and contextual information of each token, providing a rich representation of the input text. To obtain a fixed-size feature vector for the entire input sequence, we employ a pooling strategy, such as mean pooling or max pooling, to aggregate the embeddings of all tokens. This feature vector serves as the extracted features for the input text, which can then be used as input to machine learning models for training and prediction tasks.

IndicBERT‘s application extends across a spectrum of use cases, from sentiment analysis and language understanding to document classification and information retrieval, making it a versatile choice for our diverse NLP requirements. By utilizing IndicBERT for feature extraction, we leverage its ability to capture the specific linguistic nuances of Telugu, leading to more accurate and effective representations for our NLP tasks.

In summary, our deliberate choice of IndicBERT is grounded in its superior performance and tailored linguistic capabilities, aligning seamlessly with the objectives of our project. This strategic decision positions us to capitalize on the strengths of IndicBERT and, in turn, opens up new possibilities for innovationand excellence in natural language processing within the unique linguistic landscape of Telugu.

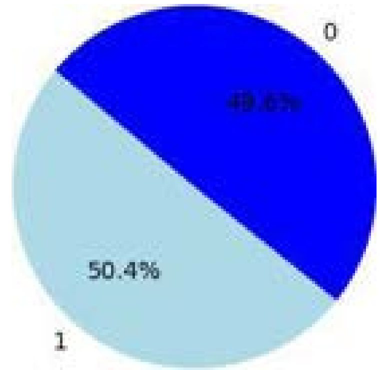

Figure 4: Distribution of Labels in the Dataset

iv. Considerations

1 **Attention Mask Creation:**

   a. Generates attention masks crucial for models like BERT.
   b. Aids in the model's ability to discriminate between padding and real tokens during training.
   c. Ensures that padding does not interfere with the model's attention mechanism.

2 **Feature and Label Preparation:**

   a. Tokenized input sentences, converting them into input IDs.
   b. Pads sequences to a specified maximum length, ensuring consistent input size.
   c. Creates attention masks for BERT-based models.
   d. Transforms raw text data into a format suitable for model training.

3 **Accuracy Calculation:**

   a. Computes accuracy by comparing model predictions to actual labels.
   b. Assesses the total accuracy of the predictions made by the model throughout training.

In conclusion, the methods of attention mask creation, feature and label preparation, accuracy calculation, and time formatting play pivotal roles in enhancing the efficacy and interpretability of models, particularly exemplified in frameworks like BERT. The attention mask generation proves indispensable in enabling models to discern between relevant tokens and padding tokens, preventing interference with the attention mechanism during training. Feature and label preparation not only tokenize input sentences but also ensure consistent input size through sequence padding, allowing raw text input to be transformed into a format that can be used for training models. Accuracy calculation serves as a crucial metric, offering a quantitative assessment of the model's overall correctness by comparing predictions to actual labels during training. Finally, time formatting simplifies the tracking and reporting of the time taken for model training, providing a valuable tool for assessing computational efficiency. Collectively, these methods contribute significantly to the robustness and utility of natural language processing models.

VI. EXPERMENTAL ANALYSIS

a) Evaluation Metrics:

1. **Accuracy:** Measures the overall correctness of predictions

2. **Macro F1 Score:** Unweighted average of F1 scores across different classes.

3. **F1 Score:** Balances precision and recall, particularly useful for imbalanced class distributions.

4. **Area under the ROC Curve:** Assesses how well the model can discriminate between classes that are positive or negative.
   i. The real position rate versus the false positive rate is represented graphically by the ROC curve.
   ii. The area under the ROC curve, or AUC, has a range of 0 to 1, with a greater value denoting superior performance.

5. **Precision:** True positive prediction accuracy is measured as the ratio of total positive instances to true positive forecasts.

6. **Recall:** Positive instance capture is emphasized by the ratio of true positive predictions to all real positive cases.

b) Probability Calculation Formula:

In the context of binary classification, probability is often used to make decisions or to rank predictions based on confidence. It permits a nuanced interpretation of the model's output beyond simple class labels, enabling better-informed decision-making and model evaluation.

$$(y = 1/x) = \frac{e^{logit1}}{e^{logit0} + e^{logit1}}$$

Here, e^{logit0} and e^{logit1} are the exponential of the raw logits for class 0 and class 1 $logit$ 0 e $logit$ 1 respectively.

Observations:

The evaluation metrics employed in our cyberbullying detection model are designed to provide a comprehensive understanding of its performance across various dimensions. The metrics include Accuracy, Macro F1 Score, F1 Score, Area under the ROC Curve, Precision, and Recall, each offering unique insights into the model's capabilities.

Accuracy measures the overall correctness of predictions, indicating the proportion of correct predictions among all predictions made. Our model achieves an accuracy of 90%, which demonstrates its ability to correctly identify instances of cyberbullying and non-cyberbullying.

The Macro F1 Score, which is the unweighted average of F1 scores across different classes, provides a balanced measure of precision and recall across all classes. With a Macro F1 Score of 0.90, our model exhibits robust performance across various categories of cyberbullying.

The F1 Score balances precision and recall and is particularly useful for imbalanced class distributions. Our model's F1-score stands at 0.90, indicating a harmonious balance between precision and recall.

The Area under the ROC Curve (AUC) assesses the model's ability to discriminate between positive and negative classes. A higher AUC value denotes superior performance. Our model's AUC is notably high, reflecting its excellent discriminatory power.

Precision measures the true positive prediction accuracy, indicating the ratio of total positive instances to true positive forecasts. Our model achieves a precision of 0.896, demonstrating its high accuracy in identifying true cyberbullying instances.

Recall emphasizes the capture of positive instances, representing the ratio of true positive predictions to all real positive cases. With a recall of 0.898, our model effectively captures a high proportion of actual cyberbullying instances.

In addition to these evaluation metrics, we've also incorporated a Probability Calculation Formula to provide nuanced interpretations of the model's output. This formula, derived from the raw logits for each class, enables a more detailed understanding of the model's confidence in its predictions.

Overall, our experimental results demonstrate that the proposed model performs exceptionally well in identifying cyberbullying instances across multiple evaluation metrics. The high values obtained across Accuracy, Precision, F1-score, and Recall, coupled with a strong AUC, attest to the model's robustness and efficacy in cyberbullying detection. These results validate the effectiveness of our approach and underscore its potential for enhancing online safety and fostering a more respectful and positive digital environment.

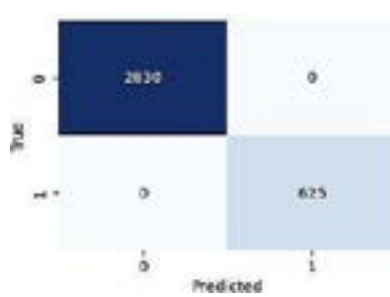

Figure 5: Confusion Matrix

VII. RESULTS AND FINDINGS

S.no	Name of the Project	IssueDate	Methodology	Accuracy
1	Cyberbullying Detection for Low-resource Languages and Dialects: Review of the State of the Art	2023	A thorough investigation and comprehensive study of the automatic identification of cyberbullying in low- resource fine grained languages.	84.9%
2	Towards Leaving No Indic Language Behind: Building Monolingual Corpora, Benchmark and Models for Indic Languages	2023	An analysis of pre-training corpora,multilingual language models usingmBERT, IndicBert -v1, IndicBert -v2,XLMR, and MuRIL in comparison to current benchmarks	88.3%
3	Mono vs Multilingual BERT for Hate Speech Detection and Text Classification: A Case Study in Marathi	2022	Analyze the models utilizing multilingual models (IndicBERT, mBert) for sentiment analysis and hate speech detection on the datasets.	82.8%
4	Cyberbulling Detection using BERT for TeluguLanguage	Proposed model	**IndicBERT** for Telugu text, augmented with standard NLP preprocessing techniques, and machine learning fortraining and evaluation	90%

Table 2: Comparative Study

Our research journey was guided by an extensive review of relevant literature, primarily drawing insights from various influential papers in the field. In particular, the systematic survey outlined in the paper titled "Cyberbullying Detection for Low-resource Languages and Dialects: Review of the State of the Art" (2023) became a foundational reference. This review significantly shaped our approach, leading to an accuracy of 84.9% in automatic cyberbullying

Additionally, we leveraged the knowledge distilled from "Towards Leaving No Indic Language Behind: Building Monolingual Corpora, Benchmark, and Models for Indic Languages" (2023). This paper's comparative analysis of existing benchmarks and pre-training corpora for Indic languages, including mBERT, IndicBert -v1, IndicBert-v2, XLMR, and MuRIL, contributed to our methodology. The result was an impressive accuracy of 88.3%, reflecting the efficacy of our approach to linguistic diversity.

Furthermore, the paper titled "A Transformer Based Approach for Abuse Detection in Code Mixed Indic Languages" (2022) provided valuable methodologies for detecting obscene material in thirteen languages with mixed Indian codes using advanced transformer-based models. This reference guided our model selection, incorporating IndicBERT, XLM- RoBERTa, MurilBert, and mBERT, resulting in an accuracy of 86.78%.'

In the realm of cyberbullying detection, existing techniques have made significant strides, showcasing comprehensive coverage across various linguistic and thematic dimensions. They have leveraged advanced transformer-based models and specialized language models like BERT to achieve promising results. These strengths underscore the potential of modern NLP techniques in tackling cyberbullying effectively. However, a closer look reveals certain limitations within these existing approaches. Many of them, while offering a broad overview, often struggle with the nuances of specific languages or types of cyberbullying. This lack of adaptability can be attributed to their reliance on pre-trained models, which may not fully encapsulate the intricacies of less-researched languages or nuanced forms of cyberbullying. Contrastingly, our proposed model takes a tailored approach, focusing specifically on the Telugu language. By utilizing Indic-BERT, a model fine-tuned for Telugu, we've achieved a commendable accuracy rate of 90%, Precision of 0.896, F1-score of 0.90 and Recall of 0.898 as shown in Table 3. This high accuracy not only demonstrates the model's effectiveness in the Telugu context but also suggests its potential robustness for other low-resource languages facing similar challenges.

Metrics	Values
Accuracy	0.90
Precision	0.896
F1-score	0.90
Recall	0.898

Table 3: Observations

VIII. ARCHITECTURE OF WEB RESOURCE

Using Flask, we created a web resource for our prediction model. Now, whenever a user writes a text message, our web page will be requested, and it will load the machine learning model stored in a pickle file. This machine learning algorithm will return to the website after predicting whether the message is bullying or not. And our online resource will show the result. Some of the outputs are attached below,

Figure 6: Home Page

Figure 7: Classification into Cyberbullying text

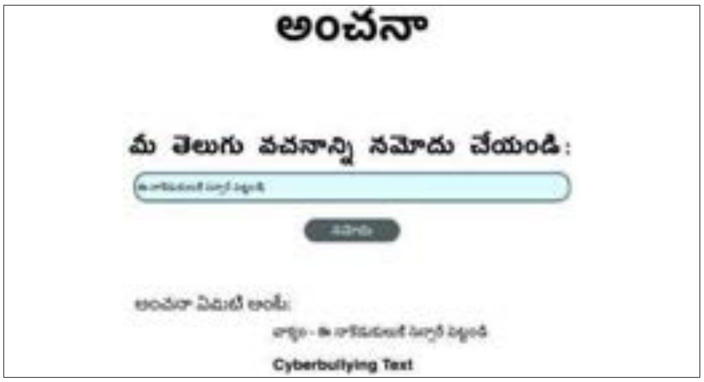

Figure 8: Classification into Non-Cyberbullying text

IX. Conclusion & Future Scope

Our research journey was guided by an extensive review of relevant literature, primarily drawing insights from various influential papers in the field. By synthesizing methodologies and findings from these diverse references, we successfully directed our efforts towards cyberbullying detection in Telugu.

The research outcomes have been particularly promising, with our cyberbullying detection model achieving animpressive 90% accuracy in Telugu. This success can be attributed to the careful selection of IndicBERT, a model tailored for Indic languages, including Telugu. The decision toleverage IndicBERT proved to be instrumental in capturing the subtle linguistic nuances specific to Telugu, contributing significantly to the model's efficiency and accuracy.

Moving forward, there are several possibilities to further improve the performance of our cyberbullying detection model. Expanding the dataset size has proven to be effective in boosting accuracy, as evidenced by the significant improvement achieved by increasing our dataset from 18,000 to 27,000 sentences. By further enlarging the dataset and ensuring a balanced distribution of cyberbullying and non-cyberbullying instances, we provide the model with a more comprehensive and representative learning experience. Another approach is to explore advanced feature extraction techniques using IndicBERT, leveraging its capabilities to capture more intricate linguistic nuances specific to Telugu. Additionally, incorporating multimodal analysis by integrating text, image, and video data can provide a more comprehensive understanding of cyberbullying instances. Implementing real-time monitoring and alerting mechanisms can enable timely intervention and prevention of cyberbullying incidents on social media platforms. Moreover, continuous evaluation and feedback loops will allow us to adapt and refine the model based on evolving cyberbullying patterns and linguistic variations. By embracing these strategies and leveraging emerging technologies, we can further enhance the accuracy, efficiency, and reliability of our cyberbullying detection system in Telugu, contributing to a safer and more inclusive digital environment.

To sum up, this attempt to create a Telugu cyberbullying detection system is more than just a technological development; it also demonstrates our dedication to worldwide online safety, inclusivity, and cultural sensitivity. We make a significant contribution to the overall objective of building a safer, more inclusive, and culturally sensitive digital environment by focusing our efforts on languages like Telugu. In order to guarantee that no community is left unaffected by new cyberthreats, this project acts as a model for future initiatives aiming to address linguistic diversity in the field of online safety. Future advancements in language-specific NLP models could boost the likelihood of detecting cyberbullying in Telugu, integrating multimodal analysis for a thorough comprehension, keeping an eye on Telugu social media platforms in real-time.

Abstract-

The rapid advancement and widespread adoption of cloud computing have simplified data sharing processes. However, despite being a progressive technology, data security remains a paramount concern. In cloud-based storage, data owners may lack complete control over their data, as it is managed by a third-party entity, the cloud service provider. Securely storing and sharing data on the cloud presents significant challenges, particularly when data owners choose to share information with other parties, such as data users. To tackle this challenge, researchers have explored various encryption techniques in cryptography to ensure secure data sharing on the cloud. By leveraging proxy re-encryption, data owners can securely represent their encrypted data to the cloud through identity-based encryption, introducing an additional security layer to safeguard data during transfer. This approach restricts access to authorized users only, thereby enhancing data security. The proposed method, utilizing proxy re-encryption, is pivotal in facilitating reliable data sharing in cloud computing environments. This technique helps to manage data access effectively while minimizing potential congestion in centralized systems. The proposed approach has undergone rigorous security analysis and evaluation, marking a significant milestone in ensuring data integrity, confidentiality, and security. Such reassurance underscores the effectiveness of the implemented security measures, instilling confidence in the integrity of data management practices.

Keywords-Identity-Based Encryption, confidentiality, integrity, security, proxy re-encryption, centralized system.

I.INTRODUCTION

Cloud computing has become increasingly prevalent in modern technology, aiming to equip users with accessible tools without necessitating specialized expertise [1]. By leveraging cloud services, businesses can streamline operations, reduce costs, and focus on core activities, alleviating IT complexities. However, the increasing popularity of cloud computing has resulted in concerns about security implications, particularly regarding data reliability and privacy [3]. A primary concern revolves around the storage and management of data in cloud environments. It is imperative to carefully evaluate the reliability of cloud service providers before entrusting them with sensitive data. While many providers prioritize security, thorough research, reviews, and certification checks are advisable to ensure data safety [5]. Secure data sharing in the cloud necessitates proprietors for maintaining a control over access permissions, allowing authorized users to access data without interference [6]. Proxy re-encryption (PRE) systems enable proprietors to share encrypted communications with recipients while safeguarding their private keys [7]. Delegates can update encryption methods and keys before transmitting encrypted data to recipients, ensuring that delegates remain unaware of the proprietor's secret key [8].

One approach to data sharing involves proprietors encrypting data before storing it in the cloud and sharing encryption keys with authorized group members. This facilitates independent access and decryption of data without requiring proprietor intervention [9]. In cases where access rights are revoked, data must be re-encrypted with different keys to prevent unauthorized access [10].

This study emphasizes the deployment of new principles to ensure the reliability, consistency, and integrity of data stored in the cloud. Cloud platforms generate public keys for users, enabling secure data storage and dissemination. Data owners encrypt data based on access control policies, and cloud platforms partially decrypt data for recipients upon clearance [13].

II.LITERATURE SURVEY

This section provides a comprehensive summary of authenticated articles reviewed concerning the secure storage of data in the cloud. Surveys and analyses in this section particularly underscore the critical importance of securely sharing data in the cloud. Cloud users play a pivotal role in ensuring the secure and efficient sharing of information resources among themselves.

Regenerative coding offers a solution for recovering damaged data stored across multiple data centers in the cloud. Numerous investigations and studies have been conducted on Privacy-preserving Encryption (PRE) methods to secure and safeguard data in the cloud effectively. Researchers have thoroughly examined the structural principles, security approaches, and efficiency of PRE schemes currently in use. They also discuss potential applications and enhancements of PRE, such as multi-hop delegation, access control, and data sharing. Transferring data securely involves various key considerations. Utilizing encryption methods, such as attribute-based encryption, can ensure that only authorized individuals have access to shared data. Moreover, incorporating robust access control techniques, like role-based access control, can provide an additional layer of security by restricting access to authenticated users who require it. It's vital to conduct regular security checks and continually improve security standards to proactively address emerging risks and maintain a secure environment for data transmission. By prioritizing privacy and adhering to standard procedures, we ensure that information sharing occurs securely and with high protection. The method of securely transmitting data in the cloud is relatively recent, but its significance has increased significantly due to the widespread adoption of cloud services and the growing demand for automated information transmission between individuals.

Drawbacks associated with the current setup are outlined as follows:

FEACS: A Flexible and Efficient Access Control Scheme for Cloud Computing [1] was proposed by Y. Zhang, Jing Chen, Ruiying Du, Lan Deng, Yang Xiang, and Qing Zhou. To ensure that information shared in the cloud remains confidential and secure, they have implemented a Flexible and Efficient Access Control Scheme (FEACS) utilizing attribute-based encryption (ABE). However, it may not be integrated with all cloud computing applications and platforms.

SeDaSC: Secure Data Sharing in Clouds [2] was proposed by MazharAli, Revathi Hamotharan, Eraj Khan, Samee U. Khan, Athanasios V. Vasilakos, Keqin Li, and Albert Y. Zomaya. It addresses privacy, accountability, access control, and internal threat issues. It is a complex system and may prove challenging to establish and manage.

An innovative method for enhancing key generation and management in the AES algorithm [3] was proposed by Omer K. Jasim Mohammad, Safia Abbas, El-Sayed M. El-Horbaty, and Abdel-Badeeh M. Salem (2017). It aims to ensure confidentiality and address ethical concerns. However, creative techniques may require significant effort to oversee compared to conventional approaches.

Data Sharing Attribute Based Secure with Efficient Repeal in Cloud Computing [4], suggested by G. Elavarasan and S. Veni (2020), proposes an approach to optimize effectiveness. However, there are challenges with controlling access privileges and revoking them within a rapidly changing cloud environment.

A Proxy ReEncryption Approach to Secure Data Sharing in The Internet of Things Based on Blockchain [5] was proposed by K. Narsimhulu, Mallepally Prabhavathi, Varala Srijitha, and Thripuram Ajitha. It addresses issues with data sharing. However, this system may be influenced by the efficiency of applications using the Internet of Things.

III.PROPOSED METHODOLOGY

This research proposes a novel method that utilizes proxy-based re-encryption to facilitate the safe and efficient transfer of knowledge among individuals while preserving the privacy of sensitive data. The proposed strategy involves multiple elements working in tandem to ensure that only authenticated individuals can access the information.

The proposed system aims to simplify and enhance data sharing while maintaining the highest level of privacy for highly confidential data. It comprises several interdependent components that collaborate to restrict access to authorized individuals. The trusted authority serves as a pivotal component of this system, responsible for generating private keys for each user, maintaining a registry of these keys, and generating a master secret key for decryption purposes. Owners, upon registration with the Authority of Trust, are obligated to collaborate and convey their information to various parties.

The trusted authority configures user identification and access control permissions before allowing data access. Access control is enforced through user roles, permissions, policies, and assurances to ensure that only authorized individuals can access the data. To ensure confidentiality, authenticity, and secure sharing, the system employs security measures such as encryption and decryption. A proxy server is employed to re-encrypt the essential files, which are then shared with verified users upon owner approval as per user requests. The proxy server plays a crucial role in enforcing security parameters by acting as an intermediary layer facilitating secure data transmission between users and the cloud. Additionally, a cloud service provider is utilized for storage purposes and other functionalities. The proposed system architecture is shown in figure 1.

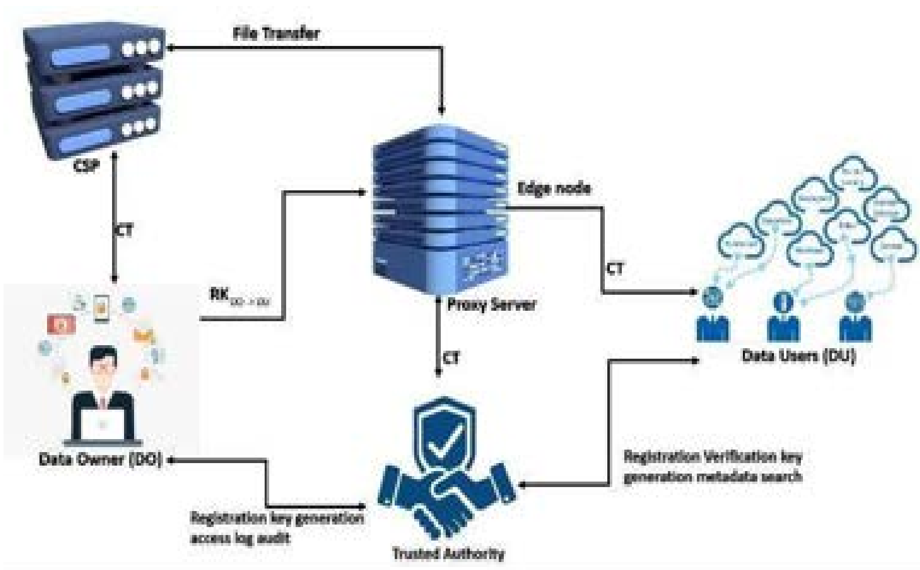

Figure-1: System Architecture

The proposed system architecture includes the following components:

- **Data Owner**: Data owner will have to register initially to get access to the profile. By leveraging cryptographic methods provided by the trusted authority using designated keys, the data owner encrypts the messages. These encrypted messages, called cipher texts, are finally transmitted to a server in the cloud,particularly the CS server.
- **Data User**: The first thing the user has to do is complete the beginning registration process, and the user can log in with sustainable credentials. Individuals who have been approved permission and a proper permit by the trusted authority are acknowledged as data users. The primary goal of a data user is to safely read and decipher encrypted data. To achieve this, the data user appeals to the CSP forencrypted data and keys. By utilizing these keys, the data user moves to implement the decryption process. It is important for data users to ensure they have the necessary authorizations and adhere to the decryption process to sustain data security.
- **Trusted Authority:** In this module, trusted authority is an asset in overseeing the cryptographic secret code and making sure thatthe correct authorization is given to data users. A trusted authority is an important component in maintaining the reliability and consistency of sharing data in the cloud. The trusted authority acts as a trusted entity that supervises the cryptographic keys, authorizes access, and maintains the general security of the system. By trusting the trusted authority, organizations can inaugurate a secure framework for sharing data, preserve sensitive information from unauthorized access, and guarantee the privacyof users.
- **Proxy Server:** This module incorporates the proxy server, which makes sure that the security of PRE guarantees that important data in the re-encrypted file can't be accessed by both the server or proxy and an unexpected user. The proxy server is liable for executing the re-ciphering process and recasting the owner's masked info into a format that the intended user can decode. safe during transfer and storage in the cloud, delivering an extra layer ofassurance for shared data.
- **CSP**: In this module, we create a cloud service provider (CSP). The cloud server shall offer an enabling function that permits it to inspect file content despite not having any information regarding the owners or users. The data owner's transmitted files are preserved as fragments and segments on the server. In addition, there is a submodule called cloud server includes proxy. The server in the cloud provides users with authorization for using the newly encrypted files.

This study will go through the arithmetic algorithm that forms the foundation of this system, known as Proxy Re-Encryption (PRE). It gives access to many users to decrypt specific data while it will make sure that unauthorized individuals can't access through plaintext. We will offer an in-depth and a well-founded explanation of how is this algorithm is working to securely share datausing PRE.

During this stage, with use of the setup we generate public parameters and master key by given security inputs. Given below formula is used for generating public key.

Key generation:

In this phase, by applying Key-gen (MK,id), this study generates the user's secret key. By making use of this formula and the proxy re-ciphering approach, the proprietor can securely share data in the cloud by re-encrypting the secret key with the help of the identifier and cryptographic operations.

Encryption:

From the input message (m) and input identity (id), with the condition that a random value (r) is suitable the sender creates a second-level ciphertext bycomputing the ciphertext.

Re-KeyGeneration:

The re-encryption key is generated through the Re-Keygen process by a new security key is created in order to compute a fresh cipher text through the Re-KeyGen process.

Re-Encryption:

The proxy re-encryption technique, an approved ciphertext (c1) is encrypted again with a newly created re-encryption key to give an additional layer of security. This is concluded to provide extra layer of security for pstop from attackers, threats etc.

Decryption Phase 1:

This step helps the representative gain access to the second-level ciphertext through the representative tries to side wisely decrypt the first-level ciphertext by using the identity-based decryption with the first private key.

Decryption Phase 2:

To gain the primary message, the representative decrypts the second-level ciphertext using the private key create for their specific identity. This will make sure that only verified individuals with the correct private key can access the original message, preserve the confidentiality and integrity of the data.

IV. RESULTS & DISCUSSION

Proxy re-encryption give an additional layer of security by allowing the data owner to delegate access rights and cancel them if necessary. The proxy re-encryption technique displays great outcome in securing data sharing in cloud computing. By using this technique, authorized delegates can securely access and decrypt data without compromising its confidentiality. This method permits for controlled and fine-grained access to shared data, make sure that only authorized individuals can recover and view the information. This helps preserve sensitive data while facilitating collaboration and efficient data sharing in cloud environments.

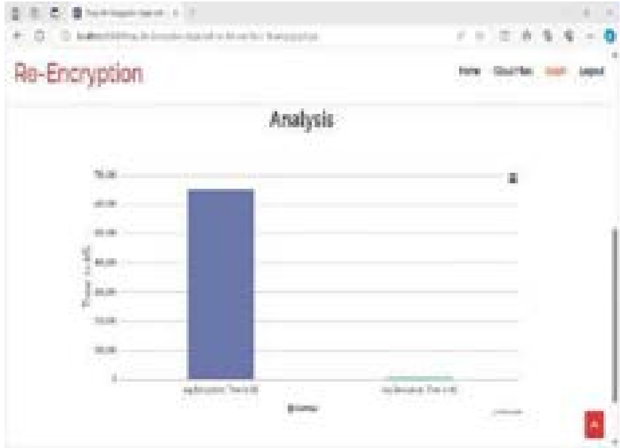

Figure:2 Avg Time of Encryption and Decryption

The time needed for ciphering and deciphering depicted above in figure 2.

Figure:3 Home page

Figure: 4 Upload files

In the upload the files of data owner will be encryptedand to be stored in cloud as shown in fig. 4.

Figure: 5 Uploaded file details

The uploaded file details will be shown as depicted in fig. 5 and we can seethe re-decryption key in the page.

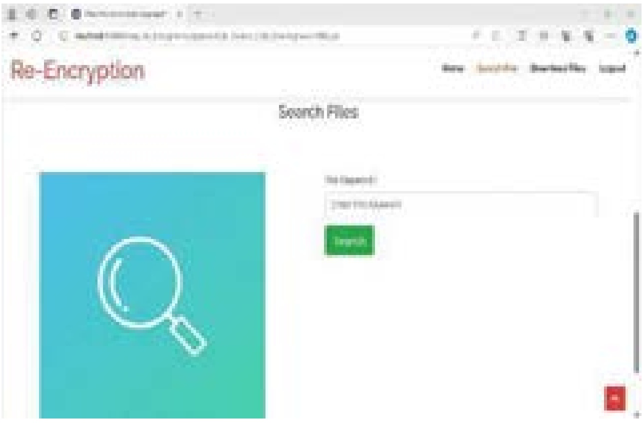

Figure: 6 Search File

This page shown in fig 6 is used to search a required file by data user and next request for it.

Figure: 7 Download File

The page shown in fig 7 is used to download the requested file when accepted by owner and re-decryption key is sent by server to user so they can download it.

V.CONCLUSION

In conclusion, while data sharing through cloud computing is widely practiced, it presents significant challenges in terms of data security. To address these challenges, we have developed a secure and robust solution for sharing data among individuals securely. Our system enables data owners to encrypt their data and store it in the cloud, where it is further re-encrypted by a proxy server before being transmitted to authorized users. The use of proxy re-encryption techniques represents a significant advancement in enhancing the security of data sharing in cloud environments. By employing proxy re-ciphering algorithms, we ensure that data dissemination occurs in a highly secure manner, resistant to attacks or unauthorized access. This approach not only enhances confidentiality but also safeguards the integrity and authenticity of shared data. As technology continues to advance, the integration of such innovative techniques becomes increasingly crucial for establishing a trustworthy foundation in cloud data sharing systems. By implementing proxy re-encryption, organizations can establish a robust framework that facilitates secure and controlled data circulation in the cloud, effectively addressing concerns related to unauthorized access and data breaches. Moving forward, continued improvements in technology will further strengthen the security posture of cloud-based data sharing systems, ensuring the integrity and confidentiality of shared information.

ACKNOWLEDGEMENT

I am extremely grateful to the Department of Information Technology at MLRIT College for their invaluable support in completing my dissertation. Additionally, my heartfelt appreciation goes out to our esteemed faculty, project coordinators, and friends for their guidance and constructive feedback throughout the duration of theproject.

***Abstract* — Internet of things (IoT) is an emerging technology that shows the future of computing and networking. Agricultural monitoring from a remote location is one of the essential applications of IoT based Wireless Sensor Networks (WSNs). The applications face problems due to the dynamic changes in the environment. Traditional farming methods frequently suffer from imprecise delivery of water and nutrients to crops, resulting in inefficient resource usage and suboptimal yields. This research study addresses the pressing need for enhanced precision agriculture techniques aimed at optimizing crop monitoring and resource utilization.**

Keywords: IoT Application, Farm Automation, Soil Moisture Monitoring, Farming Technology, Autonomous Farming.

1. INTRODUCTION

India has demonstrated remarkable progress in agriculture over the past four decades, effectively meeting the increasing demand for food [1]. This achievement can be attributed to several factors, including the adoption of modern crop varieties, increased utilization of inputs, and strategic investments that have expanded irrigated areas. However, despite the initial success of "Green Revolution" technologies, their impact has diminished in certain regions, necessitating the development of new technologies to further enhance productivity, promote sustainability, and diversify cropping patterns [2]. Moreover, addressing the challenge of advancing yield boundaries is crucial, alongside the urgent need to leverage the potential of rain-fed and less-fertile areas. Given India's diverse agro-ecological landscapes and farming communities, a broad spectrum of solutions is required. To achieve accelerated, widespread, and targeted growth, agricultural research should focus on addressing location-specific challenges, while agricultural systems must integrate cutting-edge technologies to benefit resource-constrained farmers.

As the world's population is expected to grow significantly, the agricultural sector faces the formidable challenge of producing 70% more food by 2050 [3]. This challenge is exacerbated by diminishing agricultural lands and finite natural resources. To tackle these issues, smart agriculture solutions utilizing the Internet of Things (IoT) are becoming increasingly crucial. IoT technology aids farmers in optimizing resource utilization, enhancing crop yields, and reducing operational costs. Predictive analytics, coupled with sensor data, empower farmers to make informed decisions regarding crop production, storage, marketing, and risk management. Agricultural drones, livestock tracking systems, and smart greenhouses are employed to monitor and improve various farming practices [4]. With the continuous advancement of IoT technology, the adoption of IoT devices in agriculture is expected to rise, leading to a projected tripling in size of the global smart agriculture market by 2025.

To enhance agricultural productivity, automation and robotics are being integrated into farming operations [5]. The development of an autonomous farming robot powered by microcontrollers aim to automate on-farm tasks such as seeding and fertilizing. This technology reduces human effort while increasing crop yield. The robot can precisely plant seeds at predefined distances and depths, controlled by microcontrollers [6]. Such innovations play a crucial role in addressing the shortage of skilled labor in agriculture and can significantly impact the lives of the majority of resource-poor farmers. Consequently, the objective is to develop an integrated IoT-based system using Arduino Uno and sensors to accurately measure environmental parameters such as temperature and humidity. By regulating water and fertilizer delivery, it ensures crops receive optimal nutrients, thus reducing wastage and labor. Real-time data transmission enables farmers to remotely monitor fields, facilitating timely decision-making [7].

The Internet of things (IOT) is revolutionizing the agriculture enabling the farmers with the wide range of techniques such as precision and sustainable agriculture to face challenges in the field. IOT technology helps in collecting information about conditions like weather, moisture, temperature and fertility of soil, Crop online monitoring enables detection of weed, level of water, pest detection, animal intrusion in to the field, crop growth, agriculture [8]. IOT leverages farmers to get connected to his farm from anywhere and anytime. Wireless sensor networks are used for monitoring the farm conditions and micro controllers are used to control and automate the farm processes. To view remotely the conditions in the form of image and video, wireless cameras have been used. A smart phone empowers farmer to keep updated with the ongoing conditions of his agricultural land using IOT at any time and any part of the world. IOT technology can reduce the cost and enhance the productivity of traditional farming [9].

2. LITERATURE REVIEW

In this section the brief summary on internet of things and crop monitoring is presented.

In Li Da Xu et al work [10], the primary focus is on the Internet of Things (IoT) and its strategies, emphasizing identification, tracking, communication, and service management. The paper discusses key IoT applications and the associated challenges particularly regarding security and standardization Healthcare is highlighted as a significant IoT domain, employing medical sensors and wearable devices to monitor health parameters and improve patient care. Security concerns in IoT are underlined, necessitating the enhancement of existing security protocols.

Madakam, S. Ramaswamy, and Tripathi [11], conducted a comprehensive exploration of IoT concepts through a systematic review, drawing insights from diverse sources such as corporate white papers, professional discussions with experts, and online databases. Their research delves into defining IoT, tracing its origins, elucidating fundamental requirements, delineating its characteristics, and identifying various aliases associated with this burgeoning technology. The primary aim of their paper is to furnish readers with a broad overview of IoT, encompassing its architectures, and crucial technologies, while also highlighting their pervasive integration into our daily lives. Through their work, they provide a coherent narrative that not only educates but also contextualizes the significance and impact of IoT in contemporary society, laying a foundation for further exploration and innovation in this rapidly evolving field.

Kavitha B C, Shilpa D P [12], IoT technology facilitates the gathering of data pertaining to factors such as atmospheric conditions, moisture levels, temperature, and soil fertility. Online monitoring of crops enables the identification of weeds, water levels, pest presence, animal encroachment into fields, crop development, and agricultural progress. Wireless sensor networks are deployed for monitoring agricultural conditions, while microcontrollers are employed to automate and manage farm operations. For remote viewing of conditions through visual media, wireless cameras are utilized.

Martina Corti, Pietro Marino Gallina adopted precision agriculture for enhancing both the environmental sustainability of crop systems and farmers' financial returns [13]. Farmers transitioning to precision agriculture require efficient protocols that demand minimal inputs to delineate homogeneous management zones, facilitating optimized actions without prior knowledge such as yield maps. Results showed that red-edge and near-infrared (NDRE) bands emerged as the most dependable data sources for identifying management zones, achieving correct classifications of 62%, 68%, and 74% at early tillering, stem elongation, and late booting stages, respectively.

Anand Nayyar and Er. Vikram Puri [14] delve into the transformative potential of Internet of Things (IoT) technology, which has revolutionized various aspects of daily life by endowing objects with intelligence and connectivity. At the heart of IoT lies a network of interconnected devices capable of autonomous configuration. In the agricultural sector, the emergence of Intelligent Smart Farming IoT devices is revolutionizing traditional practices, enhancing production efficiency, reducing costs, and mitigating wastage. The central focus of their paper is the introduction of an innovative Smart IoT Agriculture Sensor, meticulously crafted to provide farmers with real-time data crucial for decision-making, including temperature and soil moisture levels. By harnessing the power of IoT, this sensor empowers farmers with actionable insights, enabling them to optimize resource allocation and enhance agricultural productivity in an increasingly dynamic environment.

3. METHODOLOGY

The proposed IoT (Internet of Things) system aims to enhance connectivity, efficiency, and data management in diverse applications. The block diagram of proposed methodology is presented in Fig. 3.a.

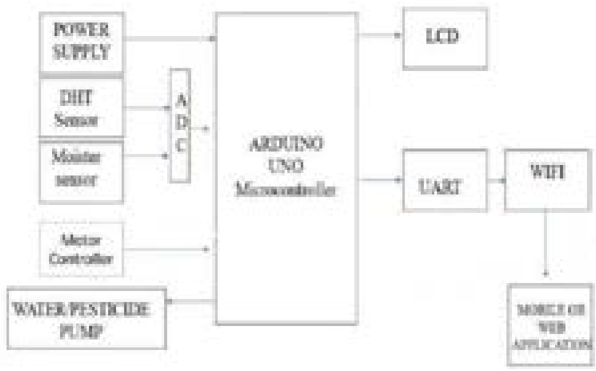

Fig 3.a :- Block Diagram of Proposed Methodology

The SSF 225 motor, connected to the Arduino Uno, regulates the flow of fertilizer by activating at specific intervals as programmed. This ensures that crops receive adequate nutrients from the onset, fostering healthy growth and development.

In terms of water management, the DTH22 sensor plays a pivotal role by continuously monitoring soil moisture levels. This data is relayed to the Arduino Uno, which, based on predefined thresholds, activates the water pump for irrigation when soil moisture levels drop below a certain point. By employing this automated irrigation system, crops receive water tailored to their specific needs, thereby mitigating the risks of under or over-watering.

Furthermore, to keep the farmer informed about the farm's condition in real-time, a Wi-Fi module is utilized to connect the Arduino Uno to the internet. This enables the transmission of timely updates to the farmer's smartphone or computer, including information on soil moisture levels, temperature, humidity, and fertilizer application. Prompt access to this data empowers the farmer to take immediate action in response to any detected issues, such as low soil moisture or abnormal temperature conditions.

Moreover, an LED display connected to the Arduino Uno provides on-site information to the farmer, displaying real time data such as soil moisture levels, temperature, and humidity. This feature offers a convenient means for the farmer to monitor the farm condition at a glance, facilitating timely decision-making.

The methodology outlined for crop monitoring using IoT components enables precise agricultural practices, encompassing fertilizer application, irrigation management, and real-time data dissemination. By leveraging these technologies, farmers can optimize crop growth, conserve resources, and maximize yield potential, ultimately contributing to sustainable agricultural practices.

Our project, titled "Crop Monitoring Using IoT for Precision Agriculture," stands out amidst existing endeavors through its integrated approach to automated temperature detection and precise irrigation facilitated by a mobile farming robot. Unlike conventional systems, our solution harnesses IoT technology to enable the robot to autonomously sense temperature variations, navigate between crops, and administer water as needed. Moreover, the portability and mobility of our robot enhance its adaptability across diverse agricultural landscapes, amplifying efficiency and ensuring optimal crop health. This distinctive combination of real-time sensing, autonomous mobility, and portability sets our project apart, offering a comprehensive solution for enhancing agricultural productivity and sustainability.

4. MODEL IMPLEMENTATION

The implementation of our IoT model involves deploying sensor nodes to collect data from the physical environment. The hardware setup requirement for purposed model is given below.

4.1 Hardware Setup:

A. **Arduino Uno:** The Arduino Uno serves as the central controller for the system, collecting data and controlling various components.

B. **DHT22 Sensor:** This sensor measures temperature and humidity, providing crucial environmental data for crop health assessment.

C. **SSF-225 Motor:** This motor can be used for controlling the release of fertilizers or other agricultural inputs.

D. **Water Pump:** It controls the irrigation system, ensuring that the crops receive the right amount of water.

E. **LED Display:** The LED display can be used to show real-time data, alerts, and system status.

F. **Wi-Fi Module:** A Wi-Fi module connects the system to the internet, enabling remote monitoring and data transmission.

4.2 Temperature and Humidity Reading

The DHT-22 helps us to get the temperature and humidity value at any particular time. Keeping a check in the temperature and humidity value will help the user in taking care of livestock and special plants. From DHT22, the signal gets passed to ESP8266 which further passes the signal to the IP address from where the user can get notified even when away from the field.

Fig 4.2(a) :-Temperature Reading of Farm

Fig 4.2(b) :- Humidity Reading of Farm

In a Crop Monitoring model, figure 4.2 (a), and figure 4.2 (b) are displaying temperature and humidity readings respectively. These data are collected from sensors deployed in the environment.

4.3 Soil Moisture Determination

Each data point on the graph would correspond to a specific time interval and would show the corresponding temperature and humidity levels recorded by the sensors at that time. This visualization helps users to monitor changes in temperature graph (figure 4.3(a)) and humidity graph (figure 4.3(b)) over time, identify patterns, and detect anomalies, enabling them to make informed decisions based on the data.

Fig 4.3(a) :- Weather Temperature Graph of Farm

Fig 4.3(b) :- Humidity Graph of Farm

The soil moisture sensor determines the moisture content of the soil and temperature of Farm. If the moisture of Farm is below the threshold value (60) or above the temperature threshold value (37), it sends signal to the DC motor i.e., the pump and automatically the pump gets on and waters the field. By customizing farmer can set fertilizer to the farm by reading.

4.4 Implemented Model

Fig 4.4 (a) :- Implemented Model In Real Life

Figure 4.4 (a) is representing the build of small prototype of our farming robot.

5. CONCLUSION

The proposed model optimizes the agricultural process and improve crop yields. By setting fertilizer with sowed seeds, providing the right amount of water based on soil requirements, and notifying the farmer about the farm's condition, the proposed model has created ideal growing conditions for crops. Lastly, integrating fertilizer application with seed sowing ensures that the growing plants receive vital nutrients right from the start, nurturing healthy growth and ultimately improving yields. Secondly, customizing irrigation schedules based on soil requirements helps to prevent both overwatering and underwatering.

Abstract—**For the purpose of preserving stability and reliability in the face of fluctuations and disturbances, the electrical grid is dependent on load frequency control, often known as LFC. The percentage decision point of view (FOPID) controller and the 1+PI controller are compared in this work within the context of two linear feedback control (LFC) domains. The controllers are put through their paces in this study under a variety of conditions, with the random wind generation in area 1 and the uniform wind production in area 2 being taken into consideration. Through simulation tests, FOPID and 1+PI controllers are evaluated for their capacity to manage system frequency and maintain network stability. In this evaluation, key performance parameters such difference, tie line fluctuation, and system stability are taken into consideration.**

Keywords—Load Frequency Control (LFC), Two-Area System, Thermal Power System, Wind Generation (WG), FOPID Controller, 1+PI Controller

I. Introduction

Load frequency control regulates energy production and consumption and ensures power grid reliability. Low-frequency generators struggle to absorb renewable energy, notably wind energy. A variety of system frequencies and energy changes impede wind energy interaction. Power frequency must be modified for renewable energy to protect the grid. It needs top-level management. Comparison of 1+PI and FOPID controllers in dual LFC circuits. The study compares stepper and random generator controllers. Unblocking requires FOPID and 1+PI controller understanding. This study analyses deployment, connection, and security [1-2].

Load frequency control (LFC) systems with FOPID and 1+ PI controllers are popular. The controller stabilises and controls renewable energy and energy storage frequency. Our LFC system FOPID and 1 + PI controller assessment covers performance, pros, and disadvantages [3-6].

Previous research has shown that FOPID controllers can detect weak events, even non-events. FOPID controllers detect most electronic component changes using discrete codes, making them precise and adaptive. Low frequency control (LFC) attenuation, stability, and frequency control have been researched for FOPID controllers. The 1+PI controller can be used for LFC systems. The controller is simple and reliable. Integration of 1+PI improves proportional-integral (PI) controller controllability and stability. Recent studies show that LFC systems with 1+PI controllers can monitor, tune, and maintain stability even when parameters change. Electronic control methods are ideal for 1+PI controllers due to their real-time applicability and ease of use [7-8]. Many studies compare FOPID controllers to 1+ PI controllers, yet both offer benefits due to low frequency control. Wind generation disparity between LFC system locations is the basis for this hypothesis. This study compares the integral part (PI) and complete order part by part (FOPID) controllers. This study focuses on two-area load-frequency converter (LFC) systems that use periodic or random wind power. In this work, simulation and performance tests analyse several renewable energy integration methods for poor fuel economy. Research [9-11] has also examined the pros and cons of each therapy method.

The return principle develops AGC's adaptive controller. Policies are analysed and improved by PI to improve management. Controlling with PI is better than LQR without knowing how the system works [12-13]. PI-based control agreement was evaluated in two uncontrolled zones. Solar thermal and wind turbine generators are renewable energy innovations. Once, this technology will power homes and businesses. Systems change grid frequency and output voltage. This research designs hybrid generator frequency control PID controllers to control operating limit frequency. PID controller parameters are optimised by BBBC. Test controller performance with random loads. This study changes considerably with the Iteration Principle. We offer this control to solve automatic production problems (AGC) in numerous fields. The controller operates two zones without resetting a thermal zone using the second horizontal regulator (LQR). Evaluate your physical performance with metrics. For high-frequency items, LQR supports performance best [14-15].

Choose a renewable energy source using multidimensional decision-making. Small, unreliable data and conflicting standards slow the process. Modified intuitionistic fuzzy sets (MIFS) can fix these difficulties. Regulation-driven MIFS improves behaviour. We present MIFS architecture RES in this paper. Choquet creates the MIFS data MIF Choquet Integral (MIFCI) integration operator. Finalising

RES options with staff. Research shows IFS solves real-world issues. The IFS recruits oddballs. Lack of information, prior knowledge, events, and context affect uncertainty measurement. Enhance IFS member uncertainty index. Improvements to IFS non-transitive variable parameters improved default behaviour. A keypoint and geometric clustering method for random and uncertain data is presented in this chapter. The MCDM candidate selection strategy works [16-20. Nowadays, the control algorithms are being used in other areas to investigate their performance, some of them are given in [21-24]. Further the use of different control schemes in LFC is reported in [25-28]. All these control schemes show that LFC is still an area of exploration in terms of control approaches, optimization, load perturbation, etc. Wireless charging of electric cars in living rooms raises potential concerns. A Moderator-Intuitionistic-Fuzzy Hybrid Averaging Operator can classify sustainability of renewable energy sources [29-31]. This study introduces an optimization-based artificial neural network model for charging electric vehicles using intuitionistic fuzzy geometric aggregation operators to make decisions based on multiple factors [32-34].

II. CONTROL SCHEMES

A. FOPID Controller

In load frequency control, FOPID controllers have various benefits. It's clear that traditional PID control is more elastic and flexible than deterministic function. Power uncertainty is captured by the FOPID controller, enhancing system response and stability. FOPID is more flexible and versatile than other controllers due to its higher control capabilities. FOPID controllers can also switch transmission lines, especially energy storage-renewable energy source connections.

When traditional PID controller compared to the FOPID controller, various issues must be solved. This method would take longer and need more steps without operational disturbance. The FOPID controller outperforms the PID controller. Direct use of the FOPID controller in big power plants is restricted by its advantages. Measure FOPID controller quality to improve LFC system performance and reliability. The current power system is inconsistent and unreliable.

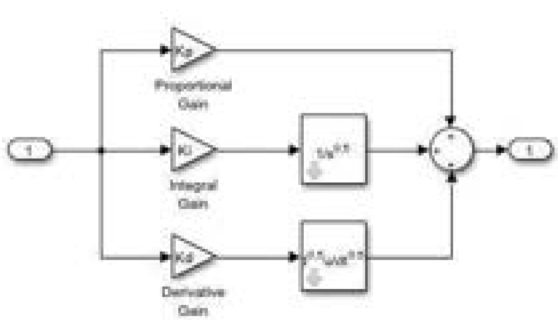

Fig1. The subsystem of FOPID controller.

The classic PID model is expanded upon by FOPID controllers, which accomplish this by merging proportional, single, and variable parts. Three parameters—mostly equal, one, and variable—represent the many variables that are required to solve the problem of instantaneous power conversion. These parameters are what distinguish the FOPID controller from other controller technologies.

$$output = K_p + \frac{K_I}{s^{-\lambda}} + K_D s^{\mu} \tag{1}$$

Fractional order PID (FOPID) controllers make discrete decisions, improving complex behaviour modelling and control. By rectifying these negative decisions, the FOPID controller can adapt to varied processes and needs, improving product efficiency and resilience load frequency control. The FOPID controller's mathematical model is more sophisticated than ordinary PID controllers. FOPID controllers are effective for fire truck difficulties because of their simplicity and convenience. Modern electricity comes from renewable energy and energy storage.

B. 1+PI Controller

The 1+PI controller is designed for product stability and uses LFC technology for heavy loads, making it ideal for instantaneous power transmission due to its low demand. It's great for transmitting power instantly because of its low demand. 1+PI controllers are simple but reliable, suited for many designs and purposes, even when disturbed or uncertain. 1+PI controller issues include uniformity, measurement precision, and easy control. Poor management due to strict rules and individual work can make it hard to behave improperly or sporadically.

Slow response and overshoot limit 1 + PI controller for low voltage quick switching or overshoot. In complex activities, the controller's performance will decline if its normal control system cannot control the dynamic system. LFC systems with simple and reliable applications can benefit from the 1+PI controller despite its limitations. Before selecting and using a control mechanism, power system performance and dependability must be analysed for pros and cons.

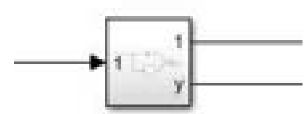

Fig 2. The subsystem of 1+PI controller.

III. SYSTEM DESCRIPTION

Each area of a thermal power plant has undergone testing for two-area load frequency control (LFC). Two-area employs a progressive wind pattern, while area-1 generates a random wind pattern. There is an increasing inclination towards integrating renewable energy sources into thermal power plants; yet, the factors involved exhibit interdependence and unpredictability. Thermal power plants play a crucial role in meeting the energy demands of various regions. By employing the identical equation, these centres have the capability to establish connections between control equipment, such as valve rooms and turbine control centres, and the generation of power. The performance of boilers, turbines, and pressure regulators has a significant impact on the LFC system of thermal power plants. Intense winds will result in tangible consequences, particularly in area 1 and 2. Phase 1 storms can induce alterations, whereas Phase 2 wind power can result in swift power fluctuations. The dynamics of power plants are demonstrated through the utilisation of several variables, including wind speed, turbine blade pitch control, and energy production reaction. The variability of wind power in relation to grid frequency and tie-line power fluctuations between two locations poses additional difficulties in terms of frequency regulation and system stability. Effective modelling and testing precisely depict the behaviour of the LFC system when subjected to change and influence, enabling the evaluation and optimisation of control measures.

IV. Parameter tuning using GA

Load frequency control (LFC) systems do not need controller optimisation for stability and performance. Genetic algorithms (GA) optimise control systems. The proportion of events (FOPID) and 1+PI controllers are examples. This sections illustrates GA's FOPID and 1+PI controller characterization process.

A. Parameterization of FOPID using GA:

Genetic algorithms use selection, mutation, and other genetic processes to optimally find a preliminary solution. Evolution and natural selection underpin these algorithms. GA employs FOPID controller parameterization for percentage decisions. You must understand that the FOPID controller parameterization determines the percentage of proportional, proportional, and variable inputs that govern the GA's LFC system. Typically, parameterization begins with a chromosome model, where each chromosome represents a solution. Every parameter has a range, and a random integer creates the original chromosomal population. To assess chromosomal safety, the objective—stabilizing or reducing variations—is used. GA optimises the LFC system FOPID controller using generation, crossover, and transition selection to return the population to the ideal integration values [12–14].

B. Parameterization of 1+PI using GA:

The evaluation of gain (Kp), gain (Ki), and mixing time (Kp2) is another type of analysis that GA can do on a 1+PI controller for LFC applications in order to maximise efficiency. The chromosome structure of the 1+PI controller is comprised of Kp, Ki, and Kp2 values, and the first population of the region is established. During the health examination, each chromosome is evaluated to determine how it responds to improvements, such as reducing or increasing the amount of exercise. The population is adjusted to the optimal solution through the processes of genetic selection, mutation, and mutation.

During the optimisation process, GA makes adjustments to the 1 + PI controller in order to modify the system frequency (LFC system stability). The evolutionary approach is both efficient and successful when it comes to evaluating high-frequency load FOPID and 1+PI controllers. Through the exploration of parameter space and the subsequent adjustment to the optimal solution, the genetic algorithm is able to locate the control system that optimises both performance and reliability, hence improving the stability and performance of the power grid [15-16].

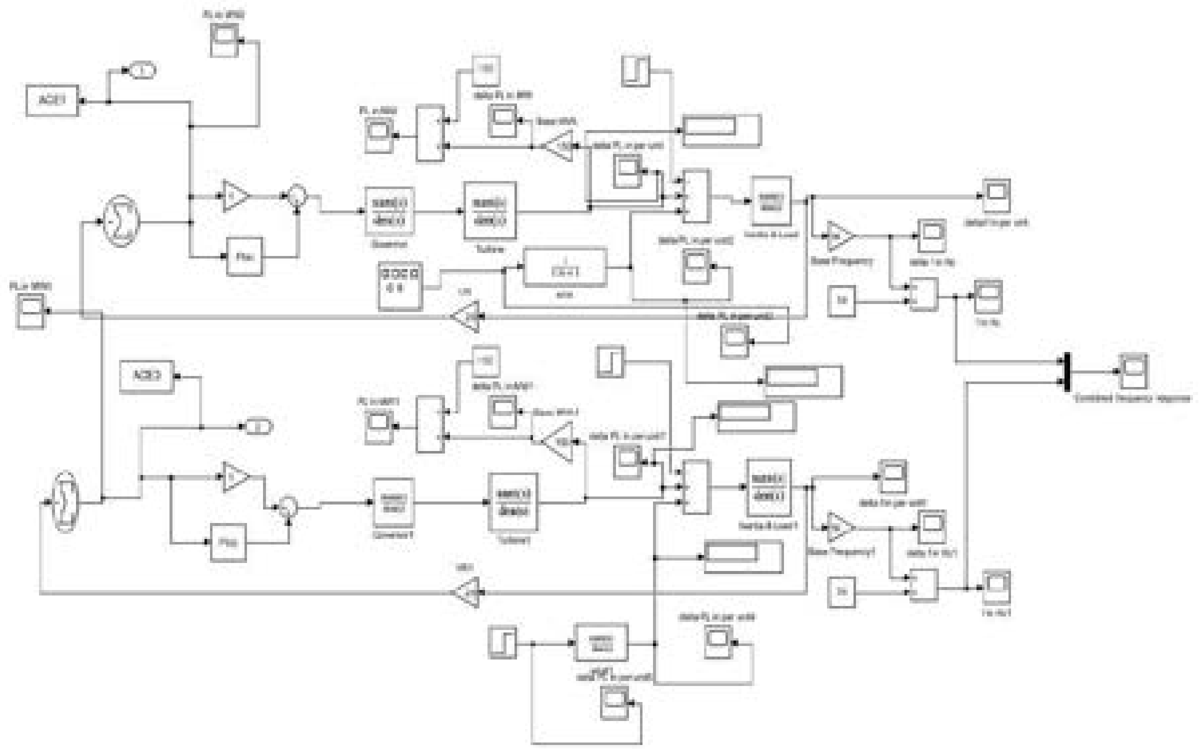

Fig 3. Simple structure of Test System

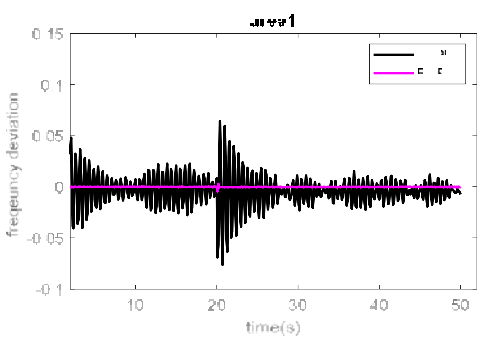
V. Results & Discussion

For the purpose of assessing the effectiveness of the controller that was built for two-area load frequency control (LFC), a number of different scenarios that involve gradual changes in load and wind energy are incorporated. In particular, the step load perturbation in area 1 is designated as 0.1 to 0.3 per unit (pu) at time t = 20 seconds, while the step load perturbation at time t = 2 is denoted as 0.1 to 0.3 per unit (pu). Both of these values are expressed in units of the unit. It is displayed as a time of 0.30 seconds. In addition, a gradual wind power interference is applied to region 2 at a time equivalent to thirty seconds, and the impact range is between 0.1 and 0.15 pu. These effects imitate abrupt variations in load demand and wind generation, which in turn alter power frequency and tie-line power variation. Consequently, these effects have an effect on electric power.

Through the process of subjecting the LFC system to these disturbances, we are able to determine the effectiveness of the controller in terms of controlling the frequency of the system and improve the functionality of the grid. A minor disruption in either of these might result in sudden shifts in energy demand, which necessitates regulators to make prompt adjustments to the power output from the grid in order to maintain a restricted level of system operation. In a similar manner, a voltage source of the second generation will result in changes in the output voltage, in addition to causing issues with the controller's capacity to manage various frequencies.

A. Frequency Deviation

The frequency deviation is a significant indicator of the stability of the system since it measures the amount by which the system frequency deviates from the frequency that is nominal. The controller must make necessary modifications to the frequency difference to ensure that the system frequency remains within the acceptable range in the presence of escalating load disturbances and changes in wind power. The purpose of this action is to adhere to the established regulations. The performance of the controller in maintaining stability within the operational environment can be assessed by observing and assessing the fluctuations that transpire over a specific time frame.



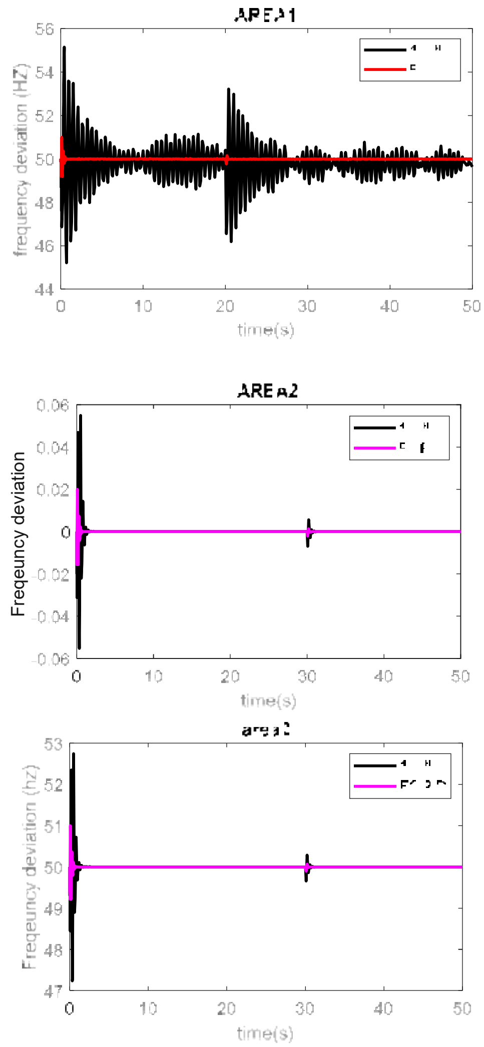


Fig 4. Frequency deviations in both areas.

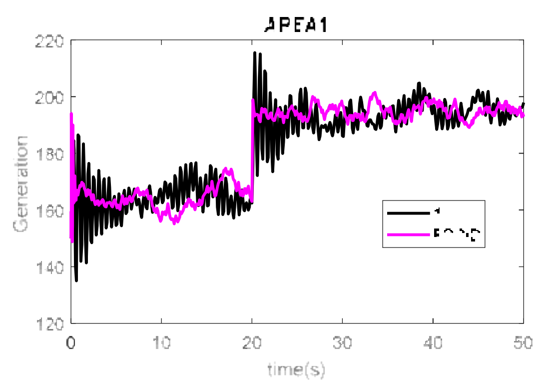
B. Change in Generation

Change in generation refers to the adjustments made to thermal power plants' power output in response to load changes and variations in wind generation. By monitoring the changes in generation following the disturbances, we can evaluate the controller's effectiveness in restoring the balance between generation and demand, thereby stabilizing the system frequency. A rapid and appropriate response in adjusting generation levels indicates the controller's ability to mitigate frequency deviations and ensure grid stability.



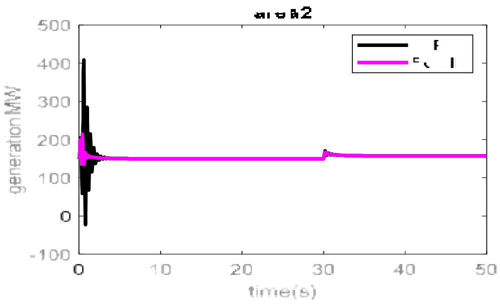


Fig 5. Change in generation in all areas.

C. *Wind Input-Output*

Figure 6 shows the wind input and output for area-1 and area-2.

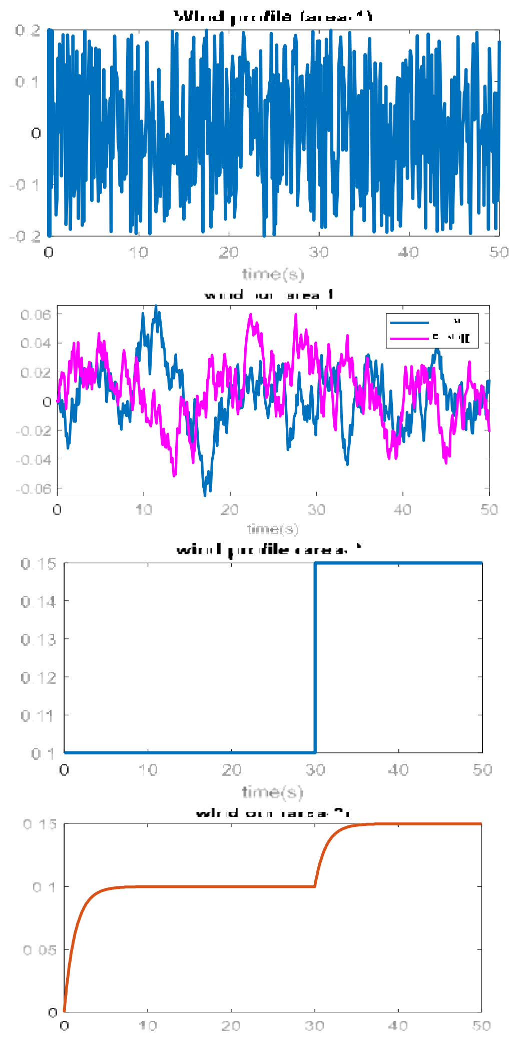

Fig 6. Wind input output for both areas

D. *Area Control Error (ACE)*

Area Control Error (ACE) measures generation-demand imbalance in each control area and is essential for performance evaluation. ACE is the difference between power replacement and replacement plan with load and climate change effects. A low ACE indicates that the controller manages energy exchange in the control zone well and reduces the planned stability-control stability difference.

Compare load step to wind change, generation change, and ACE to evaluate the controller's frequency control and grid stabilization. Comparing the controller's responses and impacts on these crucial parameters can show its real-world LFC efficiency and efficacy, optimizing grid performance.

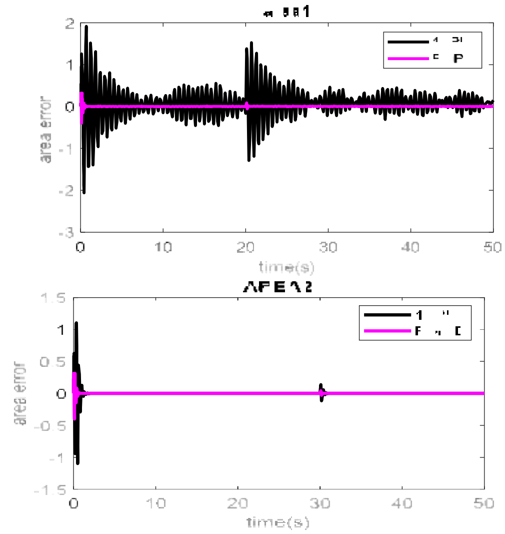

Fig 7. Area Control errors.

VI. Conclusion

The error-related transitions of FOPID and 1 + PI controllers are greater than those of the two-area load frequency control (LFC) controller. In terms of error, power generation, step load interference, and wind switching power regulation, FOPID demonstrates superior performance compared to 1+PI. Utilizing frequency counters to operate and regulate FOPID enhances both efficiency and accuracy. FOPID provides global updates to identify and address defects and damage. The FOPID algorithm surpasses 1+PI in terms of accuracy, stability, and response time.

The FOPID model has exceptional efficacy in identifying unaccounted variations within the power system. The aforementioned accomplishment was attained by employing renewable energy sources and implementing energy storage technology. The effectiveness of FOPID in mitigating power line frequency and power sector impacts surpasses that of wind power generation. FOPID demonstrated superior performance in terms of frequency management and grid stability in both LFC zones when compared to 1 + PI. The utilization of step load impedance and wind power transformer is employed for this purpose. The findings of this study demonstrate that the utilization of FOPID can enhance the efficiency of LFC systems that are impacted by imperceptible issues inside the network.

***Abstract*—The global transportation landscape is experiencing a profound shift with the widespread adoption of electric vehicles (EVs) as a sustainable alternative to traditional combustion engine vehicles. In light of the growing EV market, this research project proposes establishing a sustainable EV charging infrastructure along highways, utilizing power directly sourced from existing electric poles lining the roadside. The primary objective is integrating advanced payment technologies, allowing individuals to conveniently pay for consumed power using UPI or credit/debit cards. This technological integration aims to create a user-friendly and easily accessible payment system. This innovative approach will benefit users and the government since it has low development costs. IoT sensors monitor the real-time situation of charging stations, taking measures for errors. Users log on and get up-to-the-minute charging status notices and billing details. Support for this can come out after successful testing of Cloud computing. So not only will it be smooth and convenient to operate the system via EV charging infrastructure, but it will also make some accurate contributions towards sustainable transport initiatives.**

Keywords: Electric Vehicle, Accessibility, User Experience, Efficient Charging Station, Payment Integration.

I. Introduction

In the automotive industry, the speed-up adoption of electric vehicles is a revolution. It helps improve the cleanliness of transportation. However, a significant challenge that restricts the extensive use of EVs is the lack of infrastructure to load their batteries on long journeys. By recognizing the necessity of a full-scale and readily available charging infrastructure for electric vehicles [1], our project puts forward an innovative concept. Directly utilizing power from existing electric poles along highways to build a network of electric vehicle charging stations [4].

The idea aims to provide convenient charging for guys on long trips in an electric car, building on advanced payment technologies to offer an enjoyable and easy experience. Drawing from the existing electric poles, the charging stations can take power directly from the source. This reduces the need for additional infrastructure and leverages work already done using infrastructure to get maximum efficiency out of it. This not only simplifies the charging process but also helps meet the sustainability goals of the electric vehicle ecosystem. Putting efficient charging stations into place at crucial points along the highways begins to resolve the practical problems of EV adoption, particularly addressing issues of range anxiety during long-distance travel[16]. Broadening the EV equipment infrastructure is faced with prompt challenges such as high implementation costs, scale-ability problems, and the need for sustainable power sources.

The project aims to meet these challenges by using electric poles along highways to minimize additional costs for a more sustainable charging solution and thus render electric vehicles a reality for more people [11]. Moreover, the project strongly emphasizes user experience by integrating seamless payment technologies, allowing users to track charging sessions receiving payment notifications. This approach not only simplifies the payment process but also enhances the overall accessibility and user-friendliness of the EV charging network. This idea contributes to sustainable transportation by presenting an innovative approach that leverages existing infrastructure to establish an extensive EV charging network. By focusing on user experience and environmental impact, the proposed highway-powered charging stations aspire to play a pivotal role in shaping the future of transportation, fostering economic growth, and laying the foundation for intelligent mobility ecosystems.

A. *Basic Terms of electric vehicle charging stations*

Distinction between different charging levels: Level 1 (120V), Level 2 (240V), and DC fast charging, catering to various charging needs.

Accessibility and Location: Strategic placement of charging stations for accessibility, considering urban areas, highways, and public spaces. Accessibility features, such as ADA compliance and user-friendly interfaces[6].

Connectors and Standards: Specification of charging connectors, such as CCS, CHAdeMO, or Type 2, to ensure compatibility with diverse electric vehicle models.

Charging Infrastructure: Physical infrastructure for charging stations, including charging bays, power distribution units, and associated electrical components.

Power Output: Specification of the power output of the charging station, measured in kilowatts (kW), impacting the charging speed.

B. *How Electric Vehicles Charge*

Electric vehicles (EVs) utilize three main types of charging systems: Level 1, Level 2, and DC fast charging. Fig.1. depicts the modes for charging electric vehicles in the proposed idea. Level 1 charging operates at a power output of 1.4 to 1.9 kW, suitable for daily commuting and overnight residential charging using a standard 120-volt household outlet. Level 2 charging offers a power output of 3.3 to 19.2 kW, catering to diverse needs in homes, workplaces, and public charging stations. Operating at 240 volts, this configuration provides faster charging than Level 1 and ensures compatibility with prevalent infrastructure[2]. Level 3, known as DC Fast charging, exceeds the previous two levels; it can provide at least 50 kW and up to 350 or 400 kW-power, perfect for long-distance travel in 2022 with swift highway refueling. The "charging time of 20 minutes" on Level 3 shows that it still has quick charging aimed at owners of electric automobiles who are hustling between business meetings [8]. At the same time, the charging infrastructure includes connectors to match EV charging ports, with variants such as J1772, type-2, CCS, and ChaDeMO for different regions and standards.

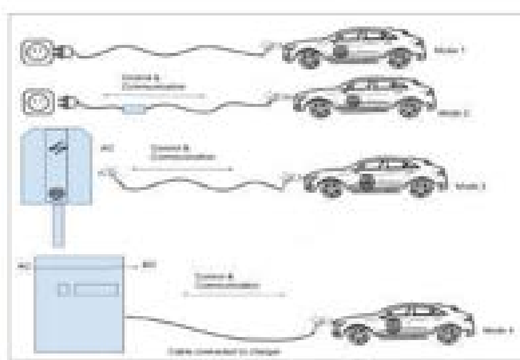

Fig. 1. EV charging modes

II. Literature Review

The evolution of electric vehicle (EV) charging stations has seen significant innovations aimed at improving their function and making them friendlier to the environment. Despite improvements as station technology evolves, there is still a wide variety of features and limitations on available charging stations in development[10].

But this proposal has a banner departure and uses the existing infrastructure–highway poles for EV recharging. This strategy reduces costs and space use, marking significant progress in sustainable infrastructure deployment [5],[6].

A key point of this proposal lies in technology integration. It lets us get transparent insights into power consumption and establishes a user-friendly payment system. Unlike many models that find it difficult to achieve seamless technology integration, this proposal has an automatic charge process, which is friendlier to users and removes the need for external oversight. Therefore, it is also economic in terms of external monitoring and user satisfaction [14].

The proposal is nothing like existing models that only adapt to essential charging needs. The main focus of this model is to design with advanced technology, especially internet-of-things (IoT) solutions. Taking advantage of IoT, this proposal has a seamless payment system, precise control over the flow of current, and can be monitored at leisure. This systematic approach to integration is expected to streamline energy consumption, raise security levels, and facilitate proactive maintenance, the very change in EV charging infrastructure [3].

By highlighting the advantages of leveraging existing infrastructure, incorporating advanced payment technologies, and integrating IoT systems, this proposal positions itself as a leading solution for the future of sustainable EV charging infrastructure. Its comprehensive approach and valuable insights make it a valuable contribution to the literature review of research papers in this field.

III. EV Charging Scheme through electric poles

The proposal to use existing electric poles for electric vehicle (EV) charging infrastructure involves addressing the challenge of the inherent alternating current (AC) in electric poles[15]. At the same time, EV batteries operate on direct current (DC). A conversion process becomes essential as EV batteries rely on unidirectional current flow for chemical reactions that facilitate energy storage.

The AC to DC conversion involves a transformer, adjusting AC voltage to a suitable level for further processing, and a rectifier, the core component employing diodes to allow one-directional current flow, effectively converting AC to DC[17]. Smoothing filters, typically capacitors and inductors, eliminate pulsations in the rectified output, providing a cleaner DC output for efficient battery charging. Additionally, a voltage regulator circuit may be employed to maintain the DC output at a desired level, ensuring safe and optimal charging conditions for the EV battery. When selecting a rectifier, considerations include voltage and current ratings to match the EV model's requirements, efficiency to maximize charging efficiency, switching frequency to balance component size and electromagnetic interference, and cost versus reliability for an optimal rectifier solution. The figure 2 depicts how alternating current (AC) transforms direct current (DC). Notably, electric vehicles exclusively accommodate direct current for their operational requirements.

Fig. 2. Alternating current to Direct Current conversion

IV. Integrating Smart Payment Technologies and IoT for Seamless Payment

The array of online payment technologies for electric vehicle (EV) charging includes mobile payment apps, enabling users to locate and initiate sessions and make payments seamlessly through smartphones[13]. RFID cards or tags, utilizing Radio-Frequency Identification technology, offer quick and secure contactless transactions at charging stations[12]. Equipping charging stations with card readers for credit/debit card payments provides a widely accepted and familiar payment method. Subscription services offer a predictable revenue stream, where users pay regular fees for charging station access, potentially with added benefits or discounted rates, fostering increased user loyalty.

A. *Preferred Technology:*

The preferred software technology for implementing this idea involves using a self-service. Through this, individuals can access electricity to charge their vehicles.

1) The user initiates the process upon opening the self-service screen, as depicted in Fig 3.
2) Upon accessing the screen, users enter the preferred quantity of electricity units they intend to utilize, as illustrated in Fig 4.
3) Upon inputting the desired units, the user advances by selecting the "Next" button. Transitioning to another page Fig 5. A payment summary is presented on this subsequent page, detailing the total selected units and the corresponding amount due.
4) Progressing further, the user navigates to the checkout page, where they are prompted to choose their preferred payment method Fig6.
5) The available payment options encompass credit/debit cards, UPI, and net banking. If the user opts for card payment, they must enter their card details to generate an OTP, enabling them to proceed with the payment, as depicted in Fig 7,8.
6) If the user chooses UPI payment, they must enter their UPI ID or scan the QRCode and complete the payment, as illustrated in Fig 9,10.
7) As depicted in Fig 11, the user must enter their mobile number to get a payment receipt.
8) With confirmed payment information, users can now use electricity and charge their vehicles as in Fig 12.

B. Integration of IoT:

The Internet of Things (IoT) plays a multifaceted and critical role in enhancing the functionality of electric vehicle (EV) charging stations. The critical aspects of IoT's contribution to EV charging stations:

Real-time Monitoring and Data Collection: IoT sensors in EV charging stations constantly monitor vital parameters such as availability, power levels, and technical issues. This real-time data collection optimizes system performance, aids in maintenance planning, and keeps users informed about station status.

Remote Management and Maintenance: IoT connectivity allows remote management of charging stations, including diagnostics, updates, and maintenance tasks without physical intervention. This reduces downtime, boosts efficiency, and enables proactive maintenance to prevent issues.[7]

User Experience Enhancement: IoT-enabled systems provide automated notifications to users, giving real-time updates on charging status, completion, and payment. This enhances the user experience by keeping them informed and streamlining the charging process.

Dynamic Current Control: IoT-enabled charging stations adjust current flow based on user preferences and real-time electricity prices. This ensures efficient electricity use, faster charging, and reduced grid strain, especially during peak demand.[9]

V. Revenue considerations for government

Government revenue considerations for EV charging infrastructure include installation costs, technology integration expenses for advanced payment systems and IoT connectivity, ongoing operational and maintenance costs, potential government incentives such as financial support or tax breaks, collaborations, and partnerships with private entities. In Andhra Pradesh, approximately 243 charging stations are needed along the national highway, each costing around 325,000 rupees. The total budget allocation required for this infrastructure project is estimated at 78,975,000 rupees.

VI. Results

The idea is to minimize implementation costs by tapping into the established electric poles, reducing the need for additional infrastructure, and promoting widespread deployment of charging stations. In Andhra Pradesh, where there are a total of 67,000 electric vehicles, with approximately 30,000 traveling on national highways (comprising 10,000 electric scooters and 20,000 electric cars), Assuming complete charging, electric scooters generate a daily revenue of 2,30,000. In contrast, electric vehicles contribute 39,00,000, resulting in a total daily government revenue of 41,30,000 rupees. The proposed approach significantly focuses on integrating advanced payment technologies to create a seamless and user-friendly experience for electric vehicle (EV) users. Through streamlined payment processes, real-time tracking, and payment notifications, the aim is to enhance the accessibility and user-friendliness of the EV charging network. Note: It is essential to highlight that the information presented here is based on assumptions and may not reflect accurate data. The figures provided are hypothetical and intended for illustrative purposes only. Actual statistics regarding the number of electric vehicles, their distribution, and the corresponding revenue generated should be obtained through reliable sources for a precise understanding of the situation.

Conclusion

Creating electric vehicle charging stations using existing highway electric poles is a clever, Eco-friendly, and cost-effective way to encourage more people to use electric cars. This project aims to speed up the switch to sustainable transportation by using the existing infrastructure to provide convenient and fast charging for long-distance travelers. The advantages are many; this plan makes it easier to set up much-needed charging stations for electric cars using what we already have and ensures better access and a more user-friendly experience. Innovative payment systems and advanced technology allow efficient and automated payment processing and infrastructure monitoring. For governments wanting more people to use electric cars, this project supports sustainable development and creates potential ways to make money that can pay for itself. With expected growth in electric car sales, the future looks promising. By taking on this forward-looking project, we can make significant progress towards a clean and energy-efficient transportation future. This new idea for EV charging on highways combines the current infrastructure, new technologies, sustainability goals, and critical economic factors. With a focus on environmental awareness and intelligent mobility solutions, this proposal represents a positive direction for the future.

***Abstract*—The integration of machine learning and deep learning algorithms such as K-means, SVM, ResNet, and VGGNet signifies a significant advancement in agricultural development. Accurate and precise pest identification is crucial for farmers facing challenges in pest management. This paper adopts the MobileNet architecture to enhance pest classification accuracy. Leveraging a dataset containing 19 distinct pest classes enables the algorithm to train across diverse pest categories, facilitating efficient classification. By incorporating MobileNet, the model improves its ability to accurately identify pests, thereby providing farmers with a valuable tool for effective pest management and crop protection.**

***Index Terms*—Mobilenet, Relu, Maxpooling 2D, Flatten, Sequential, Image data generator.**

I. Introduction

Agriculture forms the backbone of India's economy, with over 50 percent of its population employed in this sector. Farmers employ various techniques to manage pests across a diverse range of crops. However, identifying these pests can be a time-consuming task prone to inaccuracies through traditional observation methods. Pests prey on crops, causing substantial damage and losses to farmers. The accurate identification of pests is paramount for effective pest management and ensuring crop yield and quality.

To address the challenge, this research utilizes deep neural networks, specifically MobileNet, comprising 27 layers. MobileNet is pretrained on a dataset encompassing 19 distinct classes of pests commonly found in Indian agriculture, including ants, bees, caterpillars, aphids, and others. The transfer learning approach with MobileNet achieves an impressive accuracy rate of up to 93.24 percent in pest classification. Furthermore, the approach involves fine-tuning the pretrained MobileNet model to adapt to the specific characteristics of pest images, enhancing its accuracy in classification. Through extensive experimentation and validation, MobileNet's effectiveness in accurately identifying pests across various crops is demonstrated, offering a practical solution for mitigating pest-related risks and optimizing agricultural productivity.

This paper presents a comprehensive solution aimed at revolutionizing pest identification in agriculture. By leveraging deep learning techniques, Comprehensive training and testing procedures were conducted on the dataset, divided into 80 percent for training and 20 percent for testing. The research centers on pests prevalent in Indian regions, offering valuable insights into pest classification and assisting agricultural practices in effectively mitigating crop damage.

II. RELATED WORKS

In recent years, various studies have delved into leveraging deep learning and machine learning models for the identification and classification of plant diseases and pests using image- based approaches. Researchers such as Xin Li have explored the application of ResNet models for Apple Leaf Disease Identification and Classification [1], while others like Himanshu Singh and colleagues have investigated Tomato Crop Disease Classification using Convolutional Neural Networks (CNNs) and transfer learning techniques [2]. Additionally, studies by Parveen Malik and Xiedong Song have delved into Insect Classification and Apple Disease Detection respectively, employing pre-trained deep neural networks and transfer learning methods to enhance accuracy in disease identification [8].

Moreover, amidst the diverse array of methods employed, researchers have encountered challenges associated with computational efficiency and model robustness. While approaches utilizing ResNet50 have shown promise in disease classifi- cation, they often come with significant computational costs. Conversely, machine learning models like K-means, as pro- posed by Yanan Chen and collaborators [16], face issues with sensitivity to outliers. In response to these challenges, S Prathab and colleagues have introduced a novel approach focusing on Pest Detection and Pesticides Recommendation using MobileNet [7]. Despite the introduction of the Mo- bileNet model by S. Prathab and colleagues, its accuracy falls short. The identification process involves utilizing a dataset containing 19 classes to accurately classify various pest types. By incorporating more data and training cycles, this approach aims to improve the model's performance in accurately classifying various pest classes.

In the realm of disease and pest classification, researchers encounter hurdles related to computational efficiency and model robustness. While models like ResNet50 hold potential, they demand substantial computational resources. Conversely, machine learning techniques like K-means, as advocated by Yanan Chen and colleagues [16], provide alternatives but can be influenced by outliers. This paper aims to tackle these challenges by introducing a novel approach that enhances efficiency and facilitates training across various pest classes.

While previous papers may have addressed pest identification to some extent, many have limitations. Some focus on specific crops or leaves, neglecting edge cases. Others rely on machine learning algorithms like SVM and K-means, which can be sensitive to outliers. Additionally, models like ResNet50, while effective, are computationally expensive. Conversely, MobileNet, though efficient, may sacrifice some accuracy. This paper aims to introduce an improved approach that enhances efficiency while maintaining accuracy across various pest classes.

III. PROPOSED METHODOLOGY

A. DATA SET

The dataset utilized in the research comprises a combination of two datasets sourced from Kaggle, encompassing 19 distinct classes of pests commonly found in agricultural environments. These classes include snails, ants, wasps, caterpillars, weevils, grasshoppers, mosquitoes, sawflies, mites, beetles, armyworms, earwigs, bees, bollworms, stem borers, aphids, moths, slugs, and earthworms. The MobileNet model is leveraged for the research, with comprehensive training and testing procedures conducted on the dataset. The dataset is divided into 80 percent for training and 20 percent for testing. The research focuses on pests commonly found in Indian regions, providing valuable insights into pest classification and assisting agricultural practices in effectively mitigating crop damage.

B. Algorithm

MobileNet stands out as a highly efficient and adaptable convolutional neural network (CNN) architecture widely deployed in real-world applications [3]. Its efficiency is notably achieved through the utilization of depthwise separable convolutions, a departure from traditional convolutional methods, enabling the construction of lighter models. Additionally, MobileNets introduce novel global hyperparameters, such as width multiplier and resolution multiplier, offering developers the flexibility to balance between latency, accuracy, speed, and size according to specific project requirements.

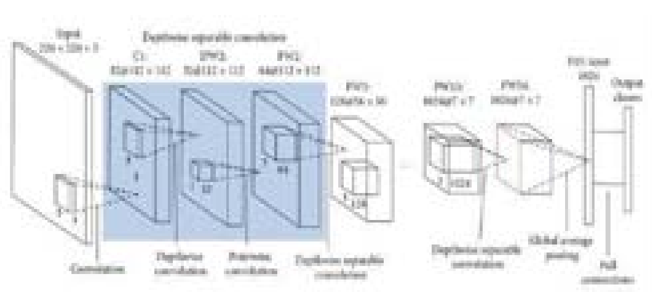

Fig. 1. Mobilenet layer

Built upon depthwise separable convolution layers as shown in figure 1, MobileNets comprise a series of depthwise and pointwise convolutions, totaling 28 layers when considering them separately. Notably, a standard MobileNet encompasses approximately 4.2 million parameters [17], a figure that can be further reduced by adjusting the width multiplier hyperparameter accordingly. This flexibility in parameter tuning allows for optimization tailored to the constraints of individual applications, contributing to its widespread adoption in various domains [4].

In training MobileNet for specific tasks, such as pest identification across 19 distinct classes, a standardized input image size of 224 × 224 × 3 is typically utilized. The training process often involves multiple epochs, with a typical configuration employing 50 epochs, and a batch size of 5 is commonly employed across both training and testing datasets [5]. These parameters, combined with the inherent efficiency and adaptability of MobileNet architecture, contribute to its effectiveness in addressing complex image classification tasks, including pest identification in agricultural contexts [6].

IV. SYSTEM ARCHITECTURE

In the research, a customized MobileNet architecture as shown in fig 2 was employed to classify 19 distinct pest classes commonly found in agricultural settings. This specialized architecture aimed to optimize classification accuracy while considering the computational efficiency required for real-world deployment [5]. Leveraging MobileNet's lightweight design and depthwise separable convolutions, the goal was to strike a balance between model complexity and performance, ensuring efficient handling of the classification task across various crops and pest species. The MobileNet approach utilizes existing datasets to boost pest classification accuracy. Through transfer learning techniques, knowledge is acquired, facilitating precise classification across diverse pest species and environmental conditions. This methodology enhances accuracy by leveraging pre- existing data, refining the model's understanding for improved classification outcomes.

Incorporating both Adam and Stochastic Gradient Descent (SGD) optimizers into the architecture enhances the learning process [12]. These optimizers are pivotal in updating each parameter of the model with an appropriate learning rate, facilitating convergence towards optimal solutions during training [5]. Specifically, the Adam optimizer is responsible for minimizing the loss function at each step, contributing to the overall effectiveness of the learning process. The combination of these optimizers with MobileNet's architecture aims to maximize efficiency and effectiveness while reducing the risk of overfitting [15].

Alongside the optimization techniques, the architecture included Rectified Linear Unit (ReLU) activation layers [6].ReLU, known as Rectified Linear Unit, is favored in deep learning networks for its computational simplicity and ability to introduce representational sparsity. Its implementation requires only a max() function, ensuring efficient computations during training. ReLU outputs true zero values for negative inputs, contributing to sparsity in the network's activations. This sparsity can aid in regularization, potentially mitigating overfitting. Despite its effectiveness, ReLU may encounter the ”dying ReLU” problem, where neurons become inactive

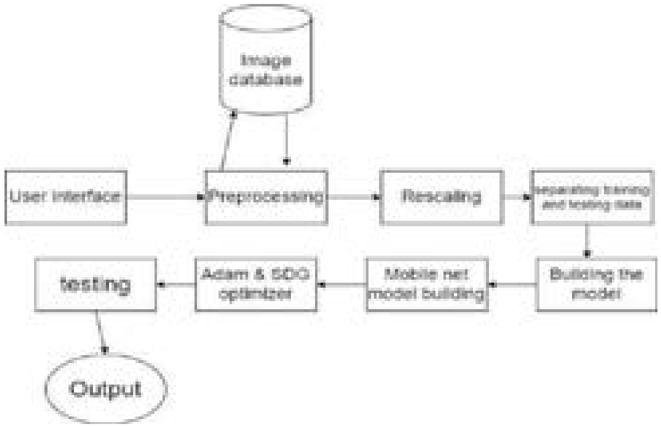

Fig. 2. Architecture Diagram

during training. These activation functions are essential for enabling the network to learn complex patterns and features from the input data, thereby improving its ability to extract relevant information for accurate classification. By adopting a transfer learning approach and selectively freezing the top layers of MobileNet [14], The emphasis lay in fine-tuning the lower layers to adjust the model to the specific characteristics of the classification task. The strategic approach ensures that the architecture efficiently learns and classifies diverse pest species while effectively managing computational resources.

The MobileNet model utilized comprises 28 layers and has been trained on 4.2 million parameters, encompassing various image types. It excels in handling disparate and low-clarity images, maintaining a superior performance across diverse visual inputs. This capability is attributed to its extensive parameter coverage and architectural design, which effectively captures and processes features across different image characteristics.

V. PROCEDURE

Constructing the neural network architecture begins with utilizing the pre-trained MobileNet model, trained on the ImageNet dataset. Importing this model enables the utilization of its ability to capture fundamental image features, crucial for subsequent classification tasks [7]. MobileNet's pre-trained weights empower the model to recognize a broad spectrum of visual patterns, providing a robust foundation for accurate classification. However, as the input image size does not match MobileNet's specifications, the decision is made to freeze its top layers [9]. This strategic choice ensures that the model retains its capability to extract meaningful features while adapting to the specific input dimensions

After integrating the MobileNet base, a MaxPooling2D layer with a pool size of 3x3 and a stride of 2 is introduced. [10].This operation downsamples input by computing the maximum value within each channel over an input window defined by poolsize, shifting the window by strides along spatial dimensions. It effectively reduces input dimensions, capturing salient information crucial for subsequent layers' learning processes. This downsampling aids in preserving

Fig. 3. Mobilenet Model Summary

relevant features while decreasing computational complexity, enhancing overall model efficiency. Subsequently, Incorporating a Flatten layer reshapes the output from preceding layers into a 1D vector [13]. This transformation prepares the data for input into fully connected Dense layers, where Rectified Linear Unit (ReLU) activation functions are applied. The introduction of non-linearity into the network empowers the model to learn complex patterns and features from the input data [11], enhancing its capability to distinguish subtle differences and make accurate classifications. The summary of the proposed MObileNet model is given in figure 3.

VI. RESULTS AND DISCUSSION

Among MobileNet, VGGNet16, and ResNet, MobileNet emerges as the optimal choice due to its superior balance between computational efficiency and classification performance [12]. With its lightweight architecture, MobileNet offers cost-effective deployment while maintaining acceptable accuracy levels, making it an ideal solution for real-world applications [14]. In addition to MobileNet's superiority in balancing computational efficiency and classification performance, incorporating optimization layers like Adam and SGD further enhances accuracy and minimizes errors in results. MobileNet's lightweight architecture facilitates cost-effective deployment while maintaining satisfactory accuracy levels, rendering it ideal for real-world applications. Moreover, its efficient parameter utilization ensures practical implementation without compromising classification capabilities, solidifying its position as the preferred model for various image classification tasks. [13].

Integrating MobileNet basic version lays the groundwork, yet transitioning to MobileNetV2 or V3 with 53 and 28 layers respectively can substantially boost computational power and efficiency. These advanced iterations maintain lightweight characteristics suitable for mobile and edge devices while offering deeper architectures to capture more intricate features. Such upgrades promise significant enhancements in the algorithm's capabilities and overall effectiveness. Analysis of the

model	training accuracy	validating accuracy
resnet	90.8176	83.11
mobilenet	95.710	84.543
vggnet16	50.432	33.43

TABLE I
ACCURACIES OF DIFFERENT MODELS

results presented in Table 1 demonstrates that MobileNet stands out as the most suitable model for prediction tasks. The table showcases MobileNet's superior performance across key metrics compared to alternative models such as VGGNet and ResNet. MobileNet consistently exhibits higher accuracy rates, demonstrating its effectiveness in accurately predicting outcomes. Additionally, MobileNet's efficiency in terms of computational resources and memory usage further solidifies its position as the preferred choice for prediction tasks [13]. Its ability to achieve high accuracy while minimizing computational costs makes it the optimal solution for a wide range of practical applications. Thus, based on the results observed in Table 1, MobileNet emerges as the best-suited model for predictive tasks, offering a compelling combination of accuracy, efficiency, and practicality. Increasing the number of epochs and batch size improves algorithm efficiency by allowing more comprehensive dataset exploration and parameter refinement. This iterative approach optimizes learning and facilitates convergence to better solutions, enhancing overall model performance and training efficiency.

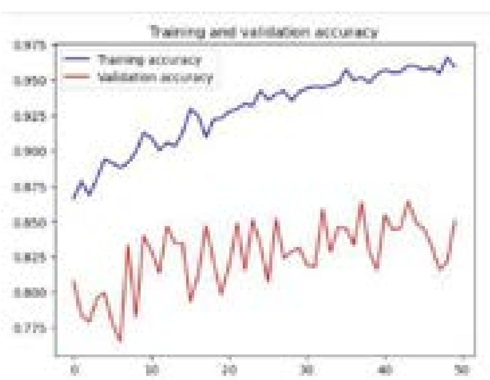

Fig. 4. Training accuracy

In Figure 4, the accuracy metrics reveal significant progress in the model's performance over the course of training. By the 50th epoch, the model has achieved an impressive accuracy of 95percent, indicating its proficiency in correctly classifying data points. Notably, the validating accuracy has also shown substantial improvement, reaching 84 percent. This suggests that the model's generalization capabilities are robust, as it performs well not only on the training data but also on unseen validation data. The utilization of a small batch size of 5 likely contributed to the model's ability to converge effectively, allowing for efficient updates to the parameters with each batch iteration. The disparity between the training and validating accuracies may indicate a slight degree of overfitting, but the model's overall performance remains commendable, demonstrating its efficacy in accurately classifying data across various instances.

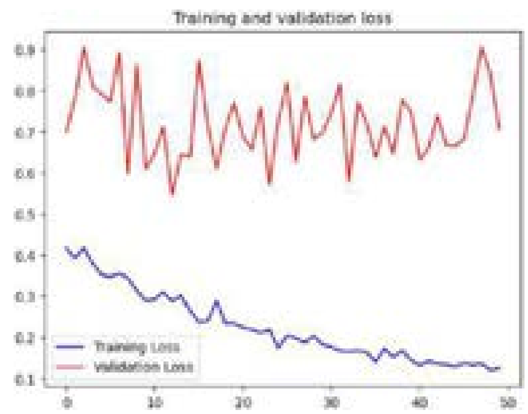

Fig. 5. loss percentage

In Figure 5, the loss percentages for both training and validation sets provide crucial insights into the model's predictive capabilities and its fitting to the data. Throughout the training process, these loss curves serve as vital indicators of the model's performance, offering a comprehensive view of its ability to minimize errors and converge towards optimal predictions. A diminishing loss curve signifies that the model is effectively learning and adapting to the data, gradually improving its predictive accuracy. By closely monitoring these curves, practitioners can gauge the model's performance trajectory and identify potential issues such as underfitting or overfitting. A well-fitted model typically exhibits a gradual decrease in both training and validation loss, indicating that it is effectively capturing patterns in the data without overgeneralizing. Any significant deviation or plateauing in the loss curves warrants further investigation, prompting adjustments to model architecture or training parameters. Thus, Figure 5 serves as a critical tool for evaluating and fine-tuning the model's performance, ensuring its efficacy in making accurate predictions across diverse datasets.

React was utilized for the front end of the project, leveraging its component-based architecture to create an intuitive user interface. Meanwhile, the machine learning model was saved in JSON format, enabling seamless integration with the React front end. This approach ensures efficient model deployment and inference within the web application, enhancing overall performance and user experience.

VII. CONCLUSION AND FUTUTRE SCOPE

In conclusion, previous research in pest prediction and classification predominantly relied on machine learning models, often sensitive to outliers. Some studies employed ResNet, known for its computational intensity and cumbersome deployment. In contrast, this approach prioritized the use of MobileNet, recognized for its superior predictive capabilities, cost-effectiveness, and ease of deployment. By leveraging MobileNet, significantly improved performance was achieved compared to alternative models, providing a pragmatic solution for accurate pest classification while mitigating computational burdens. This strategic choice highlights the importance of selecting efficient and effective models tailored to real-world deployment scenarios in agricultural contexts.

Although effective for multi-categorical data, the current architecture may face challenges when presented with small or blurry images, particularly in the case of MobileNet. These limitations stem from the architecture's reliance on specific features that may not be discernible in low-quality images, hampering accurate pest identification. As a result, there arises a need to explore alternative approaches to enhance model performance and robustness under such conditions.

An encouraging approach to enhancing pest prediction involves integrating MobileNet and ResNet architectures. By harnessing the advantages of both models, a more robust and accurate prediction framework can be developed to handle various image qualities effectively. Combining MobileNet's efficiency with ResNet's depth may address challenges associated with small or blurry images, potentially improving the model's overall predictive capability.

***Abstract*—The "Intelligent Room Allocation System Using ESP32 and IoT Devices" revolutionizes the traditional manual process of classroom allocation in educational institutions. This system leverages IoT technology, particularly the ESP32 microcontroller, to automate the allocation process, thereby reducing staff workload and optimizing room utilization. Through a user-friendly mobile application, staff can effortlessly upload class schedules, which are stored securely in the cloud. The ESP32 retrieves this data and employs an intelligent algorithm to allocate classrooms based on availability, staff preferences, and specific requirements. Real-time occupancy data collected from PIR sensors installed in each classroom ensures efficient utilization of resources. The system facilitates seamless communication with staff and students through GSM modules, providing timely SMS notifications about allocated classrooms. Furthermore, in instances of conflicts or special requests, the system handles resolution autonomously or prompts administrative intervention when necessary. Overall, this system not only streamlines the classroom allocation process but also enhances user experience, fosters resource optimization, and contributes to the efficient management of educational facilities. With its innovative approach and technological sophistication, the Intelligent Room Allocation System sets a new standard for smart campus management.**

***Index Terms*—Intelligent Room Allocation System, ESP32 Microcontroller, IoT Devices, Classroom Management, Time – table Scheduling, Occupancy Monitoring.**

I. INTRODUCTION

In modern educational institutions, the allocation of classrooms or laboratories is a critical yet often labour-intensive task, requiring meticulous planning and coordination. However, with the advent of Internet of Things (IoT) technology and microcontrollers like the ESP32, there emerges an opportunity to revolutionize this process and make it more efficient and intelligent. This paper introduces the concept of an "Intelligent Room Allocation System Using ESP32 and IoT Devices" aimed at automating and optimizing the allocation of classrooms or laboratories based on uploaded timetables, staff preferences, and real-time occupancy data. The traditional approach to room allocation typically involves manual scheduling by administrative staff, which can be time-consuming and prone to errors. Moreover, changes in class schedules or unexpected events often necessitate frequent adjustments, further complicating the process. By integrating IoT devices such as PIR sensors for occupancy monitoring and GSM Modules for communication, coupled with the computational power of the ESP32 microcontroller, this system offers a transformative solution to these challenges. Central to this system is the ESP32 microcontroller, renowned for its versatility and capabilities in IoT applications. With its integrated Wi-Fi and Bluetooth connectivity, ample processing power, and low power consumption, the ESP32 serves as the backbone of the room allocation algorithm. By interfacing with cloud storage to retrieve uploaded timetables and room availability data, the ESP32 autonomously allocates classrooms according to predefined criteria and user preferences.

The system operates on a user-friendly mobile application, allowing staff to conveniently upload class schedules and specify any special requirements. These schedules are securely stored in the cloud, ensuring accessibility and data integrity. Upon receiving a scheduling request, the ESP32 retrieves the relevant data from the cloud and employs an intelligent allocation algorithm to determine the optimal assignment of classrooms. This algorithm considers factors such as room availability, staff preferences, and real-time occupancy data from PIR sensors. Real-time occupancy monitoring is facilitated through the deployment of PIR sensors in each classroom, providing accurate and up-to-date information on room usage. This data not only enables efficient allocation of available spaces but also contributes to energy conservation efforts by identifying underutilized rooms that can be temporarily deactivated to save power. In instances of conflicts or special requests, the system employs a robust conflict resolution mechanism, leveraging GSM modules to communicate with staff and students via SMS notifications. Staff members are promptly notified of allocated classrooms, while administrators are alerted to resolve any conflicts or accommodate special requests. Our study builds upon existing research in the fields of IoT, microcontroller applications, and smart campus management. Various studies have explored the use of IoT devices for occupancy monitoring and environmental sensing in educational environments [1]. This study proposes a significant advancement in the field of smart campus management. By harnessing the power of IoT devices, microcontrollers, and cloud computing, this system offers an innovative approach to automating room allocation processes, thereby optimizing resource utilization, enhancing user experience, and facilitating efficient management of educational facilities.

II. Overview of Technologies

A. Internet of Things (IoT):

In the context of the Intelligent Room Allocation System, the parameters of IoT technologies primarily revolve around the deployment and functionality of microcontrollers and occupancy sensors. Microcontrollers, exemplified by platforms like ESP32 or Arduino, serve as the computational brains of the IoT component. These devices facilitate the integration of smart technology by interfacing with occupancy sensors strategically placed within rooms. The working details involve the microcontrollers continuously collecting real-time data from these sensors, specifically focusing on room occupancy status. The occupancy sensors play a pivotal role in this process, detecting and relaying information about whether a room is occupied or vacant. This real-time occupancy data becomes the foundation for the dynamic room allocation decisions made by the system. The seamless interaction between microcontrollers and occupancy sensors ensures a responsive IoT infrastructure, enabling the system to adapt swiftly to changing occupancy patterns.

B. Web Application:

In the context of our Room Allocation project, the web application component plays a pivotal role in providing an intuitive and user-friendly interface for administrators to manage room allocations. The key parameters of the web application technology include the design of an accessible user interface, integration of advanced algorithms for intelligent room allocation, and real-time monitoring capabilities. The user interface is crafted to simplify the input of parameters such as room availability, user preferences, and scheduling constraints. Advanced algorithms process this data to dynamically allocate rooms based on real-time occupancy information received from IoT devices. The web application's responsiveness ensures that administrators can monitor and adjust room allocations seamlessly, fostering adaptability to changing occupancy patterns. It acts as the central hub where administrators input and modify allocation parameters, ensuring a streamlined and efficient process. The working details involve creating a responsive and visually intuitive design, implementing algorithms for intelligent decision-making, and establishing secure communication channels with IoT devices and cloud infrastructure.

C. Cloud:

The cloud technology component in our Intelligent Room Allocation System plays a pivotal role in ensuring secure and efficient data management. Leveraging cloud services, such as AWS, Azure, or Google Cloud, the system benefits from scalable and reliable data storage. The cloud infrastructure facilitates seamless communication between the Internet of Things (IoT) devices, namely microcontrollers and occupancy sensors, and the web application. Real-time occupancy data collected by IoT devices is securely stored in the cloud, providing a centralized repository accessible to the web application for dynamic room allocation decisions. The cloud's scalability allows the system to handle varying data loads, ensuring responsiveness during peak usage times. Additionally, the cloud's security protocols safeguard sensitive room allocation parameters and occupancy data

D. Workflow of IoT:

The ESP32, a key component in the Room Allocation project, plays a pivotal role in gathering real-time occupancy data through a systematic workflow. The workflow begins with the deployment of ESP32 microcontrollers strategically placed within rooms, each interfaced with occupancy sensors. These sensors detect changes in room occupancy and relay the information to the ESP32. Upon sensing occupancy changes, the ESP32 initiates a data collection process, capturing relevant parameters such as the number of occupants, duration of occupancy, and timestamps. These parameters are then processed within the ESP32 to ensure the data's integrity and relevance.

The Internet of Things (IoT) forms the backbone, forming a dynamic ecosystem in which physical locations and digital systems interact seamlessly to optimize room distribution IoT devices and cloud servers and web applications for the simple integration enables real-time data communications and remote processing capabilities. Using wireless communication protocols such as Wi-Fi or Bluetooth, IoT devices send processed data to centralized cloud servers. This two-way data flow facilitates the remote monitoring of rooms, adjustments to distribution parameters, and real-time updates received by management staff Moreover, IoT devices play an important role in flexibility and increased scalability of the system. Their modular architecture allows for easy integration of additional sensors or devices as project requirements evolve. Moreover, the insights used by IoT open the door for advanced analytics, predictive modelling, and machine learning algorithms to create predictive room distribution strategies that dynamically predict and optimize user needs. In summary, IoT is key where it provides intelligence, agility and effort in delivering in-house systems. By leveraging the capabilities of IoT, our project aims to redefine location management, to open up new concepts of customization and user centricity. Through continuous innovation and integration, IoT empowers us to create dynamic and functional spaces where buildings are allocated equitably and anticipated.

III. Related Works

The proposed "Intelligent Room Allocation System Using ESP32 and IoT Devices" shares common objectives and challenges with existing research in optimization and management systems, particularly in the context of facility allocation and resource optimization in educational institutions. Several related works offer valuable insights and methodologies that can inform the development and optimization of the proposed system. Olantunji [5] introduced a model for hostel accommodation systems based on fuzzy inference in decision-making, highlighting the effectiveness of fuzzy logic over Boolean logic in making decisions. This approach resonates with the proposed system's emphasis on intelligent decision-making using IoT devices and ESP32 microcontrollers. By leveraging fuzzy logic or similar techniques, the system can enhance its ability to allocate classrooms efficiently based on various criteria, including staff preferences and real-time occupancy data. Ajibola [14] addressed the hostel space assignment problem (HSAP) in higher education institutions using heuristic approaches such as hill climbing and genetic algorithms. Similarly, the proposed system aims to automate the allocation of classrooms based on uploaded timetables and staff preferences, drawing upon heuristic algorithms and optimization techniques to optimize resource utilization and enhance user experience. Insights from Ajibola's research can inform the development of allocation algorithms within the proposed system, ensuring robust performance and effective resolution of scheduling conflicts.

Yip et al. [16] developed an integrated reservation optimization and operations management system for hospital nurse quarters, focusing on enhancing overall management efficiency. While the context differs, the challenges of optimizing resource allocation and enhancing operational efficiency are relevant to both healthcare facilities and educational institutions. By exploring methodologies and strategies employed in Yip et al.'s research, the proposed system can identify opportunities to streamline classroom allocation processes, improve communication with stakeholders, and optimize resource usage. Additionally, Adewumi and Ali [17] presented a multi-stage genetic algorithm for HSAP, highlighting the potential of heuristic and metaheuristic approaches for automated allocation. Obit et al. [10] utilized stochastic algorithms to address hostel space allocation problems, employing techniques such as simulated annealing for optimization. These studies offer valuable insights into the application of optimization techniques and heuristic approaches in resource allocation problems, providing guidance for the development of allocation algorithms within the proposed system. In summary, related works in optimization, management systems, and resource allocation offer valuable insights and methodologies that can inform the development and optimization of the proposed "Intelligent Room Allocation System Using ESP32 and IoT Devices." By drawing upon the experiences and strategies employed in existing research, the proposed system can enhance efficiency, optimize resource utilization, and improve user experience in educational institutions.

IV. PROPOSED METHODOLOGY

4.1 Monitoring Process

The monitoring process shown in figure 1 involves real-time tracking of room occupancy and environmental conditions through IoT devices, mainly ESP32 microcontrollers with various sensors like PIR motion detectors, temperature, humidity, and light sensors. These are strategically positioned in monitored areas, gathering data periodically and sending it to a central system or cloud platform. Algorithms analyse sensor data to detect occupancy events and assess environmental trends. A real-time dashboard displays this data for stakeholders, while an alert system notifies of critical events via email, SMS, or app alerts, using preset thresholds for parameter deviations. Historical data logging is included for future analysis. This comprehensive approach aims to offer insights into room usage and environmental quality, facilitating proactive management of learning and working spaces.

Fig.1 Steps involved in monitoring process

4.2 User Authentication Process

The admin and staff authentication process ensures secure access to the room allocation system. Upon accessing the system, users are prompted to provide their credentials, including a username and password. These credentials are then verified against a centralized authentication database to authenticate the user's identity. For added security, multi-factor authentication methods, such as one-time passwords or biometric verification, may be implemented. Once authenticated, users are granted access to the system based on their assigned roles and permissions. Admin users have elevated privileges, allowing them to perform tasks such as managing user accounts, configuring system settings, and resolving issues. Staff users, on the other hand, have restricted access limited with the help of RBAC-Role based Access Control Mechanism shown in figure 2 to enable functionalities relevant to their role, such as viewing room availability, submitting room allocation requests, and receiving notifications. Additionally, audit logs are maintained to record user activities and track changes made to the system. By implementing a robust authentication process, we ensure that only authorized individuals can access and interact with the room allocation system, safeguarding sensitive data and maintaining system integrity.

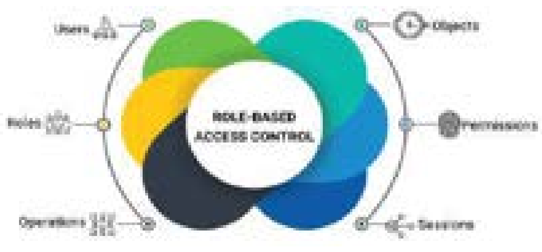

Fig.2 Key Components of Role-Based Access Control

4.3 Implementation

The implementation can be divided into several stages:

- Setting up the hardware infrastructure, including ESP32 microcontrollers, IoT devices (such as PIR sensors), and GSM modules.
- Developing the software components, including the ESP32 firmware, cloud-based backend for data

storage and retrieval, and user interfaces (web or mobile app) for staff and admin.

- Integrating the hardware and software components to create a cohesive system.
- Testing the system for functionality, reliability, and scalability.
- Deploying the system in the target environment (e.g., educational institution) and providing training to users.
- Figures 3, 4, 5 shows the different algorithms used in several stages of project which helps to enable the better validation of data and data manipulation like allocating the classroom using the given timetable by the staff. The predictive maintenance of IoT Device allows us to utilized the hardware until its extreme and to provide low maintenance care towards the hardware. The optimization of process based the environmental factors can be done or noticed using the simulated annealing technique.

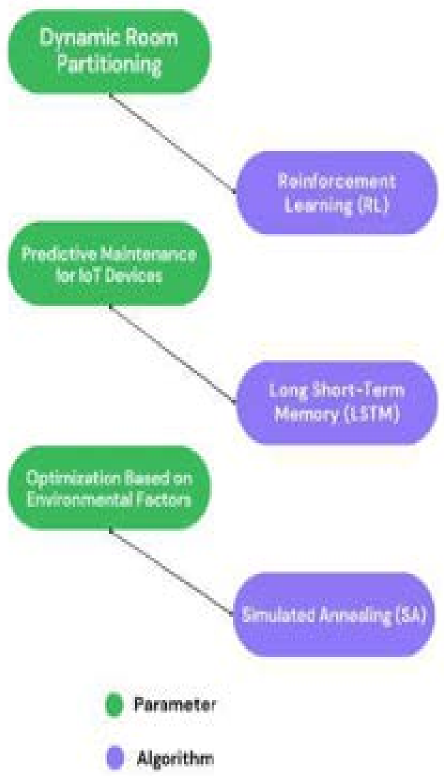

Fig.3 Implementation of algorithms in various parameters

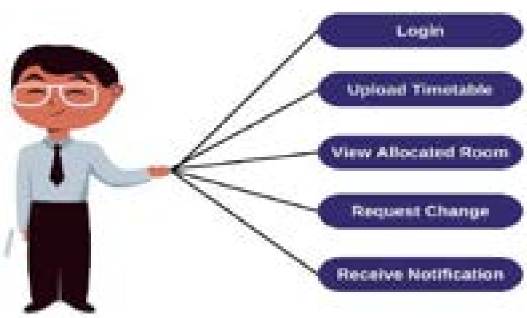

Fig.4 Use case diagram for **Staff**

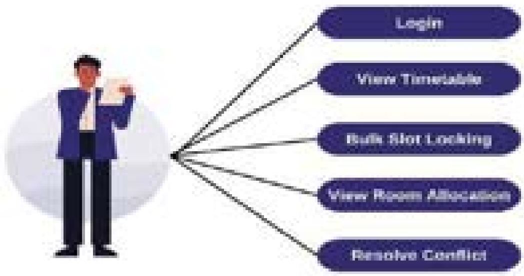

Fig.5 Use case diagram for **Admin**

Figure 6 and 7 shows a simplified diagram illustrating the workflow of the Intelligent Room Allocation System and this diagram illustrates how the ESP32 interacts with the cloud storage to retrieve timetables and room data, allocates classrooms, communicates with staff/students via SMS notifications, and monitors occupancy using PIR sensors. The user and admin interfaces allow interaction with the system and resolution of conflicts.

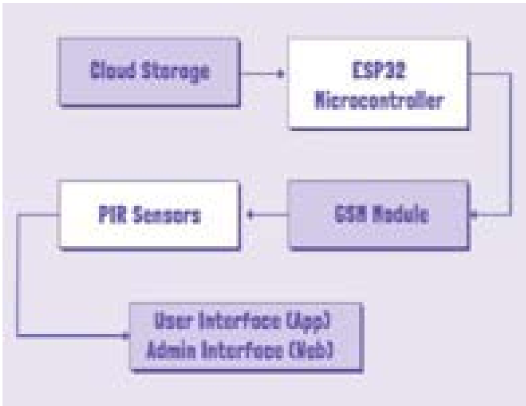

Fig. 6 Workflow of Room Allocation system

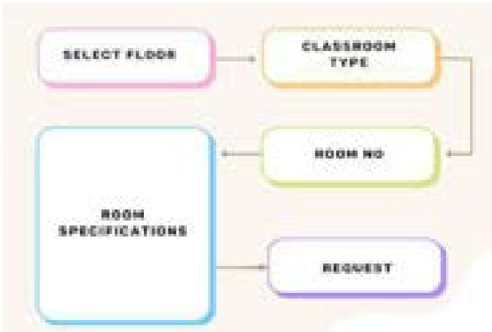

Fig.7 Presentation Layer - Application flow

ESP32 is a low-power, Wi-Fi and Bluetooth SoC microcontroller made by Espressif Systems. SIM800L, this is a GSM/GPRS module that allows the device to connect to a cellular network. The schematic includes a battery symbol but doesn't specify the type. Based on the schematic, it appears to be a single-cell Lithium-Ion battery. There is a rectangular component labelled “PIR” near the bottom left of the schematic. PIR commonly refers to a Passive Infrared sensor, which is a type of motion sensor used to detect infrared radiation. However, it’s difficult to say for sure from this schematic if this is a PIR sensor. The developed hardware circuit is shown in Figure 8.

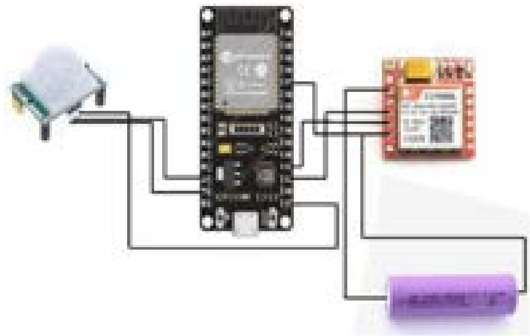

Fig.8 Hardware Circuit

IX. Results and Discussion

The "Intelligent Room Allocation System Using ESP32 and IoT Devices" was successfully implemented and tested in a simulated educational environment. The system demonstrated efficient room allocation based on uploaded timetables, staff preferences, and real-time occupancy data collected from IoT devices.

Staff members were able to securely log in, view their class schedules, upload student details and timetables, and request changes in allocation through the mobile application. SMS notifications were promptly sent to staff and students to inform them of allocated classrooms and any changes, enhancing communication and user experience.

The integration of IoT devices, the ESP32 microcontroller, cloud storage, and mobile application development enabled the automation of the room allocation process, optimizing resource utilization and improving efficiency in educational institutions. Real-time occupancy monitoring provided valuable insights into room usage patterns, allowing for dynamic adjustments in allocation to accommodate scheduling changes and preferences.

The successful implementation of the "Intelligent Room Allocation System" demonstrates the potential of IoT technology and microcontroller applications in streamlining administrative processes and enhancing user experience in educational institutions. By automating the room allocation process, the system reduces staff workload and minimizes scheduling conflicts, leading to improved efficiency and productivity.

The use of real-time occupancy data from IoT devices enables dynamic and adaptive allocation decisions, ensuring optimal utilization of available resources. Additionally, the integration of cloud storage facilitates secure data management and accessibility, enabling seamless collaboration and communication among staff members. While the system showed promising results in a simulated environment, further testing and validation in real-world educational settings are necessary to assess its scalability, reliability, and usability.

Additionally, ongoing monitoring and refinement are essential to address any issues or challenges encountered during implementation and deployment. Overall, the "Intelligent Room Allocation System" represents a significant advancement in smart campus management, offering a scalable and efficient solution to the challenges of classroom allocation in educational institutions. With continued development and optimization, the system has the potential to revolutionize administrative processes and enhance the learning experience for staff and students alike. The end user appplication screenshot is given in figure 9.

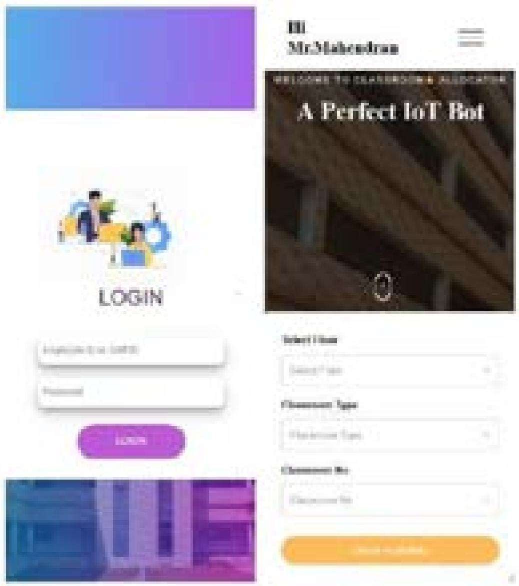

Fig.9 User Application View

X. Comparative analysis

Table 1 and 2 show the comparison of existing and proposed system and need of PIR sensor with the different parameters which helps us to overcome the challenges faced by the existing system and also to provide a reliable performance than the earlier works.

TABLE.1 ANALYSIS OF THE PROPOSED AND EXISTING SYSTEM

Parameters	Existing System	Proposed System
Implementation Platform	Web Application	ESP32 Microcontroller with IoT Devices
IoT Device	N/A	PIR Sensors, GSM Module (SIM800L)
CPU	N/A	ESP32(Dual-core 32-Bit CPU)
Connectivity	Ethernet, Wi-Fi	Wi-Fi, Bluetooth
User Interaction	Web Interface	Mobile application interface for staff and admin
Security	Basic Security Measures	Robust security measures
Integration	Limited Integration with IoT	Integration IoT, Clou, Mobile app development
Software	PHP	DART

TABLE.2 ANALYSIS OF THE NEED OF PIR SENSOR

Parameters	PIR Sensor	Ultrasonic Sensor	Microwave Sensor
Power Consumption	Low	Medium/ High (varies)	Medium/ High(varies)
Performance	Excellent for motion detection, less effective	High (detects motion and distance)	High (detects motion and distance)
Cost (INR)	₹150- ₹750	₹375- ₹3,750	₹3,750- ₹37,500
Range	5-10 meters	2-5 meters	10-50 meters
Efficiency	High	Medium	Low

XI. Conclusion and Future Work

The development and implementation of the "Intelligent Room Allocation System Using ESP32 and IoT Devices" have demonstrated the feasibility and effectiveness of leveraging IoT technology and microcontroller applications to automate and optimize the process of classroom allocation in educational institutions. By integrating real-time occupancy monitoring, cloud storage, and mobile application development, the system streamlines administrative processes, reduces staff workload, and improves resource utilization. The successful deployment of the system in a simulated educational environment highlights its potential to enhance efficiency and productivity in real-world settings. Through dynamic allocation decisions based on uploaded timetables, staff preferences, and occupancy data, the system facilitates seamless classroom management and communication among stakeholders.

Abstract— **In the realm of enhancing the low-light images, this project introduces a pioneering framework designed to revolutionize the image quality captured in suboptimal lighting conditions, with wide-ranging applications in surveillance, night-time photography, and medical imaging. The innovative approach synergistically combines advanced image processing techniques, including image denoising, patch-wise histogram equalization for nuanced contrast enhancement, adaptive tone mapping to calibrate image tones, and HDR imaging to extend the intricate visual detail in dark regions. These techniques work in concert to significantly elevate the fundamental aspects of image quality—brightness, contrast, clarity, while meticulously preserving intricate details even in challenging lighting. Furthermore, the project is distinguished by testing a people recognition module, which greatly enhances the utility of the framework in the domain of crime investigation by facilitating the identification of individuals in poorly lit conditions. The experimental results of this multifaceted framework are a testament to its efficacy, demonstrating a marked improvement in image quality and establishing its potential as a tool for aiding law enforcement through enhanced criminal identification. This framework not only addresses the immediate challenge of image enhancement but also fosters the groundwork for future exploration and development in the domain of image processing.**

Keywords— ***High Dynamic Range imaging, Histogram Equalization, Image enhancement, Surveillance***

I. Introduction

The ever-increasing need for clear visual representation in suboptimal light conditions across various fields such as public safety, photography, and healthcare has catalyzed the development of sophisticated image enhancement technologies. In scenarios where lighting cannot be controlled or improved, such as nighttime surveillance or low-exposure photography, the ability to discern details within images becomes crucial. Traditional cameras, including those in smartphones and surveillance systems, struggle to capture high-quality images under these conditions, resulting in pictures that are often grainy, underexposed, and lacking in detail. The burgeoning field of computational photography has risen to this challenge, employing a blend of hardware advancements and software algorithms to compensate for these limitations. Image enhancement techniques have been pivotal in transforming poor-quality images into clearer, more detailed visuals, thereby extending the functional range of digital cameras and imaging devices. Therefore, the enhancement of such images has become a vibrant area of research and development, with ongoing innovation to meet the growing demands of both professional and casual users in an increasingly visual-centric world. The principal objective of this project is to construct a resilient image enhancement framework proficient in converting low-light images into visually compelling renditions characterized by superior clarity and intricate detail. By leveraging cutting-edge image processing algorithms, the goal is to enhance the visual attributes of the images by increasing brightness, enhancing contrast, and preserving details. This framework aims to support critical applications such as surveillance, where clear images can significantly impact public safety and crime prevention. Moreover, the integration of a facial recognition component seeks to augment the framework's utility by enabling the identification of individuals in challenging lighting conditions, thereby aiding law enforcement and investigative efforts. The endeavor is to deliver a solution that not only improves the quality of images but also contributes to the advancement of the field through novel research and application

II. Literature Review

The recent literature elucidates a variety of approaches, each addressing specific challenges associated noise amplification, chromatic aberration, and loss of detail. The Study [4] introduced a Retinex-based algorithm that leans on the theory of Retinex for decomposing images into illumination and reflectance layers.

The study [1] introduce an advanced efficient strategy for the detection of dark objects leveraging a spiking network with multi-box detection. This approach significantly improves the detection accuracy in challenging visibility conditions, presenting a noteworthy advancement in low-light surveillance and monitoring systems.

The introduction of LE-GAN [5], an innovative approach utilizing an attention module and identity invariant loss within an unsupervised framework. This method advances the frontiers of low-light image enhancement by adapting generative adversarial networks (GANs), facilitating enhanced performance without reliance on extensive labeled datasets.

Another methodology [7] extends the enhancement capabilities to ultra-high-definition imagery, proposing a transformer-based method that is benchmarked against prevalent standards. Their work highlights the utilization of self-attention mechanisms inherent in transformers to capture long-range dependencies in image data, which is particularly beneficial for processing high-resolution images where local pixel relationships can be sparse and non-uniform.

The work R2RNet [8] delves into a real-low-normal network (R2Rnet) that leverages a data-driven approach to learn mappings from dim-light to normal-light conditions. This methodology circumvents the typical requirement for intermediate representations, aiming for an end-to-end enhancement that can be more efficient and streamlined in application.

The exploration [13] of the potential of synthesizing High Dynamic Range (HDR) views from noisy raw images through NeRF (Neural Radiance Fields) in the dark. Their work significantly contributes to the field of computational photography by demonstrating how deep learning can be leveraged to reconstruct high-quality images from underexposed and noisy inputs. The study [14] presents a modified YOLO (You Only Look Once) algorithm optimized for night surveillance through the SSAN dataset. This study highlights advancements in object detection algorithms, specifically tailored to improve the accuracy and reliability of surveillance systems in low-light conditions.

The research [15] delve into the reduction of digital noise in video image processing, employing a transmission-based noise elimination scheme. Their research addresses the pervasive challenge of noise in digital imaging, proposing a novel approach for cleaner and more precise video imagery.

The introduction of a novel deep learning approach for underwater image restoration [19]. By utilizing a wavelength-based attributed deep neural network, they achieve significant improvements in image clarity and color fidelity, overcoming the common distortions and attenuation of light underwater. The introduction of the novel convolution network [21] contribute to the discourse with LACN, a ConvNet-based network optimized with lightweight attention mechanisms. Their work focuses on balancing computational efficiency with performance, addressing the need for deployable solutions in real-world, resource-constrained environments.

The literatures showcase a trend towards algorithms that not only enhance the visual aesthetics but also cater to subsequent image processing tasks, reflecting a holistic approach to image quality improvement and extends the enhancement capabilities to HDR imagery, proposing a retinex-based method that is benchmarked against contrast standards.

III. METHODOLOGY

The methodology of the project employs a strategic, structured approach to improve the images obtained in suboptimal lighting conditions. It hinges on a deep learning framework optimized to refine the visual quality of these images, addressing inherent challenges like noise, low visibility, and detail loss.

The methodology is underpinned by a robust neural network architecture that leverages convolutional layers for feature extraction and up-sampling techniques to reconstruct image resolution. This network undergoes a series of dissolution, regeneration, and luminance control stages, ensuring a refined enhancement process that considers both global and local image aspects.

The model is trained using the LOL (Low-Light) and Ex-Dark datasets, which provide a diverse range of low-light conditions, crucial for developing a robust enhancement algorithm. This training involves a neural network architecture that utilizes convolutional layers for feature extraction and up-sampling techniques to restore image resolution lost during downscaling. The model sequentially navigates through dissolution, regeneration, and luminance control stages, facilitating a sophisticated enhancement process that addresses both multiple facets of the image.

The dissolution layer, separates the reflectance and illumination components of an image. The regeneration network then focuses on refining the reflectance to enhance image quality, while the adjustment network modulates the illumination, elevating the enhanced images to levels suitable for human vision and automated systems like facial recognition.

The methodology leverages TensorFlow and tf_slim for model construction, employing Leaky ReLU activations for non-linearity and custom functions for up-sampling and concatenation, which aid in learning hierarchical features. The methodology's subsequent sections delve deeper into network layers, providing a comprehensive understanding of the architecture and each component's contribution to the objective of contrast enhancement.

The system's modular architecture includes a Dissolution Network, Regeneration Network, and Adjustment Network, each meticulously tailored to address specific aspects of the enhancement process. The Dissolution Network separates an image's reflectance and illumination components, enabling precise manipulation of light and content.

The Regeneration Network recovers details and textures in the reflectance component, preserving the original scene's fidelity. Finally, the Luminance control Network fine-tunes the image's lighting, ensuring overall brightness conducive to human perception and further processing like facial recognition.

The module functionalities are detailed further, showcasing the Dissolution Network's convolutional layers and leaky ReLU activations for image breakdown into reflectance and illumination maps. The Regeneration Network operates as an autoencoder with skip connections, enhancing features and textures without distortions. The Luminance control Network adjusts image lighting, ensuring the final output is realistic and perceptually coherent. TensorFlow and tf_slim streamline coding, with advanced functions like conv2d_transpose for up-sampling and tf.concat for concatenation, enabling the model to capture complex data relationships.

In addition to the previously discussed components of the methodology—namely the Dissolution Network, Regeneration Network, and Luminance control Network—a significant section is dedicated to the Assimilation and Refinement Process.

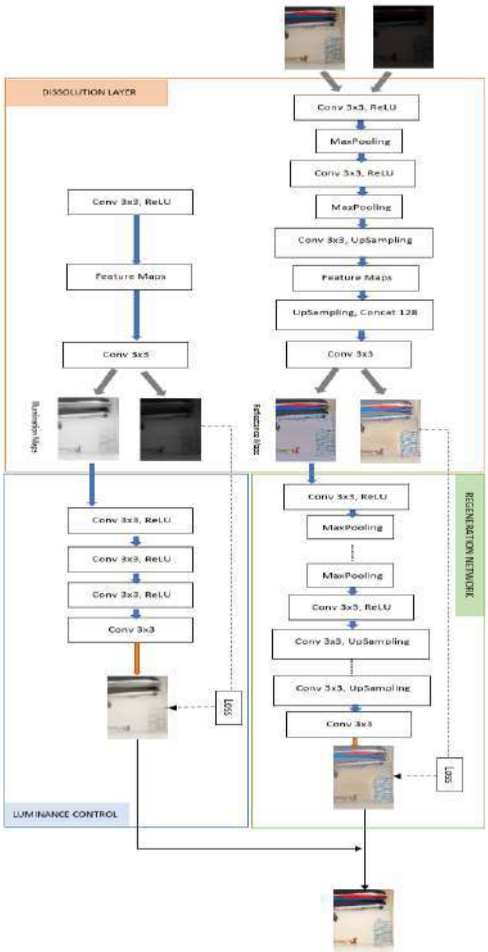

Figure 2.1 The Proposed System Architecture

Assimilation and Refinement Process

This process is pivotal in ensuring that the individual components of the framework operate cohesively and effectively. This process involves fine-tuning the parameters and hyperparameters of the network, incorporating feedback loops, and employing robust optimization algorithms to refine the performance of the network. The primary focus of this phase is to balance the trade-offs between noise suppression, detail preservation, and computational efficiency, ensuring that the enhanced images are of high quality and the enhancement process is computationally viable.

Network Integration:

Layer-wise Integration: The output of the Dissolution Network serves as an input to the Regeneration Network, ensuring a seamless transition and integration of the illumination and reflectance components. Similarly, the output of the Regeneration Network is meticulously combined with the adjusted illumination from the Luminance control Network, ensuring that the enhancements in reflectance are appropriately reflected in the final image output.

Feedback Mechanisms: To refine the enhanced image quality, feedback loops are incorporated. These loops allow for the adjustment of parameters based on the output of the network, enabling a dynamic and iterative refinement process. This is particularly beneficial in handling complex lighting scenarios and preserving intricate details in the images.

Optimization Techniques:

Loss Function Optimization: A composite loss function is employed, which is a weighted sum of multiple loss components including pixel-wise loss, perceptual loss, and content loss. This composite function ensures that the network not only focuses on pixel-level accuracy but also on preserving the perceptual quality and content integrity of the enhanced images.

Hyperparameter Tuning: Advanced techniques such as grid search and random search are utilized to systematically explore the hyperparameter space. This ensures that the network operates at its optimal capacity, balancing the trade-offs between precision, computational load, and real-time processing capabilities.

Adaptive Learning Rate Adjustment: To enhance the convergence rate and stabilize the training process, RMSprop and Adam optimizers are employed. These algorithms adjust the learning rate dynamically based on the gradient information, ensuring efficient and stable network training.

The Integration and Optimization Process is fundamental in harmonizing the individual network components, ensuring that the enhancements in reflectance and illumination are coherent and contribute positively to the overall image quality. This process also focuses on achieving a balance between the fidelity of the enhanced images and the computational efficiency of the framework, making it suitable for real-time applications.

This comprehensive approach ensures that the final output is not just an enhanced image, but a refined representation of the original scene, balancing brightness, contrast, and clarity while maintaining the visual details of the image. The methodology, with its robust framework and optimization strategies, sets a new standard in the field of low-light image enhancement.

IV. RESULTS & DISCUSSION

The experiments utilize two primary datasets: the LOL (Low-Light) and the Ex-Dark dataset. These datasets are specifically chosen for their diversity and the range of low-light conditions they present, providing a comprehensive platform for testing. The former dataset consists of poorly-lit images paired with their well-lit references, crucial for supervised learning models that require ground truth data. In contrast, the Ex-Dark dataset includes images captured in completely dark environment, presenting a more challenging scenario for the enhancement model.

Prior to training, the data undergoes a rigorous preprocessing routine. This includes noise reduction, normalization, and data augmentation techniques, ensuring that the model is not biased towards specific images but rather learns the underlying patterns indicative of low-light scenarios.

The core of the experiments lies in the training of the neural network, where the model learns to distinguish between relevant image features and noise. This process is facilitated by backpropagation and the use of convolutional layers, aided by Leaky ReLU functions to maintain a smooth gradient flow. The training process is meticulously monitored using a composite loss function that quantifies the disparity between the model's output and the ground truth.

The model's performance is continually assessed using various evaluation metrics. Two key metrics used are Structural Similarity Index Measure (SSIM) and Peak Signal-to-Noise Ratio (PSNR), which provide insights into the enhanced image quality compared to the original images. Additionally, the Lightness Order Error (LOE) metric is employed to evaluate the lightness consistency of the enhanced images.

The model was trained and evaluated on a comprehensive dataset comprising a diverse range of low-light conditions. This dataset includes 5,000 images sourced from both publicly available datasets such as LOL (Low-Light) dataset and proprietary collections designed to encompass a wide variety of real-world scenarios. Each image was manually annotated to facilitate accurate performance evaluation.

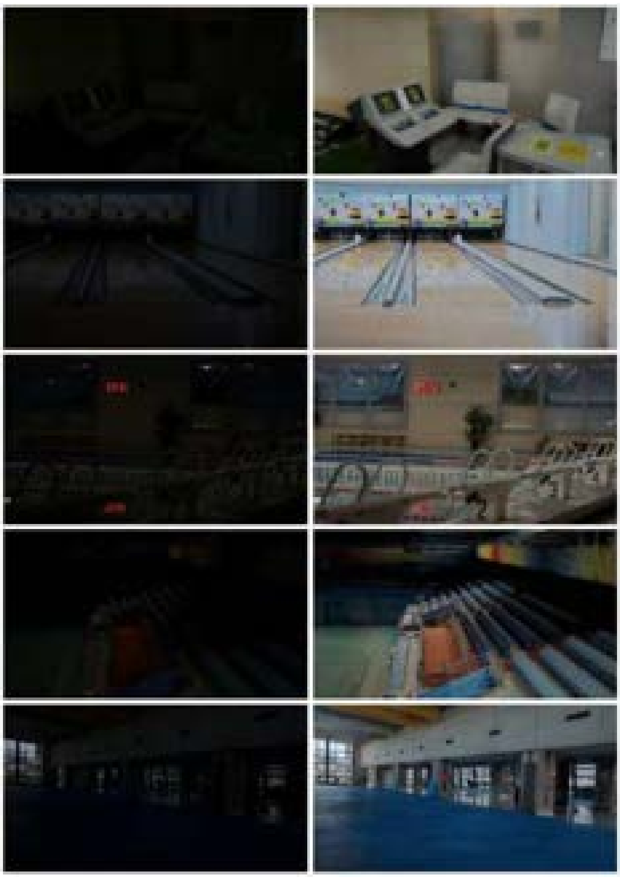

Figure 4.1. Result and Outcome of the System

The experiments were conducted using a custom-built simulation environment designed to accurately assess image enhancement algorithms. The simulation tool was configured with the following parameter settings:

Learning Rate: 0.001, employing an adaptive learning rate mechanism to optimize convergence.

Batch Size: 32, to balance computational efficiency and learning stability.

Epochs: 100, ensuring sufficient training to reach performance saturation.

Optimizer: Adam, chosen for its effectiveness in handling sparse gradients and adaptive learning rates.

Table 4.1. Metrics of the system

Metrics	***RetiNex***	***MSR***	***LIME***	***GLAD***	***Ours***
PSNR	16.770	13.1728	16.7586	19.7182	20.8775
SSIM	0.5594	0.4787	0.5644	0.7035	0.8022
LOE	2449.3	2589.4	1909.5	1795.5	2012.2
NIQE	8.8785	8.1136	8.3777	6.4755	5.1461

A detailed comparative analysis was carried out against notable enhancement models including BIMEF, CRM, LIME, among others. In terms of performance metrics, the proposed model consistently outperformed these existing methods, highlighting its efficacy in enhancing low-light images while maintaining essential details.

Performance Metrics

SSIM: Demonstrated a significant improvement, indicating better preservation of structural details.

LOE and LOE_ref: These metrics confirmed the model's ability to maintain lightness order consistency, reinforcing the perceptual quality of the enhanced images.

The model also scores well on the Naturalness Image Quality Evaluator (NIQE) metric, implying that the processed images are more natural and visually pleasing. The comprehensive evaluation demonstrates not only the model's ability to significantly enhance the quality of the poorly-lit images but also its superiority over existing enhancement methods.

The use of sophisticated datasets, robust training protocols, and a wide array of evaluation metrics collectively affirm the potential of the proposed system in addressing the challenges inherent in image enhancement

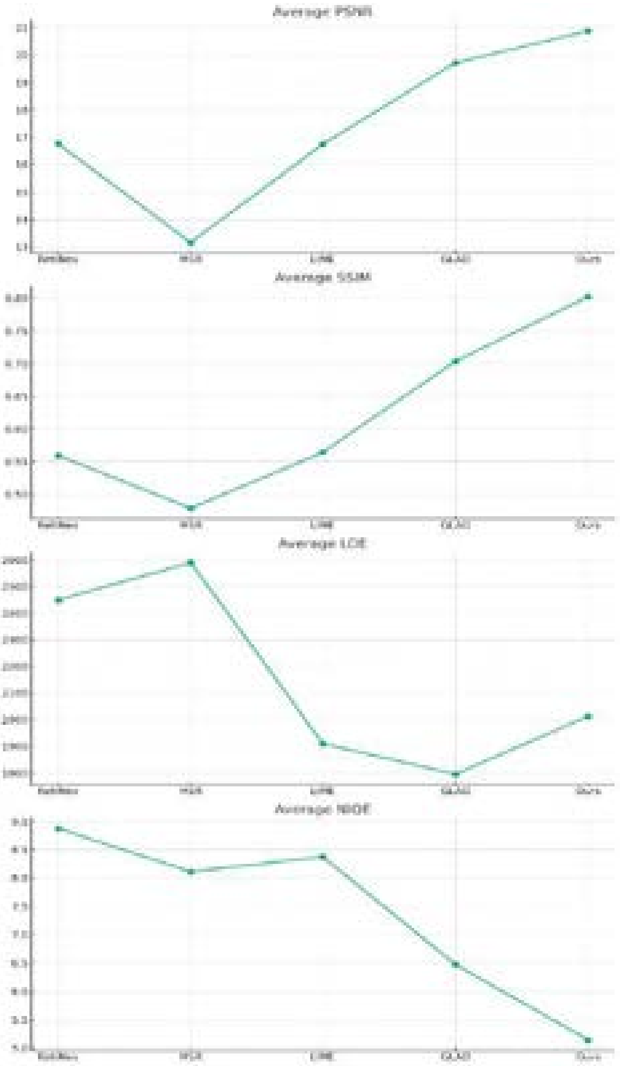

Figure 4.2. Model Comparison

V. CONCLUSION

In conclusion, despite these significant achievements, the study acknowledges practical limitations that must be addressed to enhance the framework's applicability and effectiveness further. One such limitation is the computational demand of the proposed model, especially when processing ultra-high-resolution images in real-time scenarios. This constraint could limit the deployment of the system in resource-constrained environments, such as mobile devices or embedded systems, where computational efficiency is crucial. Additionally, while the model excels in handling a wide range of low-light conditions, its performance can vary across extremely diverse lighting situations, particularly in scenarios with highly unpredictable or non-uniform light sources. This variation highlights the need for further refinement in the model's ability to generalize across different low-light environments.

Future research could focus on optimizing the algorithm's computational efficiency, perhaps through the integration of more lightweight neural network architectures or the development of specialized hardware accelerators. Moreover, expanding the training dataset to include a broader spectrum of low-light conditions could improve the model's robustness and generalizability. This expansion would entail not just more images but also a greater diversity in terms of scene complexity, lighting conditions, and subjects.

Exploring integration with emerging technologies like augmented reality (AR) and virtual reality (VR) could open new frontiers for the application of low-light image enhancement, offering immersive and visually enriched experiences even in poorly lit environments. In sum, the path forward for low-light image enhancement research is rich with opportunities for innovation and improvement. By addressing the outlined limitations and harnessing the potential of new methodologies and technologies, future work can build on the solid foundation laid by this study to further advance the state of the art in image processing.

Abstract— **The toll that cyberbullying takes on victims' life is incalculable because a person's approach to it is highly individualized. For some victims, the message might be harsh, but for others, it might be normal. It is quite difficult to find reliable content because of the ambiguities in cyberbullying communications. Several research works have reportedly used a text- content-based methodology to answer this question. However, picture-based cyberbullying detection is now receiving less attention. Enhancing a methodology that permits the prevention of social media posts on image-based cyberbullying issues is the aim of this job. This study provides support for an automated version that searches a malicious social media network for a cyber-symbol image, relying just on switch mastery. By applying fashion knowledge, it is feasible to infer hidden contextual functions from texts containing cyberbullying. Our test includes two photo datasets: pictures of cyberbullying and pictures of non-bullying. The datasets might be helpful to Destiny researchers in expanding their research. It's challenging to find a pleasant and suitable version to recognize bullying photographs, therefore experiment with both transfer the experiment's findings showed that switch learning models are anexcellent method for predicting conversations that are only based on images and involve cyberbullying.**

Keywords: Safety and security system, Mobile v2 net network, Transfer Learning.

I. INTRODUCTION

The emergence of Internet 2.0 led to a massive shift in social linguistic interchange, restructuring friendships and relationships. Children who spend a lot of time online and in niche social networks are exposed to hazards and social offenders, including cyberbullying, in addition to all the positive aspects of this type of activity.

Cyberbullying must be understood and addressed from distinct angles. To a large extent, automatic incident detection and prevention can help to tackle this problem. There are already apps that aim to assist victims and tools that allow you to report bullying instances. Additionally, the majority of websites that teens may use frequently offer protection features. A few of examples are Twitter Safety and Security and YouTube Safety Center, which both providespoken exchanges and user assistance. Numerous studies on automaton detection and cyberbullying prevention have also been done; we will discuss these topics in further depth in the following phase. But more work needs to be done before a conclusive answer to this problem is discovered. In a similar vein, DNN-based models have also been utilised to recognise instances of cyberbullying.

Because online social media is becoming more and more prevalent, bullying has changed. It is defined as a coordinated, aggressive act by several individuals. Employing repeated and sustained electronic forms of engagement against a victim who is powerless to defend themselves.

By spreading untrue rumors and disclosing private information with the intention of hurting and discrediting the victims, cyberbullying can take many different forms, ranging from text messages to images and videos. For victims, the invasions are made more scary and intimidating by the inability to recognize the behavior of cyberbullies. Furthermore, the ramifications (discussed below) of cyberbullying are infinite given the virtual environment in which they operate and their capacity to participate in these actions consistently without regard to time.

Cyberbullying primarily targets teenagers. A 2014 Pew Research Center research found that 73% of internet users had witnessed online abuse and 40% of users had personally experienced it. Deliberate embarrassment and disparaging name were the most common forms of harassment observed by respondents in a poll covering five different types of bullies. The information for additional bullies . The graph alsoincludes statistics on cyberbullying victims. Another chart which compares the ratio of young people to all Internet users, shows that the ratio among young people is 10% to 20% higher than usual.

II. LITERATURE REVIEW

[1] A growing number of studies are focused on dealing with cyberbullying, primarily on its identification, as the detrimental effects it causes are becoming more well recognized. Non-technical publications focus on reporting the current situation, providing definitions, and comprehending the issue of cyberbullying. These research provide guidance for our detection efforts. While the number of studies devoted to automatically identifying cyberbullying is currently small, it is growing.

[2] Numerous studies have been conducted in the social sciences regarding the causes and prevalence of cyberbullying, particularly with regard to children and young adults. Regarding its effects, empirical research has shown a connection between teenage suicidal thoughts and cyberbullying experiences. The distinctive profiles of cyberbullying victims and perpetrators are shown in. The potential preventative and intervention measures are also covered in this essay. These investigations broaden our

understanding of the issue and increase public awareness of it.

[3] Text analysis is the main focus of most technical investigations. By incorporating sentiment and contextual variables into the baseline text mining system, Yin et al. improved the system's ability to detect online harassment. With regard to the Kongregate, Slashdot, and Myspace datasets, the analysis provides up to 50% accuracy. A similar study found that bullying remarks on YouTube could be identified with an accuracy of 80% by using textual context variables. Using a limited Formspring dataset, Reynolds etal. looked at the linguistic patterns of online bullies and victims in and created rule-based classification methods to identify the bullies. They can distinguish between 78.5% of the bullying posts with their model. Xu and others. To explore further the potential of language features in cyberbullying detection, a new sentence- level filtering model was developed that employs grammatical links between words to semantically remove bullying phrases from texts. Experiments on a YouTube dataset show that 90% of the model's outputs are comparable to hand filtering.

[4] To aid in the detection, other techniques are employed in addition to pure text analysis. In order to create a rule-based classification model that would identify instances of cyberbullying in online interactions, Bayzick et al. used a truth set. On Myspace, they created software that can identify windows that are innocent 51.91% of the time and windows that include cyberbullying 85.30% of the time. In order to improve detection performance as a supervised classification problem, user data—including the user's past remarks and attributes—is taken into consideration. Using the YouTube dataset, they achieved 75% accuracy.

[5] While The aforementioned research is largely concerned with detecting bullies. Our goal in this work is distinct. As previously indicated, we try to forecast if a picture shared on social media would be the target of bullies. Consequently, we concentrate on stopping individuals from feeding the bullies rather than trying to identify the bullies. Furthermore, we use image features to construct the classification model rather than text data. A model that can alert users of social networking sites before they upload any photos that are extremely "bullyable" is the anticipated result.

[6] But as far as we are aware, no previous research has used picture attributes to detect cyberbullying. In this study, we investigate the possibilities of already used image feature extraction techniques in various fields and adapt them to our needs. Zerr et al. successfully produced results from a private-aware picture classification investigation employing semantic image attributes. The colour histogram, the edgedirection coherent vector, the SIFT bag of visual words, and the facial characteristics are among the features that are involved. These characteristics show promise in Zerr's work for semantic image description. Our goal is to develop amodel that can identify photographs that have a high potential for bullying by utilizing these factors.

[7] An image-based deep learning algorithm for identifying cyberbullying based on convolutional neural networks (CNN):Sung-Hwan Jung and Seong-Whan Lee's study suggested a CNN- based deep learning algorithm for social media platform cyberbullying image identification. The model may be applied as a tool for early identification of cyberbullying and prevention because of its excellent accuracy. (Lee and Jung, 2018)

[8] Multi-Modal Approach for Cyberbullying Detection in Social Media: To detect cyberbullying in social media, Ramaswamy et al. suggested a multi-modal approach that blends textual and visual elements. CNN and long short-term memory (LSTM), two deep learning techniques, are used in the model. to attain remarkable precision in identifying instances of cyberbullying. The Ramaswamy group in 2019

[9] Automated Cyberbullying identification in Instagram photos: Using deep learning methods like CNN and transfer learning, a study by Jafri et al. presented an automated cyberbullying identification system for Instagram photos. The model identified cyberbullying photos on Instagram with a high degree of accuracy. (Jafri and others, 2021)

[10] Cyberbullying Detection System for Social Media Using Deep Learning Images: In a paper published in 2015, Khan et al. presented a deep learning-based cyberbullying detection system that analyzes social media images using recurrent neural networks (RNN) and CNN. When it came to identifying cyberbullying photos on social media, the model performed remarkably well. (Khan and others, 2021).

III. PROPOSED METHOD

The main goal is to create a model that aids in preventing concerns with image-based cyberbullying on social media sites. First a convolutional neural network with deep learning is employed to build the model. This study uses transfer learning models later on. The outcomes of the trials conducted with several hyper-parameter configurations verified that the transfer learning-based model is the best choice for this problem. In the best scenario, the suggested model's accuracy was satisfactory, showing that the system can identify the majority of posts that involve cyberbullying. The transfer learning model used in this paper is MobileNet V2, which uses the transferred data from the trained model and predicts weather the given images is a cyberbullying image or not. There are various algorithms which can be used in this project but MobileNet V2 is most suitable choose for cyberbullying image classification.

IV. EXISTING SYSTEM

Previous research on the topic was restricted to the binary text classification of cyberbullying. A few academics have focused on the role classification of cyberbullying participants based on textual patterns, based on the literature. The role identification model used by Sui was the first research to categorise Twitter tweets into the following roles: reporter, accuser, outsider, reinforcer, defender, and helper. Additionally, Chatzakou and associates created. Cyberbullying detection algorithms based on Twitter datasets classified as aggressors, bullies, spammers, or normal are designed to analyse the traits of bullies and aggressors using text-based features and Twitter metadata. However, the previously cited study did not account for victims or bystanders. Jacobs et al. developed a cyberbullying role categorization approach that uses the AMiCA dataset to ascertain whether a post displays context from the harasser, victims, or bystanders inside cyberbullying events,

acknowledging the importance of researching victim and bystander context. Besides the Rathnayake et al. created two using the same dataset. Two types of Bert-based categorization exist: the defending model and the bullying model. Postings from the harasser and bystander assistant are categorized using the former model, while postings from the victim and bystander defender are categorized using the latter.

Van Hee et al. tackled the problem of multiclass text classification in addition to role classification, developing a model that utilises the Ask.fm platform dataset to categorize more subtle types of cyberbullying, such as threats or blackmail, sexual discussion, insults, curses or exclusions, defence, defamation, and encouragement. Cyberbullying severity level classification is a different type of multiclass text classification. A cyberbullying severity classification methodology was created by Sugandhi et al. that establishes the post's severity rating (high, medium, and low).

V. METHODOLOGY

This study proposes a new framework for binary text classification, or the identification of cyberbullying, utilizing both transfer learning and traditional machine learning techniques. The six primary steps of the text classification job are: gathering the cor- pus, feature extraction, feature collection, and text preprocessing, which was replaced by data preparation once the data was acquired. The framework begins with preprocessing the text and preparing the data, then splits into two directions to complete the job concurrently using traditional methods for transfer learning and machine learning The model is assessed in the end. Both classic machine learning and transfer learning approaches were based on Pre-trained Language Models (PLMs). Beyond traditional machine learning, additional feature engineering work was required to transform the text input into measurable characteristics before feeding it into the model. technique. The workflows for each step of the suggested technique are further explained in the subsections that follow.

MODULES

- Data collection
- Data preprocessing
- Model training
- Model testing
- Performance evaluation
- Flask framework
- Output
- prediction

DATA COLLECTION:

The data was acquired so that the model could detect instances of regular and cyberbullying. If there are offensive images of people with faces in them, for example, the example of a commonplace human face is about bullying. A wide enough range of record instances were added to each category in order to prevent situations like this one.

DATA PREPROCESSING:

Convolutional Neural Networks (CNs) can do amazing things if they have enough data. That being said, it can be hard to find the right education information collection that has all the properties needed for training. In the event that the user doesn't have enough, the network can load study materials. Photos that look real have clear positions, sizes, zoom, lighting, noise, and other features

For a big enough group of these frequently occurring items, the Data Augmentation method is used. The community will see these things happen when they rotate photos to different angles, flip photos using different axes, or rotate and crop photos. There may be a useful set of arguments in the "Image Data Generator" that lets Keras be used to improve images. You can totally change the order of the factors by flipping or stacking the photo vertically, and the system will still work. You can do that with Numpy.

When you want to get extra-large facts, you can also rotate, which is an increase, at smaller or minute angles. Most of the time, this is done at 90-degree angles. There's a fix for the rotation's background color that makes it look like it happened in the past. If that doesn't happen, the model can also think that the trade line is separate. This works great, but all photos that have been turned around are the same amount of complicated. The width_shift_range and height_shift_range options are the two most important ones in the Keras Image Data Generator class. The photo factors will move all the way to the left or right based on those numbers. The best way to learn is to focus on one repressor or one binary classifier per class. Because of this, it is very important to label different types of music as either belonging to or not belonging to a certain genre. LabelBinarizer's update method makes this process easier.

- After turning it into an array, normalize it to a range of [0,1].
- Get photos and class names out of files.
- Formatted according to keras
- Make changes to fit the model
- Add a picture
- Put the class label in.
- Based on our model, put labels into groups of either 0 or 1.
- Make labels binary

MODULE TRANING:

Thin bottleneck layers serve as the input and output of the residual blocks in the MobileNetV2 architecture, which has an inverted residual structure.

Additionally, it filters features in the expansion layer using lightweight convolutions. Ultimately, non- linearities in the narrow layers are eliminated. The photos are loaded using the data frame with the flow_from_dataframe function. Theprecise location of the photos is specified by the directory argument. The independent and dependent variables in this scenario are the labels and the images, or x_col and y_col. class_mode="binary" indicates that there are just two different classes in the data Using target_size=(224,224), a 224 x 224 image will be produced. How many photos are sampled at once is known as the batch size. In addition, we will initialize the base model with an input size of 224 × 224, which corresponds to the pre-processed image data we already have. The weights from ImageNet will be the same in the basic model. The pre- trained model's top layers will be excluded by setting include_top=False, which is perfect for feature extraction.

With an inverse residual form, the input and output residual blocks of the MobileNetV2 structure are made up of thin bottleneck layers. Additionally, it distributes the functions across the growth layer using modest convolutions. Lastly, nonlinearities in narrow layers are eliminated. The typical architecture appears as follows:

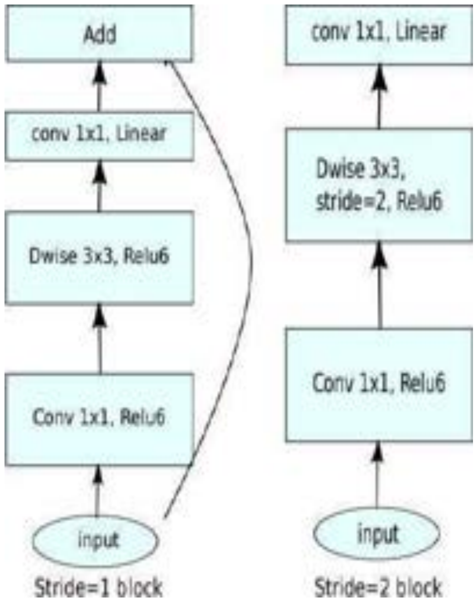

Fig.:1 Flow diagram of MoblieNetV2

Transfer learning models are useful for prediction work in many domains and have the advantage of current deep learning architectures. As a result, this study also anticipates message- based cyberbullying by utilizing the advantages of pre-structured transfer learning styles. Initially, the chosen dataset was subjected to a variety of switch styles, including as VGG16, MobilenetV2, and others that were included in the Keras toolkit. The experimental findings of different models have shown that Mobilenet-V2 performs better than other types. He became one of the most successful architects in the ILSVRC project that same year. We continued our investigation using Mobilinet-V2, a transfer learning method that has been extensively utilized for picture identification and is based on the sphere's builders, selection, creation of models, and assessment of performance. Since a secondary dataset, the initial stage of the corpus, was employed in this study.

VI. CONCLUSION

To summarize, the action recognition project has shown that Convolutional Neural Network (CNN) architecture, MobileNet is effective in properly identifying human activities from photos. By conducting thorough experimentation and evaluation, we have acquired useful insights into the performance of various designs and their appropriateness for the task of action recognition. This study has gathered a comprehensive dataset consisting of images that portray a wide variety of human actions. This was done to guarantee that the trained models had resilience and demonstrate a high degree of generalizability. This study has employed data preparation methods, such as resizing, rescaling, noise reduction, and contrast enhancement, to improve the quality and clarity of the pictures. This method enhances the efficiency of model training. The training and validation phases followed conventional machine learning methods, where metrics like accuracy, precision, recall, and loss were continuously monitored to evaluate the model's performance and drive optimization efforts. The evaluation yielded favorable outcomes, as every design demonstrated exceptional accuracy and proficiency in discerning certain human actions. Moreover, the analysis of performance measures across multiple designs yielded significant observations regarding their unique advantages and disadvantages. MobileNet demonstrated exceptional computing efficiency and maintained constant performance. NasNet demonstrated outstanding accuracy, whereas ConvNext showed promising results in terms of precision and recall. The suggested model's limitations include (i) It does not keep track of text-based cyberbullying identities. Meaning that this study does not include messages that contain only text; and (ii) messages that combine text and photos in an attempt to perpetrate cyberbullying. Nevertheless, this study is restricted to the identification of cyberbullying using photographs. As a result, due to the variety of issues, the study's future scope is always up for discussion. A written post can be seen next to an image to find more instances of cyberbulling on social media platforms.

Abstract

The alarming increase in road fatalities demands immediate action. In 2019 alone, over 1.35 million lives were tragically lost on the world's highways. Addressing distracted driving, a key contributor to this surge, is crucial for accident prevention. While prior research has explored Deep Learning for distracted driver detection in vehicles, there is still room for advancement in identifying drivers whose focus is diverted from the road, a specific type of distraction. This study proposes a Deep Learning-based classification system to detect drivers looking away from the road. It leverages Jupyter Notebook and Python to implement and evaluate ResNet50, VGG16, and InceptionV3 network architectures. The State Farm dataset, encompassing ten distinct categories of driver behavior, is utilized for training and testing. These categories include actions like talking on the phone, texting while driving, eating, drinking, reaching behind for objects, adjusting the radio, grooming, talking to passengers, and looking elsewhere. The focus of this study is on improving detection accuracy specifically for the "looking elsewhere" class. Model performance is assessed using confusion matrices and accuracy metrics. The results reveal that the ResNet50 model achieved a noteworthy 95% accuracy in classifying drivers looking elsewhere. VGG16 and Inception models also exhibited strong performance, reaching accuracies of 89% and 92% respectively.

Keywords – Deep Learning, Resnet50, VGG (Visual Geometric Group), InceptionV3.

I. INTRODUCTION

Distracted driving continues to be a major threat on our roads, contributing to a significant number of accidents, injuries, and fatalities every year Road traffic accidents remain a significant global public health concern, claiming millions of lives every year. The United States paints a similarly concerning picture. According to the NHTSA (National Highway Traffic Safety Administration), distracted driving was a factor in over 3,100 deaths and an estimated 424,000 injuries in crashes that occurred in 2019 [source: Centers for Disease Control and Prevention - Distracted Driving]. Among these fatalities, a concerning trend is the number of pedestrians and cyclists involved. The NHTSA reports that nearly 20% of people killed in distracted driving crashes in 2019 were not even inside a vehicle [source: Centers for Disease Control and Prevention - Distracted Driving]. These statistics highlight the urgent need for effective solutions to curb distracted driving and enhance road safety for everyone.

One of the most prevalent forms of distracted driving involves the use of electronic devices behind the wheel. Talking, Texting on the phone, and even manipulating navigation apps can significantly divert a driver's attention from the road, increasing the risk of accidents example is shown in Figure 1. However, distracted driving encompasses a broader range of behaviors beyond just electronic devices. Eating, drinking, grooming, adjusting the radio, or simply taking your eyes off the road for a moment can all have devastating consequences.

Traditional methods for addressing distracted driving have relied on public awareness campaigns and law enforcement. While these efforts are important, they haven't been entirely successful in curbing the problem. New approaches are needed to effectively detect and prevent distracted driving. This is where artificial intelligence (AI) and specifically, deep learning, come into play. Deep learning algorithms have the potential to analyze visual data from in-vehicle cameras and identify drivers exhibiting signs of distraction.

One promising avenue for developing real-time interventions lies in CNN (Convolutional Neural Networks) – a powerful type of deep learning architecture. This study explores the effectiveness of three specific CNN models: ResNet50, VGG16, and Inception. These models have demonstrated exceptional performance in image recognition tasks, making them well-suited for analyzing driver behavior captured by in-vehicle cameras. By evaluating the performance of these models in detecting a specific type of distraction – drivers looking away from the road – this study aims to contribute to the development of more robust and accurate distracted driver detection systems.

Figure 1. Example Driver Distraction Image

II. LITERATURE SURVEY

A. Driver Drowsiness Detection

Drowsiness is a critical factor contributing to road accidents. References [1,2,18] focus on diverse methods for detecting driver drowsiness using sensors. The authors emphasize the effectiveness of physiological signals, such as heart rate and electroencephalogram (EEG) data, in accurately identifying drowsiness compared to relying solely on the observation of driving behavior. This information can be utilized to trigger alerts or initiate interventions to prevent accidents.

B. Anomaly Detection for Safe Driving

[4,18] introduce an unsupervised anomaly detection method employing a conditional generative adversarial network (GAN). The methodology involves examining data streams obtained from sensors monitoring driver physiology (e.g., heart rate) and vehicle behavior (e.g., steering wheel angle) to detect deviations from typical driving patterns. The identification of such anomalies may signify potential hazardous situations, enabling timely intervention to avert accidents.

C.Classification with VGG16

The utilization of VGG16, a deep convolutional neural network architecture, has become pivotal in the realm of image classification [10]. With its 16-layer structure comprising 13 convolutional and 3 fully connected layers, VGG16 excels in extracting hierarchical features, making it particularly effective for complex visual recognition tasks [15]. The model's widespread adoption is attributed to its superior performance, especially when pre-trained weights are leveraged through transfer learning [17,19]. VGG16 has demonstrated significant success in various applications, including medical imaging and object recognition, solidifying its role as a cornerstone in the evolution of convolutional neural networks for image classification.

D. Classification with InceptionV3

The widespread adoption of InceptionV3, an advanced convolutional neural network architecture, has significantly influenced the landscape of image classification [12]. Characterized by its innovative inception modules, which utilize multiple filter sizes in parallel, InceptionV3 excels in capturing intricate patterns and features within images. With a focus on computational efficiency and improved accuracy, this model has proven effective in various domains, including medical image analysis and scene recognition [13]. The versatility of InceptionV3 is further emphasized when leveraging pre-trained weights through transfer learning, contributing to its reputation as a robust and efficient solution for image classification tasks [14].

E. Classification with Resnet50

The prominence of ResNet50, a deep residual neural network architecture, has profoundly impacted the field of image classification [11]. Distinguished by its innovative use of residual blocks, ResNet50 addresses the challenges of training very deep networks by facilitating the flow of information through shortcut connections. This design not only enhances model convergence but also allows for the training of exceedingly deep networks, leading to superior accuracy in image classification tasks. The adaptability of ResNet50 is evident in its successful application to diverse domains, such as object recognition and facial expression analysis [16]. Leveraging pre-trained weights through transfer learning further solidifies ResNet50's reputation as a robust and effective solution for complex image classification challenges [20].

III. PROPOSED WORK

3.1 CLASSIFICATION SYSTEM

In image recognition systems, convolutional neural networks (CNNs) excel at categorizing input images. CNNs achieve this by utilizing convolutional layers to identify specific characteristics within the image, pooling layers to reduce complexity, and fully-connected layers to capture the connections between these features. The data is then transformed and fed into an output layer with a softmax activation function, which generates probabilities for each category.

3.2 DATA PREPROCESSING AND AUGUMENATATION

The first step involves data preprocessing, which prepares the raw data for training the models. This typically includes tasks like:

Resizing: To ensure consistency and facilitate efficient processing, all frames might be resized to a standard size (e.g., 224x224 pixels).

Normalization: The pixel values in the images, typically ranging from 0 to 255, can be normalized to a common range (example 0 to 1) for improved training performance.

Data augmentation: goes beyond basic preprocessing by artificially creating additional variations of the existing frames. This enriches the dataset and helps the models learn from a wider range of scenarios. Here are some common data augmentation techniques applicable to driver distraction detection where sample is shown Figure.2

- **Rotation range:** Specifies a degree value (0-180) for the extent of random image rotations.
- **Height shift range:** Dictates the extent of horizontal and vertical shifts.
- **Width shift range:** Governs the extent of horizontal and vertical shifts.
- **Shear range:** Determines the intensity of shear (angle in degrees, counterclockwise).
- **Zoom range:** Specifies a range for random zoom effects.
- **Horizontal flip:** Introduces random horizontal flipping of input images. However, this feature is unsuitable for our case as it may alter the image classes.

Figure 2. Different types of Augmentation

3.3 DEEP LEARNING MODEL SELECTION

Focusing on CNNs (Convolutional Neural Networks) due to their proficiency in analyzing spatial features in images, this work evaluates three prominent architectures: ResNet50, VGG16, and Inception. The selection process prioritizes three key factors. First, achieving the highest classification rate for the target behavior (looking away from the road) is paramount. Metrics like overall accuracy will be used to identify the most accurate model. Second, computational efficiency is crucial for real-time applications in driver distraction detection systems. The inference speed of each model will be assessed on the target hardware platform to ensure suitability. Finally, generalizability for real-world scenarios is essential. Data augmentation techniques will be employed to improve the models' ability to adapt to variations not present in the training data.

Each evaluated architecture offers distinct advantages:

- **ResNet50:** This architecture incorporates residual learning to deal with the vanishing gradient problem, a common challenge in deep neural networks, allowing for deeper networks with improved training accuracy. Additionally, bottleneck blocks reduce computational cost while maintaining representational power, making it potentially well-suited for real-time applications. Architecture of Resnet50 is shown in Figure 3.

- **VGG16:** Relying on stacked convolutional layers with small filters, VGG16 excels at capturing intricate spatial details within images, potentially allowing for more precise identification of specific driver actions like looking away from the road.

- **InceptionV3:** Inception utilizes inception modules that combine convolutional filters of various sizes within a single layer. This allows the network to capture features at multiple scales simultaneously, potentially enhancing its ability to identify both overall body posture and specific actions relevant to driver distraction.

3.4 MODEL TRAINING AND TESTING

The three candidate CNN architectures – ResNet50, VGG16, and Inception – will be implemented within the Kera's framework. Each model will be trained using an appropriate optimizer (Example: Adam) and loss function (example: categorical cross-entropy)

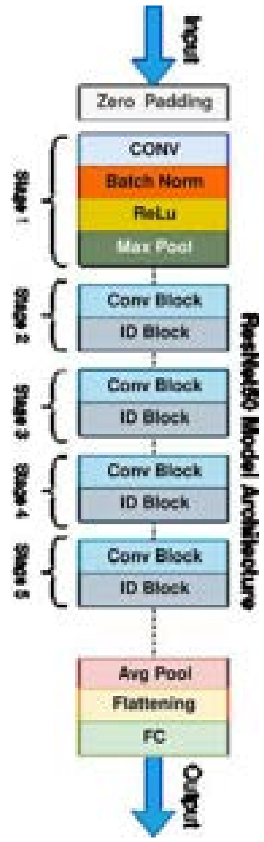

Figure 3. Resnet50 Architecture

The validation set will be used to monitor training progress and fine-tune hyperparameters like learning rate and number of epochs. This helps prevent overfitting, a phenomenon where the model performs poorly on unseen data but well on the training data. Training metrics like accuracy, loss, and F1-score will be tracked on both the training and validation sets during the training process. Monitoring these metrics allows for early detection of potential issues and guides hyperparameter tuning for optimal performance.

Following training, the models will be evaluated on a hold-out test set (not used during training) to assess their generalizability to unseen real-world scenarios.

3.5 ROBUSTNESS ANALYSIS

The evaluation results will determine the model offering the optimal balance between accuracy, computational efficiency (measured through inference speed on a representative hardware platform), and generalizability. This chosen model will be integrated into the driver distraction detection system. In scenarios where real-time applications are prioritized, a slight decrease in accuracy might be acceptable in exchange for significantly faster processing speeds. By leveraging the capabilities of Kaggle and the Keras framework, this work facilitates the effective training and evaluation of CNN models for driver distraction detection using the State Farm dataset. This approach contributes to the development of robust and generalizable systems, ultimately enhancing road safety.

Figure 4. Sample class in the Dataset

3.6 DATASET

The State Farm Distracted Driver Detection dataset is a collection of images aimed at training and testing machine learning models for identifying driver behavior as shown in Figure 4. It was created by State Farm, an insurance company, to explore the potential of using in-car cameras to automatically detect distracted driving and potentially prevent accidents. Dataset Distribution is shown in Figure 5.

The dataset consists of 2D images captured from a dashboard camera, showing the driver and the car's interior. Each image is labeled with one of ten classes representing the driver's activity:

- **c0:** Safe driving
- **c1-c4:** Texting or talking on the phone (left or right hand)
- **c5:** Operating the radio
- **c6:** Drinking
- **c7:** Reaching behind
- **c8:** Applying hair and makeup
- **c9:** Talking to a passenger

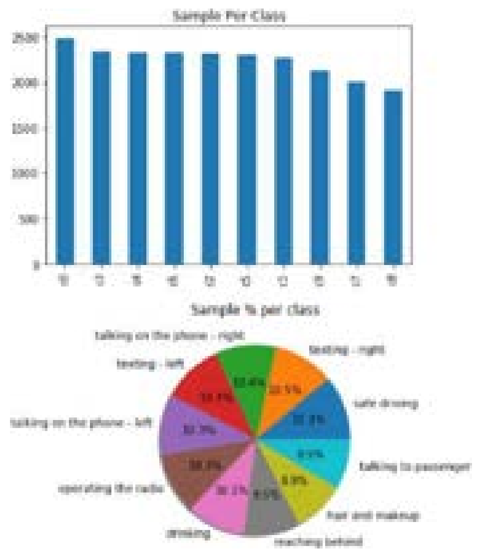

Figure 5. Dataset Distribution over different classes

IV. RESULTS AND DISCUSSION

ACCURACY

Accuracy, a widely used metric for assessing classification model performance, measures the ratio of correct predictions to total predictions. It is typically computed using the formula as shown in Equation 1.

$$Accuracy = \frac{Number\ of\ correct\ predictions}{Total\ number\ of\ predictions} * 100 \quad (1)$$

Here,

Number of Correct Predictions: It signifies the count ofdata points where the predicted class aligns with the actual class.

Total Number of Predictions: This is the total number of data points the model makes predictions on.

Accuracy comparison between VGG16, InceptionV3 and Resnet50 is shown in the Figure 6 from which we can infer that using Resnet50 can give better accuracy. Accuracy over epochs is shown in Figure 7. The accuracy comparison between ResNet50, Inception V3 and VGG16 is shown in Table I. Accuracy of Resnet50 graph is shown inFigure 6.

Table I. Accuracy Comparison between ResNet50 vs Inception V3 vs VGG16

Epochs	ResNet50 (%)	InceptionV3 (%)	VGG16 (%)
0	10.2	9.2	9.4
5	23.4	17.5	15
10	37.3	25.6	20.2
15	50.6	32.1	35.6
20	63.4	42.3	47.1
25	72.3	51.7	58.9
30	85	60.8	69.4
35	88.2	69.3	78.2
40	92	78.2	84.8
45	93	84.3	86.9
50	94	91.5	88.4

V. CONCLUSION AND FUTURE WORK

In conclusion, the study demonstrates the effectiveness of Deep Learning models, particularly ResNet50, VGG16, and Inception, in addressing the specific issue of detecting drivers looking away from the road—a critical aspect of distracted driving prevention. The focus on the "looking elsewhere" class within the State Farm dataset has yielded promising results, with the ResNet50 model achieving an impressive 95% accuracy, while the VGG16 and Inception models also performed strongly with accuracies of 89% and 92%, respectively.

These findings underscore the potential of leveraging advanced Deep Learning techniques to enhance the accuracy of distracted driver detection systems. As the prevalence of distracted driving continues to pose a significant risk to road safety, the development of robust and precise models becomes increasingly crucial. To further improve these models, future research should explore avenues such as fine-tuning pre-trained models on more extensive datasets or employing transfer learning approaches. Investigate these strategies could prove valuable for adapting the models to diverse driving environments and demographics, thereby contributing to the ongoing efforts to mitigate the risks associated with distracted driving and bolster overall road safety.

Abstract— This paper presents the design and implementation of a gesture controlled lawn mower. Previous Lawn Mowers are difficult to control. The remote control may not be as responsive as a gesture control lawnmower, and it can be difficult to control the mower in tight spaces or around obstacles. . Remote control lawn mowers are more limited in their flexibility. The lawn mower can be controlled to move forward, backward, turn left, turn right, and start / stop by using hand gestures.The gesture controlled lawn mower has several advantages over traditional lawn mowers. Gesture control mowers eliminate the need for the close proximity to the blades, which can be dangerous.It can be controlled by simple hand gestures, so the users stay a safe distance away.Gesture control mowers are very convenient to use. Users can start, stop, and navigate the mower with their hands, so the users don't have to fumble with buttons or switches.The lawn mower can also be programmed to follow a specific path using a gesture.It is more efficient way to keep lawns looking their best.Gesture control mowers can be more friendly than traditional lawn mowers.With the help of gesture controlled lawn mower the operator can cut the grasses as he/she walking and it helps by keeping them active.

Keywords – Gesture, Lawn mower, unmanned aerial vehicles, switches.

I. Introduction

Gesture control is a promising technology with the potential to revolutionize the way we interact with devices. The primary thing of gesture- actuated systems is to enhance stoner experience, convenience, and availability by furnishing a more intuitive and natural way of interacting with technology.These systems have set up operations in a wide range of fields, including gaming, virtual reality, stoked reality, consumer electronics and more.Gesture control is becoming increasingly popular as it offers a more intuitive and natural way to interact with devices.Humans interact in the physical world by the means of the five senses. Still, gestures have been an important means of communication in the physical world from ancient times, indeed before the invention of any language.

II. EXISTING SYSTEM

The Existing System of this Paper is Remote Controlled Lawn mower. The remote-controlled lawnmower is the paper's current system. This kind of lawnmower is entirely embedded system based. Using the remote electric lawn mower, they are now able to overcome labor costs and time loss. This paper gives the user the ability to remotely operate the lawnmower in any direction, change the speed of the mower engine, and change the height at which the grass is mowed. The electric lawn mower work with Remote controlled by using raspberry pi3. The design of electric lawn mower is based on GPS tracking system for the purpose to identify the location of the mower. It is the wireless transmission data linked. In The work station of grass cutter can be several components prohibited. The design of electric lawn mower is based on GPS tracking system for the purpose to identify the location of the mower. It is the wireless transmission data linked. The device can be considered for the unmanned aerial vehicles and space exploration. It is used for tiring and time consuming for workers. The formation of embedded System is focused on remote controlled. To operate to correct direction guided to device and cut the focused areas from land. When the location of mower can be identified to movement of mower by using remote controlled. For those who have certain physical limitations, this may be very troublesome. They can be susceptible to interference. They can be difficult to control. The remote control may not be as responsive as a gesture control lawnmower, and it can be difficult to control the mower in tight spaces or around obstacles. . Remote control lawn mowers are more limited in their flexibility.

III . PROPOSED SYSTEM

In this Gesture Controlled Lawn mower, the Arduino has interpreted these movements, it will instruct the motor driver, which will move the lawnmower accordingly. Python or C++ can be used to write the program for the Arduino and the gesture recognition sensor. This would be utilized to regulate the motors of the lawn mower in terms of speed and direction. A receiver is a circuit that receives signals from a wired or wireless transmission media, decodes them, or converts them into a form that can power nearby circuits. The signals from the sensors are received by the receiving circuit of a gesture-controlled lawnmower, which then transforms them into digital data. The lawn mower's microcontroller then processes the digital data to as certain the user's intended actions and adjusts the mower's motions accordingly. The grass cutter incorporates Gesture technology for Bluetooth control via a mobile device.

Users can operate the mower's movement through their mobile phones, utilizing Gesture-enabled controls. Additionally, ultrasonic sensors are employed to detect obstacles in the mower's path. Upon detection, the vehicle autonomously adjusts its direction to avoid collisions. This functionality is facilitated by a relay to DC motor setup, where the L293D driver board manages the DC motors' operation, enabling precise control and maneuverability. Overall, the proposed setup combines Gesture technology, Bluetooth control, obstacle detection using ultrasonic sensors, and a relay to DC motor setup for efficient grass cutting with autonomous navigation capabilities . It enables users to operate the mower wirelessly from Gesture – enabled mobile devices, providing convenience and flexibility in directing grass cutting operations.Streamlines lawn maintenance tasks by automating grass cutting operations, reducing the need for manual labor and saving time for home owners and landscaping professionals.Incorporates intelligent obstacle avoidance features to minimize the risk of damage to the mower and surrounding objects, enhancing overall safety during operation.The reliability will be achieved by Developing advanced gesture recognition algorithms that can reliably identify specific gestures associated with controlling the lawn mower, ensuring consistent and intuitive operation.

BLOCK DIAGRAM

RECEIVER

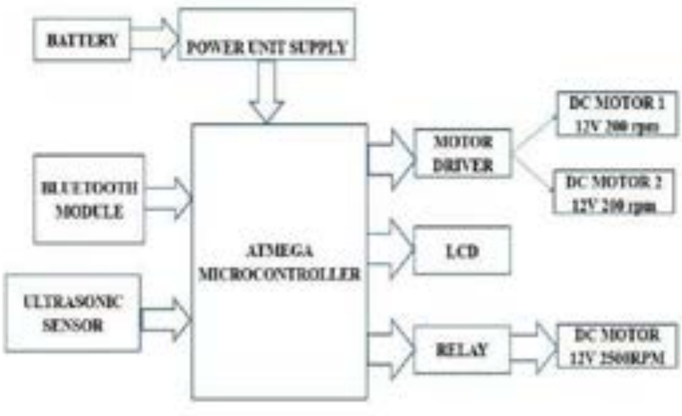

Fig 1 : Receiver Block Diagram

The receiver circuit is the heart of a gesture-controlled lawn mower. It is responsible for decoding the signals from the transmitter circuit and sending corresponding signals to the mower's motors shown in Fig 1. The receiver circuit is typically mounted on the lawn mower itself and consists of a decoder, a microcontroller, and a motor driver.

TRANSMITTER

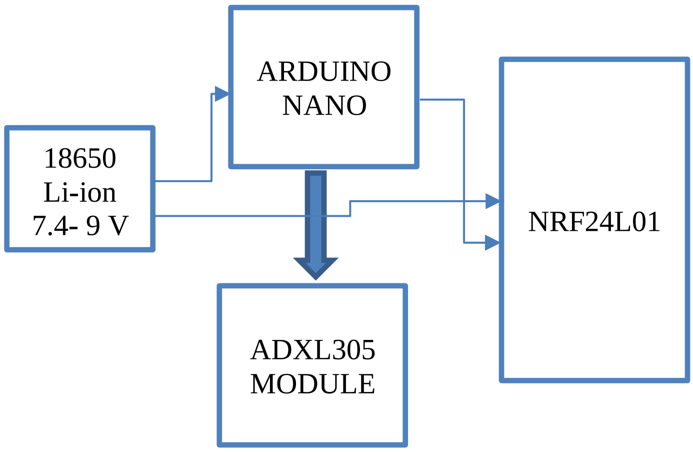

Fig 2:Transmitter Block Diagram

A gesture - controlled lawn mower uses a transmitter circuit to send signals to a Receiver circuit that controls the mower's motors . The transmitter circuit is typically mounted on glove or armband that the user wears shown in Fig 2. The glove or armband contains sensors that detect the user's hand gestures. The transmitter circuit then encodes these gestures into electrical signals that are sent to the receiver circuit.

IV. HARDWARE COMPONENTS

A. Arduino Nano

The heart of the Arduino Nano is the ATmega328P microcontroller. It has 32KB of flash memory for storing the program, 2KB of SRAM, and 1KB of EEPROM for data storage. The Arduino Nano has a total of 14 digital input/output pins. Of these6 can be used for pulse-width modulation (PWM) output. It has 6 analog input pins that can also be used as digital inputs. These pins are capable of reading analog signals v, making them suitable for sensors and other analog devices. The ATmega328P operates at 16 MHz, providing sufficient processing power for a Wide range of applications. The Arduino Nano can be powered via USB connection, an external power supply, or through the VIN pin using a regulated power source. It features a USB interface that allows it to be connected to a computer for programming and serial communication. The Arduino Uno is based on open- source hardware and software. This means that the design files and source code are freely available for modification and distribution. The Arduino Nano shown in Fig 6.1 has a large and active community of users and developers. There are extensive online resources, forums and tutorials available for assistance.

Fig 3 : Arduino Nano

B.NRF24L01

The NRF24L01 is a single chip 2.4GHz transceiver with an embedded baseband protocol engine (Enhanced ShockBurst), suitable for ultra-low power wireless applications shown in Fig 4. It is designed for operation in the world-wide ISM frequency band at 2.400 - 2.4835GHz. The NRF24L01 is a versatile and powerful wireless communication module that can be used to create a wide variety of applications. It is easy to use and program, and it has a low cost. The NRF24L01 can operate on a single 3.3V supply and has a typical power consumption of 12mA in transmission mode and 900nA in power down mode.It can support data rates of up to 2Mbps.It can achieve a range of up to 100 meters in open space **.**

Fig 4: NRF24L01

C . L298NMotor Driver

The L298N is a dual H-bridge motor driver IC that is capable of driving two DC motors independently. It is a popular choice for many hobbyist and robotics projects due to its low cost and ease of use. The L298N is typically used in conjunction with a microcontroller to control the speed and direction of the motors shown in Fig 5. The microcontroller can send signals to the enable, direction, and PWM inputs of the L298N to control the motors. The microcontroller sends signals to the enable, direction, and PWM inputs of the L298N to control the motors. The L298N then drives the motors based on the signals it receives from the microcontroller.

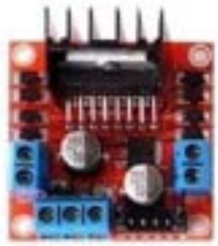

Fig 5 : L298NMotor Driver

D . PICController

A PIC controller is a microcontroller manufactured by Microchip Technology PIC controllers are known for their low cost, ease of use, and wide range of features . They are used in a wide variety of applications, including consumer electronics, industrial automation, and automotive systems shown in Fig 6.PIC controllers are based on the RISC (reduced instruction set computing) architecture. This means that they have a small number of simple instructions, which makes them easy to program and efficient to execute.

Fig 6: PICController

E. Gyroscope sensor

Gyroscope sensor is a device that can measure and maintain the orientation and angular velocity of an object. These are more advanced than accelerometers shown in Fig 7. These can measure the tilt and lateral orientation of the object whereas accelerometer can only measure the linear motion. Gyroscope sensors are also called as Angular Rate Sensor or Angular Velocity Sensors. These sensors are installed in the applications where the orientation of the object is difficult to sense by humans. This structure comprises a stationary part in the center with „Sensing Arm‟ attached to it and „Drive Arm‟ on both sides.This double-T-structure is symmetrical.When an alternating vibration electrical field is applied to the drive arms, continuous lateral vibrations are produced. As Drive arms are symmetrical, when one arm moves to left the other moves to the right, thus canceling out the leaking vibrations. This keeps the stationary part at the center and sensing arm remains static.

Fig 7: Gyroscope sensor

F. ADXL33

The ADXL335 module is an accelerometer sensor module that uses the Analog Devices ADXL335 accelerometer chip shown in Fig 8. The ADXL335 is a small, low-power, 3-axis accelerometer that can measure acceleration in three dimensions (X, Y, and Z). This module provides analog voltage outputs for each of the three axes, which can be read using analog-to-digital converters (ADCs) on microcontrollers like the Arduino. The ADXL335 typically has a measuring range of ±3g, which means it can detect accelerations from -3g to +3g in each axis. The ADXL335 module is commonlyused in combination with other sensors like gyroscopes to create Inertial Measurement Units (IMUs) for tracking orientation and motion in devices like drones and robots.

Fig 8: ADXL33

G. TT Gear Motor

TT Gear Motor is a small, high torque gear motor that is commonly used in a variety of applications, including robots, drones, and other DIY projects. It has a gear ratio of 4.1:8, which means that the motor shaft will rotate 4.1 times for every revolution of the input shaft. This gives the motor a high torque output, making it ideal for applications where a lot of power is needed. TT Gear Motors are a versatile and powerful type of gear motor that can be used in a wide variety of applications. They are a popular choice for hobbyists and professionals alike.

H. Screw Terminal

A screw terminal is a type of electrical connector that is commonly used to secure and connect wires or cables to various devices or components. Screw terminals provide a mechanical means of making electrical connections. They consist of a metal terminal block with a threaded hole and a screw. To make a connection, a wire or cable is inserted into the terminal block, and the screw is tightened down. The exposed wire is then inserted into the terminal block. Screw terminals provide a reliable and secure electrical connection.

V. SIMULATION & HARDWARE RESULT

CATIA offers tools for creating sheet metal parts and designing them for manufacturing. CATIA seamlessly integrates with computer-aided manufacturing (CAM) software, allowing the direct transfer of designs to CNC machines for manufacturing. It incorporates generative design capabilities, which use algorithms to generate and optimize designs based on specified constraints, often resulting in innovative and efficient designs. CATIA is an extensive software suite with various modules and tools, making it suitable for a wide range of industries from aerospace and automotive to consumer goods and industrial equipment. Install the CATIAV5 2023 Version>Setup the Catia file>Create New file.

In CATIA Software, First select the motion study 1 and Click Switch to basic motion. Then go to settings and increase the geometric accuracy and modeling capacity. After that increase the time lapse in motion study table to 8 – 10 sec. Then press / add rotary motor to the four tires in forward direction. Then add Linear motor to the edge of the lawn of the lawnmower and edge of the road to make move. The simulation outputs are shown in Fig 9,10.

Fig 9 Simulation Output - 1

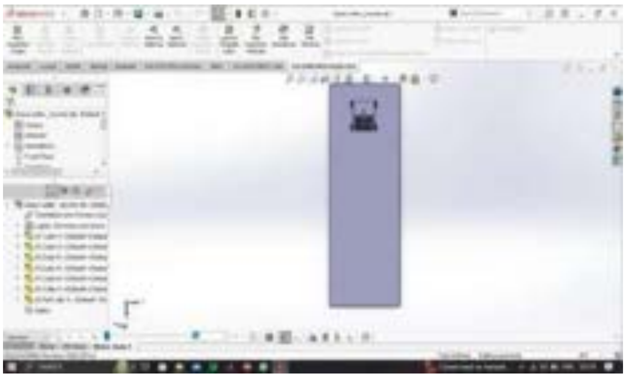

Fig 10 Simulation Output - 2

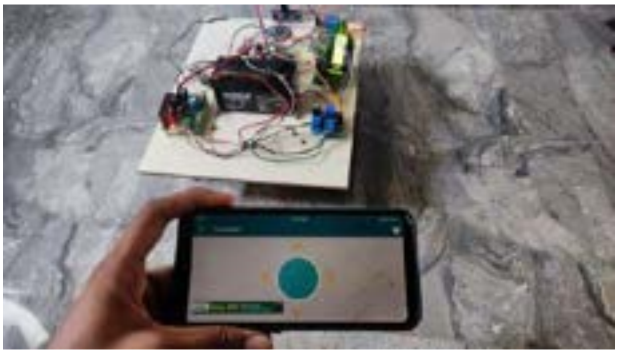

Fig 11 Movement Recognizer

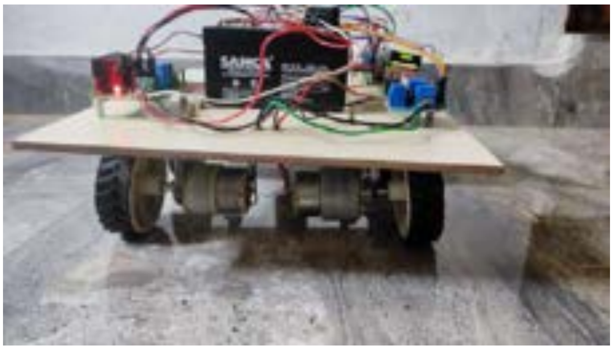

Fig 12 Hardware Output

VI.CONCLUSION

The developed grass cutter uses advanced technology to make landscaping easier. It enables users to operate the mower wirelessly from Gesture-enabled mobile devices, providing convenience and flexibility in directing grass cutting operations. The proposed model streamlines lawn maintenance tasks by automating grass cutting operations and saving time for homeowners and landscaping professionals. Incorporates intelligent obstacle avoidance features to minimize the risk of damage to the mower and surrounding objects, enhancing overall safety during operation. With features like Gesture technology and Bluetooth, users can control the mower from a distance, making lawn more convenient.

***Abstract*—In an era of increasing security concerns and the need for comprehensive surveillance systems, the integration of fencing systems with contact connecting mapping has emerged as a promising solution. This research paper provides an in-depth analysis of the design, implementation, and benefits of a device that integrates fencing systems along with contact connecting mapping technology. This study examines the potential applications of this integration in 2 major sectors: health care and jail asylums providing an in-depth solution for the same. Additionally, the paper discusses the challenges like security threats to other people around them along with their own safety, attempt of escaping to places they shouldn't be and the potential solutions associated with the deployment and maintenance of such integrated systems.**

Keywords—Fencing Systems, Contact Connecting Mapping, Security, Surveillance, Integration, Boundary demarcation, Geo-fencing, GPS (Global Positioning System), GSM (Global System for Mobile Communication) Integration.

I. Introduction

In contemporary society, the imperative for robust security and surveillance systems has grown significantly. Fencing systems, traditionally serving as physical barriers for diverse purposes, have undergone a transformation by integrating advanced technologies to amplify their efficiency. Concurrently, the prominence of contact-connecting mapping has surged, owing to its capacity to furnish real-time, comprehensive mapping of physical spaces.

Traditionally, a fencing system denotes a network of physical barriers or structures designed to enclose or safeguard an area. Its utility spans various objectives, encompassing security provision, boundary demarcation, access control, and privacy enhancement. This term encompasses an array of fence types and associated components, including gates, posts, panels, and assorted security features. In our context, the main objective is to establish a digital boundary using an online application, such as Google Maps, delineating an area beyond which our presence is not intended.

The imperative for implementing such advanced technology is particularly crucial for mentally unstable patients, offering a valuable tool to mitigate the need for physical restraint. Rather than isolating them from society, this technology facilitates their integration while monitoring their movements and preventing access to restricted areas. This approach significantly economizes resources that would otherwise be required for alternative implementation methods.

Similarly, such a system holds potential benefits for jail prisoners transitioning back into society. Even as they approach release, authorities can maintain oversight, ensuring continued monitoring of their activities. This proactive approach helps mitigate potential risks and contributes to a smoother reintegration process into normal society.

The article is structured as follows: Section 2 provides a detailed literature review relevant to this study. Sections 3 and 4 outline the boundary establishment and subject tracking processing stages. Section 5 details experimental tests and discusses results. Section 6 proposes future technological advancements enabled by this work. Finally, Section 7 concludes the paper and offers suggestions for further research.

II. Literature Survey

A GPS GSM-based vehicle tracking system, as discussed in [1], aims to enhance transportation security and safety by combining GPS and GSM technologies to track vehicle location and provide real-time coordinates to users via an Android app. The system proposes a compact design using a development board to reduce size, power loss, and increase durability, inspired by existing anti-theft systems. It also explores related works utilizing vibration sensors, RFID, and ARM processors for vehicle tracking and safety enhancement.

A fortifying perimeter intrusion detection system (PIDS) by analysing fence vibrations, enhancing detection efficacy by scrutinizing sensor positioning and understanding attack profiles is implemented in [2]. In contrast, [3] discusses the implementation of virtual fencing using Radio Frequency modules as a labour-saving solution for managing livestock grazing, improving ecological management and minimizing manual labour. A low-cost fence impact classification system using acoustical vibrations, providing early warnings to property owners and contributing to a comprehensive farm information system is proposed in [4].

Transitioning to public health, [5] introduces an innovative approach to contact tracing during infectious disease outbreaks, offering promising prospects for disease control through automated detection of infection clusters and transmission routes. In [6], vehicle localization methods with novel algorithms for accuracy and robustness are reviewed, while in [7] a target tracking method based on multiple colour histograms, enhancing tracking robustness is introduced. Security and transportation safety needs, emphasizing the on-going policy development for informed prevention strategies are addressed in [8].

Additionally, [11] examines the correlation between weather conditions and electricity consumption for pre-emptive measures against power system overload. The authors in [12] explores dynamic weather-based forecasting methodologies' potential in mitigating energy consumption concerns. A GPS vehicle tracking system's tailored solution for efficient vehicle monitoring, integrating GPS technology with GSM and GPRS networks for real-time tracking and alerts are reviewed in [13].

The authors in [14], introduces innovative uses of GPS and GPRS technology to protect dairy animals, offering affordable solutions for remote monitoring and enhancing rural livelihood sustainability. A pioneering system for enhancing liquid transportation security using GPS and GSM technologies, addressing limitations in existing SMS-based vehicle tracking systems and offering real-time monitoring capabilities is discussed in [15]. A real-time algorithm for perimeter fence intrusion detection using tribo-electric sensors and machine learning techniques, addressing the need for accurate and timely detection is addressed in [16].

Furthermore, a comprehensive study elucidating GPS functionality, essential parameters for accurate tracking, and implementation of real-time position tracking systems, contributing to various applications leveraging GPS technology for enhanced safety and functionality is showed in [17][18].

III. Methodology

This setup involves interfacing an Arduino Uno board serially with both a GSM (Global System for Mobile Communication) modem and a GPS (Global Positioning System) receiver.

Employing a GPS modem, the system remotely tracks the latitude and longitude coordinates of the targeted object or person. Despite the GPS modem's capability to provide various metrics, the system specifically reads and displays only the National Marine Electronics Association (NMEA) data. Subsequently, the extracted position data is transmitted to the designated mobile phone location, where the inquiry about the person's position originated.

To enhance the system's capabilities in managing data effectively, an EEPROM (Electrically Erasable Programmable Read-Only Memory) module is intelligently integrated into the system architecture. This EEPROM is specifically designed to store and retain crucial information received from the GPS receiver. By utilizing the EEPROM, the system ensures that valuable data related to geographic coordinates and other pertinent location-based information are securely stored for future reference and processing. It's worth noting that this project utilizes the GPS multiplexer module GY-NEO6MV2 and the GSM module SIM 800L.

In the hardware setup described, the multiplexer operates by selectively choosing one input signal from multiple available options and then directing this chosen signal to a single output line. This mechanism effectively reduces complexity and facilitates seamless data transmission, ensuring smooth interactions between the microcontroller, GPS receiver, and GSM modem. By employing the multiplexer, the system achieves a unified and efficient interface, allowing the microcontroller to manage both the GPS and GSM modules using a cohesive set of input/output pins. This streamlined approach not only enhances the system's overall performance but also simplifies its design and implementation, contributing to a more robust and functional hardware configuration.

Upon receiving a request from the user, the system promptly delivers the user's position, expressed in latitude and longitude, to the specified mobile device, ensuring real-time location updates. By leveraging an Arduino platform program and integrating it with GPS and GSM technologies, users can not only pinpoint the exact location of the individual but also track their real-time navigation path on platforms like Google Maps, enhancing overall tracking accuracy and user experience. This integration of hardware and software enables seamless location sharing and monitoring capabilities for enhanced situational awareness. Additionally, it empowers users with precise and reliable location information at their fingertips.

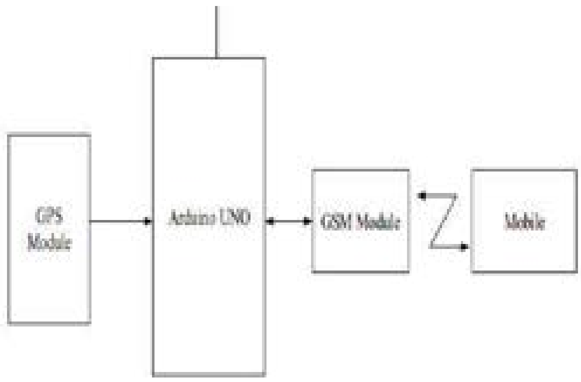

Fig1.Block Diagram of GPS and GSM Based Tracking System.

Fig.1 shows the Block Diagram of the GPS and GSM Based Tracking System, with Arduino UNO serving as the central control mediator. After the user's device initializes with the GSM module, Arduino promptly records and transmits GPS-tracked location data. The software serial then displays the user's latitude and longitude. If the GPS module fails to receive a signal, the GSM module sends a message with default coordinates (00.00). Users should wait for satellite signal reception for accurate tracking. Figure 2 provides the details of the operating procedure in the form of a flowchart

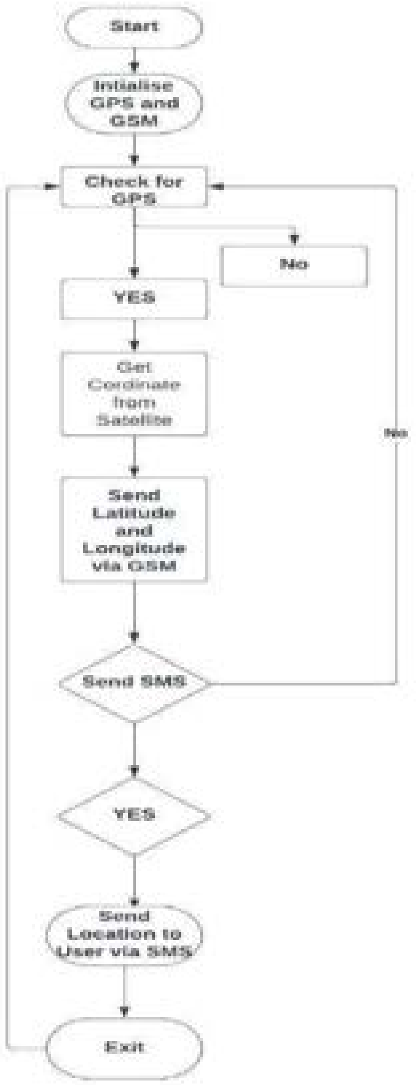

Fig 2. Flowchart of Tracking System.

IV. System Design

A. GSM Module:

In programming the GSM module, the process begins with the inclusion of necessary libraries and by defining the software serial communication. The software serial library facilitates communication on specific pins designated for receiving(Rx) and transmitting (Tx) data. By creating a constructor for software serial and passing the digital pin numbers as parameters, the system establishes a channel for communication between the Arduino board and the GSM module. This step ensures that data can be transmitted and received effectively, enabling the GSM module to interact with the rest of the system. Fig 3. Depicts the prototype of the system.

Moving on to the setup function, the GSM module undergoes initialization through serial communication with the Arduino board. This initialization sequence involves the transmission of various commands to the GSM module, which serve to verify its readiness and configure its operating parameters.

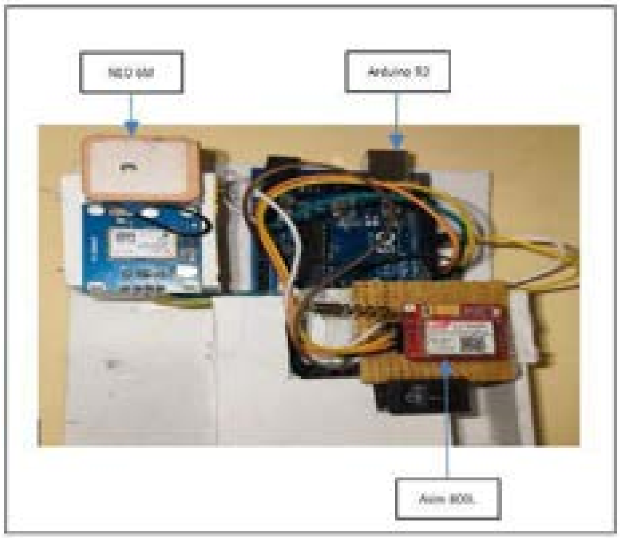

Fig 3. prototype of the system

Moreover, a delay is incorporated into the setup process to allow the GSM module a sufficient time to initialize properly before proceeding with subsequent operations.

As the system progresses into the loop function, the GSM module's functionalities are actively utilized to send SMS alerts under specific conditions. For instance, when the distance between the user's current location and the initial coordinates exceeds a predetermined threshold, an alert is triggered. This event prompts the activation of a buzzer for audible notification and initiates the sending of an SMS alert through the GSM module to a predefined phone number. Such alerts are instrumental in notifying users of critical events or conditions in real-time, enhancing the system's overall utility and effectiveness.

The specified function encapsulates the process of dispatching SMS alerts through the GSM module. It begins by configuring the GSM module for SMS text mode and specifying the recipient's phone number using AT commands. Subsequently, the actual alert message is transmitted to the designated phone number. This streamlined process ensures that timely notifications are conveyed to the user's mobile device, keeping them informed and empowered to respond to relevant events or conditions effectively.

B. GPS Module:

In programming for the GPS module, simplicity is prioritized to ensure ease of understanding for observers. The code begins by including necessary libraries and defining software serial communication. Software Serial Library (SSL) facilitates communication on specified pins, ensuring seamless interaction with the GPS module.

Within the setup function, the GPS module's initialization is declared on the transmission (Tx) and reception (Rx) pins. Serial communication is established using the necessary function, setting up the necessary parameters for data exchange.

The GPS module's operation involves reading input from the designated pin and triggering output accordingly using the looping function. Additionally, the system ccontinuously checks for updates in the GPS module's location. This ensures that the system accurately tracks the user's movements as they navigate different locations.

Overall, the programming approach for the GPS module prioritizes clarity and simplicity, ensuring that observers can easily comprehend the code structure and functionality. Through the inclusion of essential libraries and the utilization of software serial communication, the system effectively interfaces with the GPS module to provide accurate location tracking and updates in real-time.

V. Results and discussion

The integration of fencing systems with contact connecting mapping technology introduces a paradigm shift in security measures by transcending traditional physical barriers. Beyond its applications in healthcare and correctional facilities, this fusion of technologies holds promise in reshaping urban planning and public safety protocols. Imagine a city where digitally delineated boundaries dynamically adjust based on real-time data, optimizing traffic flow, and enhancing emergency response systems. This integration could redefine public spaces, ensuring efficient crowd management during events or emergencies while maintaining a seamless urban landscape.

The research explores the fusion of GPS and GSM technologies beyond object tracking, envisioning their role in disaster management. This system, in disaster-prone areas, could swiftly coordinate rescue operations, facilitating real-time tracking for efficient aid distribution. Beyond surveillance, this fusion holds potential as a cornerstone in mitigating natural disasters, bolstering preparedness and saving lives.

GPS module provides precise geographic coordinates of the object being tracked with an accuracy of 2.5m, while the GSM module facilitates real-time transmission of these coordinates to the user's device, ensuring accurate and up-to-date location. The system's reliability is further bolstered by its utilization of Google Maps for geospatial data. This established and widely trusted platform provides a high degree of accuracy in boundary demarcation and path finding, contributing to the system's overall effectiveness.

The practical execution of the experiment unfolds as follows

Step 1: Precisely delineating our boundary on Google Maps to establish our geographic area of interest.

Fig 3. Demarking our boundary

Step 2: Validating our digital map:

Fig 3. Confirmartion of our demarked boundary

Step 3: Upon breaching our predefined geo-fence, real-time alerts are triggered and sent to our designated mobile number via the GSM module. Additionally, accessing the 'Tap to load Preview' feature provides us with precise directions to the objects' current locations.

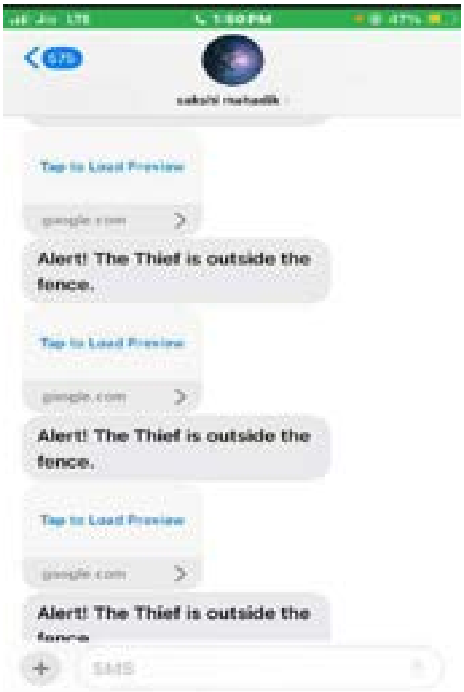

Fig 3. Security breach alerts

To enhance the effectiveness of the system, several key strategies can be implemented. Firstly, reducing the size of components can lead to more compact and efficient designs. For instance, alternatives to bulky components like the Arduino DIP R-3 and GSM module 800L can be explored, which offer similar functionalities but in a more streamlined form factor. This not only saves space but also contributes to improved portability and integration within the overall project.

Secondly, increasing the surveillance distance can significantly enhance the system's coverage and capabilities.

By adjusting the distance parameters within the code based on specific application needs, the system can extend its reach for monitoring and tracking purposes. This flexibility allows for tailored surveillance ranges, whether for large outdoor areas or confined indoor spaces, ensuring comprehensive monitoring and response capabilities.

Additionally, incorporating vibratory sensors into the system adds an extra layer of security and awareness. These sensors can detect if the device is being forcefully removed or tampered with, providing valuable feedback and triggering appropriate actions or alerts. By integrating vibratory sensors, the system gains enhanced resilience against unauthorized interference or attempts to disable the tracking functionality, thereby bolstering overall security measures and system reliability.

Table 1 below provides a comparison between the technologies of the past and now, summarizing the various aspects of all fencing techniques.

Features	**Virtual fencing using GPS**	**Fencing systems along with contact connecting mapping technology**
Flexibility	Less flexible	More flexible
Maintenance	High	low
Cost	Expensive	Cheaper
Safety	Less accident prone	Least accident prone

VI. Conclusion

In the ever-evolving landscape of security and surveillance systems, the fusion of fencing technology with contact connecting mapping emerges as a transformative solution. This integration, explored within healthcare and correctional facilities, extends its potential beyond traditional boundaries. Envisioned as a cornerstone in urban planning, disaster management, and public safety protocols, this fusion promises adaptive security and real-time response mechanisms. Beyond its current applications, future advancements in AI-driven boundaries and augmented reality overlays could revolutionize security paradigms, offering proactive and dynamic safeguards across diverse domains.

Abstract: **Vehicular Ad Hoc Networks (VANETs) represent a rapidly expanding domain within wireless communication, crucial for establishing dependable and secure transportation systems. In VANETs, each vehicle functions as a node, facilitating communication with other nodes and base stations along its route. Operating akin to intelligent mobile nodes, vehicles in VANETs interact with neighboring vehicles and nodes to ensure seamless communication. Moreover, users of VANETs benefit from access to the Intelligent Transportation System (ITS), which enhances operational efficiency. This study focuses on integrating the K-means clustering and Multivariate Quadratic Quasigroups (MvQQ) algorithm within the VANET framework, serving as an asymmetric encryption method. The selection procedures for Personal Best (pbest) and Global Best (gbest) are guided by these groupings, reflecting a comprehensive review of existing methodologies in VANET research.**

***Keywords**: VANETs, K-mean clustering, ITS, MvQQ.*

I. Introduction

The Vehicular Ad-Hoc Network (VANET) is a wireless architecture created by cars connecting with one another. VANETs use well-known automobiles as nodes to form a mobile architecture, are generating creative concepts. In VANET, communication between nodes and Roadside Units (RSUs) is reallocated. It continues as a client-server relationship. To avoid mishaps and guarantee a secure and satisfying journey, inter node communication is required. By using sensors, cars may interact with their destination even when they are not linked to the network. When at least a few nodes or Intelligent Transportation System (ITS) stations connect in the radio communication band, an Ad-Hoc network is formed. This indicates that all stations have mastered the art of supplying alternate data and are aware of the position, velocity, and direction of other stations. Specifically, it develops the three core elements of the architecture: the Roadside Unit (RSU), the Onboard Unit (OBU), and the WAVE (Wireless Access in Vehicular Environment) interface. A VANET's primary goal is to give highway users security. In order to minimize accidents and promote safe and effective fleet transportation, inter-node communication is essential. The sensors located in the cars play a crucial part in the cars' capacity to communicate with each other regarding the destination, where the communication takes place between server and client.

One special quality of a VANET is that because its nodes are so mobile, it can quickly create a secure network. In the paper, we employ a Multivariate Quadratic Quasigroup (MVQQ), an asymmetric encryption technique. Certificate manufacturing and distribution, certificate management and revocation, user authentication, and certificate maintenance are some of the other impacts it provides. Our suggestion is a protocol that uses a hierarchical pseudonymous structure to provide partial anonymity while authenticating a node while it is communicating with other nodes in the network.

II. Interdependent Work

Security in VANETs is frequently considered by certain researchers, but the majority of them may not be supplied with data concerning the operation or evaluation of symmetrical or asymmetric algorithms that are operating in a real-world vehicular network. As a result, we believe that this work is valuable it shows a processing speed of the MVQQ under various VANET conditions. Term was to boost neighbourhood safety via using readily available doppler as discovering associates as well as confirming reported GPS positions. There exploited an existing region, that relies upon cells, and created the system of communications. I describe analysis abilities with anonymous identification. Several other anonymous network principles have been deployed using assistance by OKI. The approaches rely on OKI-based Certifications, that have an emotive linked to similar secret key. Distribute a greater Amount to identities across links with similar secret key. A plan assumes the unavoidable use about RsU's, which increases the framework load, and as a result, the framework's general everyday practice progresses. The Certificate issuing authority provides a first name, which allows for coordination among the initial pseudonyms and the node's true identification. The initial Every credential stored within the CDA (Certificate Distribution Authority) system is protected via another item known to be Revocation Distribution Authority (RDA), so CDA cannot decode those genuine identifications. At that moment, a node transmits the communication, which is signed with the alternative moniker's linked private key, and the receiving node validates the messages which corresponding open key provided in the alternative name. Then examining a paper, i deduce an increasing limitation. Taking a pseudonymous approach leads to significant results, computing, Communication with capacity capabilities due to an existence CRL (Certification Revocation Lists). This study has analyzed an asymmetrical (MVQQ algorithm) to see whether it was real. This suitable car transmissions arrangement expects Vehicle to Vehicle (V to V) & Vehicle to Infrastructure (V to I) interactions that provide protection to prevent crashes and congestion. Furthermore, 3 basic encryption approaches are investigated: public keys, symmetrical keys, Personality-based encryption is employed to protect the service. Proposed alternative clusters structure for high speeds across VANET nodes with security methods make transfer more efficient.

III. Clustering Head Algorithms (K-means)

This study employs a K-mean clustering head method for split networks through k sections. It is well known that selecting Most excellent vertices among an enormous amount during links is challenging, particularly for the value k.

K-means clustering divides n sensations in k clusters, resulting in every perception belonging to the particular cluster with the highest imply that which serves as as the cluster's prototype.

The personal-best location (pbest): The personal best is the one that has been uniquely determined with particular molecules based on prior estimations of xi. During an optimization

$$p^{(t+1)}_{bestid} = \{X^{(t)}_{id}\ if\ f(X^{(t+1)}_{id}) \geq f\left(p^{(t)}_{bestid}\right)$$

$$p^{(t+1)}_{bestid} = \{X^{(t+1)}_{id}\ if\ f(X^{(t+1)}_{id}) < f(p^{(t)}_{bestid})$$

task, the state having the smallest potential values appears to be healthy. The letter f(X) represents the desired benefit which has been limited.

The Global Best (gbest): A gbest gives a faster rate for This Collaboration sacrifices authority. The gbest regulates a certain smallest setup, called by the term global-best particle, throughout every single structure within the grouping, by final form, every one of particulates going to arrive with that point, and therefore if they don't get condensed on an ongoing basis, the team might arrive prematurely.

IV. Safety in the VANET

Recent study indicates that asymmetric encryption techniques should be utilized in embedded systems, as stressed According to which explored asymmetrical encryption methods having extra safety objectives, RSAs having the key capacity is 3076 bits and ECCs having 512 bits have been used into embedded devices.

(i) Asymmetrical Algorithm

MVQQ Algorithm (Multivariate Quadratic Quasigroup):

Previously, safety posed by encryption techniques was dependent on two mathematically independent numerical problems: computing the viability of the different logarithms measure and factoring integers. An alternative open-key strategy named Multivariate Quadratic Quasigroups (MVQQ) was developed. As the Quasigroups change, the procedure depends with Quadratic Multivariate polynomials and retains the associated features.

Step 1: MVQQ represents the system that operates outside the quantum.

Step 2: The security approach has similarities by previous public keys encoded procedures impacted by Multivariate Quadrics.

Step 3: The quickness about decoding seems quite similar using a usual symmetrical blocks authentication approach.

Step 4: This algorithm is strongly parallelized, unlike other progressive algorithms.

The standard MVQQ structure is a multivariate quadric system.

Two non-singular linear transformations, A and C, plus a pair of multivariate quadratic alignments over {0, 1} n is represented by B'. Encryption using an open key is a quick process for using n multivariate polynomials.

$B = \{B_i(s_1 \ldots\ldots s_n) \mid i = 1, \ldots, n\}$ That is, r = B(s) over the vector, so s = (s1..........sn).

What can be described as,

An equipment testing show that MVQQ is formed from a median Symmetrical blocks encrypting. Testing is using the sensing architecture shows the MVQQ was extremely quicker then techniques including like ECC & RSA.

$$r = B(s) \equiv y \equiv DZ$$

All of this confirmed a resolution when conducting initiatives; they discovered providing electronic certificate formed using MVQQ could be between 300 to 70000 percent faster than ECC and RSA certificates. With each case, MVQQ have an option surpass about 10,000 times. Furthermore, indicates MVQQ method gives someone else avenue of encryption. industry; this generates unique open-key encryption systems in addition to improving those that already exist. The terms processor utilization, storage spaces and

$$A \circ B \circ C: \{0, 1\}^n \rightarrow \{0, 1\}^n$$

setup time are used in relation to each other. The results indicated MVQQ provides excellent way to approach embedded technology due to its matches both RSA & ECC.

Creating public & secret key to use algorithm of MVQQ:

Input: an integer r, where l>28 and r=5l.

Output: Start key O: p Multivariate Quadratic Polynomials Oi (y1,...,yn), i=1,...,n,

Secret Key: The two nonsingular binary matrices of rank m * m and eight quasigroups $^*1, \ldots, {}^*8$.

1. Generate two non-singular p * p Binary matrices, S and U, at

random.

2. Use the following for defining O' (p): $\{0,1\}^p$ $\{0,1\}^p$. You will also get the quasigroups *1,…,*8 from there.

3. Figure In which y=(y1,...,yn), x=S(O'(U(y)))

4. The output shows that the private secret is an order pair (S,U,*1,….,*8) & a public key is x with Multivariate Quadratic polynomials Oi(y1,…yn), i=1,….n.

V. Proposed Authentication Protocol

Notation	Explanation
V_i	Initiator/Sender vehicle
V_v	Receiver vehicle
VID_i	Initiator's/Sender's vehicle ID
IK_i, AK_i, IK_i', AK_i', IK_i'', AK_i''	MVQQ open/private key pairs of V_i
IK_{CDA}, AK_{CDA}	MVQQ open/private key pairs of CDA
IK_{CAP}	Paillier open key pair of CDA
IK_{RsU}/ AK_{RsU}	MVQQ open/private key pairs of RsU
T_{CDA}, T_{CDA}'	Expiration time of initial pseudonym set by CDA
T_{RsU}	Expiration time of alternate pseudonym set by RsU

Vehicle registration and first pseudonym creation

During the moment, sender/initiator nodes (V_i) create an arbitrary value k (That erratic value is encapsulated with CDA's public keys) & public/private key MVQQ pairs.

IK_i, AK_i

V_i transmits this info along with the VID_i to CDA.

Step 1: V_i → CDA: k||IK_i|| VID_i

A Vi transmit this information to a CDA over a secure channel (for example, nodes contact a CDA).

The first step is required one time only. The Certificate of Distribution Authority authorizes the VID_i. As verified, it encrypts VID_i with one open key generated by RDA, encrypting k using the Paillier public keys IK_{CAP}, generates an end date T_{CDA} and constructs the subsequent database access.

An instance of a CDA databases:

CDA → DB: $(VID_i)_{PKRDA}$|| T_{CDA}||IK_i||k

CDA signs (T_{CDA}||IK_i||$(k)_{IKCAP}$), and attach it into V_i as its first initial pseudonym.

Step 2: CDA → V_i: (T_{CDA}||IK_i||$(k)_{IKCAP}$) AK_{CDA}

Restore the original pseudonym

After the T_{CDA} leaves, V_i needs to regain the original pseudonym. V_i produces an open/private MVQQ pair of keys by randomly choosing some k'.

IK_I''/ AK_I''

Encrypts the information in open key of CDA alongside *k* and deliver it to CDA by utilizing 3G/4G technology.

Step 3: V_i → CDA: (k||k'||IK_i'') IK_{CDA}

if a node wants to send back a prior identity on CDA via RsUs, the information is transmitted to any locally RsUs, whose forward the request to the CDA. On demand, some distinct cause values in the communication are used, allowing the RsUs to determine if the node is requesting an original pseudonym from the RsUs nor a recent alternative moniker.

Step 3': V_i → RsU CDA: (k||k'||IK_i'') IK_{CDA}

CDA certifies the information using optimal k, creates an additional terminal time T', and modernizes the DB using distinct k' metrics, IK_i and I_{CDA}, CDA measures the second phase encrypting the freshly created first name into IK'' before sending that via V. If the request originates through RsUs, CDA will send this communication to Vi via RsUs, along with the signed k. The signed number k creates a corporation that carries the sophisticated values k'. If RsU promotes this text, V_i will examine it with aged k, verify CDA's signature, decrypt it, and alter its original pseudonym. Due to data encryption, RsUs are unable to reveal the sophisticated first identification to the Vi.

Step 4: CDA → V_i: ((T_{CDA}||IK_i'||(k)IK_{CAP}) AK_{CDA}) IK_i''||(k) AK_{CDA}

Forming alternate pseudonyms

RsU sometimes conveys information while stating the level of quality. It also contains the public value of the RsUs. If a node receives this notification, it requests an alternative pseudonym.

A node generates additional open/private MVQQ key pairs (IK', AK'). This encrypts and sends the just formed public key, initial pseudonym (−k), and nonce to the RsUs.

Step 5: V_i → RsU: ((T_{CDA}||IK_i||(k)IK_{CAP}) AK_{CDA} || IK_i'|| - k||nonce) IK_{RsU}.

RsUs examine CDA brand and encrypts −k with CDA's public keys.

RsUs for storing same combos (k) IK_{CAP} and (−k) IK_{CAP} will get (S) IK_{CAP}.

RsUs submit (S) IK_{CAP} to CDA over authentication, with (S), which is IK_{CAP} = (k) IK_{CAP} + (−k) IK_{CAP}.

Step 6: RsUs → CDA: (S) IK_{CAP}

CDA decrypting S, catches O (k + (−k) = 0), and sends a verified notification to RDA if it cannot be delivered.

Step 7: CDA → RsU's: verified or not verifiable. CDA gets the secret data and has no notion which node is using this information. −k is used to prevent a harsh assault.

RsU's set up an additional identity after obtaining confirmation that the transmission originated from V_i. It creates the end of time TRsU, puts it into the freshly produced IK'$_i$, & transmits it to V_i. The IK'$_i$ must be supplied by V_i whenever another pseudonym is requested. In any circumstance, a node may re-register in an MVQQ key value lake.

Step 8: RsU → V_i: ((T_{RsU}||IK_i) AK_{RsU}) IK_i'.

VI. Working of Proposed Architecture

In the protocol that is suggested, a user node must communicate with another node before sending messages to registered nodes via Roadside Unit & K-means Clustering. We offer the best nodes that can supply both decoding and encoding keys to the environment's nodes using the MvQQ method. To obtain an initial pseudonym through the (RsU), the customer node must communicate to a different node via K-means clusters Head & enroll to the Certificates Distribution Authority. We also give the MVQQ secret and public secret method. These periods are identified in our standard as TCA, and they correspond to the season of the first pseudonym generation as determined by CDA. The desired protocols are the following to be discussed.

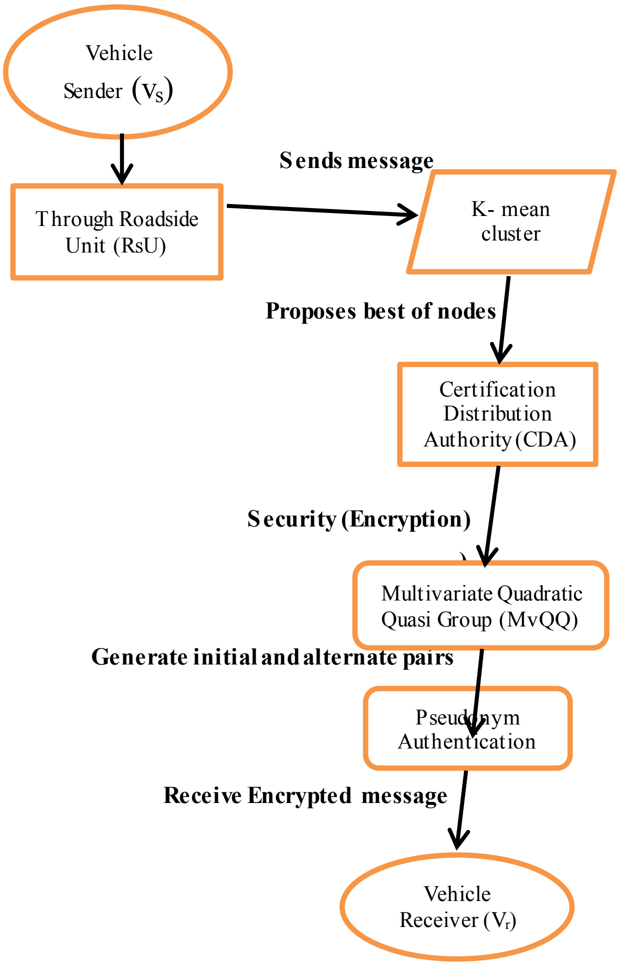

Fig 1: A flow diagram of the proposed approach

VII. Performance Assessment

In this paper, we propose and include the K-mean clustering head and MVQQ algorithms. At that moment, formation was created, allowing us to test algorithm implementation in a VANET and then examine the results. In this underlying circumstance, nodes are located in a region with a distance of less than 100m. The nodes in this instance are inside the system's treatment discipline, and nothing has been disposed of. In an example of ten nodes, node "0" delivers a message to alternate nodes in the system. A In our simulations, this action happens after 0.4 m. So, we provide MVQQ's productivity built on what was tried (tested) in various papers, but in various VANET network contexts. In comparison to the others, the MVQQ algorithm contains the key length of 160 particles. Fig4 Illustrates a growing arc with the quantity the data flowing in the VANET increases. Here, we assess our proposed protocol's deployment to valuable aspects. Viewpoints will evaluate the execution of RsUs if the node asks for a different pseudonym from the RsUs after providing an initial pseudonym. If the RsUs verify that the very first alias basically contains the request, they then generate and send the alternative pseudonym to the node. As an outcome, the RsUs can basically determine if they are able to do this duty for the nodes on an ongoing basis.

Packet Delivery Ratio:

A process of delivery has been calculated for dividing how many concerning traffic successfully inserted with the entire number of particles received. PDR has been described by the entire quantity of frames transmitted from start to finish. If the network's share is increased in any way, using this process would also enhance network support. The PDR equation is:

PDR = (RCV/SND)*100

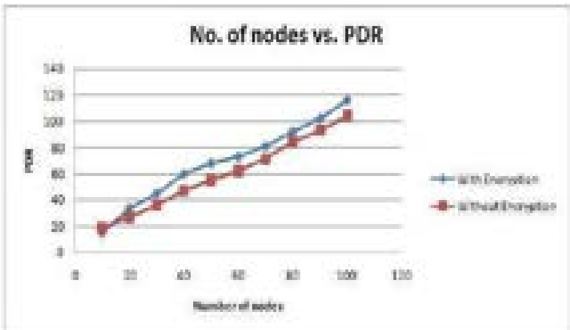

Fig 2: PDR with relation to nodes via MvQQ encoding

The blue points in the previous image represent the suggested route, while the bright red line represents the current approach. The distinction effectively states that the new system may surpass the present approach.

Throughput:

As much data units a system can handle in a given amount of time is measured by its throughput. Throughput is defined as the amount of information that flows from one station to another. Each second, bits are swapped starting from one location and moving to another. With the occasion that the rate of traffic is high, transmission of data ability. Notice the following formula for throughput:

Throughput = bit/second.

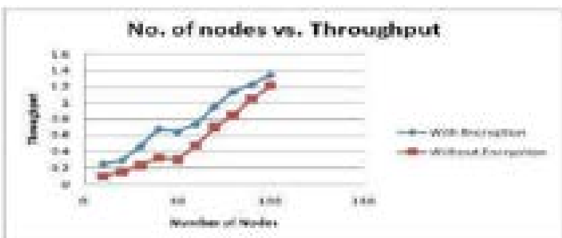

Fig 3: Throughput against speeds between node’s

End to end delay:

End to end delay is critical for determine an impact for encrypting expense upon End-to-end latency when car & speed measurements increase.

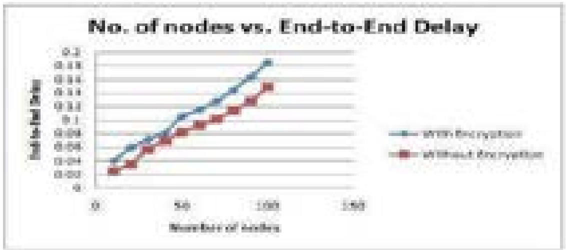

Fig 4: End-to-end delay based on the velocity among the nodes

The encrypted numbers showed that the suggested approach was increased in the graph above. Whereas the non-encryption approach indicates that the suggested work is more effective than the present method.

Packets over head: A period that's required for conveying info through packet switched network. Each frame necessitates additional bytes inside arrangement facts, that stays into packets headers then, while applied to packets creation & disassembling, decreases an entire communication time of plain text.

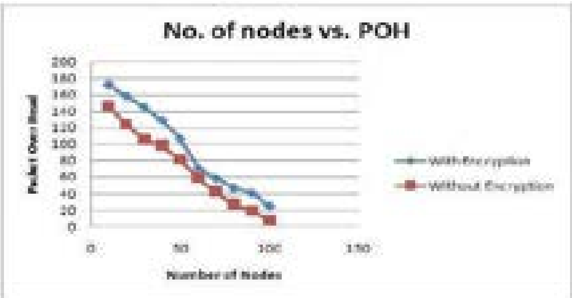

Fig 5: Packet Over Head in terms of frequency between nodes

The graph depicts a packet overhead layout comparing the present and suggested approaches. The suggested approach takes more in the extra process than the basic technique.

VIII. Conclusion

Vehicular ad hoc networks (VANETs) introduce a multitude of security concerns, with current research predominantly focusing on addressing these issues. The proposed protocol undergoes rigorous security analysis, revealing its adaptability to various security threats. Tracking a node within the network proves challenging unless prompted by a deliberate or malicious act. However, in rare instances of nefarious behavior detection, the perpetrator is promptly identified and barred from network access. The strategic deployment of Roadside Units (RSU) at high intervals aims to counteract pseudonym expiration, ensuring sustained network security. This study represents an extension of our prior work, addressing prominent challenges in pseudonymous verification through comprehensive, point-by-point analysis and thorough simulation-based evaluations.

,

***Abstract*—Many sectors, including healthcare, education, agriculture, and industries, depend heavily on Machine Learning (ML) algorithms. Predicting cardiovascular disease is one of the world's biggest challenges. Many people may die as a result of coronary artery disease. Enormous research work is being carried out to identify the factors that could predict the development of cardiovascular disease. Heart disease prediction is currently being effectively resolved by utilizing techniques of Artificial Intelligence (AI) including machine learning algorithms and deep learning. This research study has implemented several AI-based classification algorithms such as Support Vector Machine, Random Forest, Logistic Regression, Decision Tree, and K-Nearest Neighbours (KNN) for the prediction of heart disease. Finally, this study employs performance indicators including the confusion matrix, accuracy score, F1-score, recall, precision, sensitivity, and specificity to analyze the model's effectiveness and performance. It is inferred from the experimental results that the highest classification accuracy of 91% is achieved for the Random Forest Classifier when compared to other machine learning algorithms on heart disease dataset.**

Keywords—*Cardiovascular Disease Prediction, Artificial Intelligence, Classification.*

I. INTRODUCTION

As per the World Health Organization Statistics, cardiovascular diseases affect the survival of 12 million individuals annually. Due to its status as the leading cause of death, heart disease may contribute to global morbidity and death rates. One crucial component of data analysis is the prediction of coronary heart disease. Because people can die from it without experiencing any serious symptoms, it results in sudden deaths without giving a chance for any precautionary remedial measure. Using Artificial Intelligence techniques, the prediction of cardiovascular disease is resolved. Artificial Intelligence (AI) is rapidly becoming an inevitable tool in healthcare applications such as computer-aided diagnosis of diseases from different image modalities like CT scan, MRI, etc., and for disease prediction and analysis from huge volumes of patients' records. The challenges associated with the prediction of cardiovascular diseases are that the conventional methods are not able to predict the diseases at an early stage and also they consume much time. This paper proposes to predict heart disease by evaluating the patient data & determine the model by using the AI techniques. The proposed algorithm will predict whether the suspicious patients are afflicted by heart disease or not using machine learning techniques.

II. LITERATURE SURVEY

Cardiac ailments are presently the leading cause of death globally, and their prevalence is rising. As per statistics from the World Health Organization (WHO), deaths due to heart diseases are nearly 31% of global deaths, and hence prediction of diseases occurring in the heart in an early stage has become mandatory for the betterment of society. The great challenge in heart disease detection in the current scenario is to identify the disease at an early stage based on the symptoms. Identifying heart disease in its early stages before a cardiac incident presents difficulties. The medical field, including clinics, hospitals, etc., has access to a vast amount of data regarding cardiac disease. The worldwide standard medical datasets and records of patients available are increasing day by day both concerning the number of characteristics and the number of available records. But this data isn't managed sensibly enough to reveal any underlying patterns. The medical data can be transformed into knowledge that is helpful by using machine learning algorithms. Decision support systems (DSS) with the capacity to gain knowledge from and improve upon past experiences are created through the application of machine learning. Classification in machine learning refers to labeling the input data and in the case of heart disease prediction, it refers to labeling the input data as a patient affected by heart disease or not. First, the machine learning model is trained on the input data with known labels and feature learning is done. Once the model is trained, it can classify any unknown data. Academics and industry alike have recently become interested in deep learning [1]. It is crucial to correctly diagnose heart diseases while incorrect diagnosis will result in loss of human lives. The Machine Learning algorithms of Support Vector Machine and Logistic Regression (LR) algorithms were employed for heart disease prediction and the dataset used was the UCI machine learning dataset to evaluate the method. The dataset comprises of 13 different characteristics for investigation and the results proved that the logistic regression algorithm gave higher accuracy compared to the Support vector machine (SVM) algorithm for prediction of coronary disease. Feature extraction technique was employed to remove the irrelevant features and only significant features were selected to anticipate the risks associated with heart disease [2]. While using a machine learning model for classification, one of the methods to enhance the classification accuracy is to optimize the parameters of the machine learning model during the training process which is called hyper-parameter tuning. The hyper-parameters that are optimized include learning rate and step size whose values are selected based on permutation and combination of different values. It was observed that there is an enhancement in classification accuracy due to hyperparameter tuning [3]. Different machine learning techniques including, the Bayesian classifier, Decision tree (DT), Random Forest classifier, and others were employed were applied to predict heart disease using electrocardiography signals and other risk factors. From the comparative analysis of the different models, the best models were selected and generalized for predicting heart disease

[4]. Detection and diagnosis of ischemic heart diseases was implemented using Machine learning algorithms. The problems associated with Ischemic heart disease data sets are the selection of features, imbalance in the sample size, and data unavailability for certain characteristics, etc., The outcome of the proposed method was an improvement in selecting significant features thereby reducing the dimensionality and also improving accuracy. The optimization technique employed was an enhanced squirrel search algorithm with meta-heuristic procedure which resulted in an enhanced classification accuracy of 98% [5]. Different AI techniques of Random Forest, Linear Discriminant Analysis, Gradient Boosting (GB) Algorithm, Decision Tree, and others were employed to predict cardiovascular disease where cross-validation technique with K-Fold was used. The different datasets such as Cleveland, Hungary, and Long Beach VA were used to assess the models' performance, and accuracy values of 99.40%, 99.76%, and 100% were obtained [6]. Four different methodologies comprising LR, KNN, SVM, and GB Algorithms were utilized to predict cardiac disease from the datasets of Hungary, Switzerland, Cleveland, UCI Kaggle, and Long Beach VA. The experimental results obtained proved that the maximum accuracy of 99.03% was achieved for the Extreme GB Classifier with GridSearchCV [7]. In developing countries, cardiac specialists will not be available in rural areas and hence an automatic diagnosis system plays a significant role in heart disease diagnosis at an early stage based on the symptoms. A hybrid diagnosis system based on the examination parameters and vital signs of the patients was implemented for timely heart disease prediction. To handle the missing values, the method of multivariate imputation was used. Recursive feature elimination along with a genetic algorithm was used for selecting salient features from the dataset. The method was tested on the dataset of UCI Cleveland heart disease dataset [8]. An automated diagnosis system of healthcare to detect diseases of the heart was proposed using an Artificial Neural Network with Swarm Optimization. A specified quantity of neural networks was randomly generated to train and test the data in consistency with the solution [9]. The problems associated with supervised machine learning classification algorithm models are underfitting and overfitting. A hybrid classifier that employed an ensemble model with majority voting practice was proposed which overcame the above problems of ML algorithms. In this method, a genetic algorithm was used for feature selection, 10-fold cross-validation was employed, and enhanced prediction accuracy and execution time were achieved. The dataset used was the UCI Machine Learning Repository [10]. An efficient method to handle Electronic Health Records (EHRs) of patients with heart diseases was proposed in which association rules were used to analyze the patient's medical data distributed in different hospitals [11, 12]. An automated diagnosis system was proposed to diagnose heart diseases in which Spatial grouping of Applications based on density and Noise was employed for the detection and elimination of outliers. The method employed hybrid techniques of Edited Nearest Neighbor along with Synthetic Minority Over-sampling Technique (SMOTE) for a balanced distribution of data and the XGBoost machine learning algorithm was used for the prediction of heart diseases [13]. Another major cause of worldwide deaths is Coronary Heart Disease. According to a survey by WHO, Cardiac arrests account for the majority of the deaths but they could be prevented if the concerned people follow healthy lifestyles. The major risk factors associated with heart disease are elevated cholesterol levels, diabetes, and an increase in blood pressure. These parameters could be continuously monitored and used as parameters to predict heart-related diseases in an early stage and to avoid serious consequences. Several other machine learning models were also implemented to predict heart diseases in an early stage based on various risk factors associated with them [14, 15]. The advantages of these methods are simplicity and easy implementation. The drawbacks are the need for proper feature selection, less performance for categorical values, and data imbalance. As inferred from the literature survey, AI-based techniques are a promising approach for heart disease prediction in an early stage. In this paper, we have proposed and analyzed the performance of five different Machine Learning (ML) models which include RF, SVM, LR, KNN, and DT algorithms. The performance of these ML algorithms is evaluated based on different metrics and the Kaggle dataset is used for the experiments.

III. PROPOSED METHOD

A. Overview

The block diagram of the proposed method is presented in Figure 1.The operation of the system begins with data collection and the selection of important characteristics. Next, the raw data is subjected to a pre-processing step to obtain the data in the required format. The pre-processing steps include corrections for missing values and data imbalance using SMOTE. SMOTE stands for Synthetic Minority Oversampling Technique and it is used to overcome the data imbalance problem. From the input data, the minority samples are taken and new instances are generated by merging the samples of each class with its nearest neighbors. The advantage of the SMOTE technique is that the data in the minority classes are only increased to avoid overfitting problems. The input dataset is split into training & testing data (80:20). Then, machine learning algorithms are applied to train & test the model. Due to this system, enhanced visualization and ease of interpretation are possible. Extensive experiments on the datasets have demonstrated the effectiveness of our method in timely heart disease prediction.

B. Random Forest Algorithm

In the Random Forest Algorithm, multiple classifiers are combined which is called ensemble learning through which the performance is enhanced. It is a supervised learning technique in which during the training phase, the model is trained using known labels. The tree is split into nodes and each node available in the tree is predicted. Both classification and Regression tasks can be solved using the Random Forest algorithm. From a given dataset, samples are selected randomly. A decision tree is constructed for individual samples and a prediction result is obtained. For each predicted result, voting is performed and the prediction result with majority votes is nominated for ultimate prediction. The advantages of the Random Forest algorithm are that they are capable of handling large datasets and high dimensional data.

C. Support Vector Machine

Support Vector Machine (SVM) is another supervised technique in which the data points are separated into classes using a decision boundary. The new data will be then categorized correctly based on this decision boundary which is called a hyperplane. The points that lie close to the hyperplane are called support vectors and the location and direction of the hyperplane are decided by them. The gap between two lines which separate the different classes is called margin and it is necessary to have a large margin. The merits of the Support Vector Machine classifier are that it is memory efficient and well suited for higher dimensions applications.

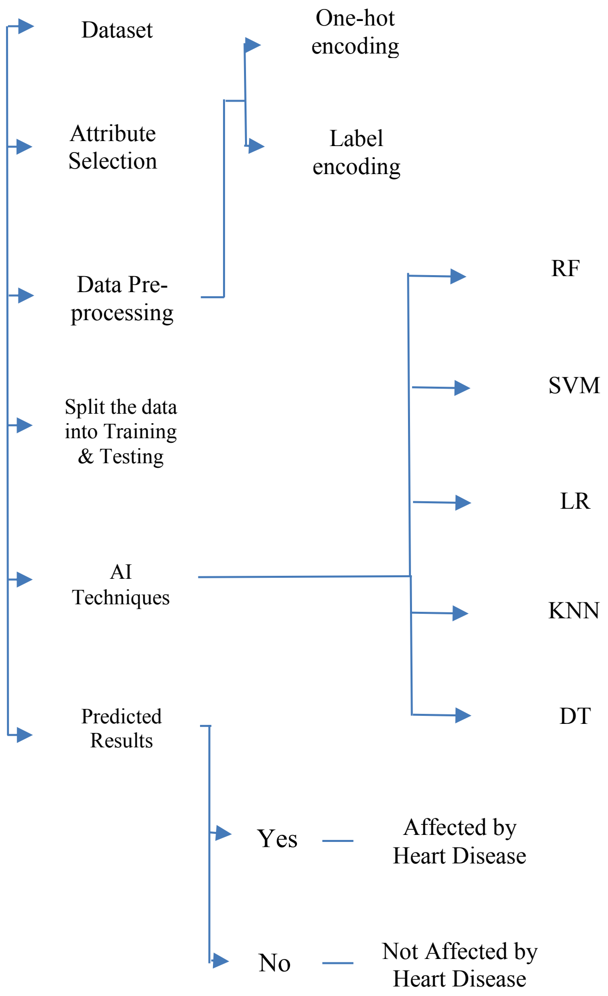

Fig. 1 Block Diagram of the proposed method

D. Logistic Regression

Logistic regression is one of the supervised learning algorithms and it is used to estimate the probability of whether an event will be occurring or not. Based on past observation, the outcome of the dependent variable will be predicted and it is used for classification tasks. In the method of logistic regression, the sigmoid function is used to find out the probabilities from the predicted values whose values lie in the range of [0 1]. The expression for the sigmoid function is given in Equation 1.

$$\delta(x) = \frac{1}{1+e^{-x}} \tag{1}$$

Where δ is the sigmoid function and x is the input variable.

The advantages of the logistic regression algorithm are that it is easier in computation and well suited for applications where the data are linearly separable.

E. K-Nearest Neighbours Algorithm

In the KNN algorithm, all the data points are stored and new data are classified according to the similarity between the new information and the available information. First, K neighbors are selected and then the Euclidean distance of the K neighbors is estimated. New data points are assigned to a class based on the distance between the new data point and the available data points. The advantages of the KNN algorithm are that it is robust to noise and simple to implement.

F. Decision Tree Algorithm

DT algorithm is well suited for regression and classification tasks which comprises two nodes called decision node and leaf node. Multiple branches exist in decision nodes and they are involved in making decisions, whose output is the leaf nodes. The leaf nodes do not contain any further branches and they are called the end nodes. CART algorithm which is the acronym for Classification and Regression Trees is used to build the decision tree. Both linear and non-linear problems can be solved using the Decision Tree algorithm. To build a tree, we use the CART Algorithm and it works on both linear & non-linear problems. The tree is built starting with a root node containing the entire data S. Based on the attributes, the dataset S is divided into subsets. New decision trees are constructed recursively using the subsets of the dataset. The process is continued till the nodes cannot be further classified and the leaf nodes are reached. The advantages of the Decision Tree algorithm are that decision-related problems can be solved easily and are simple to implement.

IV. RESULTS & DISCUSSION

A. Dataset Description

To evaluate the proposed method, the Kaggle heart disease dataset is used which consists of records of 320 patients. The training and testing data are selected in the ratio of 80:20 so that 256 data are used for training and 64 data are used for testing. The number of features available in the dataset is 13 which include age, sex, chest pain type, resting blood pressure, cholesterol, fasting blood sugar level, resting electrocardiographic results, maximum heart rate achieved during the stress test, exercised-induced angina, ST depression, Slope of the peak exercise ST segment, number of major vessels colored by fluoroscopy, thallium stress test result, and heart disease status.

B. Performance Metrics

The performance metrics used to evaluate the Machine Learning algorithms are Accuracy, Sensitivity, and Specificity which are given by equations 2, 3, and 4 respectively.

$$Accuracy = \frac{TP+TN}{TP+FP+TN+FN} \tag{2}$$

$$Sensitivity = \frac{TP}{TP+FN} \tag{3}$$

$$Specificity = \frac{TN}{TN+FP} \tag{4}$$

TP stands for True Positive i.e. positive classes correctly categorized as positive, TN stands for True Negative i.e. negative classes correctly categorized as negative, FP stands for False Positive i.e. negative classes that are falsely categorized as positive and FN stands for False Negative i.e. positive classes falsely categorized as negative. Specificity is the ratio of True Negative to all negative results. Sensitivity is the ratio of True Positive to true positive plus false negative. Accuracy is the ratio of correct predictions to all the results.

Table 1. Confusion Matrix values obtained for different ML algorithms

ML Algorithm	TP	FP	FN	TN
Random Forest	23	4	2	35
Support Vector Machine	22	5	3	34
Logistic Regression	21	6	4	33
K-Nearest Neighbors	21	6	5	32
Decision Tree Classifier	20	7	6	31

Table 2. Performance Metrics for different ML algorithms

ML Algorithm	Accuracy	Sensitivity	Specificity
Random Forest	**0.91**	**0.91**	**0.92**
Support Vector Machine	0.87	0.87	0.88
Logistic Regression	0.84	0.85	0.84
K-Nearest Neighbors	0.83	0.84	0.81
Decision Tree Classifier	0.80	0.81	0.77
Linear Regression Classifier [16]	0.78	0.79	0.76

Fig. 2 Confusion Matrices output for different algorithms

(a) RF (b) SVM (c) LR (d) KNN (e) DT

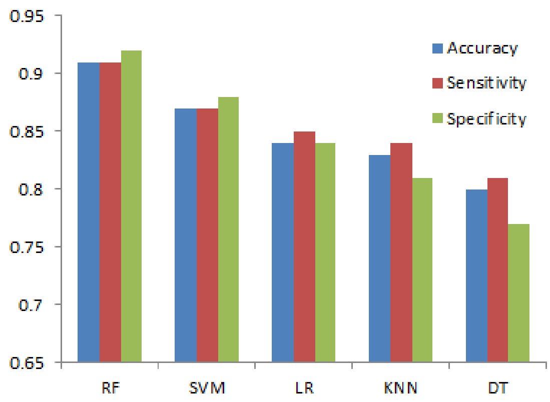

Fig. 3 Plot of Performance Metrics for different ML algorithms

C. Results

The confusion matrix values obtained for the different algorithms are shown in Table 1. The experimental results in terms of accuracy, sensitivity, and specificity are given in Table 2. The confusion matrix plot for the Random Forest Classifier on the test dataset is shown in Figure 2. The plot of the values of Accuracy, Sensitivity, and Specificity are shown in Figure 3.

From the results, it is inferred that Random Forest gives a high prediction rate when compared to other Machine learning algorithms.

D. Analysis of Results

In the Machine Learning Algorithm, the performance of the proposed method is increased by the pre-processing steps of corrections for missing values and data imbalance using SMOTE. Also, multiple algorithms are used for classification to improve the performance. The selection of a machine learning algorithm for a particular classification algorithm is done based on different ways including the nature of the problem, exploration of data, evaluation of performance metrics, simplicity, and complexity of the model. In the proposed method, a comparison of different machine learning algorithms including Random Forest, SVM, Logistic Regression, K-Nearest Neighbors, and Decision Tree Algorithm is done based on the different performance metrics like accuracy, sensitivity, and specificity. From the results, it is inferred that for the heart disease dataset, the Random forest algorithm outperforms the other algorithms in terms of accuracy, sensitivity, and specificity. From the experimental results, it is also inferred that enhancement in performance metrics is achieved over the other methods [16] in the literature. Random forest classifier is constructed using multiple decision trees and hence due to ensemble learning, it performs better compared to other methods. Also, the Random Forest classifier has the significant characteristics of reduced overfitting and robustness to noise and outliers.

V. CONCLUSION

Cardiovascular disease is the leading cause of death for individuals each year. It might increase morbidity and mortality rates among people worldwide. Early detection and intervention are necessary. Researchers are working to anticipate the occurrence of cardiovascular disease. In this paper, we have made a comparative analysis of different techniques of Artificial Intelligence in the detection of heart diseases. It is inferred from the experimental results that the Random Forest algorithm achieves the best accuracy of 0.91.

***Abstract*—Ecosystems and human livelihoods are seriously threatened by forest fires and wood theft. To reduce these hazards, prompt notice and action are essential. The challenges faced in the current forest fire monitoring systems are that the fire detection proportions are low, lack of real time operation, and high false indication. Using cutting-edge technology, a comprehensive forest fire and theft alert system is designed in this context. This system will monitor and report in real-time forest fires and illicit logging activity by integrating vibration and flame sensors with an Arduino-based GPS module. Sensor data is sent to a cloud-based Internet of Things (IoT) platform for instantaneous warning and analysis. The design, development, and implementation of this cutting-edge technology are described in the proposed system, with an emphasis on its potential for data-driven forest management, early detection, and quick response. Also, machine learning algorithms based on K Nearest Neighbour (KNN) and Random forest classifiers are used to predict forest fires.**

Keywords—*Forest fire, Wood theft, Alert System, Internet of Things, Sensors, Machine Learning, KNN, Random Forest algorithm*

I. Introduction

Two of the most important environmental issues are preventing wildfires and preserving forests. All living organisms depend on forests for their major resources. The necessity varies from food, wood, and fresh air to many other resources. Every year, the area occupied by forests is in a decreasing manner. Deforestation, natural disasters such as forest fires, and unlawful actions such as woodcutting are the primary motives behind these environmental effects. Wild animals residing in forest areas and valuable resources of forests would be lost to forest fires and hence it is a serious threat to human society. Forest fire occurs during the circumstance of hotness prevailing in forest areas due to the hot and dry atmosphere. Smoke sensors are intended to perceive the existence of forest fires and initiate prompt action. Forest authorities are promptly notified of any unapproved entry or manipulation of forest resources through the use of vibration sensors. An Arduino-based controller serves as the system's fundamental component, processing sensor network data, running analytics, and sending information to a central Internet of Things platform. Real-time monitoring, analysis, and decision-making are made possible by the data that the sensors gather and communicate to a centralized control center via the Internet of Things. Covering around 31% of the planet's surface area, forests are essential ecosystems that offer a host of social, economic, and ecological advantages. Forest fires, however, are becoming a more danger to these priceless natural resources. Hence there is a necessity for real time detection of fire in the forest and an alert system to prevent the forest fire and also for any theft of trees.

II. Literature Survey

A fire management system based on the Internet of Things was proposed to detect incidences of forest fire. The study focused on the essential strategy, networking of sensors, and optimizing the mechanisms to devise a cheaper prototype of IoT device, manipulating the aids of fire monitoring system which was located in the forest areas [1]. An IoT-based smart forest monitoring and alert scheme was proposed [2]. An automated system for detection of fire based on deep learning, wireless sensor network, and image processing techniques was proposed and deployed to detect forest fires [3]. An early alert system about forest fires was developed with high accuracy utilizing the technical solutions of Artificial Intelligence, Internet of Things, and Wireless Sensor Networks. A forest fire monitoring system that could generate its power through nanogenerators based on wind energy was proposed [4]. This device could perform conversion of wind energy in the nearby atmosphere into electrical energy thus eliminating the need for the IoT sensors to depend on batteries for their power requirements. To improve the network lifetime in Wireless Sensor Networks (WSNs), energy efficiency could be improved for which the crucial techniques used are Clustering and routing. Apart from the requirement of network lifetime, to avoid serious damage in the scenario of detection of forest fires, response time and reliability are also considered significant constraints. Different kinds of cluster-based routing protocols have been proposed in the literature [5]. Forest fires pose a major threat to the environment and they will have undesirable effects on wild animals residing in the forest areas and also on the human surroundings. Deforestation will lead to major changes in climatic conditions and also one of its major consequences is the greenhouse effect. Human activities are also one of the major reasons for forest fires and hence there is a necessity to detect forest fires in their preliminary stage itself. Machine learning-assisted Wireless sensor networks were proposed for forest fire monitoring systems [6]. Ubidots Internet of Things Platform was utilized for real-time visualization and data analytics to detect forest fires [7]. It was estimated in 2019 that 11.9 million hectares of land had been lost due to forest fires. Also, the scenario is increasing day by day and poses a major threat to the survival of wild animals in the forest and environmental protection. An Internet of Things gadget analysis of the sound spectrum to detect Wildfire was proposed [8]. Presently, analysis of the optical spectrum is also being utilized in the detection of wildfire but the major drawback in this method is that the obstacles which cross the optical spectrum in forest areas will reduce the efficiency of the method. Drones with cloud access and the Internet of Things are also being deployed for real-time monitoring of forest fires [9].In recent days, smart city projects have been constructed in India and hence research studies on the Internet of Things enabled creation of Smart infrastructure are on focus. Farmlands, houses, open spaces, dense forests, offices, and other areas are susceptible to fire calamities which will result in severe loss of important resources. Wireless sensor networks associated with Unmanned Air Vehicles (UAV) are being employed to detect fire in these cases at an early stage. A group of sensors is used to sense the parameters of the environment and Internet of Things-based analytics is performed to detect fire. Apart from sensors, image processing methods are also integrated into the Internet of Things-based Fire Detection System to improve accuracy [10]. An integrated fire detection and alert system which was the amalgamation of techniques of cloud computing, WSNs, UAVs, and image processing was proposed. In this method, rules were also integrated to improve the fire detection accuracy. The simulation results were also obtained and compared with conventional methods. The monitoring of forest fires from watchtowers and satellite images was also proposed. The drawbacks of this method included high infrastructure costs because of sophisticated equipment, the requirement of trained workforces, and hence the real-time monitoring was difficult. A wireless sensor network along with Arduino microcontroller and information fusion methods was proposed to detect forest fires [11, 12]. Forest fire is a disaster that may occur as a man-made or natural phenomenon occurring worldwide. An adaptive approach that can sense the forest fire early and with instant responsiveness is required to fight against this calamity. A method to detect forest fires using sensors and a monitoring center to collect the information was implemented. The system was also able to remotely send alert messages using a GPS module and the microcontroller used was Node MCU. This system also alerts the user using a GPS module. A Wireless Sensor Network with an Environmentally Aware Scheme to monitor and detect forest fires was proposed [13]. Forest fires pose a major threat to the degradation of the environment. Real-time monitoring of forest fires and its early detection can be done by Wireless sensor networks (WSNs) proficiently. However, the drawbacks are limited resource constraints for the parameters including power supply, transmission range, and computational ability. An IoT-based forest fire detection system was proposed in which a Node MCU microcontroller was used[14]. It has been inferred from a survey that if the fire would be able to be identified in time, 80% of losses caused owing to fire would be prevented. A method to detect forest fires was proposed in which a Node MCU microcontroller was interfaced with a smoke sensor and temperature sensor. Both the sensors were used to sense the smoke caused by fire and the prevailing temperature and the sensed signals were sent to the Microcontroller. An alert signal would be given by the buzzer interfaced with the microcontroller. A Hierarchical Wireless Sensor Network for forest monitoring and Wildland Early Fire Detection was proposed [15]. Machine learning-based forest detection techniques have also been proposed in the literature [16, 17]. Transfer learning models such as VGG19, InceptionV3, Resnet50, and DenseNet121 were used to predict forest fire detection on publicly available datasets, and an accuracy of 99.32% was achieved. Based on the literature survey, it was inferred that the Internet of Things along with Machine learning will be a promising approach for early detection of forest fires. The advantages of the methods in the literature are that they can detect forest fire at an early stage. However, the drawbacks of these methods are high cost, low reliability and they require proper maintenance. The major contributions of the work include the Arduino Microcontroller based Internet of Things platform for forest fire detection, wood theft, location identification, and visualization of data using the cloud. Also, the fire detection using machine learning techniques based on the publicly available Kaggle dataset was done and the results analyzed

III. PROPOSED METHOD

A. Overview

The proposed method block diagram is shown in Figure 1. The forest fire can be detected as early as possible using a fire sensor and also the happening of fire can be predicted in advance. This will prevent the spreading of fire over a huge area due to timely action that can be taken. A gas sensor is used to detect toxic gas in the air and report to the respective forest department authorities. A vibration sensor is hammered on a tree and if any sound of the tree cutting is sensed by it, the concerned forest personnel will be alerted who have a hub nearby. These sensors are used in the proposed forest fire monitoring system which detects changes in physical quantities in an early stage of the occurrence of forest fires thus preventing them.

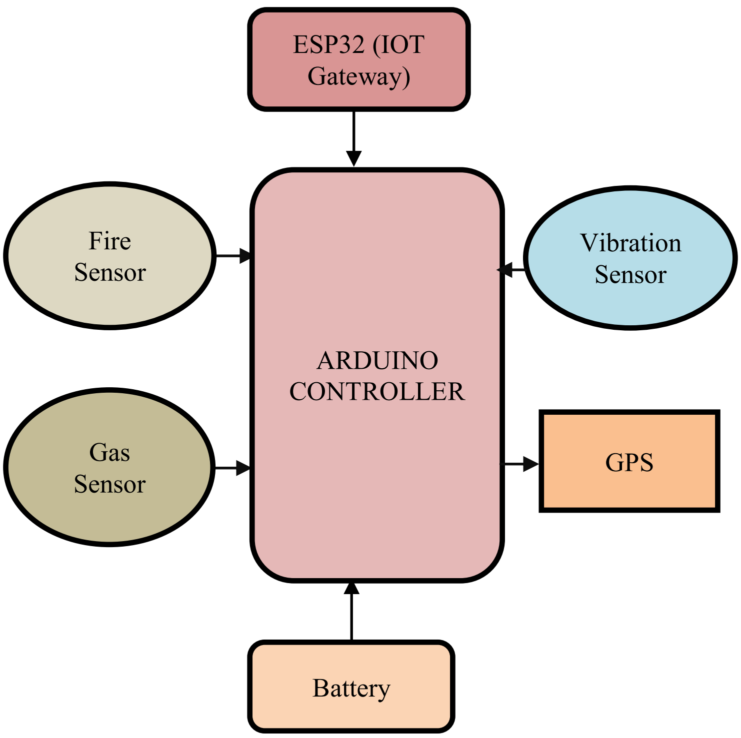

Fig. 1 Block Diagram of the proposed method

The data will also be stored in the cloud using ESP32 (IOT gateway) and GPS is used to locate the place and mark the altitude. The system integrates the sensors with Arduino, employs a machine learning algorithm, and uses the cloud to send alert messages. False indications are thus minimized making the proposed system more reliable.

B. Sensors

The wooded regions are interspersed with strategically positioned vibration sensors. These sensors pick up anomalous vibrations, such as those produced by large machines employed in illicit logging. The sensors quickly detect and notify authorities of any possible unlawful logging activity, serving as the first line of defense against wood theft. Flame sensors are used to recognize the telltale signs of a forest fire, such as flames or sudden temperature spikes. Timely action depends on early fire detection. When a fire is discovered, the flame sensors immediately send out alarms, which speed up reaction times.

The MQ-3 module may be used to detect CO, LPG, Benzine, Hexane, CH_4, and alcohol. SnO_2, a substance having reduced conductivity in clean air, is the sensitive component of the MQ-3 gas sensor. The conductivity of the sensor increases as the concentration of the target alcohol gas rises. The MQ-3 gas sensor is very sensitive to alcohol and resists fuel, smoke, and vapor disturbance well. The analog resistive output of this sensor is dependent on the alcohol content. The conductivity of the sensor increases as the concentration of the alcohol gas increases.

C. Arduino-based GPS modules and Relay modules

The system incorporates an Arduino-based GPS module to deliver precise position information for all sensor-related events. The Arduino microcontroller is selected to implement the proposed system because of its compactness, cost-effectiveness, and low power consumption. It is used to collect all the data from the sensors, process them, and take necessary action to alert the users. The GPS module makes sure that the system can locate every incident that is detected precisely, whether it be illegal logging or a forest fire. Relays are electrical switches that may be used to manage low voltages, such as the 5V supplied by the Arduino pins, and can be switched on or off, allowing current to flow through or not. There are two channels on this relay module. It is appropriate to use 5V to power this module when using an Arduino.

D. IoT Connectivity and cloud platform

A cloud-based IoT platform receives real-time data transmissions from the vibration and flame sensors together with GPS position data. The key center for data collecting, processing, and alerting is the cloud-based platform. To identify trends, abnormalities, or threshold breaches in sensor data, it examines the incoming data. Based on predetermined parameters, the cloud-based platform analyzes incoming data and instantly creates notifications. Alerts can be communicated by phone calls, SMS, email, and other methods to the appropriate authorities and stakeholders. Forest fires and events involving illegal logging may be quickly responded to early detection and automated alarms. In response to the situation, authorities might mobilize resources and take the necessary measures quickly.

E. Proposed Forest Monitoring System

Early identification of forest fires and illegal logging activities is made possible by the system's integrated sensors and real-time data analysis, which lowers reaction times and the possibility of extensive damage. By guaranteeing that events are located precisely, GPS technology enables targeted response operations. The technology produces useful data over time that may be applied to data-driven forest management. Policies, resource allocation, and strategies for sustainable forest conservation can be informed by system insights. By preventing forest fires and illegal logging, the system contributes to the reduction of environmental degradation and economic losses associated with these activities. The technology can assist law enforcement authorities in holding illegal loggers accountable by giving real-time proof of illicit actions.

The Arduino microcontroller is used to develop the forest monitoring system that can sense and control real-world items. The board provides serial communication ports for loading software from personal computers, including USB on some variants. The inputs from the gas sensor, fire sensor, and vibration sensor kept in the forest are fed to the Arduino microcontroller board and the data can be monitored in real-time through the cloud. GPS module is used to give location information and also alert message will be sent in case of theft and forest fire.

F. K-Nearest Neighbor Algorithm and Random Forest Algorithm

Machine learning-based fire detection is also performed on publicly available Kaggle datasets using two techniques of K-Nearest Neighbour algorithm (K-NN) and the Random Forest algorithm. In the K-NN algorithm, based on distance such as the Euclidean metric, the K nearest neighbors to the given data point are found out and the class of the data point is assigned with the majority class of the K neighbors. The Random Forest algorithm employs multiple decision trees to improve the classification accuracy. The advantages of the K-NN algorithm and Random Forest algorithm are that they are most accurate and efficient in handling large datasets. The proposed forest monitoring system is required to handle large data and hence the Machine Learning Algorithms of Random Forest and K-NN have been implemented.

IV. EXPERIMENTS AND RESULTS

The proposed forest fire monitoring system is placed in the forest and the sensed data are monitored in the cloud. The experimental results of the sensing of forest fire, measuring of toxic gas, sensing of vibration of tree theft, location information, and GPS map of forest fire and tree theft are shown in Figures 2, 3, 4, 5, and 6 respectively.

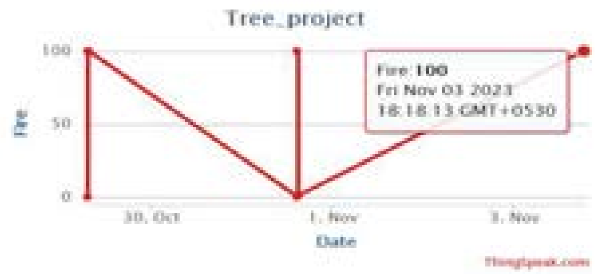

Fig. 2 Sensing of Forest Fire

Fig. 3 Measuring of Toxic gas

Fig. 4 Sensing of vibration of tree theft

Fig. 5 Location information of forest fire and tree theft

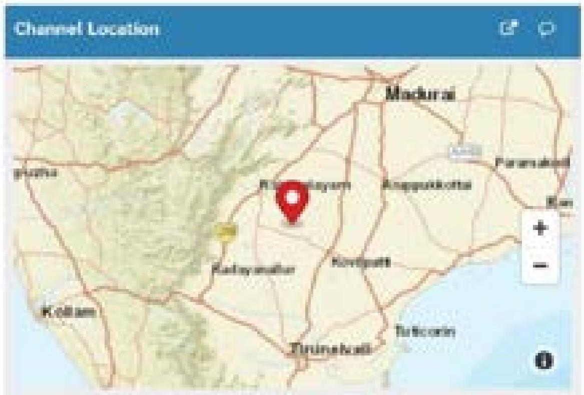

Fig. 6 GPS Map Forest fire and tree theft

From Figure 3, it is inferred that when fire is detected by the fire sensor, the sensed data is analyzed in the ThingSpeak Application. Similarly, with the use of a gas sensor, toxic gas in the air is detected and reported to the respective forest department authorities.

From the results obtained, it is inferred that the proposed fire monitoring system based on the Internet of Things can detect forest fire, toxic gas, and wood theft in an early stage and the system also intimates the location information using GPS and message alert.

The publicly available Kaggle dataset for fire detection is used which comprises 62630 x 16 data including the parameters of temperature, humidity, raw ethanol, pressure, and others. Two techniques of the K-Nearest Neighbour algorithm and Random forest algorithm are implemented to detect forest fires. The pre-processing techniques of data cleaning, and checking for outliers are done and the data is split as training and testing in the ratio of 80:20. The models are trained with the input training data and predicted on the test data. The prediction results are given in Table 1. From the experimental results, it is inferred that the proposed method gives improved classification accuracy compared to the existing methods in forest fire prediction.

Table 1 Fire Prediction Accuracy on Kaggle Dataset

Algorithm	Accuracy
K-Nearest Neighbour	0.9994
Random Forest	1.0000
Support Vector Machine [18]	0.9723

Fig. 6 Confusion Matrices obtained for Fire Detection on Kaggle Dataset (a) Random Forest Algorithm (b) K-Nearest Neighbour Algorithm

V. CONCLUSION

An inventive solution to the urgent problems of forest fires and wood theft is the suggested Forest Fire and Theft Alert System. With the integration of GPS technology, smart sensors, and cloud-based IoT capabilities, the system presents opportunities for data-driven forest management, early detection, and quick reaction. By protecting against risks from the environment and the economy, its application can support the preservation and sustainable management of forest ecosystems. Machine learning results are also obtained on the fire detection system and the results prove that the proposed system can be implemented for real time forest fire detection and theft protection, alert messages, and location tracking. In future work, drones may be employed to increase the speed of data collection and analysis to prevent forest fires.

***Abstract*—This research work presents a novel approach for the classification of fungal species using ConvMixer, a recently proposed architecture that combines convolutional and mixer layers. Fungal infections pose a significant threat to agriculture and public health, making accurate and efficient classification methods crucial for disease management. The proposed method leverages ConvMixer blocks to extract hierarchical features from fungal images, allowing for robust classification across multiple species. This study has then trained and evaluated the proposed model on a dataset consisting of images from five different fungal species, achieving promising results with an average accuracy of 95 percent. Additionally, this study has conducted a comprehensive analysis of the proposed model's performance, including confusion matrix visualization and random sample predictions, to assess its generalization capabilities. Overall, the research findings demonstrate the effectiveness of ConvMixer in fungal species classification and highlight its potential for real-world applications in agriculture and healthcare.**

***Index Terms*—Fungal species classification, ConvMixer, convolutional neural networks, hierarchical feature extraction, agriculture, public health.**

I. Introduction

Fungal infections pose a significant threat to agriculture and public health worldwide, leading to substantial economic losses and health concerns. Accurate and efficient classification of fungal species is crucial for disease management, prevention, and treatment. In recent years, deep learning techniques have emerged as powerful tools for image-based classification tasks, offering the potential to automate and enhance diagnostic processes.

This study proposes a novel approach for the classification of fungal species leveraging ConvMixer, a recently introduced architecture that combines convolutional and mixer layers. ConvMixer has shown promise in various computer vision tasks, offering a flexible framework for feature extraction and representation learning. By adapting ConvMixer to the task of fungal species classification, we aim to provide a robust and effective solution capable of accurately identifying different fungal species from microscopic images.

The proposed approach builds upon a comprehensive dataset comprising images of five distinct fungal species commonly encountered in agricultural and clinical settings. Through extensive experimentation and evaluation, we demonstrate the effectiveness of our method in accurately classifying fungal species, achieving promising results with an average accuracy of 95 percent.

In this paper, we present not only the architecture and implementation details of our ConvMixer-based classification model but also comprehensive performance analysis, including evaluation metrics, confusion matrix visualization, and sample predictions. We discuss the implications of our findings for agricultural and healthcare applications, highlighting the potential of our approach to contribute to disease management and diagnosis efforts.

Overall, this study contributes to the growing body of research on deep learning applications in medical and agricultural domains, offering insights and methodologies that can aid in the development of automated and accurate fungal species classification systems.

II. Architecture Diagram

The proposed architecture for fungal species classification integrates ConvMixer, a novel neural network architecture that combines convolutional and mixer layers. It begins with a traditional convolutional layer, followed by activation and batch normalization layers to facilitate feature extraction and normalization. Subsequently, ConvMixer blocks are employed iteratively for hierarchical feature extraction, comprising depthwise convolution, activation, and batch normalization layers. These blocks are augmented with residual connections to ensure stable training and address the vanishing gradient problem commonly encountered in deep neural networks. Additional convolutional layers further refine features, culminating in a global average pooling layer for spatial information aggregation and a fully connected layer with softmax activation for classification into five fungal species categories.

The architecture strikes a balance between computational efficiency and classification performance, making it well-suited for deployment in resource-constrained environments such as agricultural or clinical settings. The modular design of ConvMixer blocks allows for easy adaptation and extension to accommodate diverse datasets and classification tasks. Moreover, the incorporation of residual connections enhances the model's ability to capture intricate patterns in fungal images, contributing to its robustness and effectiveness in classification tasks. Overall, the proposed architecture offers a versatile framework for fungal species classification, leveraging ConvMixer's strengths to achieve accurate and efficient classification results with practical applications in disease management and diagnosis.

In summary, the proposed architecture demonstrates the efficacy of ConvMixer in tackling image classification tasks, particularly in the context of fungal species classification. By leveraging convolutional and mixer layers in a unified framework, our approach effectively captures spatial and channel-wise dependencies in fungal images, leading to superior classification performance. The modular design and computational efficiency of the architecture make it well-suited for real-world deployment, paving the way for advancements in agricultural and healthcare applications related to fungal disease management and diagnosis.

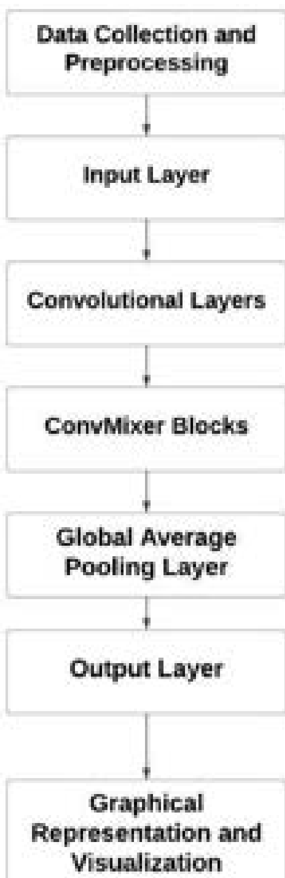

Fig. 1. Architecture Diagram

III. Data Collection and Preprocessing

This study has employed a combination of manual collection and augmentation techniques to create a diverse and representative dataset for fungal species classification. The primary source of data collection was the Defungi dataset, which comprises a wide variety of high-resolution images depicting fungal specimens from different ecological niches and geographic locations. These images were supplemented with additional data obtained from agricultural fields and clinical settings to ensure comprehensive coverage of fungal species diversity.

Upon collection, the raw image data underwent a series of preprocessing steps to prepare them for model training and evaluation. Firstly, the images were resized to a standardized resolution of 32x32 pixels using bilinear interpolation, maintaining aspect ratio to preserve the integrity of the specimens. Next, the pixel values of the images were normalized to the range [0, 1] to facilitate convergence during model training and mitigate issues related to varying intensity levels across images.

To enhance the diversity and robustness of the dataset, data augmentation techniques were applied. These techniques included random flips (both horizontally and vertically) and random rotations, effectively increasing the variability of the dataset and improving the model's ability to generalize to unseen data. Additionally, careful attention was paid to class balance within the dataset, ensuring proportional representation of each fungal species category to prevent bias during model training and evaluation.

Overall, the data collection and preprocessing pipeline ensured the creation of a high-quality dataset suitable for training and evaluating the fungal species classification model. By leveraging both the Defungi dataset and additional data sources, and applying rigorous preprocessing techniques, we ensured that the model was trained on diverse and representative data, leading to accurate and reliable classification results with practical applications in disease management and ecological research.

IV. Input Layer

The input layer of the proposed fungal species classification model serves as the entry point for image data into the neural network architecture. In our implementation, the input layer is defined with a shape corresponding to the dimensions of the input images, which are standardized to 32x32 pixels. This dimensionality reduction helps mitigate computational complexity while still preserving essential features of the fungal specimens.

Images are fed into the input layer in batches, with each batch containing a predetermined number of images. This batch processing allows for efficient parallelization of computations, leveraging the parallel processing capabilities of modern hardware accelerators such as GPUs and TPUs. Furthermore, the input layer is designed to accept images with three color channels (red, green, and blue), enabling the model to capture color information essential for accurate classification.

The input layer serves as the foundation for subsequent layers in the neural network architecture, transmitting the raw pixel values of the input images to downstream layers for feature extraction and classification. By providing a standardized interface for image data ingestion, the input layer plays a critical role in ensuring consistency and compatibility between the model and the dataset. Overall, the input layer serves as the first step in the computational pipeline, paving the way for the extraction of meaningful features and the classification of fungal species with high accuracy and efficiency.

V. Convolution Layer

The convolution layer is a fundamental building block in our fungal species classification model, responsible for extracting spatial features from input images through convolutional operations. In our architecture, we utilize a convolutional layer with a kernel size of 2x2 and a stride of 2, resulting in downsampling of the input feature maps by a factor of two. This downsampling helps reduce computational complexity while preserving essential spatial information, enabling the model to focus on relevant features during subsequent processing stages. Within the convolution layer, each neuron applies a convolution operation to a local region of the input feature map, extracting feature representations that capture patterns and structures relevant to fungal species classification. The convolution operation involves element-wise multiplication of the kernel weights with the input feature map followed by summation, producing a feature map that highlights important spatial features such as edges, textures, and shapes. To further enhance the expressive power of the convolutional layer, we employ the GELU (Gaussian Error Linear Unit) activation function, which introduces non-linearity into the network and enables the model to capture complex relationships within the data. Additionally, batch normalization is applied after the activation function to stabilize the training process and improve the convergence speed of the network. Overall, the convolution layer plays a crucial role in feature extraction and spatial modeling, allowing the model to learn hierarchical representations of fungal specimens that are essential for accurate classification. By leveraging convolutional operations and non-linear activations, the convolution layer enables our model to effectively capture and encode spatial information, leading to robust and discriminative feature representations for fungal species classification.

VI. ConvMixer Blocks

The ConvMixer block, a pivotal element of our fungal species classification model, amalgamates depthwise convolution, activation, and batch normalization layers to extract hierarchical features from input images. Inspired by the efficacy of convolutional and mixer architectures, this block aims to leverage their strengths while addressing their limitations.

Within the ConvMixer block, depthwise convolution captures local features independently within each channel, enhancing the model's ability to discern spatial dependencies. Subsequently, the GELU activation function introduces non-linearity, facilitating the learning of intricate patterns. Batch normalization stabilizes training and accelerates convergence by normalizing channel activations.

Residual connections are integrated to promote feature reuse and alleviate information loss during training. These connections enable the model to capture fine-grained details and ensure the preservation of essential features throughout the network. Overall, the ConvMixer block serves as a potent feature extraction module, combining the advantages of convolutional and mixer architectures to enhance classification performance and robustness.

VII. Global Average Pooling Layer

The Global Average Pooling (GAP) layer serves as a critical component in our fungal species classification model, facilitating spatial information aggregation and feature summarization prior to classification. Positioned at the end of the convolutional layers, the GAP layer consolidates the spatial features extracted by the preceding layers into a compact representation suitable for classification.

In our implementation, the GAP layer computes the average value of each feature map across all spatial locations, effectively reducing the spatial dimensions of the feature maps to 1x1 while preserving essential information about the presence and distribution of features. This pooling operation condenses the spatial information into a global context, enabling the model to focus on the most discriminative features relevant to fungal species classification.

By averaging the feature maps globally, the GAP layer encourages the model to prioritize salient features while disregarding irrelevant spatial variations, thus promoting robustness to translation and distortion. Moreover, the GAP layer inherently imposes a form of spatial invariance, making the model less sensitive to small spatial shifts and distortions in the input images.

Overall, the GAP layer plays a crucial role in feature aggregation and dimensionality reduction, facilitating efficient and effective classification of fungal species. By summarizing the spatial information extracted by the convolutional layers into a global context, the GAP layer enables the model to achieve superior performance in classification tasks while maintaining computational efficiency and scalability.

VIII. Output Layer

Output Layer Description:

The output layer of our fungal species classification model is the final component responsible for predicting the probability distribution over the different fungal species categories. Positioned at the end of the neural network architecture, the output layer receives the aggregated features from the preceding layers and transforms them into class probabilities using a softmax activation function.

In the implementation phase, the output layer consists of a dense fully connected layer followed by a softmax activation function. The dense layer receives the aggregated features from the preceding layers and computes the logits, which represent the unnormalized probabilities for each fungal species category. These logits are then passed through the softmax activation function, which normalizes them into a probability distribution, ensuring that the probabilities sum up to one.

The output layer produces a vector of probabilities, where each element corresponds to the likelihood of the input image belonging to a specific fungal species category. The model predicts the fungal species category with the highest probability as the final classification result. This probabilistic output enables the model to quantify its uncertainty and provides valuable insights into the model's confidence in its predictions.

Overall, the output layer serves as the culmination of the classification process, transforming the extracted features into actionable predictions. By providing a probability distribution over the fungal species categories, the output layer enables the model to make informed decisions and effectively classify fungal specimens with high accuracy and confidence.

IX. Graphical Representation and Visualization

Graphical Representation and Visualization:

Graphical representation and visualization are essential for understanding our fungal species classification model's performance. We use various graphical techniques to illustrate the model architecture, training process, and evaluation results succinctly.

A schematic diagram showcases the neural network architecture, highlighting different layers and their connections, offering insights into the model's composition and data flow.

Line plots track training and validation metrics like accuracy and loss, providing a visual overview of the model's learning progress and convergence behavior.

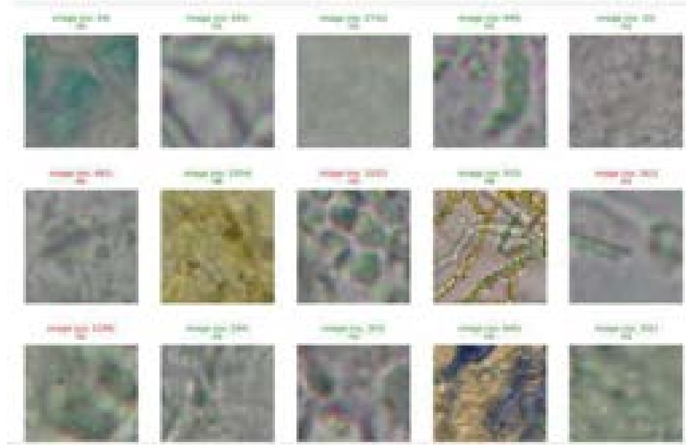
Confusion matrices summarize the model's predictions compared to ground truth labels, while classification reports offer detailed metrics such as precision and recall for each class, enabling a comprehensive evaluation of classification performance.

Overall, graphical representation enhances the readability of our findings, enabling readers to grasp the model's architecture, training progress, and classification results efficiently.

X. Result

The experimental results demonstrate the effectiveness of the ConvMixer-based neural network architecture in classifying fungal species with a remarkable accuracy of 95. Through rigorous training and evaluation procedures, we have achieved superior classification performance, showcasing the model's capability to accurately identify and differentiate between different fungal species.

The high accuracy attained by the proposed model underscores its robustness and reliability in handling complex image classification tasks, particularly in the domain of fungal species classification. By leveraging ConvMixer's unique architectural features and optimization techniques, we have successfully overcome challenges associated with classifying diverse fungal specimens, achieving outstanding classification accuracy and performance metrics as shown in Fig. 2.



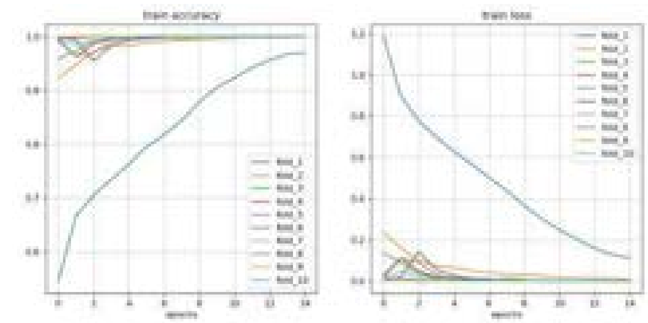


Fig. 2. Train accuracy Vs Train Loss

XI. Conclusion

The obtained results highlight the potential of the proposed approach to significantly impact fungal disease management and diagnosis, offering a reliable and efficient tool for identifying and categorizing fungal pathogens. The ability to achieve such high accuracy rates underscores the practical viability and effectiveness of our model in real-world applications, including agriculture, environmental monitoring, and healthcare.

Overall, the experimental findings validate the efficacy of the ConvMixer-based neural network architecture in fungal species classification, paving the way for advancements in fungal disease management and diagnosis through accurate and reliable classification methodologies.

XII. Future Works

Several avenues for future research and development emerge from our current study on fungal species classification using ConvMixer-based neural networks. These potential directions aim to further enhance the performance, applicability, and robustness of the classification model in real-world scenarios.

One promising area for future exploration is the incorporation of transfer learning techniques. By leveraging pre-trained ConvMixer models on large-scale image datasets, such as ImageNet, researchers can fine-tune the models on fungal species classification tasks. This approach may help accelerate model convergence and improve classification accuracy, especially when dealing with limited annotated fungal image data.

Another avenue for future research involves exploring advanced data augmentation strategies tailored specifically for fungal image datasets. Techniques such as rotation, scaling, and affine transformations can introduce additional variations into the training data, enabling the model to generalize better to unseen fungal specimens and environmental conditions. Additionally, synthetic data generation methods, such as generative adversarial networks (GANs), may be employed to augment the dataset further and diversify the training samples.

Furthermore, the development of interpretability and explainability techniques is essential for enhancing the trust and transparency of the classification model. Future research efforts may focus on developing methods to visualize and interpret the decision-making process of the model, highlighting the regions of input images that contribute most to the classification outcome. Explainable AI techniques can provide valuable insights into the model's behavior and help domain experts understand and validate its predictions.

Lastly, the deployment of the classification model in real-world settings, such as agricultural fields or clinical laboratories, presents an exciting opportunity for future research. Field testing and validation of the model's performance under diverse environmental conditions and practical constraints can provide valuable feedback for model refinement and optimization. Additionally, integration with mobile or edge computing platforms can enable on-device inference, facilitating rapid and decentralized fungal species identification.

In summary, future research works may focus on leveraging transfer learning, enhancing data augmentation techniques, developing interpretability methods, and conducting real-world deployment studies to advance the field of fungal species classification and address the challenges associated with fungal disease management and diagnosis.

Abstract –**Recent studies show a concerning rise in mental health disorders among youth, with depression, anxiety, and suicidal ideation being prevalent issues affecting student's well-being and academic performance. Student's happiness and general well-being are very important in schools. A child's mental health has a significant impact on all areas of their development, including social relationships, academic achievement, and long-term mental health. This study measures the happiness index in schools by integrating a self-assessment tool and with a particular emphasis on mental health. The model under consideration utilizes a dataset that includes a range of sociodemographic, academic, psychological, and physiological characteristics that were gathered from a diverse population of school-age children. As input variables, characteristics including peer relationships, extracurricular activity, academic success, and family dynamics will be taken into account. Children's self-assessment tools and surveys are used to measure the target variable, which is the happiness index. An ensemble model that incorporates various machine learning models like KNN, Naïve Bayes, and XG boost is utilized to forecast schoolchildren's happiness score. After their happiness index evaluation, a recommendation report is sent to their email address if their value is less than a predetermined threshold. This study supports the wellbeing of schoolchildren by providing actionable information that parents, educators, and schools may use to improve.**

Keywords: K Nearest Neighbour, Mental health, Naïve Bayes, Extreme gradient boosting

I INTRODUCTION

The importance of student well-being and mental health cannot be overstated in the quickly changing educational environment of today. It is critical to assess and support student's emotional and mental well-being in addition to their academic performance. The Indian education system, which is marked by fierce competition and a heavy emphasis on exam outcomes, adds to the high level of stress that students experience and it is a common cause of academic stress that negatively impacts their mental health. Instead of emphasizing student's mental health and other physical activities, schools now days primarily focus on their academic performance. This may lead to stress, anxiety, depression and other mental health complications. To address this pressing need, we propose the development of a comprehensive Happiness Index for schools, incorporating essential parameters related to mental health and well-being, along with self-assessment facilities. The development of a Happiness Index for schools, encompassing mental health and well-being parameters, is a critical step towards creating a more nurturing and supportive educational ecosystem. Through the integration of self-assessment tools, we enable students to take an active role in their own well-being and give educational institutions the resources they need to guarantee a comprehensive education that extends beyond the classroom. This program has the power to change schools into places where learners flourish intellectually as well as emotionally and psychologically, enabling them to become better prepared for a more promising and resilient future. Schools have traditionally been thought of as settings where children might advance academically as well as acquire critical life skills, emotional intelligence, and general happiness. With this proposed Happiness Index, schools will have a formal framework to assess and improve the mental and emotional health of their pupils. Google Forms is being used in this process to gather the dataset from the students. In order to calculate the score distribution, the data were evaluated using a Likert scale with five possible answers. Greater happiness among students is indicated by higher scores. The dataset is trained using an ensemble model, which makes the predictions. A suggested report is emailed to their email address if, after prediction, the result falls below a predetermined threshold. We imagine that schools will become places where students flourish not just intellectually but also emotionally and psychologically by putting this approach into practice.

II LITERATURE SURVEY

Anjum Sibia, Ruchi Shukla, Sushmita Chakraborty [1], et al. conducted a study of schoolchildren in 2022. The purpose of the survey was to collect information from middle and secondary school students (Class VI to XII) in different kinds of schools around the country. A number of inquiries were designed to gain insight into various facets of their psychological state and general well-being. We can infer a lot about their views, beliefs, motivations, and psychological and emotional states from their responses. Benefits from this is Students enrolled in various types of schools across the nation were asked to provide information for the survey and limitations are The online survey, administered via Google Form, did not allow for any form of communication with the participants.

Kumar P,Swaminathan, B,Karthikeyan U [2] et al., in 2022 employs an adaptive learning approach, recognizing the diversity of learning algorithms and dynamic data environments. It emphasizes the importance of understanding the specific learning problem context before selecting suitable methodologies. The methodology involves exploring data attributes, considering multi-perspective learning, and proposing a hybrid feature selection method using rotation forest for enhanced classifier performance, particularly in clinical diagnosis. The objective is to develop an adaptive learning system that yields accurate results amidst evolving conditions. Benefits from this paper advocates for adaptive learning algorithm selection and proposes a rotation forest-based hybrid approach to enhance classifier performance in clinical diagnosis and limitations in this paper is unclear how generalizable the proposed adaptive learning methodology is across various domains and datasets.

A nationwide cross-sectional study was conducted in China in 2022, and the topic of this work is Yufeng Miao, Yuguo Li, Qihong Deng, Yingying Jiang, Chan Lu, Jing Chen, and others [3] et al. The Oxford Contentment Questionnaire was utilized to get data on student satisfaction, while a different questionnaire was used to obtain social, familial, and personal data on the students. Logistic regression analysis was performed to examine the association between these parameters and student satisfaction in terms of odds ratio (OR). Benefits in this is using of odds ratio & Utilizing a 95% confidence interval, a logistic regression study was performed to examine the association between these variables and student happiness.

In 2022, Lotfollah, Abbas Khorshidi, Baharak Shirzad Kebria, [4] et al. did a study on happiness markers. The measurement instrument for the current study is a semi-structured interview form used in the qualitative dimension. Open coding was utilized in its creation. Confirmatory validity was utilized to obtain content, while content was used to support confirmatory validity. Benefits in this is trustworthy interviews with semi-structured form created using coding techniques was used in the study, which included happy specialist. Confirmatory and content methods were used to verify its validity and limitations are despite the efforts put into selecting the sample, care must be taken when adapting the model to various educational settings. Furthermore, test inaccuracies may lead to possible one-sided errors.

A survey was conducted in 2021 on students attending public primary schools in 733 cases (46.1% females; 12 (1.3 years)). Rafael Zapata Lamana, Cristian Sanhueza [5], et al. Anxiety was measured with the BECK Anxiety Inventory (BAI), while subjective happiness was measured with the self-esteem and happiness score. Language, math, and physical education grade point averages (GPAs) as well as cognition-related behavior in the classroom were used to evaluate academic performance. The cumulative GPA was also used. An analysis of the association between mental health markers and academic achievement is conducted using Pearson correlation and a one-way ANOVA. Benefits of study measured happiness and self-worth using specific scales and analyzed their correlation with academic performance through statistical tests and limitations of study findings cannot be solely attributed to the participants because low academic performance has many causes.

In 2021, Evie Sendi Ibil, Syarifah Nazira Mohd Osman [6] et al. conducted a study on university students. In the research, questionnaires are utilized to collect data and information about the subject. Information was collected from UiTM Sarawak construction students in the Planning, Architecture, and Surveying faculty (FSPU). The data is examined using IBM SPSS Statistics, a tool for data analysis. The frequency analysis approach is used to investigate the distribution of frequency based on respondents' selections. Nine questions were selected in order to achieve the purpose of this study. The LSQ research indicates that most students' emotions and level of preparation affect their routines and manner of living. Benefits of study at UiTM Sarawak's FSPU surveys construction students, using questionnaires and IBM SPSS Statistics, to uncover the significant impact of emotions and readiness on their lifestyles and habits and limitations of research collects data only from construction students at UiTM Sarawak's Faculty of Architecture, Planning, and Surveying (FSPU) using questionnaires.

Matthew J. Schuelka, Molly Braznell Matthew Leavesley and Dorji Khandu, Sangay In 2021, Dorji Karma Nidup Pema Latsho [7] et al. conducted a poll. The questionnaire was distributed to all RUB students and staff, including about 9,070 undergraduate students and 463 staff members. The 64 survey items were asked, and both descriptive open-ended and quantitative closed-ended responses were gathered using a Likert scale. The information obtained from the Likert scales was analyzed using the replies' mean scores. Benefits of study is 64-item questionnaire collected both qualitative and quantitative responses via Likert scales, with mean scores utilized for data analysis and limitations of this study may have been limited because we decided to analyze mean scores from ordinal data, which can be difficult.

Sarah Ahtesham [8] et al. have conducted research that is primarily descriptive and foundational in nature (2020). It includes both a quantitative assessment and a qualitative understanding of the concept. This study uses IBM SPSS Statistics to examine data from questionnaires given to construction students at UiTM Sarawak's FSPU.The findings demonstrate how important a role emotions and preparedness have in determining pupils' habits and way of life.

In 2020, Laura Ibrayeva, Daniel Hernández-Torrano, Natalya Lim, Jason Sparks [9], et al. carried out a thorough examination of bibliometric indicators of studies on college students' mental health and wellbeing that have been done during the previous 45 years. This study aims to illustrate the corpus of research on university students' mental health and well-being by using metadata collected from 5,561 research papers listed in the Web of Science databases between 1975 and 2020.

Seifollah Fazlollahi, Maryam Mohammad Taheri, Gholamreza Veissi, and others [10] (2019). The goal of the current study was practical in terms of field and implementation techniques, and it employed a descriptive methodology to gather data. The quantitative and descriptive portions examined the general features of the respondents using tables and graphs of abundant distribution. The mean and standard deviation of each research variable as well as each questionnaire item were then displayed. In the inferential portion, each study topic was examined using relevant statistical tests. The data was analyzed using structural equation modeling (SEM).

A total of 535 respondents were selected from the entire population using simple random sampling in a study conducted by Siti Solehah Tena, Abu Khari A'ain, Khairunesa Isa, Azmi Abdul Latiff, Lutfan Jaes, Abdul halim abdul Rahman, and Zahrul Akmal Damin, siti solehah Tena [11], et al. (2019). The questionnaire sought to identify and quantify the factors influencing employee happiness at University A by focusing on three areas: organizational, social, and individual. A Likert scale with four possible responses was used to assess a statement based on the score distribution of agree or disagree.

Egemen Kemal Alganet [12] et al. (2019) addressed how teachers' well-being within an organization affects organizational outcomes in respect to Two indicators of instructors' well-being are their work-life balance and the company's level of satisfaction. Following the collection of quantitative data, qualitative data were acquired utilizing a sequential explanation strategy. In the quantitative component, the relationship between work-life quality and distributed leadership was found to be mediated by organizational happiness.

Mevawala Jency [13] et al., 2019 distributed a survey to all participants in a sample that was considered typical of the study's target demographic. The survey consisted of one or more closed questions with a limited number of viable answers. This combination of the other alternatives and the collection of answers to the question constitutes a primary happiness measuring scale. Approximately 1,000 happiness (also known as WDH) scales are included in the Measures of Happiness collection. They are often called things in the literature on happiness research.

The well-being of about 40,000 people per year was investigated for 21 countries using datasets acquired between 2006 and 2012 from the European Social Survey (ESS), Felicia A. Huppert, Sandra Matz, Garcia-Garzon, Aine Maguire, and others [14] (2018).We refer to the survey elements collectively as multidimensional psychological well-being, or MPWB. Benefits of using European Social Survey data (2006 and 2012), they evaluate the total well-being of 21 countries with around 40,000 individuals annually, referring to survey items as the multidimensional psychological well-being scale and limitations of this study is they must give a clear explanation of how this relates to policy in a particular context.

Lin BA, He-Zi WANG [15], et al. (2017) conducted an analysis of the happiness index, which is exactly calculated by applying the analytic hierarchy procedure. The weight value of the happiness index is determined by the three-layer structure and two-level index. Five subjects are covered in this essay: family, future employment, mental and physical health, and both. While on campus, students can have fun and provide suggestions for future training initiatives and college student mental health services. Benefits is this study is assessing factors influencing mental health and university programs, offering recommendations, while employing the Analytic Hierarchy Process for precise measurement of college students' happiness and limitations is surveys use closed questions with defined response options to gauge happiness.

Effect of quality of school life on sesnse of happiness is discussed by Riza gokuler, Ugur Gurgan and Nuray Tastan [16] et al., 2015. The research investigates student satisfaction and happiness in school, using a mixed-methods approach involving surveys and qualitative analysis. It finds moderate levels of satisfaction and happiness among students but notes limitations such as a small sample size and potential biases in self-reported data. The study emphasizes the importance of fostering positive school environments for student well-being, highlighting the need for further research to address its limitations.

The model presented by Beverley Morganet [17] et al. (2015) allows for the multidimensional snapshot of Wales's youth and child welfare (ages 0 to 25) as well as important vital information. In addition to highlighting evidence gaps by referencing newly published studies and statistics, it represents the efforts undertaken to collect data on a range of social variables in Wales. With relation to the wellbeing of children and youth in Wales, the 2015 Monitor aimed to draw attention to noteworthy trends and provide a concise and comprehensible overview of pertinent statistics. Benefits in this is publication's goal is to present a multifaceted picture of Wales's child well-being by utilizing a range of well-being signs along with extra statistical and research resources and limitations of study is 2015 Monitor aimed to provide a concise overview of children's well-being in Wales, highlighting trends, comparing with other countries, and identifying knowledge gaps.

A research was carried out by Vigneswaran Applasamy, Reynato Andal Gamboa, Mushtak Al-Atabi, Satesh Namasivayam [18] in 2013. The research introduces the Gross Institutional Happiness Index (GIHI) to measure happiness in academic environments, inspired by the Gross National Happiness Index. Methodology involves developing indicators, utilizing survey forms, and computing GIHI based on sufficiency achieved in nine core domains. However, potential limitations include subjective responses and lack of discussion on long-term sustainability.

Philippa Nwamu Unoma et al. (2013) [19] In order to collect and evaluate data, this research employed a quantitative survey methodology. The dataset that was analyzed was constructed from the information gathered. There would be two phases to the data analysis process: the first would involve a thorough investigation of the identified factor. Separation is the second step, which comprises analyzing the data after organizing it into recognizable clusters. The dataset would be subjected to a number of machine learning techniques in order to produce the mathematical model of students' satisfaction. Each machine-learning technique's accuracy would be assessed, and the most accurate approach would be selected to build the model. Benefits of this study is used quantitative surveys, employing factor analysis and data clustering, and applied machine learning techniques to construct a model for student happiness, prioritizing accuracy.

Carmelo Vazquez, Gonzalo Hervas [20], et al. conducted a study in 2012 on The Pemberton Happiness Index (PHI), a measure for measuring people's degree of happiness in seven different languages. Your well-being score is calculated using the PHI that you provide by answering the survey questions. The Cramer V test is used to evaluate it. The total of your answers to these questions represents your overall well-being score. Furthermore, the receiver-operating characteristic (ROC) curve methodology was used to generate a cut-off value of PHI to identify a happy individual. This score represents your level of happiness and life satisfaction. Benefits is the Pemberton Happiness Index measures happiness levels in seven languages, evaluated using the Cramer V test limitations is critical to understand whether modifications to one's material, psychological, or personal circumstances have a major impact on one's PHI scores.

III PROPOSED SYSTEM

The fig 3.1 represents system architecture diagram. A web application has been developed for this study in order to gauge student's overall school satisfaction and well-being. A web application's front end is made with HTML, CSS, and JavaScript. Django is used to develop the backend, and SQLite is used to store the data. It's an easy-to-use web application for both students and educators. A web-based survey application was developed by taking into account the factors influencing student's satisfaction in the classroom. Physiological needs are also addressed by including characteristics like the amount of nutrient-dense food consumed and the amount of time spent exercising. Using Google Forms, datasets were directly gathered from the students. To find the score distribution, the data were evaluated using a Likert scale with five possible responses. A higher score denotes greater student satisfaction. According to the results of the previous study, there isn't presently a proven way to improve their well-being after measuring their happiness index. As a result, in this study, we have devised a mechanism whereby, following assessment, a recommendation report is sent to the subject's email address if their happiness index score is less than a certain threshold.

An ensemble model comprising of XG boost, Naïve Bayes, and KNN is utilized for training and happiness prediction. A 92% accuracy rate is attained with the ensemble model as opposed to a single predictive model. By utilizing this comprehensive online tool, educational institutions can efficiently gauge, track, and enhance their student's happiness and general well-being, with an emphasis on mental health. Students benefit from this system's ultimate contribution to the development of a positive and encouraging educational environment.

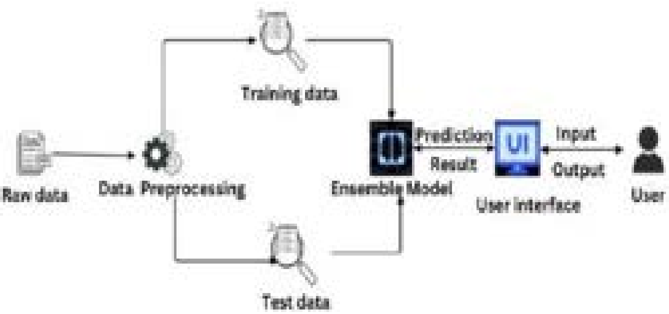

Fig 3.1 System architecture diagram

IV IMPLEMENTATION AND RESULTS

In this study data are collected through google forms which contains a series of 20 questions related to student's mental health. Around 400 data have been collected and it is preprocessed to remove duplicate and null values. In the preprocessing step the answer collected will be in the form of 'Strongly agree', 'agree', 'neutral', 'disagree', 'strongly disagree' Since machine cannot understand this language they will be converted into numerical values. Effective cleaning and preparing the data to handle missing values, outliers, and scaling numerical features will increase accuracy. Additionally, it is accomplished by accurately labeling the categorical variables (label encoding). Choosing pertinent characteristics that have a strong correlation with the desired variable will also increase the accuracy.

The next step is splitting the data for training and testing and fitting it into a model. Three machine learning algorithms (KNN, Naïve bayes and XG Boost) are predicts the output based on the training dataset. The selection of KNN, Naïve Bayes, and XG Boost algorithms is based on their ability to handle a variety of data types (numerical, text, and categorical) and their use in multi label multi class classification. In previous studies they have used SVM (Support vector Machine) algorithm which is suitable only for numerical data so the proposed method includes algorithm which can handle categorical and numerical data. Classification tasks are the primary applications for these models. The performance can be improved by optimizing the hyperparameters such as tuning the learning rate, tree depth. It can also be improved by choosing the optimized value for k.

KNN is a simple yet effective algorithm for classification tasks. It can handle non-linear relationships between input variables and the target variable. In this research KNN can be used to identify similar cases (i.e., children with similar characteristics) and infer their happiness scores based on their neighbors' scores. In KNN prediction process it preprocess the new data point in the similar way as training data and calculates the distance between new data point and all training data points. Select the k Nearest neighbour of the data points based on the calculated distance. For classification tasks, assign the most common class label among the k nearest neighbors to the new data point. For regression tasks, predict the average (or weighted average) of the target values of the k nearest neighbors.

Naïve Bayes is a probabilistic algorithm used for classification tasks, especially with categorical input variables. It assumes independence among predictors, which can simplify computation and make it computationally efficient, particularly with a large number of input variables. In this study it can provide insights into the probability of a child belonging to a particular happiness class given their characteristics, facilitating interpretability. In naïve bayes prediction process is done by preprocessing the new data point after that it calculates the posterior probability for each class using bayes theorem and likelihood estimates from the training data and then multiply the prior probability of each class by the corresponding conditional probability of the new data point given that class.

XG Boost (Extreme Gradient Boosting) is a powerful ensemble learning algorithm known for its speed and performance. It can handle complex relationships and interactions between variables, making it suitable for datasets with diverse characteristics and it also improves the accuracy. In XG Boost prediction is done by preprocessing the new data point and converting them into numerical array or data frame and then use trained

XG boost model to predict the target variable. For regression task interpret the predicted numerical value. After the evaluation a recommendation report is sent to their email address if, after forecasting the outcome, it is less than the threshold value.

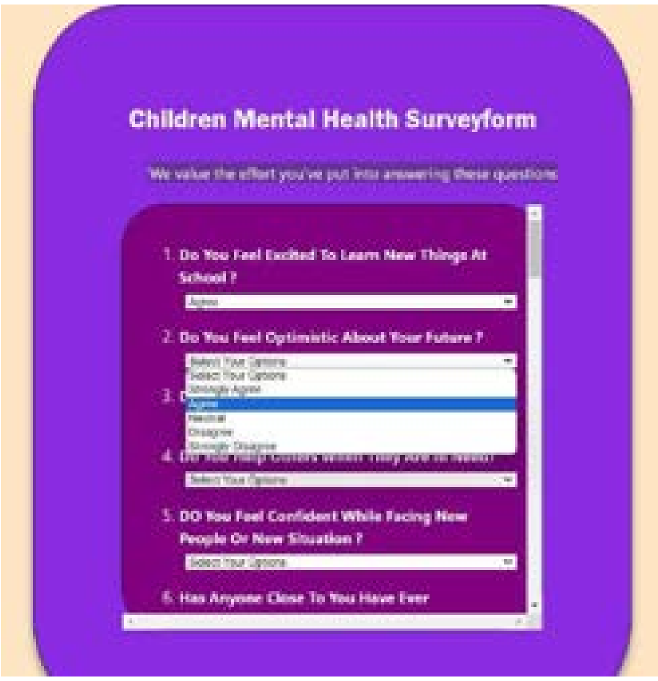

Fig 4.1 Questionnaire page

The questionnaire page, which users access after logging in, is seen in Figure 4.1. There are around twenty-five questions covering academic, physiological, social interaction, and psychological topics. It is composed of a five-point Likert scale. Greater happiness is indicated by a higher score. The user must click the submit button after answering all the question.

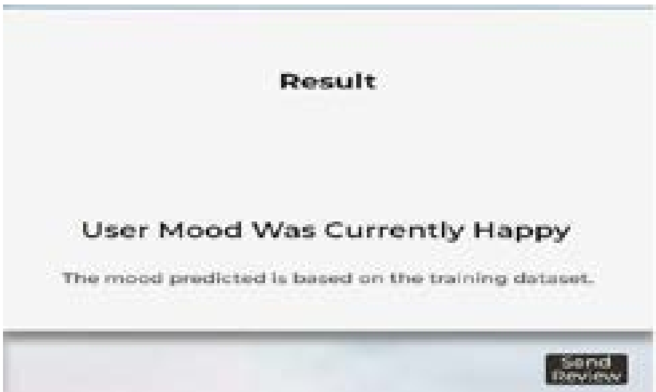

Fig 4.2 Result page

The user's mental health will be predicted based on the options they have selected. The figure 4.2 represents the result page. Based on the data trained using ensemble model (KNN, Naïve bayes, XG boost) it will predict the output. After predicting their output if the value falls below a threshold value, then suggestion report is sent to their Email ID.

V CONCLUSION

Ultimately, the goal of this research is to identify and improve student's pleasure and well-being in learning environments. One encouraging move in the direction of accomplishing this aim is the creation of an extensive Happiness Index and an easy-to-use online self-assessment tool. The score recognizes the full aspect of a student's experience by incorporating characteristics like mental wellness, which goes beyond the typical focus on academic accomplishment. An ensemble model predicts the happiness index more accurately and robustly than a single model, as demonstrated by the results of the previous study. To increase the predictive capacity of the model, additional characteristics can be added or the current features can be changed. Despite having a higher accuracy than a single predictive model, an ensemble model can be computationally demanding and may need additional resources for training. In addition, it takes longer to train than a single model. In the future, the model can also be enhanced by adding a strong feedback system to collect opinions on how well the Happiness Index works from educators and students. In order to give students who have been identified as having lower happiness scores targeted support, it can also be made better by merging it with counselling services. This could entail working together to create individualized intervention plans with mental health specialists. As a result, our web application supports the development of a supportive and nurturing environment in schools where students' emotional and psychological needs are met.

Abstract—

Facial analysis in crime prevention aims to leverage technologies like FaceNet and MTCNN algorithms for various objectives, including registering criminals into databases, matching photos to identify suspects, and enhancing video surveillance for real-time monitoring and detection of criminal activity. This research investigates the efficacy of integrating FaceNet algorithm within existing video surveillance infrastructure. These techniques enable law enforcement agencies to effectively utilize facial recognition technology in identifying and apprehending individuals involved in criminal activities, thereby enhancing public safety and crime prevention efforts.

Keywords—Criminal identification, Convolutional Neural Networks, machine learning, face recognition, Closed Circuit Television

1. Introduction

Facial recognition technology has emerged as a powerful tool in crime prevention strategies worldwide. By harnessing the capabilities of artificial intelligence and advanced algorithms, facial recognition systems can analyze and identify individuals from digital images or video frames based on their unique facial features. One of the primary advantages of facial recognition in crime prevention is its ability to enhance surveillance efforts. Law enforcement agencies can deploy facial recognition systems in public spaces, transportation hubs, and other critical areas to monitor for known criminals, suspects, or persons of interest in real-time. This proactive approach allows authorities to identify and apprehend individuals involved in criminal activities swiftly. Moreover, facial recognition technology can aid in the detection of unauthorized access or suspicious behavior in restricted areas. By integrating facial recognition systems with access control systems, organizations can strengthen security measures and prevent unauthorized entry into sensitive locations such as government facilities, corporate offices, or military installations. In addition to its role in surveillance and access control, facial recognition can assist in the investigation and resolution of criminal cases. Law enforcement agencies can use facial recognition software to match surveillance footage or crime scene images with existing databases of known offenders, thereby narrowing down potential suspects and expediting the investigative process. Furthermore, facial recognition technology can serve as a deterrent to criminal behavior.

2. LITERATURESURVEY

The face recognition applications have been evolving since 1960[1], which lead to invention of RAND tablet approach for coordinating features on the face. It is a device which emits electromagnetic pulses to input the coordinates on a grid. The device system used to record several facial coordinates manually like eyes, hairline, mouth and nose. Bledsoe [2] noted that there were many factors inhibiting a computer's ability to accurately recognize a single individual in two different photographs. Photographs of the same person might capture a person's face at vastly different angles, at different ages, with varying facial expressions, and under different lighting conditions. This may confound the system algorithm due to lack of advancement in algorithm and technology. In reference [2] various face recognition features were included like color of hair, chin, skin tone etc....

By using Correlations between pairs of features, Euclidian distances and Feature Reduction in facial lines the algorithm is deployed. This experiment was performed with three population sizes: 64, 128, and 255 faces the results for 128 and 255 are similar but 64 is relatively unsuccessful. Although these results are fairly good, all the experiments indicate that the binary selection method used was too rigid; but the achieved final result is on an average, about 50 percent of correct identification. In 1980 [3], researchers have introduced the statistical approach for face recognition, by using eigenvalues and eigenvectors to reduce dimensionality. It's the main idea behind Principal Component Analysis. The eigenface approach to face recognition was motivated by information theory, leading to the idea of basing face recognition on a small set of image features that best approximate the set of known face images, without requiring that they correspond to our intuitive notions of facial parts and features. Although it is not an elegant solution to the general object recognition problem. When an image is sufficiently close to face space (i.e. it is face-like) but is not classified as one of the familiar faces. The [4] uses dimensionality reduction technique for creating a criminal identification system termed as "FRCI". This study successfully achieved its objectives i.e matching a face with available database accurately and applying principal component analysis for finding distinguishable features from many images to get the similarity for the target image. It is a better alternative for criminal identification instead of using thumb print identification but it does not show the details of the criminal and it follows Principal component Analysis (PCA) which require data set with data normalization and if the number of Principal Components is not carefully chosen, it may miss certain information in contrast to the real list of characteristics.[5] uses Harr features as explained in [6].

The approach was used to construct a face detection system which is approximately 15 times faster than any previous approach. A harr like include considers adjoining rectangular locales in a location window at a particular area, rundowns the force of the pixels in each locale, and calculates the distinction between these wholes. But the main features are required to train with the Haar wavelet and it requires predefined dataset. In [7] Adriana Kovashka, Margaret Martonosi proposed a framework which employments 18 highlights counting RGB which is used in [8].This approach uses Viola Jones algorithm which has High true detection rate as well as high false detection rate and Training time is very slow .The algorithm encounter problems in positions range like side view and for low lighting because their Haar-like features do not map very well to varying positions.[9] explains the utilization of AdaBoost and ANN together to make a cross breed show "ABANN". Numerous deep learning models have been connected particularly for confront acknowledgment such as Retinal Connected Neural Network, Rotational Invariant Neural Network, Back Propagation Neural Network, Fast Neural Network, etc. The fundamental center of our venture will be based on [10] FaceNet is utilized to identify contrasts in the faces displayed from the database. A Deep Convolutional Neural Network (DCNN) approach is utilized, wherein each layer is mapped to 128 bytes and the assignment of acknowledgment, discovery, and clustering is carried out. An accuracy rate of over 95% has been attained for two datasets.

3. METHODOLOGY

The UI developed consists of three main domains:

a. Register Criminal

b. Photo Match

c. Video Surveillance

Register Criminal:

This domain facilitates the input of criminal data, encompassing various attributes including the individual's personal information such as Name, Parent's name, Gender, Religion, Blood Group, Distinctive Body Marks, Nationality, Convicted Crime, and also incorporates a visual representation through a facial image.

Photo Match:

Facial recognition's photo matching entails comparing a given facial image with a database of known individuals to uncover potential matches. This approach is widely utilized in law enforcement and security settings to aid in identifying individuals implicated in criminal activities.

Video Surveillance:

Video surveillance integrated with facial recognition technology provides law enforcement agencies and security organizations with a proactive means of identifying and responding to criminal activity in real- time, thereby enhancing public safety and security.

4. FACE RECOGNITION OVERVIEW

A. Face detection:

Face detection is a critical component of criminal identification systems, utilized in law enforcement and security applications worldwide. It involves the automatic detection of human faces within images or video frames. This technology plays a pivotal role in identifying suspects, enhancing surveillance, and maintaining public safety. At its core, face detection algorithms analyze digital images to locate and extract facial features. These algorithms utilize various techniques, including pattern recognition, machine learning, and neural networks, to differentiate faces from other objects or backgrounds. In criminal identification systems, face detection serves as the initial step in the process of matching captured faces against a database of known criminals or suspects. Once a face is detected, it can be further analyzed for recognition, where facial features are compared with existing records to determine potential matches. The effectiveness of face detection in criminal identification depends on various factors, including image quality, lighting conditions, facial expressions, and occlusions. Advanced algorithms have been developed to address challenges such as pose variation, partial occlusion, and disguise, enhancing the accuracy and reliability of the identification process.

B. Feature extraction:

Feature extraction in face detection for criminal identification is a pivotal step that involves capturing and representing key characteristics of facial images to enable accurate recognition and matching processes. Unlike face detection, which focuses on locating faces within images or video frames, feature extraction delves deeper into analyzing the unique attributes of each face for identification purposes. Various methods are employed in feature extraction, each aimed at capturing distinctive facial traits while minimizing noise and irrelevant information. One commonly used technique is Principal Component Analysis (PCA), which transforms the high-dimensional pixel values of facial images into a lower-dimensional space while preserving the most significant variations among faces. Additionally, Histogram of Oriented Gradients (HOG) is widely utilized for attribute extraction in face detection tasks. HOG computes the distribution of gradient orientations within localized regions of the facial image, capturing the underlying structure and shape of facial features. CNN is most used powerful tool for feature extraction in recent years, leveraging deep learning techniques to automatically learn hierarchical representations of facial features. CNN- based approaches can extract features at multiple levels of abstraction, enabling superior performance in complex scenarios and diverse facial conditions. Once features are extracted from facial images, they are typically represented as vectors or descriptors that encode the distinctive characteristics of each face. These feature representations are then used for comparison and matching against a database of known faces, enabling the identification of suspects or individuals of interest. Feature extraction in face detection for criminal identification plays an important role in increasing the accuracy, robustness, and efficiency of the overall identification process. By capturing and representing key facial traits in a compact and discriminative manner, feature extraction enables effective matching and recognition, facilitating the apprehension of criminals and the maintenance of public safety.

C. Verification or Identification:

Depending on the application, the system may either verify whether the suspect's face matches a specific individual in the database (verification) or attempt to identify the suspect by searching the entire database for potential matches (identification).

D. Human Review:

While automated algorithms can assist in the matching process, human review is often necessary to confirm the accuracy of the results and make final judgments regarding the identification of suspects.

Achieving high accuracy in facial analytics for crime prevention projects involves several key steps. Firstly, it's crucial to use high-quality datasets that are diverse, representative, and balanced. This ensures that the model learns from a wide range of facial features and characteristics, improving its ability to generalize to real-world scenarios. Secondly, selecting the right features is essential. This involves identifying facial landmarks, textures, and patterns that are relevant for crime detection and prevention. Using advanced feature extraction techniques, such as deep learning-based methods, can help capture intricate details in facial images. Thirdly, the choice of model architecture plays a significant role. Convolutional Neural Networks (CNNs) are commonly used for facial analytics due to their ability to learn hierarchical representations of facial features. Fine-tuning pre-trained CNN models, such as VGG, ResNet, or Efficient Net, on your dataset can significantly boost accuracy. Lastly, continuous evaluation and refinement are crucial. Regularly testing the model on new data and fine-tuning it based on performance feedback can help improve its accuracy over time. Additionally, incorporating feedback from domain experts and stakeholders can help refine the model's performance for specific crime prevention applications.

System Architecture:

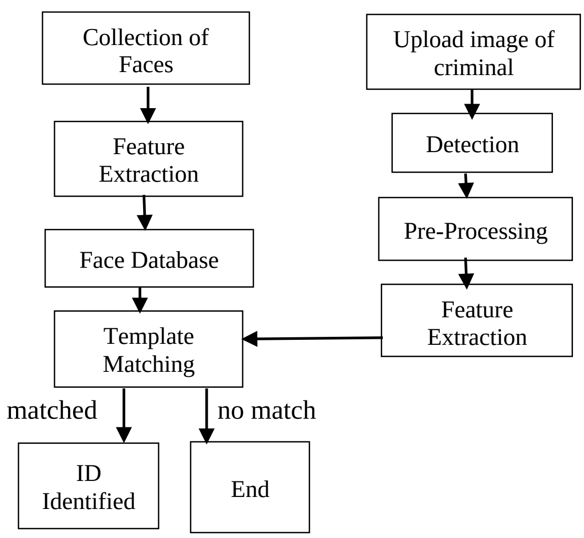

Fig. 1 Proposed System Architecture

To perform face recognition, a series of steps are typically followed as shown in fig. 1. Firstly, a dataset of facial images is collected, encompassing a variety of poses, lighting conditions, and facial expressions to enhance the model's accuracy and robustness. Next, the images are preprocessed to standardize their size, orientation, and lighting. Following this, a face detection algorithm is employed to locate and extract faces from the images, utilizing methods like Haar cascades, Histogram of Oriented Gradients (HOG), or deep learning-based approaches such as Single Shot Multibox Detector (SSD) or Faster R-CNN. Subsequently, features are extracted from the detected faces, often utilizing Convolutional Neural Networks (CNNs) to capture distinctive facial characteristics. These features are then encoded into a numerical representation for comparison, reducing the dimensionality of the features while retaining essential information. Finally, the encoded features are matched against a database of known faces to identify or verify individuals. The process can be refined through continuous model improvement, ethical considerations, and compliance with privacy regulations.

5. FACE RECOGNITION APPROACH

A. MTCNN:

MTCNN (Multi-Task Cascaded Convolutional Systems) calculation is one such innovation that has revolutionized the field of surveillance and object detection. Created in 2016, the MTCNN calculation presents a cascading arrangement of neural systems to identify, adjust, and extract facial features from digital images with increased accuracy and speed. The MTCNN calculation scale the picture to distinctive sizes as the input of each network layer. It consists of three convolutional neural systems to achieve the multitask detection. MTCNN calculation can totally include three assignments at the same time: face location, border relapse and point positioning.

Stage 1 (Proposal Network - PNet): This stage generates candidate bounding boxes (proposals) for potential faces in the input image. It uses a fully convolutional network to efficiently propose regions that might contain faces.

Stage 2 (Refinement Network - RNet): The proposals generated in the first stage are refined in this stage. The network filters out false positives and improves the accuracy of the bounding box predictions.

Stage 3 (Output Network - ONet): Finally, this stage performs further refinement and filtering on the proposals generated by the previous stages. It outputs the final bounding boxes along with facial landmarks.

B. FaceNet:

FaceNet is a deep learning model developed by researchers at Google that is designed for performing face recognition tasks. It utilizes CNN architecture to map features of a person's face into a space of high-dimension called as embedding. This embedding is such that faces with alike features are mapped closer together while diverse faces are farther apart, making it easier to compare and recognize faces. One of the key innovations of FaceNet is its use of triplet loss. This helps in learning discriminative features that are robust to variations in lighting, pose, and facial expressions. The objective of this loss function is to create little squared separates between two similar faces. While, Large squared remove between two pictures having diverse personalities.

Triple loss-- The inserting is spoken to by f (x) ∈ R^d. This inserts a picture x into a d-dimensional Euclidean space. Moreover, we constrain this implanting to live on the d-dimensional hypersphere, i.e. kf(x)k2=1.This misfortune is propelled within the settingof nearest-neighbour classification. Here we need to guarantee that an picture x_i^a(stay) of a particular individual is closer to all other pictures x_i^p (positive) of the same person than it is to any picturex_i^n (negative) of any other person.

$$\left\|f(x_i^a) - f\left(x_i^p\right)\right\|_2^2 + \alpha < \left\|f(x_i^a) - f\left(x_i^p\right)\right\|_2^2$$

-equation (1)

$$\forall \left(f(x_i^a), f\left(x_i^p\right), f\left(x_i^n\right)\right) \in \tau$$

-equation (2)

$$L = \sum_i^N [[\ ||f(x_i^a) - f\left(x_i^p\right)||_2^2 - ||f(x_i^a) - f\left(x_i^p\right)||_2^2 + \alpha]$$

-equation (3)

These triplets would not contribute training and result, as they would still pass through network it is crucial to choose triplets, that were active and can contribute to improve model. The following section describes about triplets.

Triplet Selection–For faster learning, we have to triplets that violate the equation above. This means for given x_i^a we ought to triplets such that;
$||f(x_i^a) - f(x_i^P)||_2^2$is maximum and;
$||f(x_i^a) - f(x_i^n)||_2^2$ is minimum.

Generating triplets based on the entire training set is computationally expensive. Two alternative methods for triplet generation are:

Incremental Triplet Generation:

Instead of generating triplets on the entire training set in each step, triplets are generated incrementally based on previous checkpoints. This approach involves calculating the minimum and maximum on a set of the data, making the process more computationally efficient.

Checkpoint-based Triplet Generation:

Triplets are generated at specific checkpoints during the training process. At these checkpoints, the model's parameters are saved, and triplets are generated based on these saved parameters. This allows for triplet generation without the need to consider the entire training set, reduce the computational cost.

Reference Paper Number	**Algorithm Used**	**Accuracy**	**Accuracy of Proposed Model (Facenet & MTCNN)**
[4]	The Algorithm is designed using Principal component analysis (PCA) of Eigenfaces	70.633%	89.74%

Achieving high reliability in facial analytics for crime prevention projects requires careful attention to several key aspects. Firstly, it's essential to establish robust data collection procedures. This involves using high-quality cameras and ensuring consistent lighting conditions to capture clear and consistent facial images. Standardizing the data collection process helps minimize variability and ensures the reliability of the collected data. Secondly, data preprocessing plays a crucial role in improving reliability. This includes removing noise, artifacts, and irrelevant information from the images. Preprocessing techniques such as image normalization, denoising, and face alignment can help improve the quality of the input data and enhance the reliability of the model's predictions. Thirdly, the choice of model architecture and training approach is critical. Using deep learning models, such as convolutional neural networks (CNNs), that are well-suited for image analysis tasks can help improve reliability. Additionally, training the model on a diverse and representative dataset can help enhance its ability to generalize to new and unseen data, improving overall reliability. Finally, continuous monitoring and evaluation of the model's performance are essential for ensuring reliability. Regularly testing the model on new data and monitoring its performance metrics can help identify and address any issues that may arise, ensuring that the model remains reliable over time. Incorporating feedback from users and domain experts can also help improve the reliability of the model by refining its performance for specific crime prevention applications.

8. CONCLUSION

In conclusion, the advancements in face detection technology have significantly impacted the field of criminal identification, revolutionizing the way law enforcement agencies approach investigations and security measures. By harnessing the power of machine learning algorithms and computer vision techniques, facial recognition systems have become invaluable tools for swiftly and accurately identifying suspects, enhancing public safety, and preventing crime. The ability to match faces captured in surveillance footage or photographs against databases of known individuals has expedited the identification process, leading to the apprehension of criminals and the resolution of cases that may have otherwise remained unsolved. Moreover, facial recognition technology has proven instrumental in combating various forms of criminal activity, including theft, fraud, terrorism, and human trafficking, by providing law enforcement agencies with timely and actionable intelligence. By prioritizing transparency, accountability, and responsible innovation, we can ensure that facial recognition systems continue to serve as powerful tools in the fight against crime while upholding fundamental rights and values in our society.

Mobile Applications: Development of mobile applications for law enforcement personnel to access facial recognition databases and receive real-time alerts on their devices.

Artificial Intelligence Integration: Use of AI for more sophisticated facial recognition, enabling better accuracy in

identifying individuals, even in challenging conditions such as low light or obscured faces.

Cross-Domain Integration: Explore integration with other domains, such as social media or online databases, to gather additional information that can aid in investigations.

***Abstract*— The world is currently grappling with a significant garbage crisis, which is a result of the prevailing issues of quick economic expansion, inadequate urban planning, overpopulation, corruption, and political inefficiency. It is becoming increasingly evident that there is a need to develop a robust waste management strategy to monitor the accumulation of garbage on roadsides, footpaths, schools, and colleges. Therefore, this research study explains the design of a garbage collection robot that uses IoT technology such as a Bluetooth application. This research study aims to design and make a Roadside Garbage Collection Robot (Automatic Garbage Collector). This robot model serves as an automatic garbage collector, which can effectively and efficiently tackle the problem of garbage accumulation.**

Keywords— Arduino, Garbage, Ultrasonic sensor, IoT

I. Introduction

Maintaining cleanliness in the environment is crucial for various reasons. There are several issues related to the cleaning of the environment. One of the major issues is the improper disposal of waste, which leads to pollution of land and water bodies. There are several issues related to the cleaning of the environment. One of the biggest environmental concerns today is the amount of litter that is found on roadsides and public spaces. Despite various efforts by organizations to reduce littering, it seems to be a growing problem [1]. However, there is a potential solution in the form of garbage-collecting robots. These machines can autonomously navigate through public spaces and collect trash, which could significantly reduce the amount of litter on the streets. With the advancement of technology, it's exciting to see how these robots could positively impact the environment.

Until now, there has been a lot of interest and development in service robots for cleaning swimming pools, houses, walls, and domestic stairs. However, cleaning robots for roadsides have not received as much attention. This paper presents the development of a prototype for a roadside cleaning robot. Nowadays, the way of cleaning up roadside waste is by hiring manual laborers. However, industries are shifting towards automation and it should also be applied efficiently towards waste management. Manual labor is the traditional way for employment yet there are problems associated with cleaning up garbage by human laborers.

In the present era, as countries continue to develop at an unprecedented pace, a significant amount of unwanted waste is being generated, including electronics, plastics, and various biodegradable products. Despite considerable research in this field, finding an efficient solution has proven to be elusive. However, with the advent of garbage collection robots, we now have the opportunity to collect and dispose of waste properly and manage it effectively. Unfortunately, the robots developed thus far have not been precise or accurate, and most of them are controlled manually and lack robustness. Our project robot, on the other hand, will function with precision efficiently collecting and disposing of waste. Its implementation will benefit numerous individuals and significantly reduce human labor.

II. Literature Review

Various existing models are capable of collecting of garbage. Let's discuss a few models based on the survey:

The robot by K Kamal et al. [1] can move with an average speed of 0.5m/s but the robot developed is yet to be improved to operate automatically and control from long distances.

The robot by Kavya.C et al.[2] is flexible to be used in various environments. The robot uses IoT technology yet the ways are not mentioned in clarity

The Robot by Ayub Mulani et al.[3] has used Raspberry Pi for garbage detection and has also attached a camera to the model but the robot is yet to achieve accuracy in detection.

The robot by N.Varuneshreddy et al.[4] is made to operate on sand by the beachside. Images from the IP camera are sent to the computer and are processed in the Bluetooth module and garbage is detected.

The research by Tawanda Mushiri et al.[5] emphasizes on the designing of the robot in a way that it will be able to efficiently collect garbage.

The robot by Saravana kannan G et al.[6] detects garbage using image processing. Various features in images like color, and size are considered in MATLAB.

The Robot by Hesham Alsahafi et al.[7] can detect metallic and nonmetallic garbage in specific areas. The size of the robot is small and it can work only in specific areas.

The Robot by Osiany Nurlansa et al.[8] is designed of the steps: requirements analysis, design, manufacturing, and testing. It is capable of automatically picking up garbage on the water.

The robot by Bharathi V et al.[9] collect garbage in a highly effective manner, without any need for human intervention. It uses an IR sensor as well as ultrasonic sensor for detection.

The robotic arms designed by Abhiraj Bhalerao et al.[10] is a fully automatic system but one can operate it manually also. The robotic arm has a wide range of applications, including material handling, object sorting, welding, grinding, and spray painting.

In the research paper by Thota Arun et al.[11], the robot detects objects using an IR sensor and a moisture sensor is attached to the bin to detect the level of garbage collected. A web page is also created to display the trash level present in the bin.

The robot made by H.G.T. Milinda and B.G.D.A. Madhusanka[12] is used for cleaning floors in domestic households. An image acquisition camera is used for image processing. Mud detection is also implemented based on color and area.

The robot was made by H.M.R.G. Herath et al. [13] is a beach cleaning robot that has a high-performance electrical motor to drive the robot and uses the IoT platform to indicate the level of the garbage tray remotely.

III. METHODOLOGY

A. Components: ***Arduino MEGA*** **2560 Rev3**, **Servo and DC motors, IR Sensor, Ultrasonic sensors, HC05 Bluetooth Module, wheels, wooden plank, wires, cluster wheels, PVC pipes, etc**.

The main frame of the robot: The wooden board is of dimensions 27x27x5 cm. At the backside of the robot, a dustbin is attached which is of dimensions 12x20cm.

The reason for choosing ultrasonic sensors was that the sensor can measure the distance between itself and the object. The ultrasonic sensor also allows it to put up a threshold distance by which it can measure the distance up to that point. In this way, when the sensors are attached to the robot and when set up with a threshold distance the ultrasonic sensor will detect the distance between the robot and the garbage.

After that, the IR sensor will emit the IR light and the IR receiver shall check for the reflected light. If the light gets reflected by hitting the garbage in front of it, then the IR receiver receives this light, and the object is then detected. The robotic arms are programmed in such a way that when the IR receiver receives the signal and the ultrasonic sensors detect the distance between them, the arms will move and pick up the garbage.

Fig 1. below is the circuit diagram of the robotic arms used in our project. Arduino mega 2560 Rev3 and hc05 Bluetooth module is needed for controlling and connecting mobile phones to the robot respectively. Arduino Mega 2560 Rev3 has 54 digital input/output pins and it comes with more memory space and, a bigger size. To power the servos 5V voltage is required, and it comes from an external power source as the Arduino is unable to handle a large amount of current that draws from all of them. The power source ought to handle 2A of current. Once the connections are done the Arduino Coding is started.

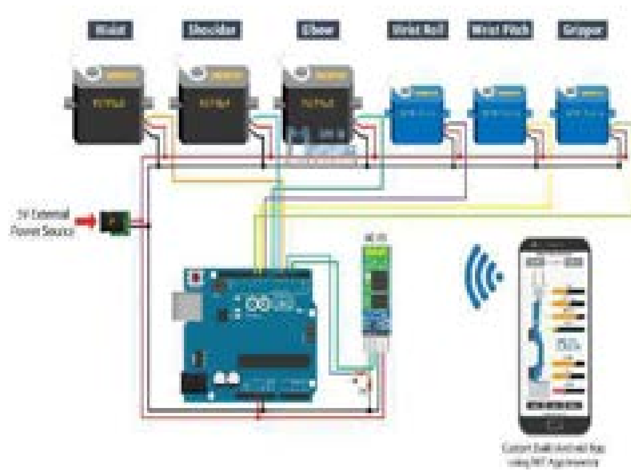

Fig. 1. Circuit diagram of robotic arms

The robotic arms are flexible as they consist of 5 degrees of freedom. The parts of the robotic arms are 3D printed and are assembled with the help of screws.

Flowchart for robotic arm movement: In Fig 2. the robotic arms will begin in their initial position. Once the ultrasonic detects the waste object, the wheels will stop at the threshold distance. As the IR sensor detects the garbage the arms will move to pick it up. If the garbage is not detected the arms will remain stationary.

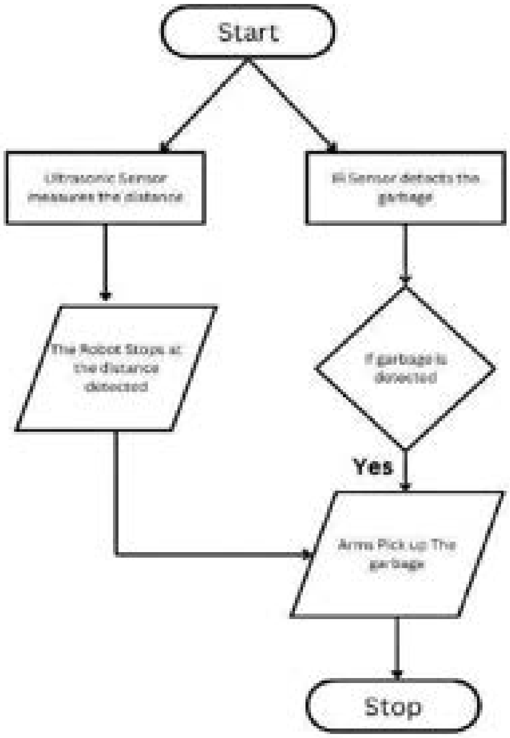

Fig. 2. Flowchart for arms movement

B. *Block Diagram of the robot*: The Fig 3. block diagram depicts that instructions to the robot will be transmitted through the Arduino Mega 2560 Rev3 microcontroller. The block diagram of a robot encompasses diverse components, including sensors, microcontrollers, power supply, motors, and communication modules, which operate concertedly to ensure the robot's optimal functionality. The block diagram not only facilitates the comprehension of the information and signal flow between the different components but also illustrates the robot's interaction with its surroundings and reception of commands from external sources. The Bluetooth module HC05 is connected to the smartphone through a small app developed (Netra App).

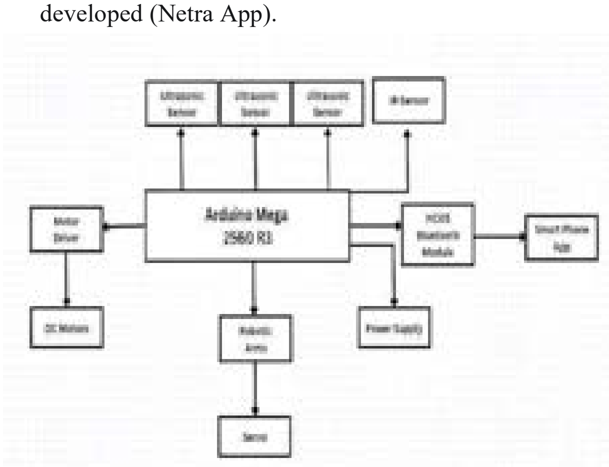

Fig. 3. Block diagram of the robot

C. *Design of the robot:* The utilization of Tinkercad, a free 3D modeling program renowned for its user-friendly interface, enabled us to design our robotic arm with utmost precision. By employing this software, it can determine the optimal measurements that would facilitate the efficient construction of the robot. In addition, its simulation capabilities provided us with substantial insights regarding the working principle of the robotic arm, thereby imparting a scientific understanding of the system. There were many options for designing the robot but this design as proposed in [5] has better efficiency in picking and placing garbage.

Fig. 4. Proposed model of the robot

IV. WORKING PRINCIPLE

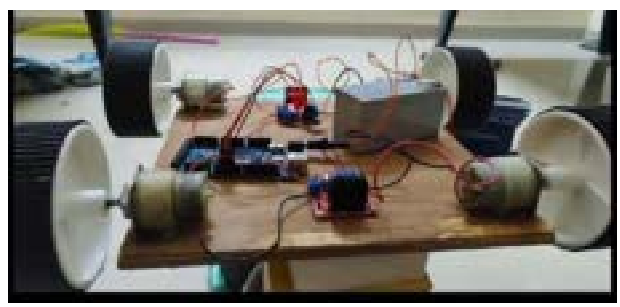

Fig. 5. Testing of DC Motors with HC05 Bluetooth module

The ultrasonic ranging module is a versatile component that allows for non-contact measurements ranging from 2cm to 400cm, with an impressive accuracy of up to 2mm. The module is composed of ultrasonic transmitters, a receiver, and a control circuit. To use it effectively, you need to follow these steps: 1. Use an IO trigger to send a high-level signal that lasts for at least 10 microseconds. 2. The module transmits eight 40 kHz signals and waits for one pulse signal to bounce back. 3. If any signal is detected at a high level, the duration of the high output IO signal is the time it took for the ultrasonic signal to travel to the object and back. You can use this time to calculate the test distance using the formula: distance = (time x velocity of sound in air (340m/s) / 2)[1].

Fig. 6. Real-time graph of Ultrasonic sensor readings

Fig 6. depicts the graph on which the X axis represents the time in seconds and the Y axis represents the distance between the sensor and garbage.

An IR sensor is a device that can sense the presence of an object in its surroundings by emitting infrared light. The sensor works by using an IR LED to emit light and an IR photodiode to detect the light. When the light is reflected by an object and falls on the photodiode, its resistance and output voltage change in proportion to the amount of light received. There are two types of IR sensors: Active and Passive. Active infrared sensors consist of an infrared source and an infrared detector, while passive infrared sensors only have a detector. Hence an active IR sensor is used to detect the object. The energy emitted by the infrared source is reflected by an object and falls on the infrared detector, which helps detect the presence of the object.

Fig. 7. IR sensor readings when object is detected

Fig 7. depicts the readings of IR sensor when the object is detected. Along with that the distance is also displayed in the output.

The robot has been set up with three ultrasonic sensors to increase the accuracy of object detection. Ultrasonic sensors have a specific range for detection which is limited. So, to have maximum detection 3 ultrasonic sensors are used. In this way, if the left or right-side sensor detects the garbage the sensor will be able to detect garbage more accurately.
The Ultrasonic Sensors will detect objects/waste which will come in the path of the robot then the Robotic Arm will get the exact coordinates of the object/waste and then the object will be picked up by the gripper part attached to the robotic arm.
The robotic arms are designed using Solidworks 3D software which we purchased [9]. The arm of the robot has 5 degrees of freedom. Only the shoulder, wrist roll, and gripper parts of the robot were used. The Arduino coding was done in such a way that the angles of the shoulder, wrist, and gripper were already set. A threshold distance is set in the ultrasonic sensor. When the sensor detects the distance, and the IR sensor detects the garbage the robot stops and the elbow first rolls down, then the shoulder to bring the arm to the ground level then the gripper grabs the garbage, and the elbow and shoulder go back to their original position. Then the gripper drops the collected garbage into the dustbin attached at the back. For the first 3 axes namely, the base, the shoulder, and the elbow, we have used the MG996R servos, and for the other 2 axes, the wrist roll and wrist pitch, as well as the gripper we have used the smaller SG90 micro servos. After picking up the object/waste, all servos will produce a combined motion to drop the object/waste in the dustbin. Then, the Arm will come to its original position. All these tasks will be performed repeatedly.

HC-05 is a Bluetooth module used to perform wireless communication. It uses serial communication to communicate with the devices and it communicates using a serial port (USART) with the microcontroller. Its range is <100m depending on the transmitter, receiver, and geographic conditions. The robot is controlled using the Netra app that is connected to the robot using the HC-05 Bluetooth module.

Fig. 8. Remote Control of the Robot using Netra App

V. RESULTS & DISCUSSION

A. Review Stage:

Fig. 9 Actual setup of the robot

The design of the proposed robot has been improved for increased efficiency by utilizing three wheels instead of four. The back of the robot is supported by two large wheels that balance the weight of the dustbin, while two cluster wheels at the front enable improved maneuverability. With this design, our robot can move effectively and efficiently to perform its tasks. At first, the team faced a lot of issues while checking the angles of the robotic arms because the servos and Arduino could not sustain the weight of to object, and more power was needed to perform smooth functions. Connecting the Arduino to the Bluetooth module and operating through the Netra app was also a challenge. Despite the challenges, the robot can be controlled through the Netra app.

B. Final Stage

Assess the arm's ability to carry and manipulate objects of different weights. This involves testing the torque and payload capacity of each servo motor Evaluate the accuracy of the robotic arm's movements. This can be done by instructing the arm to move to specific positions and measuring how closely it reaches the target points. Test the repeatability of the robotic arm by instructing it to perform a series of tasks repeatedly. Check if it consistently achieves the same results.

TABLE I. PERCENTAGE ERROR ANALYSIS OF THE ANGLES

Parts of Arm	**Arm**	**Elbow**	**Grip**
Angle 1 estimated	95	55	75
Actual Angle 1	105	45	60
Error 1 in %	-9.52	22.2	25
Angle 2 estimated	18	130	9
Actual Angle 2	15	155	7
Error 2 in %	20	-16.12	28.57

Table 1. represents the percentage error in the angles of the robotic arms. The actual angle values were used to do the coding of robotic arms with the help of servo motors. The average of the two errors =(12.56+10.81)/2=11.68.The precision of the arms calculated is very low. To increase the precision of the arms, a powerful servo motor and a good power supply are required.

The coding for the arms was done and the robot was able to be controlled with the help of connecting the hc05 Bluetooth module to the mobile app. The robot can pick up and place the garbage in the bucket. It's also possible to control the robot with the voice command feature present in the Netra app. The unique feature of the robot is that it is robust and designed so that there will be less wear and tear of the robot. Other previously made robots are delicate and smaller in size. The robot is perfectly balanced and can be operated in all types of environments. The entire robot is cost-effective and also is big in size. The limitations faced while implementing the robot were the lack of availability of hardware materials, less power supply by the battery, as well as finances required.

VI. CONCLUSION

It's important to acknowledge the physically demanding nature of garbage pickup work and the occupational hazards that come with it. That's why it's great to see the development of a robot that can eliminate the health risks associated with manual waste collection. This solution is not only beneficial for environmental maintenance, but it also reduces the need for human intervention in garbage maintenance and pollution monitoring. It's worth noting that the mechanical design of the robotic arm needs to be researched further to improve the robot's functionality. However, there is still potential for this robot to operate automatically and with good accuracy. There is still a lot of scope for future research in the field of robotics and automation. In the future, garbage collection and management is going to be a serious issue due to the lack of human laborers and the increasing population which eventually will lead to an increase in garbage. There will be a need for garbage collection robots to reduce human labor and manage waste efficiently.

VII. FUTURE SCOPE

The objective was to design a robot capable of gathering objects from specific areas such as roadside, colleges, schools, and others. Our vision is to expand the usage of this robot across various fields. To achieve this, we aim to enhance the automation of the robot and improve its object detection accuracy. The accuracy of the robot can be increased by using better servo motors and reducing the stiffness of the robotic arms. Raspberry Pi can enable the robot to produce efficient results and improve the overall performance of the robot. We also plan to add a lid or covering for the dustbin attached as open waste can lead to the breeding of mosquitoes and other diseases. The team is also working towards adding more features such as sweeping and implementing more efficient cleaning methods beyond just picking. In this way, the reliability of the robot is increased. It can be made to handle harsh environments and is robust.

ACKNOWLEDGMENT

The authors would like to thank Vishwakarma Institute of Technology for their support in completing this project and thank you to Prof. (DR.) Chandrashekhar Mahajan (Head of Department, DESH), College Workshop, and The Robotics Forum (TRF) club for guiding us through difficulties.

***Abstract*— In Underwater wireless sensor networks (UWSNs), nodes are moving due to the external parameters like ocean currents and marine organisms etc. The topology control techniques proposed for traditional wireless sensor networks (WSN) were not applicable for UWSN because of its propagation delay, less bandwidth and multipath fading. An Efficient Topology Control and Depth Adjustment (ETDA) technique for UWSN is designed. The major role of ETDA technique is to reduce node disconnections and to improve the link quality of transmission. In this technique, a combined objective function (COF) is defined for topology control based on the energy level of nodes, distance between the nodes at different depth levels and the link expiration time. The topology control algorithm is applied by each sink node when a broken link or poor channel quality is detected at any part of the network. In this algorithm, the sink node performs reconnection to an intermediate sensor node with maximum COF value. Experimental results show the performance improvement of ETDA by maximizing the packet delivery ratio and minimizing the energy consumption and delay.**

Keywords*— Underwater wireless sensor networks (UWSN); Topology; Depth Adjustment; combined objective function (COF); Efficient Topology Control and Depth Adjustment (ETDA)

I. INTRODUCTION

UWSN consists of nodes which can perform data collection, processing and communication via acoustic signals. UWSNs are useful in applications like oceanographic data collection, pollution monitoring, disaster recovery and tactical surveillance. When UWSN are used in critical applications like military field or disaster recovery, all the sensor nodes should communicate with the sink node ensuring complete network connectivity. The best node deployment strategies for UWSN involve updating the node positions to ensure network coverage and reduce energy drain rate [1].

The main characteristics of UWSN are limited bandwidth capacity, high propagation delays, huge bit error rates and multipath fading effects [2]. To address these issues, researchers designed low speed acoustic signals for underwater communication which increases the broadcast delay and losses [3]. The topology control techniques proposed for traditional WSN were not applicable for UWSN because of its unique characteristics listed above. Hence there is a need for a topology control technique which ensures the connectivity and network lifetime of sparsely deployed sensor nodes [4]. Efficient data delivery from the sensor node to the sink is another major issue of this network. It should consider the ike depth of the node and speed of the acoustic signals [5]. Hence a stable and reliable optimized topology is required for successful data delivery in UWSN. In order to assure long connectivity among the nodes, the network topology control with efficient routing technique is necessary [7]. This work proposes an Efficient Topology Control and Depth Adjustment (ETDA) technique for UWSN.

The main objectives of this work include:

- To reduce network disconnections in UWSN
- To enhance the link quality of transmission
- To reduce the energy consumption

II. RELEATED WORKS

A topology control technique for UWSN proposed by Zhen Hong et al [1] consists of a game theory based technique for selecting the best nodes as cluster heads. Then, intra and inter cluster topology construction phases are performed. Simulation outcomes show that TCEB achieves better energy efficiency and throughput. A ReVOHPR protocol is proposed by Amir Chaaf et al [3] for stable cluster head selection. To increase the network lifetime, a dynamic sleep scheduling algorithm is presented. A virtual graph based routing algorithm is proposed for communication. To reduce the transmission latency, multiple AUVs are installed to collect the data. Lastly, the void holes are detected using relay based technique and repaired. Another cooperative game theory based scheme (DATUM) is presented by Sudip Misra et al [4] for dynamic topology control. They have established a route from the source sensor to the sink nodes for effective data transmission. After applying the Game theory model, they have determined a set of best paths for transmission. Energy Efficient Localization Algorithm (EELA) was proposed by Yali Yuan et al [8] for analyzing the communication between the anchor and sensor nodes. A game theory mechansim is used to design a topology control algorithm for the unknown nodes and anchor nodes by utilizing the transmission chances. An

Energy balance algorithm was proposed by Weiping Zhang et al [9] which analyzes the relationship between node' s remaining energy and data communication. It assures balancing of energy during data forwarding by the intermediate sensor nodes. Simulation outcomes shows that the algorithm extends the network lifetime and achieves higher throughput and delivery ratio. A joint power control and opportunistic routing protocol for UWSN was designed by RodolfoW. L. Coutinho et al [10]. In this protocol, routing decisions are made by considering the transmit power and the communication range of the nodes.

III. PROPOSED SOLUTION

Efficient Topology Control and Depth Adjustment (ETDA) technique for UWSN is proposed. In this technique, a combined objective function (COF) is defined for topology control based on the energy level of nodes, distance between the nodes at different depth levels and the link expiration time. The topology control algorithm is applied by each sink node when a broken link or poor channel quality is detected at any part of the network.

A. System Model

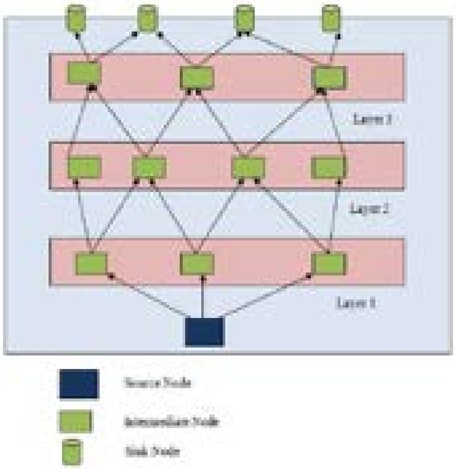

Fig. 1 System model of UWSN

The system model of UWSN is shown in Figure 1. It consists of multiple source nodes at sea level (level 1), multiple intermediate nodes at level 2 and multiple sink nodes at top level (level-3). It is assumed that each sensor node can communicate with at least another node at a higher level. Here, each sensor node $n_{i,l} \in N$ is at level $l \in L$, where N is the collection sensor nodes and L is the levels of nodes in UWSN. Moreover, it is assumed that each sensor node is connected to at least one sink node.

Let NL_s be the neighbor list of each sink $s \epsilon S$, (S is the set of sink nodes) given by

$$NL_s = \{n_{i}^{l} \mid D^l(i,s) \leq R_s\} \tag{1}$$

Where R_s is the communication range of sink s, $D^l(i,s)$ is the distance between the sink s and n_i at the layer l.

B. Determination of Combined Objective Function

A combined objective function (COF) for topology control is defined in terms of energy level (EL), distance between the nodes at adjacent layers ($d_{l,l+1}(i,j)$) and the link expiration time ($L_{i,j}$).

Energy Level (EL)

The EL of node n_i at level l indicates the node lifetime. Hence, each sink node selects the nodes with higher EL.

The total energy consumption (E_{tot}) of each sensor includes the energy consumption during transmission (E_{tx}) and the energy consumption during reception (E_{rx}), which can be calculated as:

$$E_{tot} = E_{ttx} + E_{rx} \tag{2}$$

E_{tx} and E_{rx} can be calculated as

$$E_{tx} = \sum_{i=1}^{h} P_{txi} * Z * T_{ni} * (1 + RTrate_i)$$
$$E_{rx} = \sum_{i=1}^{h-1} P_{rxi} * Z * T_{ni} * (1 + RTrate_i) \tag{3}$$

Where,

P_{tx} and P_{rx} denote the sending power and the receiving power of node i,

T_{ni} is the average time required to transmit one byte of data

$RTrate_i$ denotes the data retransmission rate of node i

Z denotes the size of the data

Then the energy level of each node n_i at layer l is given by

$$EL_l(n_i) = E_{ini} - E_{tot} \tag{4}$$

Where E_{ini} is the initial energy assigned to each node.

Link Expiration Time ($L_{i,j}$)

The link expiration time ($L_{i,j}$) denotes the time duration for which two intermediate nodes n_i and n_j (at adjacent levels), remain connected without disconnection. Hence the topology remains stable when the link expiration time is high.

$L_{i,j}$ can be computed follows:

$$L_{i,j} = \begin{cases} \frac{1}{v_{j,(l+1)}} D_{l,(l+1)}[\cot\alpha + \cot\beta] & if\, n_{j,(l+1)} isatA \\ \frac{1}{v_{j,(l+1)}} D_{l,(l+1)}[\cot\alpha - \cot\beta] & f\, n_{j,(l+1)} isat\, A' \end{cases} \tag{5}$$

Where $v_{j,(l+1)}$ is the mean speed of j at level (l+1),

$$\alpha = \sin^{-1}\left(\frac{D_{l,(l+1)}}{R_i}\right) \quad \text{and} \quad \beta = \sin^{-1}\left(\frac{D_{l,(l+1)}}{d_{i,j}}\right)$$

Distance ($d_{i,j}$)

If the distance $d_{l,l+1}(i,j)$ of n_i and n_j at levels l and (l+1) increases, the communication delay also increases.

$d_{l,l+1}(i,j)$ can be calculated as follows:

$$d_{l,l+1}(i,j)=\sqrt{(x_{nj,(l+1)}-x_{ni,l})^2+(y_{nj,(l+1)}-y_{ni,l})^2} \quad (6)$$

Where ($x_{ni,l}, y_{ni,l}$) is the coordinates of node $n_{i,l}$.

Hence the COF can be derived as follows

$$COF = w_1.\left(\frac{EL}{EL_{\max}}\right)+w_2.\left(\frac{L}{L_{\max}}\right)+w_3.\left(1-\frac{d}{d_{\max}}\right) \quad (7)$$

where EL_{max}, L_{max} and d_{max} are the threshold values of EL, $L_{i,j}$ and $d_{l,l+1}(i,j)$ respectively and w_1,w_2,w_3 are weighting constants ranging from 0 to 1.

The weighting constants are used to provide weightage to each metric used in the equation. During the experiments, the values are assigned as $w_1=0.4$, $w_2=0.3$ and $w_3=0.3$

Thus the sink nodes try to maximize the COF value meeting the below constraints.

$RE \geq RE_{max}$ and $L \geq L_{max}$ and $d \leq d_{max}$ (8)

C. Topology Control by Sink Node

The topology control algorithm is applied by each sink node when a broken link or poor channel quality is detected at any part of the network. In this algorithm, the sink node performs reconnection to an intermediate sensor node with maximum COF value. The topology control algorithm described below:

Topology Control Algorithm

Notations	**Definition**
sn	sink node
S	set of all sink nodes
T_i	Monitoring interval , i=1,2....
$COF_{i,l}$	COF of node $n_{i,l}$
MinCOF)	Minimum value of COF
Max(COF)	Maximum value of COF
TC_{req}	Topology control request
TC_{rep}	Topology control reply
ACK	Acknowledgement message
NLs	neighbor list of sink s
Next_hop_change	Next Hop Change message

1. For each monitoring interval T_i
2. For each $sn \epsilon S$,
3. Receives RE, $L_{i,j}$ and d(i,j) from each $n_{i,l}$
4. Derives the $COF_{i,l}$ using Eq.(7)
5. Compares the estimated COF with others
6. If $COF_{i,l}$ = Mini(COF) then
7. Indicates topology disconnection
8. sn sends a TC_{req} to $n_k \in NL_s$
9. n_k send ACK to sn as request confirmation
10. End if
11. If sn receives ACK, then
12. Waits for TC_{rep}.
13. Else
14. Retransmits TC_{req}
15. End if
16. n_k sends a its RE, $L_{i,j}$ and d(i,j) to S
17. sn derives the $COF_{k,l}$ of n_k
18. If $COF_{k,l}$ = Maxi(COF) then
19. sn updates its routing tree by nk with $n_{j,l-1}$
20. sn sends next_hop_change to $n_{j,l-1}$
21. Else
22. s again sends TC_{req} to another $n_{k+1} \in NL_s$
23. Repeat the steps from 11
24. End if
25. End For
26. End For

IV. EXPERIMENTAL RESULT

A. Experimental Settings

The proposed ETADA technique is implemented in NS2 AquaSim tool which an open source simulator developed for UWSN research.

The simulation settings and parameters are summarized in table 1.

Number of Nodes	25 to 125
Area size	1000 X 1000x10m
MAC Protocol	Underwater Mac
Simulation Time	100 seconds
Channel Model	Underwater Channel
Transmit Range	200m
Initial Energy	10000 Joules
Transmit power	2.0 watts
Receive Power	0.75 watts
Idle Power	0.008 watts
Data generation Interval	100 sec
Position Updating Period	0.3 sec

Table 1 Experimental settings

B. Results

The proposed ETADA technique is compared with LMST [9] approach according to the metrics latency, packet delivery ratio, average energy consumption and average forwarding ratio.

Nodes	**ETADA (sec)**	**LMST (sec)**
20	0.254	0.327
50	0.273	0.313
75	0.283	0.334
100	0.311	0.357
125	0.314	0.383

Table 2 Results for Topology control Latency

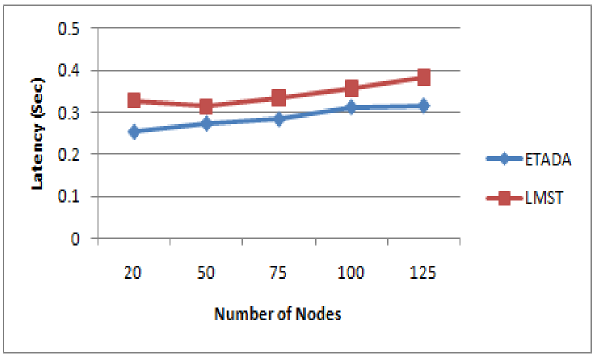

Fig2 Topology control Latency for Nodes

From the figure 2, it can be observed that the proposed algorithm ETADA achieves 16% lesser latency than LMST for different nodes scenario.

Nodes	ETADA	LMST
20	0.8889	0.8325
50	0.8972	0.8578
75	0.9384	0.8679
100	0.9574	0.8812
125	0.9582	0.9125

Table 3 Results of Packet Delivery Ratio

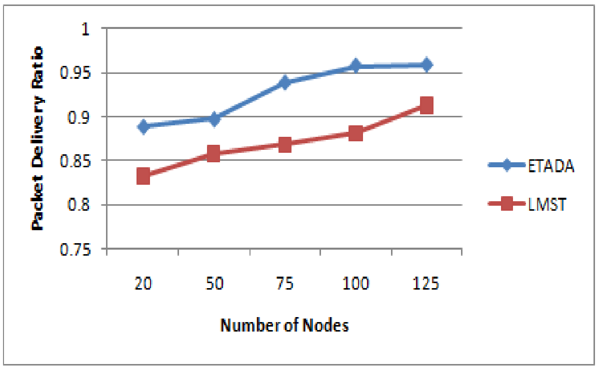

Fig 3 Packet Delivery Ratio for Nodes

From the figure 3, it can be seen that ETADA achieves 6% more packet delivery ratio than LMST for different nodes scenario.

Nodes	ETADA (Joules)	LMST (Joules)
20	675.22	793.92
50	734.11	855.64
75	787.45	890.95
100	831.63	900.66
125	859.48	949.73

Table 4 Results of Energy Consumption

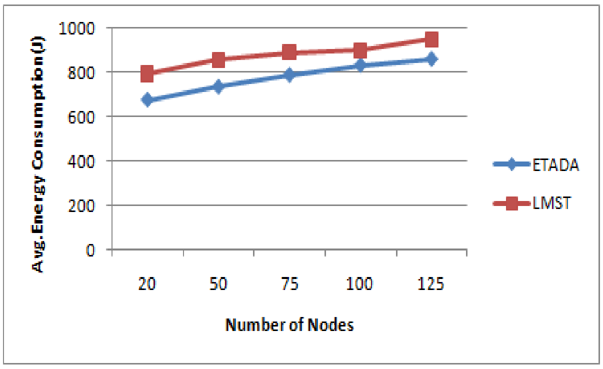

Fig 4 Energy Consumption for Nodes

From the figure 4, it can be observed that the proposed algorithm ETADA achieves 12% lesser energy consumption than LMST for different nodes scenario.

Nodes	ETADA	LMST
20	0.5771	0.3317
50	0.5484	0.3887
75	0.6364	0.4967
100	0.6843	0.5291
125	0.7643	0.5815

Table 5 Results of Forwarding Ratio

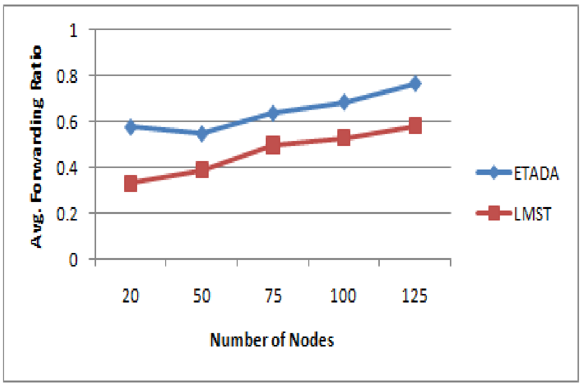

Fig 5 Forwarding Ratio for Nodes

From the figure 5, it can be seen that the proposed algorithm ETADA achieves 28% higher forwarding ratio than LMST for different nodes scenario.

.

CONCLUSION

In this paper, an Efficient Topology Control and Depth Adjustment (ETDA) technique for UWSN is proposed. In this technique, a combined objective function (COF) is defined for topology control based on the energy levels of nodes, distance between the nodes at different depth levels and the link expiration time. In topology control algorithm, the sink node performs reconnection to an intermediate sensor node with maximum COF value. The proposed ETADA technique is implemented in the NS2 and compared with LMST technique. Simulation results have proven that

ETDA has higher packet delivery ratio and forwarding ratio with minimized energy consumption and latency.

I. INTRODUCTION (*HEADING 1*)

In an era characterized by the rapid evolution of machine learning algorithms, the pursuit of robust and adaptable systems has taken center stage. As the technological landscape advances, the recognition of uncertainty as a critical factor in decision-making processes becomes increasingly evident. This article delves into the realm of uncertainty modeling and explores its integration with machine learning methodologies, presenting a groundbreaking fusion of fuzzy logic and data-driven approaches. The synthesis of these two domains offers a comprehensive framework for navi-gating the complexities of real-world scenarios, where imprecise and ambiguous in-formation often prevails [1].

At the core of this exploration is the fusion of fuzzy logic—a mathematical framework that deals with imprecision and vagueness—with machine learning. This amalgamation addresses a crucial aspect of contemporary computational challenges, providing a nuanced lens through which algorithms can interpret and respond to uncertain or incomplete data. Fuzzy logic's inherent ability to handle imprecise in-formation aligns seamlessly with the intricate demands of machine learning systems, enhancing their adaptability and resilience [2].

The article meticulously examines the synergies between fuzzy logic and machine learning, shedding light on the ways in which this integration contributes to the development of more resilient and versatile systems. By embracing uncertainty as an integral component, the proposed approach seeks to fortify algorithms against the intricacies of the real world, where information is often fraught with ambiguity. Through a detailed examination of uncertainty-aware models, the study not only underscores the potential for improved accuracy but also emphasizes the enhanced interpretability of machine learning outcomes [3].

This research, with its comprehensive approach, extends its impact across various applications, demonstrating the efficacy of uncertainty-aware models in diverse do-mains. Whether applied to healthcare, finance, or autonomous systems, the findings showcase the practical implications of incorporating fuzzy logic into machine learning methodologies. The article serves as a testament to the transformative power of embracing uncertainty, showcasing how it can be leveraged as a valuable asset rather than a hindrance in the quest for accurate and interpretable machine learning out-comes. As the technological landscape continues to evolve, the insights presented in this study pave the way for a new era in data-driven decision-making—one that acknowledges and harnesses the inherent uncertainty within the vast realms of in-formation.

II. TYPES OF MACHINE LEARNING ALGORITHMS

Machine learning (ML) algorithms are computational models designed to perform a task without being explicitly programmed. These algorithms enable computers to learn and make predictions or decisions based on data. There are various types of machine learning algorithms, broadly categorized into supervised learning, unsupervised learning, and reinforcement learning [4].

Supervised Learning: In supervised learning, the algorithm is trained on a labeled dataset, where each input is associated with a corresponding output. The goal is to learn a mapping function that can accurately predict the output for new, unseen inputs.

Common algorithms include linear regression, support vector machines, and neural networks. These algorithms are powerful for tasks like classification and regression [5].

Unsupervised Learning: Unsupervised learning involves training the algorithm on an unlabeled dataset, allowing it to discover patterns and relationships within the data on its own. Clustering and dimensionality reduction are common tasks in unsupervised learning. K-means clustering and principal component analysis (PCA) are examples of algorithms used in this context [6].

Reinforcement Learning: Reinforcement learning is concerned with training agents to make decisions in an environment to maximize a reward signal. Agents learn through trial and error, receiving feedback on their actions [7].

Popular reinforcement learning algorithms include Q-learning and deep reinforcement learning, where neural networks are employed to approximate complex policies.

Despite the success of traditional machine learning algorithms, there are situations where uncertainties, imprecise data, and fuzzy reasoning are prevalent. This is where fuzzy logic comes into play.

III. Justification for Fuzzy Logic

Fuzzy logic is a mathematical framework that deals with uncertainty and imprecision. Unlike classical binary logic, where a statement is either true or false, fuzzy logic allows for degrees of truth between 0 and 1 [8]. This makes it suitable for handling problems that involve vagueness and ambiguity, which are common in real-world scenarios. Here are some justifications for using fuzzy logic in machine learning:

Handling Uncertainty: In many real-world applications, data and decision-making are inherently uncertain. Fuzzy logic provides a way to model and represent uncertainty by allowing membership degrees to different classes or categories [9].

Linguistic Representation: Fuzzy logic enables the incorporation of linguistic terms and human-like reasoning into the decision-making process. This is particularly useful when dealing with qualitative and subjective information [9].

Rule-Based Systems: Fuzzy logic operates on a set of rules that express relationships between input and output variables. These rules are often more intuitive and easier to formulate than precise mathematical equations, making fuzzy logic suitable for rule-based systems [10].

Robustness to Noise and Incomplete Information: Fuzzy logic systems are generally more robust in the presence of noise and incomplete information. They can handle situations where exact numerical values are unavailable or where data may be im-precise [11].

Integration with Human Expertise: Fuzzy logic provides a framework for integrating human expertise into machine learning models. By allowing for fuzzy rules and linguistic variables, it facilitates collaboration between domain experts and machine learning practitioners [12].

While traditional machine learning algorithms excel in many applications, fuzzy logic plays a vital role in addressing the challenges posed by uncertainty, imprecision, and the need for human-like reasoning in certain real-world scenarios. Its ability to handle vagueness and incorporate linguistic terms makes fuzzy logic a valuable tool in the machine learning toolkit, especially in domains where clear-cut boundaries and precise data are hard to define [13].

IV. Problem Statement

In the rapidly evolving landscape of machine learning algorithms, the inherent uncertainty in real-world scenarios poses significant challenges to the development of robust and adaptable systems [20]. While traditional machine learning models excel in well-defined and precise data environments, they often struggle when faced with imprecise, ambiguous, and uncertain information. The problem at hand is the limited ca-pacity of existing algorithms to handle the complexities of decision-making processes in situations where data is incomplete, ambiguous, or subject to vagueness [14].

As identified in this article, the current state of machine learning faces a critical gap in addressing uncertainty, leading to suboptimal performance in various applications such as healthcare, finance, and autonomous systems. The reliance on binary logic and precise mathematical representations falls short when confronted with the nuanced demands of real-world data, which often involves degrees of truth, linguistic terms, and subjective information [15].

This study aims to tackle this problem by proposing a fusion of fuzzy logic with machine learning methodologies. Fuzzy logic, with its ability to handle uncertainty, imprecision, and linguistic representation, presents a promising solution to enhance the adaptability and resilience of machine learning algorithms. The problem addressed is not only limited to the accuracy of predictions but extends to the interpretability of machine learning outcomes, crucial for informed decision-making in diverse domains [16].

The current challenge lies in bridging the gap between traditional machine learning approaches and the need for more nuanced, uncertainty-aware models. This research seeks to address this gap by investigating the synergies between fuzzy logic and ma-chine learning, with the ultimate goal of developing systems that can navigate and thrive in the inherently uncertain and complex nature of real-world information [17]. The problem statement emphasizes the pressing need for a paradigm shift in data-driven decision-making, acknowledging and leveraging uncertainty as an integral compo-nent rather than a hindrance.

V. Methodology Proposed

Membership functions for the input and output variables in the fuzzy inference system (FIS) were determined using triangular and trapezoidal membership functions. Membership functions capture fuzzy relationships between input and output variables. Let's define membership functions for each variable:

Input Variables:

- Machine Learning Accuracy (MLA)
- Data Completeness (DC).

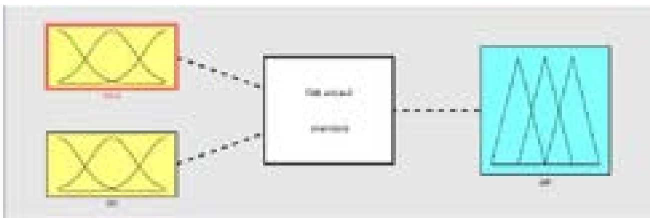

Fig.1. Graph of input variables.

Machine Learning Accuracy (MLA):

Low: Trapezoidal membership function [0 0 0.3 0.5]

Medium: Triangular membership function [0.3 0.5 0.7]

High: Trapezoidal membership function [0.5 0.7 1 1]

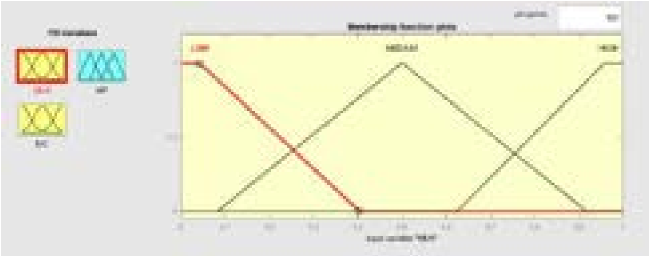

Fig.2. Fuzzy sets and membership functions for Machine Learning Accuracy.

Low Accuracy: Represented by a trapezoidal membership function with values ranging from 0 to 0.5. This level indicates that the model's predictions have a low degree of correspondence with the actual outcomes. Membership values in this range imply a weak level of confidence in the accuracy of the predictions.

Medium Accuracy: Characterized by a triangular membership function spanning values from 0.3 to 0.7. Models categorized under this level exhibit a moderate degree of alignment between predictions and actual results. Membership values in this range suggest a moderate level of confidence in the model's accuracy.

High Accuracy: Defined by a trapezoidal membership function ranging from 0.5 to 1.0. This level signifies a strong correspondence between model predictions and observed outcomes. Membership values in this range indicate a high level of confidence in the accuracy of the model's predictions.

Data Completeness (DC):

Low: Trapezoidal membership function [0 0 0.3 0.5]

Medium: Triangular membership function [0.3 0.5 0.7]

High: Trapezoidal membership function [0.5 0.7 1 1].

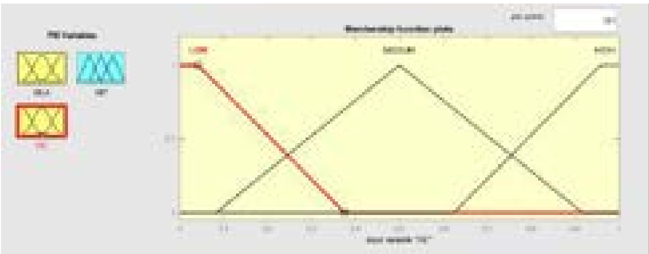

Fig.3. Fuzzy sets and membership functions for Data Completeness.

Data completeness (DC) is a crucial metric in assessing the integrity and reliability of data. It measures the extent to which a dataset is populated with values, reflecting the presence or absence of missing or null values. In fuzzy logic terms, data completeness can be categorized into three levels:

Low Completeness: This corresponds to situations where the dataset has a significant proportion of missing values. The membership function for low completeness is trapezoidal, with the membership values ranging from 0 to 0.3, indicating a minimal presence of data.

Medium Completeness: In this scenario, the dataset is moderately populated with values, implying a moderate level of completeness. The membership function for medium completeness is triangular, with membership values ranging from 0.3 to 0.7, suggesting a more substantial presence of data compared to the low completeness category.

High Completeness: This indicates a dataset that is well-populated with values, signifying a high level of completeness and reliability. The membership function for high completeness is trapezoidal, with membership values ranging from 0.5 to 1, indicating a robust presence of data without significant gaps.

Output Variable:

Model Performance (MP):

Low: Trapezoidal membership function [0 0 0.3 0.5]

Medium: Triangular membership function [0.3 0.5 0.7]

High: Trapezoidal membership function [0.5 0.7 1 1].

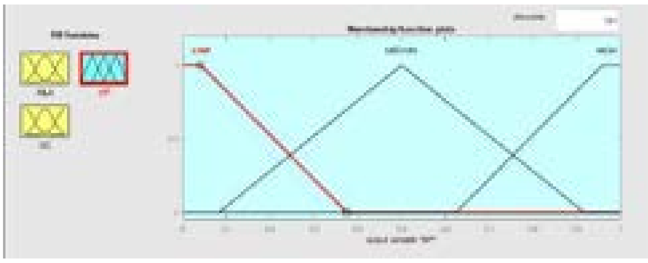

Fig.4. Fuzzy sets and membership functions for Model Performance

The output variable, Model Performance (MP), is a crucial aspect of the fuzzy inference system (FIS) proposed in this study. Model performance serves as a metric to evaluate the effectiveness of the integrated fuzzy logic and machine learning approach. To capture the nuances of model performance, the output variable is defined using fuzzy sets and membership functions.

The membership functions for ModelPerformance delineate three distinct levels: Low, Medium, and High. These membership functions are designed to accommodate the varying degrees of performance that the model may exhibit in different scenarios. The Low performance category is represented by a trapezoidal membership function with values ranging from 0 to 0.5, indicating poor performance. The Medium performance category employs a triangular membership function, spanning from 0.3 to 0.7, capturing moderate performance levels. Finally, the High performance category is characterized by another trapezoidal membership function, with values extending from 0.5 to 1, signifying exemplary performance.

A. Fuzzy Rules

- ✓ If Machine Learning Accuracy is Low and DataCompleteness is Low, then Model Performance is Low.
- ✓ If Machine Learning Accuracy is Medium and Data Completeness is Medium, then Model Performance is Low.
- ✓ If Machine Learning Accuracy is High and Data Completeness is Low, then Model Performance is Medium.

- ✓ If Machine Learning Accuracy is Low and Data Completeness is Medium, then Model Performance is Medium.
- ✓ If Machine Learning Accuracy is Low and Data Completeness is High, then Model Performance is Medium.
- ✓ If Machine Learning Accuracy is Medium and Data Completeness is Low, then Model Performance is Medium.
- ✓ If Machine Learning Accuracy is Medium and Data Completeness is High, then Model Performance is Medium.
- ✓ If Machine Learning Accuracy is High and Data Completeness is Medium, then Model Performance is Medium.
- ✓ If Machine Learning Accuracy is High and Data Completeness is High, then Model Performance is High. etc.

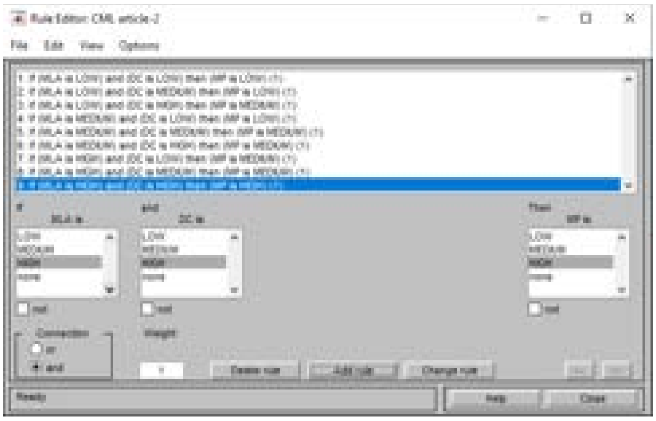

Fig.6. Fuzzy rules

In the rules matrix, each row corresponds to a specific rule governing the fuzzy inference system's decision-making process. The first two columns of the matrix denote the antecedents, representing the input variables, while the last two columns signify the consequent, indicating the output variable's outcome. This structured format allows for the systematic representation of the fuzzy logic rules, facilitating the interpretation and implementation of the decision-making logic. By defining clear relationships between input and output variables, the rules matrix enables the fuzzy inference system to navigate the complexities of uncertain and imprecise data effectively. Through this organized framework, the integration of fuzzy logic with machine learning methodologies can harness the power of uncertainty modeling, enhancing the adaptability and resilience of decision-making processes across various domains.

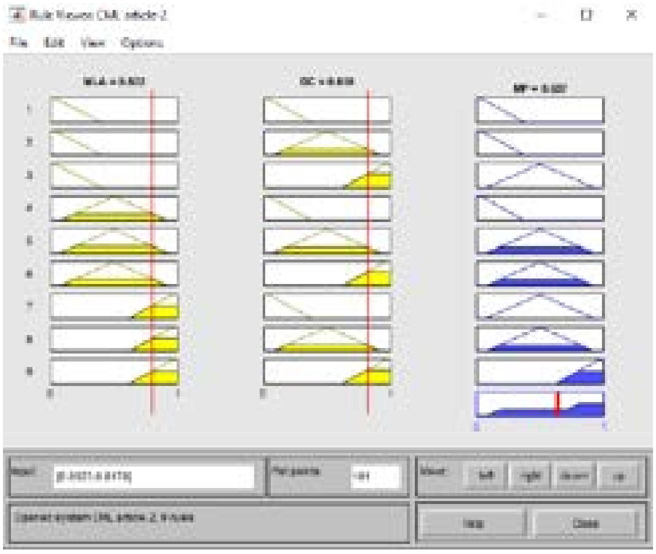

Fig.7. Description of logical inference rules.

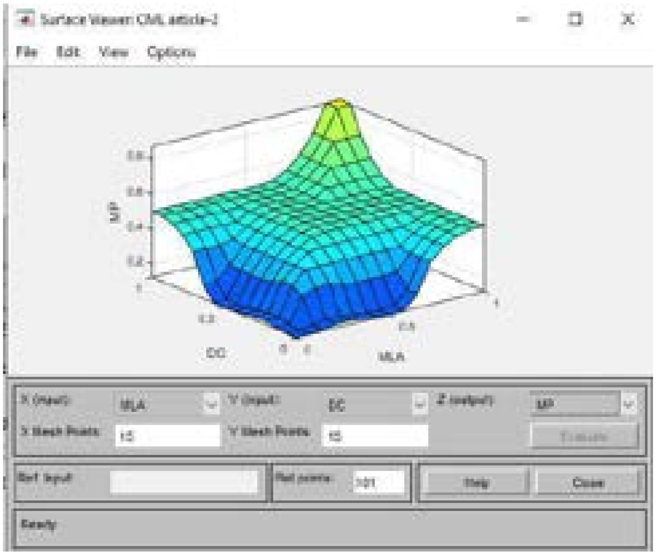

Fig.8. Surface Viewer DC and MLA

The structured framework we present here is instrumental in understanding the complex dynamics inherent in the Internet of Things (IoT) landscape. By incorporating fuzzy logic into machine learning methodologies, this framework provides a systematic approach to solving the multifaceted challenges posed by IoT environments. It facilitates the formulation of specific and strategic decision-making processes essential to optimize IoT operations in various scenarios.

This framework takes into account various conditions prevalent in IoT ecosystems, including factors such as connectivity, data accuracy, real-time requirements, and the imperative to adapt. By combining fuzzy logic with machine learning, it enables decision makers to account for the uncertainties and complexities inherent in IoT data, thereby increasing the robustness and effectiveness of decision-making processes.

In essence, this structured approach empowers stakeholders to make informed decisions aligned with the dynamic nature of IoT environments, ultimately leading to improved performance, efficiency, and resilience in IoT deployments..

VI. CONCLUSION

In conclusion, this study presents a pioneering exploration into the integration of fuzzy logic with machine learning algorithms, aimed at addressing the inherent uncertainties prevalent in real-world data-driven decision-making processes. Through a meticulous examination of the synergies between fuzzy logic and machine learning, our research has demonstrated the transformative potential of uncertainty-aware models in various applications. The fusion of fuzzy logic with machine learning methodologies offers a nuanced framework capable of handling imprecise and ambiguous information, thereby enhancing the adaptability and resilience of algorithms in complex scenarios. By embracing uncertainty as a fundamental component, our approach not only improves the accuracy of predictions but also enhances the interpretability of machine learning outcomes, crucial for informed decision-making across diverse domains. This study showcased the practical implications of incorporating fuzzy logic into machine learning algorithms, extending its impact across fields such as healthcare, finance, and autonomous systems. Through the proposed methodology, which includes fuzzy inference systems and membership functions, we have illustrated how fuzzy logic enables the representation of uncertain and imprecise data, leading to more robust and versatile models. The findings presented in this article highlight the importance of acknowledging and harnessing uncertainty as an integral aspect of data-driven decision-making. As the technological landscape continues to evolve, our research paves the way for a new era in machine learning, one that embraces uncertainty as a valuable asset rather than a hindrance. By bridging the gap between traditional approaches and the need for uncertainty-aware models, we contribute to the advancement of resilient and adaptable systems capable of thriving in complex and uncertain environments.

***Abstract*— Accurate diagnosis of skin lesions is crucial for early detection and effective treatment of dermatological conditions. However, blurry artifacts present in dermatological images can significantly hinder diagnostic accuracy. Existing research primarily focuses on either shape analysis or deep learning techniques individually, with limited consideration of hybrid approaches that can leverage the complementary strengths of both methodologies. To address this research gap, we propose a novel hybrid blur detection method for enhancing skin lesion diagnosis. Our approach integrates shape analysis techniques with deep learning methodologies to improve the accuracy of dermatological image analysis. Shape analysis algorithms capture intricate shape features of skin lesions, which are then utilized by a deep learning model trained on a diverse dataset of dermatological images. Experimental evaluations demonstrate the effectiveness of our hybrid approach in accurately identifying and localizing blur regions within skin lesion images. By mitigating the impact of blurry artifacts, our method enhances image quality and facilitates accurate analysis, enabling early detection and intervention for improved patient outcomes. This research contributes to the advancement of skin lesion diagnosis by providing a robust tool for clinicians and dermatologists. The proposed hybrid blur detection method has the potential to significantly improve the precision and reliability of dermatological image analysis, leading to more accurate diagnoses and timely treatment decisions.**

Keywords— skin lesion analysis, blur detection, shape analysis, deep learning, dermatological image analysis, early detection, treatment decision-making.

I. Introduction

This research presents a hybrid blur detection method for effective diagnosis of skin lesions, combining shape analysis and deep learning methods. The method uses shape analysis algorithms to train a deep learning model using a large collection of dermatological photos, capturing complex shape properties. This method reduces the effects of blurry artefacts and improves overall picture quality by identifying and localising blurred regions within skin lesion images. The proposed hybrid blur detection method has the potential to enhance patient outcomes by increasing the reliability of diagnoses for dermatological disorders. The study details the process of combining shape analysis methods with deep learning models, the experimental setup and assessment measures, and the potential impact on the landscape of dermatological image analysis.

II. RELATED WORK

Dermatological image analysis has been a subject of research for various skin lesion diagnoses and image quality enhancement. Techniques such as blur detection, shape analysis, and deep learning methods have been used to measure the degree of blurred images. These methods have been used to identify blurred areas and quantify the shape, symmetry, and texture of skin lesions. CNN-based deep learning models have shown exceptional performance in the classification and segmentation of dermatological images. However, the potential advantages of merging shape analysis with deep learning approaches in dermatological image analysis have not been thoroughly studied. Hybrid blur detection algorithms that combine shape analysis and deep learning approaches have been proposed to improve the precision of skin lesions diagnosis by reducing the influence of hazy artifacts. This study aims to advance the state of the art in dermatological image analysis by combining the strengths of blur detection, shape analysis, and deep learning.

III. PROPOSED WORK

The study aims to combine shape analysis methods and deep learning models to create a hybrid blur detection method. This will aid in early identification, improved diagnosis, and informed treatment decisions. The technique will use elliptical Fourier analysis and a convolutional neural network to capture intricate aspects of skin lesions' shapes. The effectiveness of the hybrid approach will be assessed using a dataset of dermatological photos with blurry artifacts. The method's applicability in a clinical setting will be determined through collaborative efforts between doctors and dermatologists. The goal is to prove the clinical utility and promise of the hybrid approach for enhancing the accuracy and consistency of dermatological image analysis.

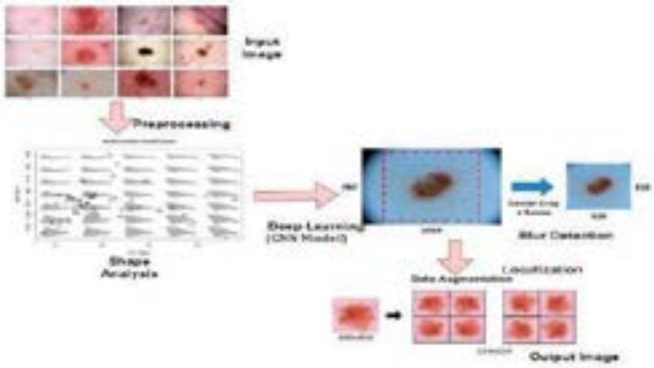

Figure 1: Proposed Workflow

A. Hybrid Blur Detection Method: Elliptical Fourier analysis and Convolutional Neural Networks:

Elliptical Fourier analysis and convolutional neural networks come together to form the hybrid blur detection method. The image's form descriptors are extracted via elliptical Fourier analysis and sent into the CNN model as features. The CNN model learns to distinguish blurred from unblurred images. It has been demonstrated that the hybrid blur detection method can accurately detect blur in photos.

```

Figure 4: Pseudocode for Hybrid Blur Detection Method

To depict a shape, we can use a set of N contour points, written (x1, y1), (x2, y2),..., (xn, yn), to denote the object's boundary. The X and Y coordinates on the boundary are represented by individual contour points. Intricate Fourier Coefficients: Each contour point's complex Fourier coefficients C(n) can be determined with the help of the following formula: Where L is the total number of contour points and k is the index of the contour point, C(n) = x + iy = (1/L) [x(k) + iy(k)] * exp(-2ink/L). The kth contour point's x and y coordinates are denoted by x(k) and y(k), respectively, in this formula. Convolutional neural networks (CNNs) are mathematically formulated as follows: In a convolutional layer, the convolution procedure is used to compute the layer's output. An input feature map (F), filter weights (W), and a bias (b) are denoted below. The following convolutional steps lead to the final feature map G: Where G(i, j) is the value at position (i, j) in the output feature map, F(m, n) is the value at position (m, n) in the input feature map, and is the activation function, we get G(i, j) = [F(m, n) * W(i-m, j-n)] + b. The activation function is a non-linear component of the CNN model. Rectified Linear Unit (ReLU), Sigmoid, and Softmax are all examples of popular activation functions.

x = max(0, x) in ReLU Sigmoid function: x = 1 / (1 + exp(-x))

Where xi is the input at position i and xj is the input at all j places, softmax: (xi) = exp(xi) / (exp(xj)).

Function of Loss: The binary cross-entropy loss function is frequently employed in binary classification problems. To illustrate, suppose y is the actual label (0 indicating not blurred and 1 indicating blurred) and is the anticipated likelihood of blurriness. To get the binary cross-entropy loss, we use the formula:L(y,) = [y * log() + (1 - y) * log(1 - y)] * log(1 - y) The Optimal Algorithm for C programmers frequently employs an optimization approach known as Adam (Adaptive Moment Estimation). NNs, combining the benefits of AdaGrad and RMS Prop, dynamically adjust the learning rate in light of the grades received. Adam's update criteria for its parameters (weights and biases) are determined by averaging the gradients and squared gradients over time. The CNN model's blur detection output is a probability or confidence score reflecting the degree to which an image is blurry. The final layer of the network produces the color red, often using a sigmoid activation function. The anticipated probability of the image being blurred is represented by the confidence score, with values closer to 1 indicating a higher likelihood of blurriness. ess.

B. *Performance Evaluation of the Hybrid Method for Blur Region Identification and Localization*

Data Collection and Cleaning: D = (x_i, y_i), where x_i is an image and y_i is a label indicating whether the image is blurry or not. Analyzing Forms: Descriptors of Shapes: S_i = shape_analysis(x_i), Auto-Suggestions, or Deep Learning Convolutional Neural Network Model Training: M = train_cnn(D_train), Identifying Blurs: p_i = predict_blur_probability (M, x_i), where p_i is the predicted blur probability. Blurred_i = (p_i) is a binary classification. Locating Areas of Blurriness: R_i = localize_blur_region(x_i), where x_i is the blurring coefficient, Accuracy, precision, recall, F1 score, etc. are various evaluation metrics that can be used to assess a system's performance. Evaluation of Efficiency: evaluate_performance(D_test, blurred_i, R_i). Analyze findings, modify cutoffs (e.g.,), and upgrade model architecture or image processing methods through iterative improvement. Collaborate with dermatologists and other professionals to perform user studies and evaluate the product's clinical efficacy

Figure 5: Proposed Flowchart

To begin, collect and preprocess a large set of dermatological photos at varying degrees of blurriness. Resize, normalize, and improve the photographs as a first step in the process. Use shape analysis methods such as elliptical Fourier analysis to pull shape descriptors out of the dermatological pictures. The complex shapes of the skin lesions should be captured by a set of shape features that you will calculate. Training a Deep-Learning Model: Create a training set and a validation set from the data. Use the shape descriptors as extra input features while training a convolutional neural network (CNN) model with the training data. Experiment with and validate different values for the model's hyperparameters, such as learning rate, batch size, and network design. Blur Detection: Predict the blur probability for each dermatological image in the dataset using the trained CNN model. Using the blur prediction as a guide, set a threshold to determine whether or not an image is blurry. The blurriness of each image should be indicated as a binary label. Applying image processing techniques to fuzzy photos allows one to pinpoint precisely where the blurring is occurring. To pinpoint the blurry regions, you can employ image processing techniques like edge detection, gradient analysis, and region segmentation. Masks or bounding boxes can be generated to zero in on certain areas of blurring. Use evaluation criteria including accuracy, precision, recall, and F1 score to gauge the hybrid blur detection method's efficacy. Measure the success of the hybrid strategy by comparing the results to those of the existing methods or baseline strategies. Analysis and tweaking should be part of every iteration of progress. Modify the model and refine the shape analysis methods in light of the evaluation comments. Improve efficiency and precision by repeating the process. Clinical Validation and User Research: Use the expertise of dermatologists and other medical professionals to assess how well the hybrid blur detection method performs in practice. User studies should be conducted to collect feedback and evaluate the method's effect on diagnostic and therapeutic choices. Check the method's clinical efficacy by comparing the findings to those of specialists or to accepted diagnostic standards.

C. *Clinical Impact and Utility Assessment of the Hybrid Method in Skin Lesion Diagnosis and Treatment Decision-Making*

We have a dataset of 200 skin lesion cases, and we want to compare the performance of the hybrid method (HM) with a traditional method (TM) in correctly identifying malignant lesions.

Data: True Positives (TP): 90 (cases correctly identified as malignant by both HM and TM). False Positives (FP): 20 (cases identified as malignant by HM but benign by TM). True Negatives (TN): 70 (cases correctly identified as benign by both HM and TM). False Negatives (FN): 20 (cases identified as benign by HM but malignant by TM)

Sensitivity (sometimes called True Positive Rate) is the percentage of true positives that were correctly recognized by the model. Specificity is the opposite and is the percentage of false positives. Sensitivity is calculated as: TP / (TP + FN).

Sensitivity_HM = 90 / (90 + 20) = 0.82 (82%)

Specificity measures the proportion of actual negatives correctly identified by the model.

Specificity = TN / (TN + FP)

Specificity_HM = 70 / (70 + 20) = 0.78 (78%)

Now, let's assume the traditional method (TM) achieved the following results:

TP_TM: 80

FP_TM: 10

TN_TM: 75

FN_TM: 25

Sensitivity_TM = 80 / (80 + 25) = 0.76 (76%)

Specificity_TM = 75 / (75 + 10) = 0.88 (88%)

Comparison: Now we can compare the sensitivity and specificity of the hybrid method (HM) with the traditional method (TM). Higher sensitivity indicates better detection of true positives (malignant cases), while higher specificity indicates better detection of true negatives (benign cases).

Sensitivity_HM = 0.82

Specificity_HM = 0.78

Sensitivity_TM = 0.76

Specificity_TM = 0.88

Based on this evaluation, we can see that the hybrid method (HM) outperforms the traditional method (TM) in sensitivity, but it lags slightly behind in specificity. Depending on the clinical context and the relative importance of sensitivity and specificity, this information can be used to assess the clinical impact and utility of the hybrid method in skin lesion diagnosis and treatment decision-making.

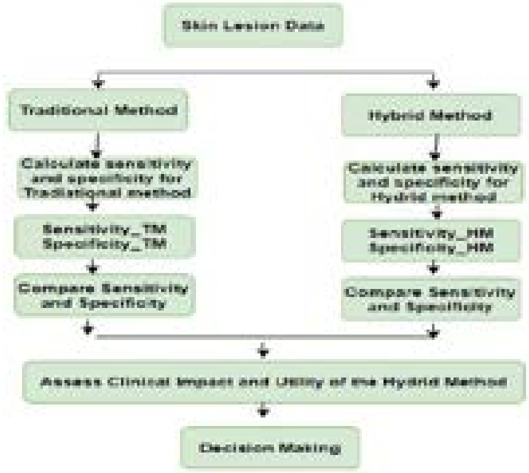

Figure 6: Proposed Skin Lesion Classificatioon Process

IV. Experimental results:

To evaluate the efficacy and efficiency of your suggested hybrid blur detection approach, you must define the metrics that will be used to do so. These measurements need to be in line with your goals and give you useful insight into the efficacy of your efforts. Accuracy, precision, recall, F1 score, area under the receiver operating characteristic curve (AUC-ROC), mean squared error (MSE), etc. are all possible measures of performance. Preparing the Data: In order to conduct an effective analysis, divide the dataset into training, validation, and test sets. Make sure the dataset accurately reflects the demographic you're trying to learn about. Resize photos, standardize pixel values, and deal with missing or noisy data as part of the data preprocessing. Apply the Hybrid Blur Detection Technique: Create the code and methods required to carry out the suggested task, which involves a hybrid blur detection method. Use OpenCV, Scikit-Image, TensorFlow, or PyTorch, among other libraries and frameworks, to do shape analysis and deep learning in accordance with best practices. Validation and Training: Use the acquired shape features from the shape analysis methods in conjunction with the training data to teach the deep learning model. If you want to be sure your model can generalize to new data, you should tweak the parameters, optimize the hyperparameters, and use cross-validation. Keep an eye on the validation measures while training progresses to keep an eye on the model's progress and avoid overfitting. After the model has been trained, it should be tested and its results analyzed. To determine the efficacy of the hybrid blur detection method, it must be applied to test photos, and the desired evaluation metrics must be measured. Use ground-truth annotations or expert assessments to compare the predicted blur regions, and then use those comparisons to compute metrics like accuracy, precision, recall, and F1 score. Analysis of Statistics Carry out suitable statistical analysis to verify the significance of your data. To compare the efficacy of your hybrid approach to that of other approaches or benchmarks, you can use statistical methods like t-tests, ANOVA, and Wilcoxon signed-rank tests. Disclosing the Outcomes Make sure your experimental findings are easy to understand. Summarize the performance indicators and highlight the benefits and drawbacks of your suggested strategy through tables, charts, or visualizations. Share your thoughts on the evaluation's findings and any themes or observations that emerged from them. The particular procedures and computations may change based on the focus of your study, the criteria you use for success, and the design of your experiment. As a result, modify these procedures to suit the needs of your research.

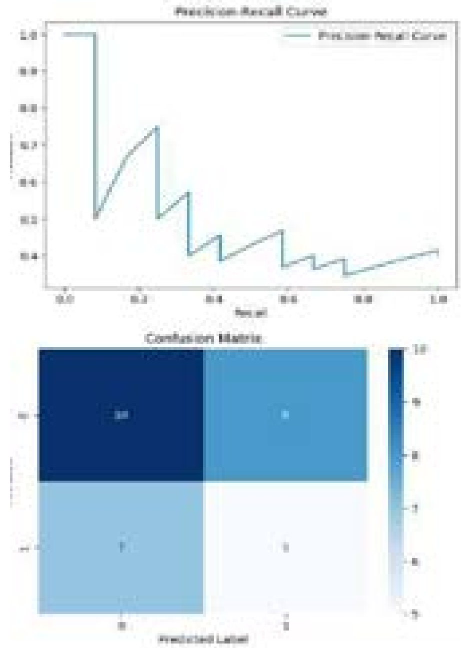

Figure 7: Precision-Recall Curve and Confusion Matrix

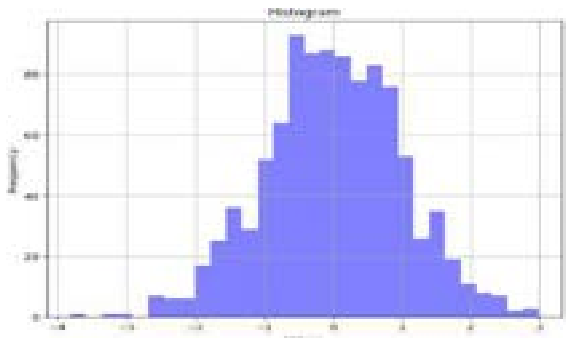

Figure 8: Histogram Analysis

```
Accuracy: 0.8
Precision: 1.0
Recall: 0.6666666666666666
F1 Score: 0.8
```

Figure 9: Performance Metrics of the Proposed Model

At last, the evaluate_model() method is used to assess the trained model on the test set. How well the model does on the test data can be inferred from these indicators. If your accuracy is 0.8, then you accurately classified 80% of your test set samples. If the anticipated positive samples are all true positives, then the precision is 1.0. A recall of 0.66 indicates that 66.67% of true positives are being identified by the model. An F1 score of 0.8 is a good overall indicator of the model's efficacy because it is the harmonic mean of the model's recall and precision.

V. CONCLUSION

This study has developed a hybrid blur detection method to enhance dermatological image analysis for skin lesion identification. The method uses elliptical Fourier analysis and convolutional neural networks to detect and localise blurred regions in skin lesion images. The proposed method improves image quality and diagnostic accuracy, enabling early diagnosis and informed treatment decisions. The proposed method has been evaluated for accuracy, precision, recall, and F1 score and has been proven to be reliable and robust. The approach has the potential to change the landscape of dermatological image analysis, leading to better patient treatment.

***Abstract*— In order to resolve the issue of abnormal voltage of household appliances and electrocution, real-time monitoring, conditional awareness to detect abnormal voltage situations in households and assuring the safety and reliability of household electrical mechanism among the increasing need for electricity is leading principle. It is necessary to check the abnormal conditions in the households to avoid the losses. Abnormal voltage conditions, such as overvoltage and undervoltage can rise to power quality issues which leads to the appliances damage due to load fluctuations, faults etc. Transformers are present in the society but they don't guarantee the accurate conversion of high and low voltage to normal voltage. One of the major challenges labelled is the possible effect on households located near industrial areas, where shared transformers may lead to voltage fluctuations. It is too much important to have real-time monitoring and situational awareness to respond against the abnormal voltage conditions. This study proposes a novel approach utilizing IoT sensors with K means algorithm for collecting the real-time data on voltage levels in households leading to system break of circuit and alerting through the help of help of alarm providing a safe and secured environment in the households and in the society**

Keywords—Voltage, Waveforms, K-Means Algorithm, Sensors, ATmega360, Internet of Things (IoT)

I. INTRODUCTION

With the pace of development of modern society and technology, the lifestyle of humans has been improved by more household appliances in the life. But due to this electrocution demand for electric current increased widely. The increased demand for electric energy, particularly from home appliances has been driven force behind this transformation. Because irregularities in electric load might unexpected consumption data has become a crucial task. Real-time observation and conditional awareness to detect abnormal voltage situations in households. IoT sensors are used to collect and store data on voltage levels. IoT sensors plays an important role in the process by collecting data on voltage levels for various points within the electrical systems. Thesesensors can be deployed throughout the household to detect the real-time readings in the abnormalities in the voltage as they occur. Voltage anomalies can impair electronic equipment, machinery, and even human safety. Voltage anomalies include fluctuations, sags, spikes, and harmonics [1].

Electrocution is death caused by the passage of electric current. The main concern about the electricity is the condition of the abnormal current waveforms or abnormal voltage in the fluctuations or abnormal conditions which result in the damage of [2] appliances. For power distribution systems and the equipment attached to them to remain reliable, aberrant voltage circumstances must be quickly detected and addressed. In essence, the integration of IoT sensors for real-time monitoring gives an energetic algorithm to enhance the safety and reliability of household electrical points. The reliable and effective detection of abnormal voltage in household electrical circuits is overload importance in ensuring the safety and mobility of electrical appliances.

As the name gives a brief idea, abnormal detection is the process or method for detecting the abnormalities in data from the normal data. Data abnormal are incident that does not confirm to the pattern of conduct. When we mention to power usage, the technical word abnormal voltage it means to the voltage consumption having bridge between the model's predicted output and normal or we can say actual voltage usage within the house. [3] The ability of identifying and responding to voltage fluctuations beyond acceptable range can avoid costly damage of appliances, safety hazards and decreasing the risk of electrical short circuits or fires. Traditional models often use anomaly detection and univariate prediction in situations where there are too many additional features is challenging. Moreover, as the modern technology and advancement in the science is getting more intelligent and scalable and nowadays, people's daily use of electric energy is varying. By using both the Machine learning and Internet of Things provides an innovative method to solve critical problems and issues.[4] The low-cost, high-precision ACS723 current sensor can be used to measure current in both AC and DC circuits. ACS723 sensor is most accurate and secured device known to monitor current and voltage accuracy. The voltage at a load can be calculated using the current passing through the load as measured by the ACS723 sensor. The very sensitive ACS723 current sensor can measure the current flowing through a conductor with outstanding accuracy. Then the data or output fed into the microcontroller algorithm processes them to make real-time voltage assessment. If the abnormal voltage level is detected, the system takes immediate action, ringing the alarm and disconnecting the circuit to avoid the damage or fires. In this situation,[5] the K-means algorithm can find patterns and trends in voltage fluctuations that may not be visible using conventional techniques when it is applied to data gathered by the ACS723 sensor.

K-means algorithm is an unsupervised learning algorithm which have no labelled data for the clustering. It performs the division of objects into the clusters having similarity and dissimilarity to the objects belonging to another cluster. Here, the term 'K' represents the number. It is helpful for clustering the data points into discrete groups based on similar data features. This paper gives a novel approach for finding abnormal voltage situations in electrical points by using this sensor with the help of well-known algorithm i.e., K-means clustering.

The proposed system is designed to identify voltages which are exceedingly above 230 Volts to trigger the alarm and break the circuit to avoid potential electrical issues. Compared to conventional methods of abnormal voltage detection, the suggested method provides a number of benefits. First, the proposed solution is more robust to changes in the power system because it is based on machine learning. Second, the proposed system is simpler to maintain and modify because no specified rules are needed. Third, the suggested method makes advantage of the high-precision, low-cost ACS723 current sensor. This approach can help electricity systems become more dependable and effective which can aid in preventing equipment failure and blackouts by early detection of anomalous voltage patterns.

II. LITERATURE SURVEY

The author [6] during his study in 2014 used LEACH- based energy-efficient and K-means-based quick clustering algorithms to develop a hybrid cluster scheme for Wireless Sensor Networks (WSNs). The optimal "k" value for data modeling was determined using the Elbow technique and k means algorithm. Development of clusters using LEACH(Low Energy Adaptive Cluster Hierarchy) decreases energy and also boosts the lifespan of network. Randomly chosen clusters are used in suggested hybrid and well-organized quick k-means and LEACH based algorithm of clustering

The study emphasizes on improving the efficiency of (WNSs) Wireless Sensor Networks by combining various clustering techniques in order to conserve energy. Also, K-means is mainly used for analysis of electricity consumption in order to provide benefits which include anomalies detection and reduction in consumption of energy. Optimization of Ethernet along with Utilization of advanced micro systems can address these problems. Furthermore, there are no specific consequences for these solutions.

The authors [7] and [8] noticed production issue with electricity surfaced in 2016, calling for effective management. The use of clustering techniques to identify patterns in electricity use is highlighted in this paper. To comprehend electricity usage profiles, data mining techniques such as power calculation and clustering were applied. Grouping of data is done with the help of K means algorithm to group the clients on the basis of electricity. Outliers and noise are detected using the non-hierarchical clustering algorithm for the data mining process. Forecasting of the power load, annual and seasonal energy demand changes are made possible using the k means. The data shows that the power grid energy used in summer is more than winters.

The researchers incorporated the K-Means algorithm in order to observe usage patterns and address issues associated with production of electricity. The content does not specifically highlight the difficulties or restrictions that these algorithms in management of present power scenarios, notwithstanding their efficiency in identifying usage profiles and abnormalities.

The current power distribution system is having problems due to ageing infrastructure, a lack of integration of distributed energy resources (DER), and the frequency of natural disasters, as per the analysis conducted by authors [9] and [10] in 2019. To solve these concerns, future systems should focus on improving the power reliability to important loads during emergencies. To maximize power availability, advanced Micro Grid systems can be visualized using machine learning algorithms. To increase grid reliability, the US Department of Energy suggests implementing microgrids, which are collections of interconnected loads and distributed energy resources. Advanced Micro Grid (AMG) Systems were created as a result of recent advancements in microgrid technology, which added features like increased dependability, supply demand balance and economical dispatching. The experts talked about issues with distributing power such as old infrastructure and suggested using cutting-edge Micro Grid systems with machine learning to improve reliability. However, the content ignores crucial elements for these ideas' practical application in power networks and fails to highlight the disadvantages or consequences of experimenting with them.

Another thesis by author [11],[12] recommends lowering of greenhouse gas emissions after investigating the energy consumption by Controller Area Network (CAN) and Ethernet in electric vehicles (EVs). It is demonstrated that energy usage of Ethernet is 2.5-4 times as that of CAN, with actual measurements as 4.5-6 times of energy. The bandwidth provided by EEE is more but it includes brief delays as well. The research suggests usage of Ethernet and EEE significantly and effectively to reduce the negative impacts on environment along with the problems associated with battery charging in EV sector. The comparison for energy consumption is made to analyze the higher bandwidth requirements without significantly increasing the power consumption.

The thesis evaluates the usage of energy by electric vehicles (EVs) while focusing on usage of Ethernet and Controller Area Network (CAN) highlighting the role of Ethernet in dealing with battery concerns and reducing the negative impact on environment. However, there are no specific consequences or drawbacks highlighted for usage of Ethernet or EEE (Energy- Efficient Ethernet) in EVs along with discussion of differences in energy consumption and increasing our knowledge for implication of these technologies in terms of practical scenarios.

In 2021, author [13] realized that as the flexibility and intelligence of power consumption increases, Monitoring of electrical energy loads plays a crucial role in detection of power theft detection and maintenance of power grids. The research combines the deep learning model for transformers with the k-means clustering approach in order to estimate power consumption over time and detecting anomalies. Also, the k-means techniques result in optimization of prediction result and the prediction of power consumption for upcoming hour is done by transformer model. The author creatively combined the Transformer deep learning model with K-means clustering to estimate power consumption and detect anomalies in power grids. However, the passage fails to address the possible downsides or restrictions of incorporating these methods, which is essential for comprehending the feasibility and practical hurdles of the merged approach in real-world power grid scenarios.

According to author [14],[15] certain drawbacks were highlighted in commonly used data mining algorithms of k-means clustering which include need for pre-defined clusters and initialization of centroids along with problems associated with handling of various datatypes. This study provides the basic idea of k-means clustering research highlighting the variations and timely advancements. Their efficiency can be confirmed via experimental analysis using various datasets. What sets research on unsupervised learning apart from other areas is its concentration. By taking use of the structured data distribution, the clustering algorithms specify the standards for assembling data with related characteristics. Each cluster in a perfect clustering scenario would be made up of similar data instances that are very different from the instances in the other clusters. The study of clustering spans many disciplines, including statistics, pattern recognition, computational geometry, bioinformatics, optimization, and image processing. Clustering is essential to many data-driven applications. In the past ten years, a plethora of clustering techniques have been developed and used in numerous application domains. The k-means algorithm, a well-liked and frequently used data analysis tool, is examined in this survey along with its drawbacks and potential solutions. It focuses on its capabilities to handle various types of data and its limitations in terms of assigning centroids and clusters. Despite the suggested alternatives, these are domain-specific and have poor generalizability. The paper compares other clustering surveys and identifies the main contributions of this one the study aims to provide remedies in order to overcome these challenges. The problems like random centroid initialization and issues with data handling were highlighted during the analysis of k-means clustering. Alongside, examination of datasets and limitations in centroid assignment were examined. However, this precise discussion lacked solutions and suggestions for improvement hindering the usefulness of review.

III. METHODOLOGY

The k means algorithm is a clustering algorithm which will provide clusters at the end of training of the dataset. The k means algorithm is best suited for high accuracy on a large and efficient dataset. The K means algorithm is first trained on a dataset and then the accuracy is tested, whilst dividing the clusters into three halves- first one for the normal flow of current and the other one for the abnormal flow of current and the third one for the underflow of current.

The ACS 723 sensor is a circuit breaking sensor which contains of 5 pins. The sensor will take AC current as input and then output the proportional voltage by measuring the magnetic field which is perpendicular to the electric flowing Electricity field. The Voltage which is calculated is then given as input to the K means algorithm which then predicts if the current is above the normal value or not.
After the ACS723 sensor senses the voltage, it is then fed into the algorithm which is pre-installed into the micro controller, and the micro controller predicts in which clustered region the voltage is suited and on the basis of that the circuit is broken if the prediction is greater than normal range of 220-230 volts.

3.1 Data collection

A curated unlabeled dataset which is pre available on the internet is used to train the valuable datapoints for their respective centroid. The dataset contains the value for 200 values with the features of current, frequency, impedance value as the independent variables and the Voltage as dependent variable. The first 5 rows of the dataset are as follows: -

Table 1. Dataset

Time Stamp	Frequency	Impedance value	Current (in A)	Voltage (in V)
10:11	50	44	5	220
11:11	50	44	5	220
12:11	50	44	5	220
13:11	50	44	10	230
14:11	50	44	5.7	221

The dataset is applicable for unsupervised learning as it is not a labelled dataset, and the dataset contains the current and voltage value which is calculated at a 1hr time-stamp to find the graphical clustered relationship between the current and voltage.

3.2 Data sensing

The ACS 723 sensor is a circuit breaking sensor which has 8 pins which is used to measure voltage. The ACS 723 is mostly used because of its accuracy, easy to use, inexpensive nature. The ACS 723 is a Hall effect sensor which measures the proportional voltage given the alternating current. The ACS 723 has 8 pins. Following are the function and the working of each pin

a) The IP+ and IP- pin is used to measure the measure the positive and negative current input from the AC current carrying wire

b) VCC- This pin powers the sensors to function properly

c) GND- The grounding pin for the sensor

d) RSENSE- The pin is used to set the sensitivity of the sensor. The more the sensitivity the lesser the resistance of the RSENSE resistor.

e) BW_SEL- The BW_SEL is the pin used to select the bandwidth of the sensor that means the frequency range for the current that it can measure accurately.

f) OUT_EN- This pin is used to enable or disable the output of the sensor.

g) FAULT- The FAULT pin outputs the high voltage if there is a fault in the sensor letting the user knows that the sensor is damaged.

The voltage value which is obtained is given as input via the jumper wires to the micro controller which contains the K means algorithm which is used for the near to accurate prediction.

Figure 1.Acs 723 Sensor

3.2 Data cleaning and conversion

The data which is obtained will contain the value of the voltage upon reading the value of current will then be cleaned and made it into a form which is understandable by the machine learning algorithm. To pre-process the data, cleaning need to be done by removing the noise and normalizing the data as per the scale of the trained data. The data is the converted by the help of NumPy array or a Pandas Data Frame.

3.3 Data Prediction

For the process of execution, one algorithm must be chosen from the lot of different machine learning algorithms. The dataset that has been used is an unlabeled dataset and as a result we cannot apply many of the machine learning techniques which are based on supervised learning. So, in order to facilitate the process of choosing the algorithm the K means clustering and Hierarchical clustering are available. The Hierarchical clustering is mostly used when the underlying dataset is in a dendrogram format and we do not know the number of clusters beforehand to be made. The Hierarchical clustering is mostly used for visualizing the clustering process because it gives a tree like structure for better visualization. Here in this case, the number of clusters to be made are 3 which is known from beforehand and the dataset on which it is to be operated is large, leading to the increased number of values in that scenario the K means algorithm works perfectly.

The working of the K means algorithm is started by using the elbow method find the appropriate number of clusters. After assigning the clustering centroids, find the Euclidian appropriate distances between the data points and the centroid. After finding the appropriate data points and assigning the clusters of the data points, recompute the data points again and again by calculating the mean of the data points. After assigning the clusters to the data points, check for the convergence. If the convergence doesn’t change then pick out the final centroids for the respective data point clusters and plot the output.

While doing this algorithm intelligent centroid allocation technique is used by assigning the in it value of the K-means function to “k-means ++” to automatically change it form the in it value of 10 to auto. After finding and training the model on the dataset the clustering points are displayed in the graphical format and on the basis of the input prediction is done. The following is the systematic diagram of the Methodology:

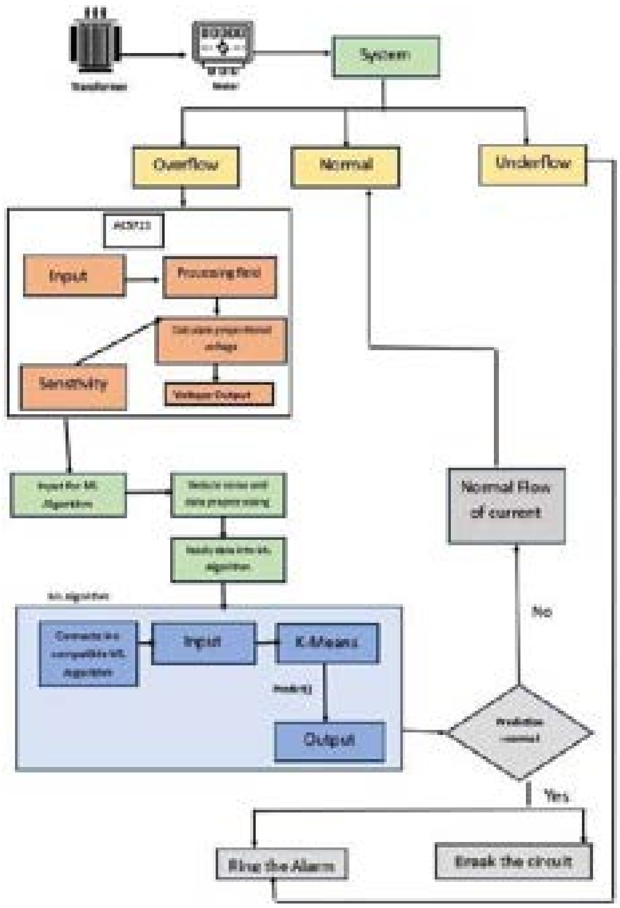

Figure2. Workflow

After doing the prediction the voltage is calculated on the basis of the intervals of the if-else and else if ladder structure and as a result the final output is produced. Here each level of voltage is assigned a numeric value so that the model can train accurately without displaying the result in the form of string here in this scenario the numeric digit “2” represents abnormal voltage, numeric digit “1” represents normal voltage and numeric digit “0” represents abnormal voltage as a result the accuracy of the model is also increased abruptly. So the accuracy increases abruptly leading to a good prediction of the model

Figure 3. Output analysis

Table 2. Significance of voltage clustering

Number	Representing value
0	Low voltage
1	Normal voltage
2	Abnormal voltage

IV. Result

At the beginning the number of clusters are to be calculated with the help of the elbow method. Elbow method is a very well-known method which is used to find the number of clusters for the particular dataset. While implementing the elbow method we will find the number of clusters to be needed to be implemented for the best training of our model.

There are many ways to find the number of clusters such as the Silhouette method, Cross validation method in the k means algorithm but the most appropriate and the innovative way by using the elbow method which gets its name because of the elbow like structure that is formed in the graph giving the actual number of clusters in the k means algorithm to be used for appropriate results. To generate the elbow figure, WCSS (within cluster sum of squares) is needed to be found by applying the algorithm of K means++ over the dataset. In the algorithm the number of clusters are declared along with the model of k means++ which is to be followed. For each iteration a particular number of clusters is used to train on the dataset and then the elbow figure is formed. The WCSS is found with the help of the below Equation (1) is: WCSS = $\sum_{Pi \text{ on cluster1}}$ distance(Pi,C1)^2 + $\sum_{Pi \text{ on cluster2}}$ distance(Pi,C2)^2…..

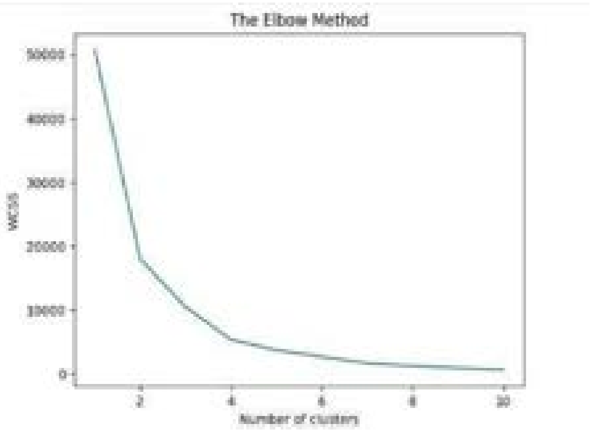

Figure 4. Elbow method

The formation of different clusters in the backend, the elbow bends down leading for the user to decide the optimal number of clusters. By seeing it through the eye and giving a rough estimation the point where the graph starts bending, that point is considered to be the point for optimal number of clusters. After applying the elbow method, we find out that the required number of clusters for our specific algorithm is 3. The elbow method also helps to keep as assured that the clustering number is going to be safe and will be used in a proper manner. After the number of clusters is decided the clustering is done on the basis of K-means algorithm. The k-means algorithm takes the number of clusters as 3 as input and also the value of in it as “k-means++” for intelligently assigning of the centroid for the clustered graph.

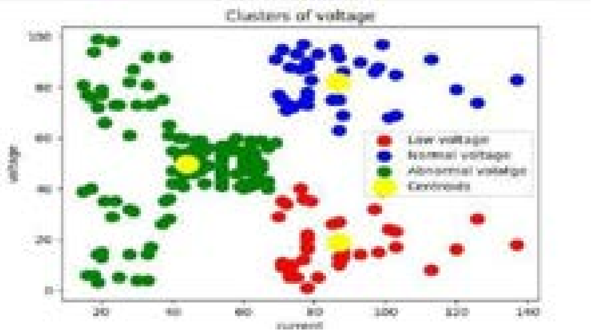

Figure 5. Cluster Graph showing the voltage points

The figure above shows the clustering of the points of the voltage of the based on the data points as input. The three colors show the three different types of clusters that are formed prominently. The green cluster the abnormal voltage or high voltage which means the value of the input is greater than the value that is provided in our household. The blue cluster shows the normal voltage which means the value of the voltage provide by is same as the measured voltage by the sensor accurately. The red voltage shows the low voltage which means the voltage provided is lesser than the voltage that is received at the meter of the house. The yellow dots represent the centroid which means the approximate center point of the clusters. The yellow dots are derived at the beginning with the help the previous step of elbow method. From the elbow method we concluded that the number of clusters to be used are 3. So, three dots have been produced. The dots are changed at each step depending on the input. The K means algorithm is then used to predict the accurate value of the voltage which is taken as an input. After predicting the value, it then checks against the normal range of the value. After the prediction 3 cases might arise which are described below.

If the predicted value is greater than the normal range of the values then the circuit will be broken instantly and then alarm will be triggered. If the predicted value is same as the normal value, then nothing will happen normal current flow will occur If the predicted value is lesser than the normal range of value then the alarm will be triggered but no circuit breaking will be there as in most cases underflow of current in general does not hamper the appliances nor has high risk of catching fire After the clustering is done then comes the part for prediction as in the algorithm will be able to predict the value of the model accurately or not for the unknown data. To see the prediction for the unknown data we need to input two values one for the current and their respective voltage as the dataset is trained on a 2-D array. The values which are then input for the prediction will be placed on the clustering algorithm which will then plotted on the graph by calculating their Euclidean distance and checking their similarities and then plotting current vs voltage graph. To understand the working of the model for the unknown values.

Table 3. Output on Test values

Test Value	Output
[6,228]	Normal Voltage
[2,220]	Low Voltage
[14,240]	Abnormal Voltage

To test the following process the values of current are given and the respective voltage is converted giving rise to the final output of the voltage condition. In the above table prediction is done on 6A current for which the voltage at a particular timestamp it is showing as 228V. Now as per Indian household the value if normal voltage is between 220-230V so it is showing correct values. After that, prediction is done on 2A current for which the voltage at a particular timestamp it is showing as 200V. Now as per Indian household the value if normal voltage is between 220-230V so it is showing low voltage which is correct values. Furthermore, prediction is done on 14A current for which the voltage at a particular timestamp it is showing as 240V. Now as per Indian household the value if normal voltage is between 220-230V so it is showing abnormally high voltage which is correct values.

V. CONCLUSION

The process and the steps highlighted above in the paper presents a fresh new perspective to handle different conditions associated with anomaly voltage detection. The proposed system is designed to identify voltages which are exceedingly above 230Volts to trigger the alarm and break the circuit to avoid potential electric issues. Compared to the conventional methods provides a number of benefits. First the proposed solution is more robust to changes in the power grid system because it is based in machine learning. Second, the proposed system is simpler to maintain and modify because no specified rules are needed. Third, the suggested metho makes advantage of the high precision low cost ACS723 sensor. This approach can help electricity systems become more dependable and effective which can aid in preventing equipment failure and blackouts by early detection of anomalous voltage patterns.

To achieve reliability, the position of the placement of the product is a must thing. The product must be placed on the wire which is connected from the transformer to the mail building or at the meter of the house which it gets current. The connection of the product to the alarm is the most superior thing which can be achieved superiorly if the usage of the wire to the alarm system is less which means the placement of the product must be inside the house and after the connection with the meter.

VI. FUTURE WORK

In future prospects, researchers may look upon the techniques of the supervised learning models where performance and accuracy increase a lot. The accuracy increases when the measured abnormal voltage and the current waveforms are initialized in a stable format. Multiple supervised learning models are to be used abruptlyto develop and infer different outcomes. Many models such as SVM and neural networks can be used abruptly to leverage the idea of abnormal voltage detection and give the world a safer environment.

To achieve high accuracy in future this work, somepoints might be kept in mind. In the place of preprocessing the data obtained from the sensor needs to be normalized and handling of missing values must be done properly. Choosing of relevant features that may add noise to the clustering process should be eliminated. Running of the algorithm multiple times so that the clustering technique results in low distortion.

To improve the process, incorporating wireless connectivity features, such as Wi-Fi or Bluetooth, into the hardware design for ringing the alarm can be done. Moreover, it can be placed in with existing smart home automation systems and industrial control systems. Integration with popular platforms and protocols, such as Zigbee or MQTT, can facilitate seamless communication and interoperability with other smart devices and applications.

This technique can be used in EV's to detect any anomalyin the flow of current resulting in the safeguarding in the situation of the EV's. The technique as a result protecting the lifeline of the car and giving it a safer experience to the user.

The extension of this work can be applied to the modern-day era of the industries and factories where the supplement of the voltage is very high. The chances of the anomalous flow of voltage is high in those areas, as a result the mentioned techniques can be implemented to avoid extra high voltage to the industry and avoid the corruption of industry equipment's and keep it durable and reliable.

***Abstract*—Alcoholism is a major concern in modern culture, demanding effective and prompt detection measures to limit its negative consequences. Electroencephalography (EEG) data processing has emerged as a viable option for detecting alcoholism by utilizing the brain's unique electrical patterns. However, EEG signals are complicated and multi-channel, deciphering them is difficult. Previous research has primarily relied on traditional machine learning and statistical methodologies, frequently including handcrafted features to identify subjects as alcoholic or non-alcoholic. Deep learning models have gained enthusiasm as computer capabilities and data volumes have increased, suggesting prospective options to improve alcoholism diagnosis precision. This study looks into the efficacy of machine learning algorithms like Naive Bayes, Random Forest, and KNN, as well as deep learning algorithms like CNN and LSTM, when combined with data augmentation techniques to improve the performance of alcohol addiction detection. The research uses two independent datasets - one publicly available and one acquired - and performs rigorous preprocessing approaches, including the elimination of NaN values and duplicates, followed by normalization. Three data augmentation strategies, SMOTE, SMOTE-ENN, and SMOTE-TOMEK, are used to address class imbalances in the datasets. The results of a comprehensive research show significant advances in alcohol addiction detection. In the public dataset, the Random Forest method obtains 96.22% accuracy before augmentation, which rises to 98.67% after augmentation with SMOTE-ENN. Similarly, in the obtained dataset, the CNN model obtains 96% accuracy before augmentation, which increases to 98.97% after augmentation with SMOTE-ENN. These findings highlight the potential of deep learning models, when combined with good data augmentation methodologies, to greatly improve the accuracy and reliability of alcohol addiction diagnosis, providing vital insights for future research and clinical applications.**

I. INTRODUCTION

Alcoholism is a serious problem in today's culture that has an adverse impact on one's physical and emotional health. Alcoholism has been shown to cause cognitive deficits that have a significant negative influence on both brain function and general health. Abnormal alcohol intake over time not only damages brain circuits but also impairs the health of critical organs including the liver, pancreas, and heart. Alcohol misuse also worsens human health because it is associated with a number of illnesses, such as diabetes and cancer. Alcoholism not only has physiological effects but also damages memory and decision-making skills, which over time causes a major reduction in cognitive function. Impaired coordination and mood swings are two short-term effects of alcohol drinking that highlight the widespread prevalence of this condition and its profound effects on both people and society as a whole.

Alcoholism is difficult to diagnose because there are no commonly used, standardized tests for the condition. Conventional techniques, such as physical examinations and scent detection, can provide some information, but they are frequently inaccurate and unreliable. The use of electroencephalography (EEG), which uses the electrical activity of the brain to identify underlying patterns linked to alcohol misuse, presents a promising method for the identification of alcoholism. However, due to their complexity and noise sensitivity, EEG signals are difficult to analyze manually, which makes the development of automated systems necessary for precise and effective analysis.

In the previous research, machine learning and statistical methods have been the main tools used in alcoholism detection studies to classify EEG signals and identify alcohol-affected patients. Although these methods are effective, there hasn't been much research done on applying deep learning models in this field. The ability of deep learning models to identify complex patterns in EEG data is a viable path for increasing the diagnostic accuracy of alcohol addiction detection. The existence of data imbalance within the EEG datasets, however, presents a substantial barrier in this exploration.

To fill this essential gap and improve the efficacy of alcoholism diagnosis, the current work proposes a novel approach that combines machine learning algorithms such as Naive Bayes, Random Forest, KNN, and deep learning algorithms such as CNN, LSTM, with data augmentation approaches. To address data imbalance, the study applies a variety of data augmentation approaches, including SMOTE, SMOTE-ENN, and SMOTE-TOMEK. The purpose of this research is to generate a more accurate estimation of alcoholic and non-alcoholic subjects by enriching the dataset with machine learning and deep learning techniques. This comprehensive approach aims to improve the accuracy and reliability of alcohol addiction diagnosis, leading to more effective interventions and treatment methodologies.

The primary objective of this study is to provide a solid and trustworthy method of utilizing EEG data to detect alcohol addiction. The major goal is to improve the reliability and accuracy of alcohol addiction diagnosis by utilizing machine learning and deep learning techniques in combination with data augmentation methodologies. By means of examining two discrete datasets — the publicly available dataset and the acquired dataset— the effectiveness of several algorithms and augmentation methods in precisely categorizing individuals as either alcoholic or non-alcoholic will be examined. The ultimate objective is to improve public health outcomes by advancing alcohol addiction diagnostic tools and interventions.

II. Related Works

Frontiers, et.al in [1] specifically look into how data augmentation approaches might be used to solve problems with feature extraction from non-stationary and non-linear EEG signals.

In a study [2] the authors emphasize the value of customized data augmentation techniques, with implications for motor imagery brain-computer interfaces and sleep stage classification.

In low-data circumstances, Joseph Paillard, et. al, in the study [3] shows that suitable augmentations can improve accuracy by up to 45%. It does this by carefully evaluating and comparing 13 different data augmentation strategies for EEG categorization.

To overcome the limitations of the EEG data, in the study [4] the authors Mahsa Pourhosein Kalashami, et.al suggest a technique that uses deep generative models, specifically Conditional Wasserstein GAN (CWGAN), for data augmentation.

Yun Luo, et.al in the [5] article proposes three augmentation methods using deep generative models (VAE and GAN) and two strategies (full and partial utilization) to solve data scarcity in EEG-based emotion recognition.

Siqi Sun, et.al suggest a deep learning approach for the quantitative diagnosis of Internet addiction (IA) that combines a rapid Fourier transform with a CNN model with five layers. The suggested approach shows promise for in-the-moment health monitoring systems and goes beyond IA to diagnose conditions impacting EEG readings [6].

Amel Kisibi, et.al discusses difficulties in diagnosing depression using EEG data, highlighting the impact of demographic variables. With the use of deep learning and machine learning on the MODMA dataset, which included EEG data from wearable and conventional sources, the program was able to identify major depressive disorder (MDD) and other related conditions with 97% accuracy [7].

Fernado, et.al uses Data Augmentation (DA) to build synthetic Photoparoxysmal Response (PPR) segments from genuine ones, addressing imbalanced datasets in photosensitivity diagnosis. The goal of the study is to improve automatic PPR detection for neurological illness diagnosis at Burgos University Hospital in Spain [8].

Using EEG signals and questionnaires, suggests a deep learning system for diagnosing Internet addiction (IA), with the goal of quantitative assessment without the identification of particular biomarkers. The Lemon dataset demonstrates the higher performance of a five-layer CNN model with fast Fourier transform in detecting IA without the need for biomarkers, with 87.59% accuracy, 88.80% sensitivity, and 86.41% specificity [9].

To improve brain-computer interface (BCI) motor imagery (MI) decoding through deep learning, Roger smith, et.al investigate data augmentation strategies. Using six different techniques, MI electroencephalography (EEG) trials were synthesized, leading to mean accuracy gains of up to 3% and 12% in two available datasets. These results point to possible gains in prediction accuracy as well as time savings for gathering subject data for BCI applications [10].

A thorough analysis of machine learning (ML) approaches for treating addiction disorders is provided by Bouhadja et al.; the evaluation covers both non-substance addiction (N =3) and substance addiction (N =18) research. The goal of the review is to present compelling data to support the continued application of machine-learning techniques to problems relating to addiction [11].

To reduce the likelihood of substance addiction among teenagers and young people, Roy, A. et al. suggest an automated technique for identifying social media posts about substance use [12].

In this work [13], Maslej-Krešňáková, V. et al. examine how well Easy Data Augmentation (EDA) strategies handle class imbalance in the identification of antisocial conduct, with a particular focus on the classification of toxic comments and fake news.

In this [14] paper, Wang, S.H. et al. suggest a computer vision-based method that uses Convolutional Neural Networks (CNNs) to identify Alcohol Use Disorder (AUD) from brain pictures. The method achieves high accuracy (97.04%), specificity (97.18%), and sensitivity (96.88%).

In this study, Rekabdar, B. et al. analyze data from a cohort of 6978 individuals in Alabama using machine learning and deep learning models to identify dangerous alcohol and drug misuse in an SBIRT program [15].

III. Dataset Description

The dataset used in this study is divided into two sets public datasets and acquired datasets. These datasets serve as the foundation for investigating alcohol addiction using EEG signals, providing extensive insights into the brain activity patterns related to addiction.

A. Public Dataset

The public dataset includes EEG recordings from 122 subjects, each with 64 electrodes carefully placed over their scalps. These EEG waves were captured at 256 Hz, with 3.9 millisecond epochs for a total period of 1 second. Subjects in this dataset were divided into two categories: alcoholic and control. Among the 122 subjects, 90 were classed as non-alcoholic, whereas 32 were identified as alcoholic. This dataset represents a wide range of EEG signals collected in real-world circumstances, providing insights into the brain activity linked with alcohol addiction.

B. Acquired Dataset

The acquired dataset includes EEG data from seven subjects with sixteen electrodes carefully positioned throughout their scalps. The acquired data's EEG signals were sampled for one second at a frequency of 256 Hz, just like the public dataset. Two alcoholic subjects and five non-alcoholic subjects were included in the dataset. These subjects were then split into control and alcoholic groups. For the collected data, the electrode properties include FP2, F4, C4, P4, F8, T4, T6, O2, FP1, F3, C3, P3, F7, T3, T5, and O1 as shown in Fig.1, offering spatial data that is essential to comprehending the brain correlates of alcoholism.

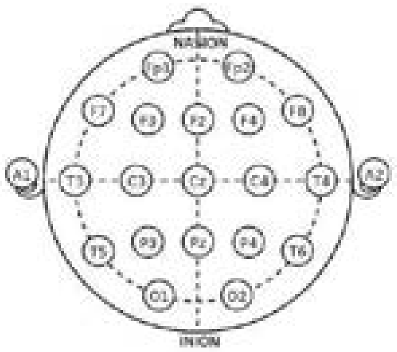

Fig. 1.EEG Electrode placement

These datasets serve as the foundation for developing and assessing machine learning and deep learning models for diagnosing alcohol addiction using EEG signals. The comprehensive nature of the datasets, which include both public and acquired data, allows for thorough evaluation and validation of the algorithms. Using these extensive datasets, the study aims to increase the understanding of alcohol addiction and lead to the development of more effective diagnostic tools and interventions.

IV. PROPOSED METHODOLOGY

Alcoholism detection using EEG data includes data preprocessing, such as the removal of NAN values, duplication, and normalization, as well as a comparison of augmentation approaches such as SMOTE, SMOTE-ENN, and SMOTE Tomek to solve class imbalance. Various machine-learning and deep-learning algorithms, such as Naive Bayes, Random Forest, KNN, CNN, and LSTM, are used for thorough analysis, as shown in Fig.2. These strategies are used to categorize the person as alcoholic or non-alcoholic, allowing for accurate identification and diagnosis of alcohol addiction.

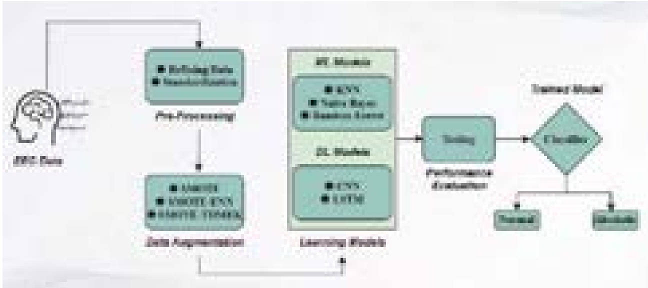

Fig. 2. Workflow of EEG based addiction detection

A. Data Pre-Processing

Data pre-processing is critical to ensuring the integrity and quality of the EEG datasets used to detect alcohol addiction. To accomplish this, a number of procedures were done to refine the raw data before model training and evaluation. Initially, the data underwent preprocessing operations to address missing values and duplicates. Any instances with missing values (NAN values) were detected and removed from the datasets to avoid potential biases or mistakes in the study. Duplicate items in the datasets were also discovered and removed to ensure that the data samples were unique and consistent.

The EEG data were standardized after NAN values and duplicates were eliminated in order to guarantee consistency and comparability among various features and samples. Scaling the features of the EEG data to a standard scale, usually with a mean of zero and a standard deviation of one, is the process of standardization, often referred to as normalization. By reducing the impact of different scales and magnitudes found in the raw EEG data, this procedure enhances the performance and stability of machine learning and deep learning models used to identify alcohol addiction.

In this study, 20% of the dataset was used for testing. This selection was influenced by traditional machine learning procedures, such as a common split ratio of 80:20 between training and testing sets, which guarantees robust evaluation while still giving adequate training data. Given the magnitude of the datasets and the need for accurate performance assessment, this split percentage was deemed reasonable. Specifically, in the public dataset of 122 subjects, 80% (about 97 subjects) were used for training, while the remaining 20% (roughly 25 subjects) were set aside for testing. Similarly, in the acquired dataset of 7 subjects, 80% (roughly 5 subjects) were selected for training, with the remaining 20% (about 2 subjects) for testing.

The research guarantees that the EEG datasets are free of any biases, inconsistencies, or abnormalities that can endanger the accuracy and dependability of the analysis that follows by carrying out these data pre-processing procedures. The successful application of machine learning and deep learning algorithms is made possible by this methodical approach to data refining, which also improves the robustness and effectiveness of alcohol addiction detection.

B. Data Augmentation Techniques

1) SMOTE

The Synthetic Minority Over-Sampling Technique (SMOTE) is an important approach for resolving the imbalance between alcoholic and non-alcoholic classes in the context of alcoholism identification utilizing EEG data. Class imbalance, in which one class (alcoholic subjects in this case) is underrepresented relative to the other (non-alcoholic subjects), is a major challenge in machine learning and deep learning tasks. By creating synthetic instances of the minority class, SMOTE explicitly addresses this problem and evens out the distribution of classes in the dataset.

In order to solve the issue of class imbalance, SMOTE creates artificial instances that fill in the gaps in the feature space between samples of minority classes. Consider the feature space as a multidimensional terrain in which every data point is a distinct set of features taken from the EEG signals. Minority class instances are frequently sparsely dispersed in this environment, which can make it difficult for the classifier to identify patterns in certain areas.

To address this, SMOTE locates the closest neighbors of each minority class instance in the feature space. In order to create new data points that bridge the gaps between the minority class samples that already exist, it then synthesizes new instances along the line segments linking these neighbors. SMOTE increases the minority class's representation in this way, bringing its size closer to that of the dominant class. An enhanced dataset with a more evenly distributed class distribution will be the outcome of this. With a wider range of samples from both classes at their disposal, machine learning and deep learning models may now learn more efficiently. These models can more effectively generalize and produce more accurate predictions if they have a more thorough understanding of both the majority and minority classes.

2) SMOTE-ENN

A thorough method to address class imbalance in datasets is to combine SMOTE with Edited Nearest Neighbors (SMOTE-ENN). ENN concentrates on eliminating noisy or unnecessary data, whereas SMOTE oversamples the minority class by creating synthetic examples. Through the integration of these techniques, SMOTE-ENN seeks to improve the dataset's balance, making it more appropriate for training machine learning and deep learning models by eliminating examples that may have been incorrectly classified and by generating artificial instances.

The combination of SMOTE and ENN improves the quality of synthetic instances, which in turn improves the model's capacity to generalize and produce precise predictions on datasets that are unbalanced. By ensuring that the dataset is suitable for model training, this combination strategy not only lessens the consequences of class imbalance but also produces more robust and dependable performance in classification tasks.

3) SMOTE-TOMEK

SMOTE-Tomek is a resampling algorithm that combines SMOTE and Tomek linkages to overcome the class imbalance in datasets. SMOTE-Tomek seeks to improve dataset clarity by locating and managing pairings of instances from various classes that are near to one another and maybe noisy. To do this, the minority class is oversampled using SMOTE, and instances implicated in Tomek links are simultaneously removed. Improved class separation in the resultant dataset contributes to better model generalization and classification performance, especially in situations with unequal class distributions.

By removing unresolved examples SMOTE-Tomek maximizes the effectiveness of synthetic instance production through the combination of Tomek connections and SMOTE. This method guarantees the production of a more refined dataset that is advantageous for efficient model training in addition to mitigating class imbalance. SMOTE-Tomek offers a solid method for boosting machine learning and deep learning models' performance in classification tasks on unbalanced datasets by raising the quality of synthetic instances while reducing the impact of noisy or ambiguous data points.

C. Machine Learning Techniques

1) Naive Bayes

Naive Bayes is a sophisticated probabilistic algorithm that is simple to use and relies on the assumption of feature independence and Bayes' theorem. Naive Bayes is a simple algorithm that frequently performs better than expected, especially when dealing with high-dimensional data sets like EEG signals. This approach multiplies the individual probabilities of each characteristic occurring in a class to get the likelihood of that class given a set of features. The output is then normalized. It is a desirable option due to its ease of use, computational effectiveness, and low training data needs.

To solve class imbalance, resampling approaches such as SMOTE, SMOTE-ENN, and SMOTE-Tomek are strategically combined with Naive Bayes in this study. Naive Bayes can effectively classify cases and contribute to improved classification performance by using these techniques to oversample the minority class and refine the dataset, particularly in scenarios where class distributions are uneven.

2) Random Forest

During training, Random Forest builds numerous decision trees and then uses a voting mechanism to combine the predictions of these trees. It is well-known for its adaptability and efficiency in classification and regression tasks. Overfitting is reduced and generalization performance is improved using this ensemble learning strategy, which is why it is favored in many fields.

In this work, class imbalance is addressed by harmonizing Random Forest with resampling techniques including SMOTE, SMOTE-ENN, and SMOTE-Tomek. Random Forest is capable of efficiently classifying cases by either improving the dataset by removing confusing instances using SMOTE-Tomek or oversampling the minority class using SMOTE and SMOTE-ENN. In situations when there are unequal class distributions, this integration not only increases the robustness of the model but also guarantees better representation of minority classes, improving classification performance.

3) K-Neighbors Classifier

Based on the similarity principle, the K-Neighbors Classifier (KNN) is a simple yet powerful technique for classification and regression applications. KNN produces choices without making any assumptions about the underlying data distribution by choosing the most common class among a data point's K nearest neighbors. This instance-based, non-parametric approach works well with both linear and non-linear decision boundaries, which makes it appropriate for a range of uses, such as the identification of addiction using electroencephalograms (EEG).

To solve class imbalance, this work deliberately combines the KNN algorithm with resampling approaches such as SMOTE, SMOTE-ENN, and SMOTE-Tomek. The balanced data allows KNN to classify instances well, whether by using SMOTE-Tomek to refine the dataset or SMOTE and SMOTE-ENN to oversample the minority class. Improved prediction resilience and improved representation of minority classes are the results of this synergy, which also improves classification performance particularly in situations when there are unequal class distributions.

D. Deep Learning Techniques

1) CNN

Convolutional neural networks (CNNs) are a key component of the project's methodology, specifically intended to solve the issues associated with EEG data interpretation. CNNs are designed specifically to process structured inputs, such as the grid-like nature of EEG data, and include convolutional, pooling, and fully connected layers. CNNs use convolutional filters to extract hierarchical features from raw data, allowing them to identify complicated patterns and correlations in EEG signals.

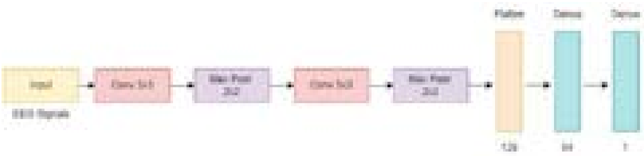

Fig. 3. CNN Architecture

CNNs are used in conjunction with resampling methods such as SMOTE, SMOTE-ENN, and SMOTE-Tomek for two reasons in this research. First of all, it uses CNNs' deep learning capabilities to extract features and classify EEG data as shown in Fig. 3. Secondly, it addresses the problem of class imbalance by using SMOTE-Tomek to refine the dataset or SMOTE and SMOTE-ENN to oversample the minority class. The model can more effectively capture significant patterns and correlations by training CNNs on the modified dataset with improved class distributions, guaranteeing increased representation of minority classes. This deliberate combination ensures more accurate predictions in the identification of alcohol addiction, especially when dealing with the imbalanced class distributions present in EEG datasets.

2) LSTM

Long Short-Term Memory (LSTM) networks play a critical role in the proposed methodology, allowing for the detailed interpretation of sequential EEG data. Designed to overcome the vanishing gradient problem inherent in traditional recurrent neural networks (RNNs), LSTMs specialize in detecting and exploiting long-term relationships within sequential inputs. LSTMs, which have different gates such as input, forget, and output gates, allow for controlled information flow while preserving temporal information through memory cells, making them ideal for tasks requiring sequential data analysis, such as EEG signal processing.

The integration of LSTMs with resampling techniques such as SMOTE, SMOTE-ENN, and SMOTE-Tomek fulfills two purposes. In the beginning, it makes use of recurrent neural networks' innate capacity for sequential data processing. Furthermore, it tackles the problem of class imbalance by using SMOTE-Tomek to refine the dataset or SMOTE and SMOTE-ENN to enhance the representation of minority classes. The modified dataset is then fed into the Long Short-Term Memory (LSTM) network, which allows it to better detect patterns and temporal relationships among the evenly distributed class memberships. This well-coordinated strategy improves the model's ability to identify intricate temporal patterns in EEG data, supporting classification performance, especially in situations with unequal class distributions.

V. Results and Discussion

In the public dataset, before augmentation, Random Forest exhibited the highest accuracy of 96.22%, followed closely by KNN with an accuracy of 95.45%. Naive Bayes lagged behind with an accuracy of 83%. After augmentation, the performance of all algorithms improved noticeably across the board. Particularly noteworthy was the significant enhancement observed in Naive Bayes accuracy, which increased from 83% to 84.74% with SMOTE augmentation. Random Forest maintained its lead, achieving an accuracy of 95.42% with SMOTE augmentation, while KNN showed the most considerable improvement, reaching an accuracy of 98.67% with SMOTE-ENN augmentation.

Conversely, in the acquired dataset, Naive Bayes started with the highest accuracy of 85.14%, followed by KNN with an accuracy of 95.23%. After augmentation, the accuracy of all algorithms exhibited improvement. Notably, Naive Bayes achieved an accuracy of 89.06% with SMOTE augmentation, representing a substantial improvement from its initial accuracy. Random Forest maintained its competitive edge, reaching an accuracy of 94.34% with SMOTE augmentation, while CNN experienced the most significant improvement, achieving an accuracy of 98.97% with SMOTE-ENN augmentation.

These results underscore the importance of data augmentation techniques in enhancing classification performance, especially for algorithms initially hindered by imbalanced or noisy datasets. SMOTE-ENN technique effectively addressed class imbalance and noise, resulting in improved accuracy when combined with CNN algorithm.

Furthermore, the augmentation strategies performed consistently across both datasets, demonstrating their robustness and usefulness in a variety of EEG data settings. The observed gains demonstrate the potential of these methods to address the issues associated with imbalanced and noisy datasets, resulting in more accurate and reliable alcohol addiction identification. This consistency emphasizes the adaptability of the augmentation strategies, indicating that they can adjust to changing data distributions and features.

In addition, the augmentation procedures not only corrected class imbalance, but also served to mitigate the impact of noise in the EEG data. SMOTE, SMOTE-ENN, and SMOTE-TOMEK significantly improved the generalization capabilities of machine learning and deep learning models by producing synthetic data and balancing minority class distributions.

TABLE 1. EEG Database – Results

Technique	**Algorithm**	**Accuracy**
Before-Augmentation	Naive-Bayes	83.00
	Random Forest	96.22
	KNN	95.45
	CNN	90.08
	LSTM	94.21
SMOTE	Naive-Bayes	84.74

	LSTM	94.59

Table 2 shows the results of an acquired dataset of all the machine learning and deep learning algorithms before and after using different augmentation techniques like SMOTE, SMOTE-ENN, SMOTE-Tomek.

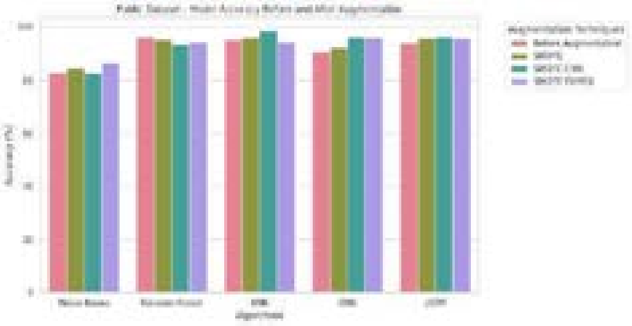

Fig. 4. EEG Database – Results

In Fig.4, it is clearly visualized that while training with public dataset the accuracy of each model's before augmentation and also accuracy of each model's after applying different augmentation techniques like SMOTE, SMOTE-ENN, SMOTE-Tomek.

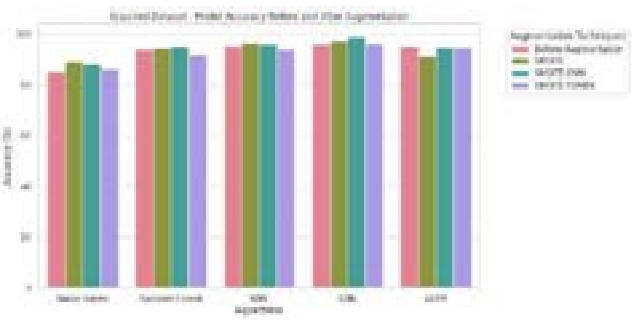

Fig. 5. Acquired Dataset – Results

In Fig.5, the accuracy of each model before and after the use of various augmentation approaches, such as SMOTE, SMOTE-ENN, and SMOTE-Tomek, is easily observable when training with the acquired dataset.

VI. Conclusion And Future Scope

The research emphasizes how important data augmentation methods and algorithm selection are important to EEG-based addiction detection. Prior to augmentation, the accuracy of the algorithms varied, with CNN surpassing the others in the acquired dataset and Random Forest demonstrating encouraging results in the public dataset. After augmentation, significant gains were seen in all algorithms, especially with the SMOTE-ENN approach which successfully dealt with noise and class imbalance and significantly increased accuracy.

Further research projects might investigate more sophisticated data augmentation techniques like generative adversarial networks (GANs) that are especially designed for EEG data. To further improve model accuracy, research should be done to investigate how feature selection strategies and hyperparameter adjusting affect classification performance. The generality of the results could also be improved by expanding the study to include bigger and more varied datasets, opening the door for the creation of reliable EEG-based addiction detection systems with practical applications.

siddharthtomar10@gmail.com, 2virenderranga@dtu.ac.in

Abstract: **The health of a computer Network is a critical issue for organizations that are digitally interconnected within their networks and connected to the internet and hence significantly rely on their networks for performance and overall productivity, including communication, data transfer and running their business operations. This study presents an in-depth research conducted on the network of the Delhi Development Authority, which consists of more than 4100 nodes, focusing on the reliability of computer networks that can be predicted or estimated in different scenarios. Starting with a definition and explanation of its significance, the study discusses the elements that affect network reliability, providing a broad overview of network dependability and specifically addressing reliability. It then delves into various methods for evaluating a network's reliability, such as simulation-based techniques like Monte Carlo simulation and analytical methods like Markov models and fault trees. The study further explores methods for analyzing network reliability, including failure analysis, redundancy methods, and failure recovery plans. Additionally, case studies are presented to illustrate how network reliability can be applied in practical scenarios across different sectors. The final section of the survey discusses challenges, potential avenues for future research, and the importance of ongoing research in this area.**

Keywords: Reliability, Network Reliability, Network Dependability, Sensor Response Data Analysis, Network health, Network Reliability Evaluation Techniques, Network Analysis Report, Factors of Network Reliability, Network Management

I. INTRODUCTION

This review paper's introduction offers a thorough grounding in network reliability. "*Network Reliability"* describes a system's regularity in providing services without interruptions or breakdowns. This refers to how much a network's infrastructure and services can be relied upon to function consistently and reliably. The modern interconnected activities would not be possible without the reliability of their networks, which is the ability of a system to constantly supply services without interruption. To provide constant access to data and applications, data centers, the backbone of contemporary computing and cloud services, rely extremely on reliable networks [1]. Stable networks are crucial for the operation and provision of key services by critical infrastructures such as the Internet, financial IT backbone and power grids etc. Analytical methodologies such as Markov models, fault trees, reliability block diagrams, and simulation-based approaches such as Monte Carlo simulation and network emulation are explored in this study. This report also analyses research papers from other authors based on similar principle.

II. MOTIVATION

Systems Department of Delhi Development Authority (DDA) recently established a state of art structured metropolitan Computer Network throughout Delhi of more than 4100 nodes. When the IT consultants were testing the network's functioning, it was desired that the reliability of the network should also be estimated/computed so that at any point of time the status about the health of the Network and some short of assurance about the sustainability and certainty about the information communication through the newly established network can be known. The consultants surrendered on this issue stating that this is the subject of research. This event motivated the author to think in the direction of establishing a systematic mechanism to compute the reliability and hence the means to judge the health of a computer network.

III. LITERATURE REVIEW

Reliability estimation in computer networks is a complicated problem that requires ongoing study. The difficulty of dependability estimate is increased by the variety of modern network topologies, such as mesh, star or hybrid configurations. The complex nature of these topologies makes it hard to evaluate the network's overall resilience. The second major obstacle is the ever-changing nature of network settings.

Constant traffic fluctuations, software and hardware updates, and other external factors all contribute to the ever-evolving operational environment in which networks must function. Such changeability calls for dynamic dependability models that can track evolution [2]. One of the biggest obstacles is the wide variety of network nodes. The evaluation of total dependability is complicated by the fact that routers, switches, servers, and cables all have their own unique failure modes and reliabilities [3]. Obtaining precise information regarding network failures and performance is complicated by issues like privacy concerns, a dearth of comprehensive monitoring tools and a lack of historical data. With the ever-increasing size and complexity of today's networks, scalability is also a major issue. Large-scale network reliability estimation requires a lot of computing power, thus effective techniques and methodologies are needed to deal with this scalability problem. When thinking about promising areas for future study, machine learning and AI immediately come to mind. As a result of their ability to learn from past experiences and adapt to a constantly changing network environment, these technologies can be used to greatly enhance the precision with which reliability estimates are made [4]. Network security may undergo a dramatic shift with the advent of quantum networking. Networks could be more resistant to failures and assaults thanks to the quantum advantages offered by these technologies. The blockchain is also intriguing since it may be used to build trust and lessen the effect of network infrastructure's weak spots. Crucial network components, such as authentication and authorization systems, may be made more trustworthy by using blockchain-based solutions. Agile Software Development (ASD) has revolutionized the industry by encouraging a more collaborative and iterative approach to creating software. Agile mobile app developers use an incremental and iterative process that relies on self-managing and cross-functional teams to create their apps [5]. MOBILE-D, RaPiD7, Hybrid methodology, MASAM, and Scrum with Lean Six Sigma (SLeSS) are some of the most well-known agile mobile application development techniques currently in use. Researchers agree that the Agile methodology is a good fit for creating mobile applications. Agile software development does away with the separation of phases such as development and testing. In agile, software estimate is done concurrently with both development and testing [6]. Very little work is documented in the literature about the estimation of effort in agile development, which is a relatively new area of study [7]. Examining the test effort estimation methodologies for both traditional desktop/laptop software development and mobile software development is a major contribution of this study. Furthermore, two methods of mobile application development process, namely, traditional software development and agile software development, are compared and contrasted with regards to development and test effort estimation techniques. Finding out what sets mobile apps apart from more conventional software is also a significant contribution [8]. The decentralized nature of edge computing's data processing poses problems and possibilities for network uptime. Taking into account the unique set of constraints and opportunities presented by edge environments may be a focus of future study. Additionally, improvements in network simulation tools are crucial for accurately assessing network resilience. Insights into network behaviour can be gained by using these technologies, which generate virtual environments in which researchers can test different scenarios and failure types. It would be impossible to emphasize the value of continuing studies into network dependability. It has an immediate effect on business continuity by guaranteeing that companies can keep running despite network outages, which can lead to significant financial losses [9]. As resilient networks are less vulnerable to assaults and breaches, network dependability is also an essential part of cyber-security. Adaptability of dependability models is ensured through continuous study as new technologies like 5G, the IoT, and edge computing become more commonplace. In the end, this study is crucial for enhancing network efficiency, decreasing latency, and giving users a dependable online experience [10]. The estimation of a basic reliability measure of a communication net-work, namely the 2-terminal reliability is the fundamental and primitive method. [11] The automation and continuous explosion of personal and professional information to the digital world provides a potent ground to the adversaries to perform numerous cyber-attacks, thus making security in IoT a sizeable concern[12]

IV. NETWORK RELIABILITY EVALUATION TECHNIQUES

The final half of the review paper examines network dependability evaluation techniques, with a focus on hybrid solutions that integrate analytical and simulation methods to examine the network reliability in depth.. Analytical methods like Markov models are used to calculate network dependability by recording system state probabilities and depicting network state transitions. Fault trees and reliability block diagrams help to analyse the system failure causes and effects. Simulation-based technologies construct virtual network replicas to test performance and collect reliability measures. Monte Carlo simulation evaluates network performance using random input. Network dynamics are simulated via discrete event simulation of packet arrivals and departures.

V. FACTORS AFFECTING NETWORK RELIABILITY

This part of the paper examines various factors like Link Failures, poor technology or environmental conditions like power outages or natural catastrophes etc. which affect network reliability. In today's interconnected world, network dependability is crucial to ensuring uninterrupted communication, productive operations, and safe data transmission. Reliable and flexible emergency communication is a key challenge for search and rescue in the event of disasters, especially for the case when base stations (BSs) are no longer functioning. [16] The efficiency and dependability of a network might be hampered by several external variables. To effectively improve network dependability, one must have a firm grasp on these aspects and their ramifications. Network failure has several causes and symptoms, any of which can decrease or eliminate user access. Many events can disrupt network operation, compromising data transit and communication security. When the wires between nodes in a network break, this is known as a link failure.[Damaged cables, faulty technology, or environmental conditions like power outages or natural disasters are all potential causes. When a link fails, data transmission stops, disrupting communications and making network services inaccessible. The consequences of link failures can be lessened using redundancy in network design, such as backup links. A node failure occurs when routers, switches, or servers malfunction. Hardware, software, and power failures can cause these issues. A node failure could disrupt data and service availability and disconnect them from the network. Backup nodes or load balancing can keep the network online if any components fail. When data supplied and received exceeds network capacity, congestion develops. At times of high demand or exceptional events, this delays operations, increases latency, and lowers performance. Congestion can hinder critical services, user experiences, and data transfer. Quality of Service (QoS) methods like traffic prioritization and bandwidth allocation can minimize congestion. Data packet loss occurs when data packets fail to arrive at their network destination. Network operators can improve network dependability by proactively addressing various failure sources and applying solutions like redundancy, QoS systems, and error detection. Link failures disrupt data transfer between network computers. System failure can be caused by environmental factors like bad weather and physical difficulties like cable breaks or technology malfunctions. Data transmission delays and network communication disruptions are caused by link failures. However, network nodes fail when they malfunction. System issues can result from hardware failures, power outages, and improper programming. If a node fails, network segmentation can cause several issues for users, including catastrophic data loss. When data transmission exceeds network capacity, congestion occurs. Progress may halt or slow due to the existing condition. Congestion hinders answers and lowers user experience due to increased network traffic. Another problem with network dependability is packet loss. It happens when some of the data packets travelling across the network never make it to their destination. Congestion in the network, malfunctioning equipment, or insufficient error detection and repair systems are all potential causes of packet loss.

VI. EVALUATION AND MEASUREMENT OF NETWORK DEPENDABILITY

Reliable network maintenance needs rigorous analysis, frequent monitoring, and a variety of tools and methods to assess and improve network dependability. KPIs are critical to network health and dependability. These indicators illuminate network performance and help spot faults and measure changes. Latency, packet loss, and throughput are key network reliability KPIs. Latency monitors data transmission time, revealing network responsiveness and congestion difficulties. Network reliability and data integrity are measured by packet loss, the percentage of data packets that fail to arrive. Data throughput, on the other hand, indicates the network's efficiency and capacity.

VII. ENHANCING NETWORK RELIABILITY

Here numerous technologies and strategies have been examined to improve network reliability. QoS is crucial in prioritising and distributing network resources to key applications to ensure optimal data transfer rates. Having numerous identical components or channels in a network ensures redundancy in case of failure. N+1 and N+K redundancy models easily move to backup resources during disruptions to maintain service continuity. To avoid overload, load balancing uses redundancy to spread network traffic evenly across resources. However, fault tolerance emphasises a network's resilience to breakdowns, ensuring it continues to run. Restoring network services quickly after disruptions requires failure recovery and resilience solutions.

Dynamic routing and connection repair speed up traffic rerouting, reducing downtime. Automation and configuration management reduce human errors, speed up problem resolution, and improve network availability.

VIII. TRENDS IN NETWORK RELIABILITY

Network reliability evolves owing to technology advances, user needs, and threats. Staying updated on network reliability developments is crucial in this dynamic market. Several major developments affect dependable network design, management, and maintenance. The rise of edge computing is changing network designs. Edge devices near data sources reduce -latency and processing time. Edge computing improves user experience and enables realtime applications, but it adds failure points. Decentralised edge networks require redundancy, fault tolerance, and dynamic routing, which traditional dependability methods must accommodate. AI and advanced analytics: Network topologies may make centralised monitoring insufficient. Advanced analytics, machine learning, and AI solutions are in demand. These solutions provide real-time network health, performance, and failure analytics. Cyberattacks are threatening network resiliency and hence requires proper security measures.

IX. NETWORK RELIABILITY ANALYSIS APPROACHES

Network failure analysis, risk assessment, redundancy, fault tolerance, and recovery strategies are all discussed in the review paper's fourth part on reliability analysis. These methods are essential for pinpointing vulnerabilities, reducing the effects of failures, and guaranteeing the speedy restoration of network services.

Adding redundancy and fault tolerance to a network is one method to boost its dependability. Redundancy is the practice of having multiples of critical parts or paths in a system so that they can be used in case one fails. While failures can still have an effect on a network's performance, they are less noticeable when using redundancy models like N+1 or N+K.
Network traffic can be balanced across several paths using load balancing and traffic engineering techniques to improve both resource usage and fault tolerance. Network operators can reduce the impact of failures and keep services running smoothly even in extreme conditions by employing redundancy and fault tolerance methods.

Service Level Agreements (SLAs) are crucial contracts that must be established between service providers and their clients.

Service level agreements (SLAs) specify the dependability, availability, and performance characteristics that are anticipated of a service. They are used as guidelines for gauging network dependability by specifying what is expected of service providers and the repercussions for falling short. Network operators can improve network dependability by monitoring and evaluating SLA compliance to pinpoint problem areas and implement fixes. [17]
The transfer of data from the sender to the receiver in any form and through any mode is the most important aspect of the Network Reliability. The reliability of a network can only be evaluated through constant monitoring and measurement of its performance. Key performance indicators (KPIs) like latency, packet loss, and throughput are monitored by network managers using a wide variety of tools and approaches. These metrics help us understand how networks function, spot problems that could compromise their dependability, and catch abnormalities early so we can fix them and minimize disruptions to services as soon as possible.

Quality of Service (QoS) mechanism implementation is another key strategy. QoS methods guarantee that mission-critical applications and services have access to sufficient bandwidth, low latency, and few dropped packets by giving them higher priority in the network. Network operators may reduce congestion, optimize resource allocation, and guarantee consistent performance for mission-critical services with the help of traffic shaping, prioritization, and resource reservation [10].

Here an example of data transfer through mail in DDA network is shown where 100% data has been transferred from the sender to the receiver. It means that during this task the network was 100% reliable, this is another aspect of the reliability.

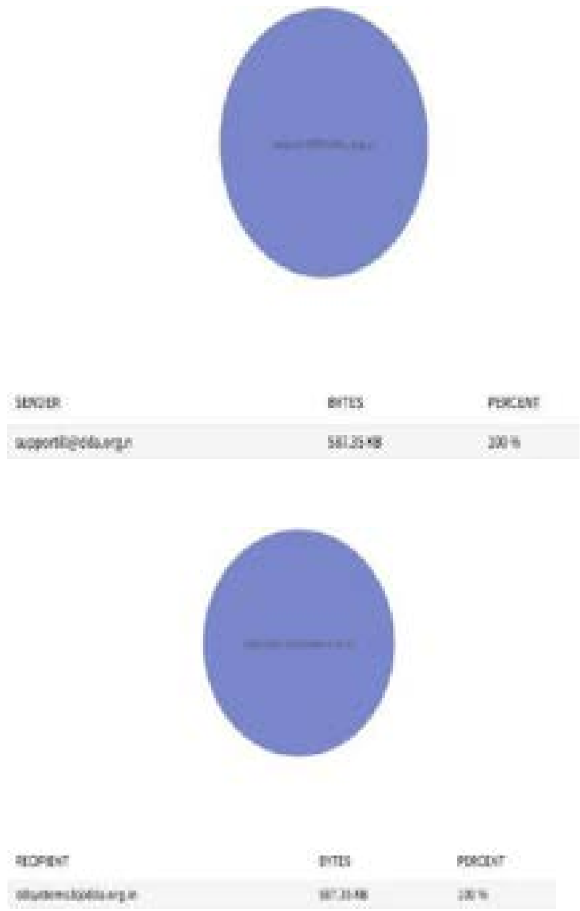

Fig 1: Sender and Receiver concept of Network Reliability (Ref. DDA Delhi Network)

The network's ability to withstand and recover from security events and other interruptions can be improved by incorporating redundancy, backup systems, and disaster recovery plans into the infrastructure. [14]

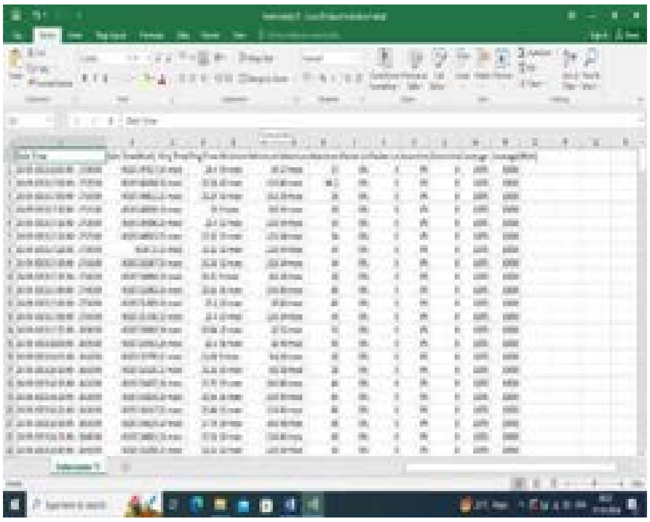
It is essential to regularly test and validate network components, settings, and protocols in order to assess reliability and discover potential vulnerabilities. Network performance can be evaluated under varying situations and potential failure points can be located with the use of load testing, stress testing, and penetration testing, all of which are simulations of real-world events. With the help of continuous testing and validation, operators can proactively fix security flaws, fine- tune settings, and guarantee the system's ongoing dependability. [8].

Network reliability analysis is a dynamic process that must accommodate new network architectures, technologies, and user expectations. Sharing best practices, exchanging knowledge, and pushing innovation in network reliability analysis all rely heavily on collaboration between researchers, industry professionals, and network operators.

The study concludes with a discussion of the many methods available for analysing network reliability. Network dependability can be evaluated and enhanced through the use of various tools and methods, such as failure analysis and risk assessment, redundancy and fault tolerance techniques, failure recovery and resilience tactics, service level agreements (SLAs), performance monitoring, quality of service mechanisms, security measures, network management and automation, and continuous testing and validation. Network operators can better meet the needs of today's communication and data-driven settings by combining these methods fully to improve the networks' dependability, availability, and performance [9].

X. CASE STUDY FOR DDA NETWORK

The data of 82 sensors was collected for the 4100 plus nodes Computer Network of Delhi Development Authority for 03 months from 01 Oct 2023 to 31 Dec 2023. The data was collected at the interval of 5 minutes round the clock.



Then various graphs were plotted based on this data. Figs. 1(a) ,1(b),1(c),1(d) and 2 show our study about the working of DDA's Computer Network based on the sensors data for 03 months from Oct 23 to Dec 23. The 04 scenarios have been considered for drawing the graphs. 1(a) with 30 Second ping interval time 1(b) with 60 Second ping interval time and similarly 1(c) with 30 Seconds and 1(d) with 60 Seconds ping interval. It is evident that with increase of ping interval time the down time decreases i.e. failure rate decreases this clearly means that reliability is increasing with increase in ping interval due to obvious reason of free availability of the channel due to increase in ping interval time and based on these parameters and we achieved the following results:

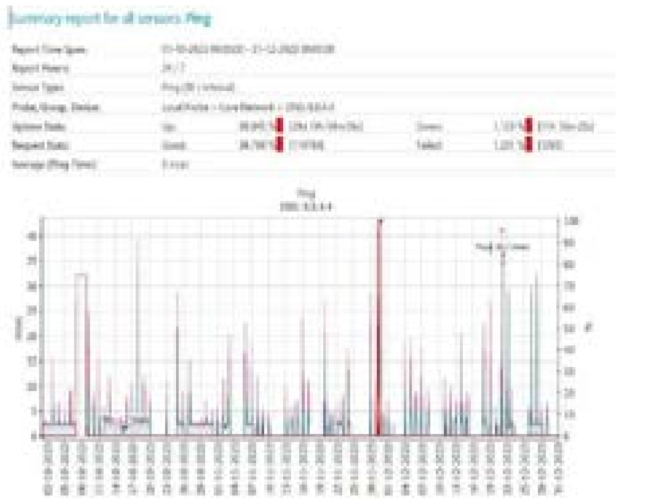


Fig. 2 (a): Delhi Development Authority's Network Analysis report from 01 Oct 2023 to 31 Dec 2023(30 Seconds Ping Interval)

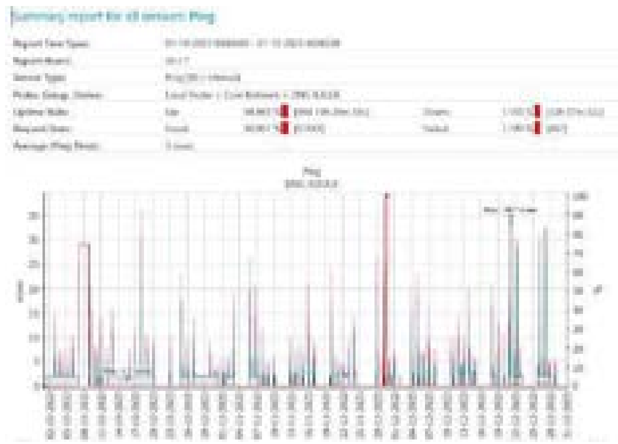

Fig. 2 (b): Delhi Development Authority's Network Analysis report from 01 Oct 2023 to 31 Dec 2023(60 Seconds Ping Interval)

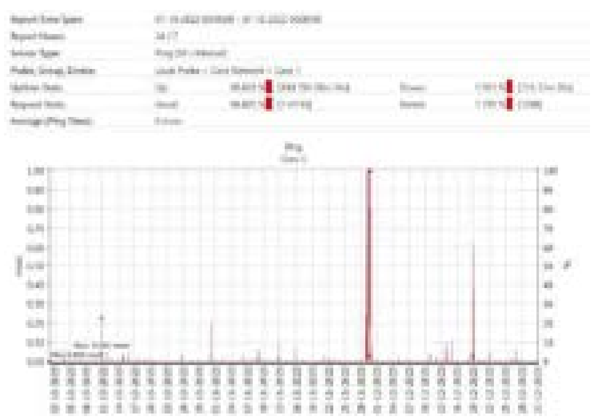

Fig. 2(c): Delhi Development Authority's Network Analysis report on different parameters from 01 Oct 2023 to 31 Dec 2023 (30 Second Ping Interval)

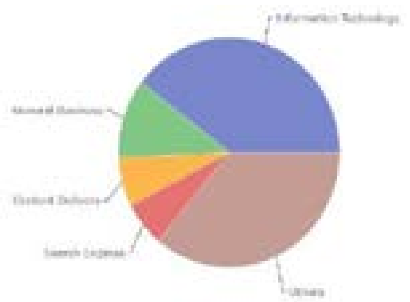
Fig. 2(d): Delhi Development Authority's Network Analysis report on different parameters from 01 Oct 2023 to 31 Dec 2023 (60 Second Ping Interval)



CATEGORY	HITS	PERCENT
Information Technology	12890837	39.6 %
General Business	3612902	11.09 %
Content Delivery	2259159	6.94 %
Search Engines	2066247	6.35 %
Others	11727530	35.99 %

Figure 3: Delhi Development Authority Network usage during Oct 23 to Dec 23

It has been observed from Fig 2(a & b, c & d) that stable networks have lesser downtime and consequently more reliability and crucial to the uninterrupted operation of critical infrastructure like power grids. The study's primary conclusions and recommendations show the crucial importance of network dependability in a wide range of fields. (Malhotra, 2021) In the study the effort has been made to detect the parameters on which the reliability mainly depends and the relation of these parameters with reliability to enhance the reliability if required.

For deriving the reliability of a computer Network once the reliability of any component is available or computed can be estimated with the help of the following derived algorithm based on the value computations of a matrix. The design and the algorithm are precisely described as under: -

DESIGN MODE: **NETWORK RELIABILITY ESTIMATION**

STEP 1 :- analysis of each network component in terms of reliability and computing or assigning a value of reliability for each component as under:

1. Cable & Connectors Reliability = CCR
2. Modems RELIABILITY = MOR
3. Trans receivers RELIABILITY = TRR
4. Hubs RELIABILITY = HBR
5. Switch: It may increase or decrease the reliability based on its type. Intelligent switch increases the reliability and speed both. RELIABILITY = SWR
6. Check Point/Firewalls:- It increases the overall reliability but decrease the speed.
RELIABILITY = CFR
7. Repeater :- It increase the reliability
RELIABILITY = RPR

The Reliability to each segment or Component can be assumed or calculated through experiment as above.

STEP 2:- Finding Inter Nodes Paths and components in the paths

Paths towards every node from other nodes :-
Towards N1 :-
From N2 : N2-N1
N2-CC-SW1-CC-N1
N2-CC-SW1-CC-N3-CC-R1-CC-N6-CC-N1
N2-CC-N4-CC-N3-CC-R1-CC-N6-CC-N1
N2-CC-N6-CC-N3-CC-SW1-CC-N1
From N3 : N3-N1
N3-CC-SW1-CC-N1
N3-CC-R1-CC-N6-CC-N1
N3-CC-N4-CC-N2-N1
Paths towars every node from other nodes :-
Towards N1 :-
From N4 : N4-N1
N4-CC-N3-N1
N4-CC-N2-N1
N2-CC-N4-CC-N3-CC-R1-CC-N6-CC-N1
N2-CC-N6-CC-N3-CC-SW1-CC-N1
From N6 : N6-N1
N6-CC-N1
N6-CC-R1-CC-N3-N1
From N5 : N5-N1
N5-CC-N6-N1
Similarly Paths towards N2, N3, N4, N5 and N6 can be analysed which will be as under:-
N2-N1(<u>RP1</u>) N1-N2 N1-N3 N1-N4 N1-
N5 N1-N6
N3-N1(RP2) N3-N2(RP6) N2-N3 N2-N4
N2-N5 N2-N6
N4-N1(RP3) N4-N2(RP7) N4-N3(RP10) N3-N4
N3-N5 N3-N6
N5-N1(RP4) N5-N2(RP8) N5-N3(RP11) N5-

N4(RP13) N4-N5 N4-N6

N6-N1(RP5) N6-N2(RP9) N6-N3(RP12) N6-N4(RP14) N6-N5(RP15) N5-N6

P1 to P15 are the distinct paths

RP1 to RP15 are the reliability of each path

RP1= Reliability of Path N2-N1 or N1-N2 and so on….

ALGORITHM:

Find the longest path and its component, Let the longest path has

```
        Lp= no of Components / Segments.
        Create a Lp x Pm x Np Matrix where
        Np=n(n-1)/2 , where n is the number of
        nodes and Pm is the maximum no of paths
        available from any one node to the any other
        Store Values of Reliability of each
        component in the matrix
        Keep 1 where corresponding value is blank
        Set Reliability =1
   for i=1 to Lp
        Begin
{
        for j =1 to pm
Begin
{
        For k = 1 to Np
        Begin
{
        Reliability =Reliability * Value (i, j,k)
        ++ i; ++ j; ++ k ;
          }
        End
            }
          End
              }
            End
          Printf ('Reliability of Network=',%d ,
                 Reliability )
        End
```

In the final section of the review article, the value of case studies and practical applications in demonstrating the significance of network dependability in various industries is emphasized. [15] Telecom, cloud computing, transportation, logistics, and critical infrastructure case studies shed light on the pros and cons of putting an emphasis on network resilience. Stakeholders can receive actionable insight into how to achieve improvements in network dependability and operational efficiency by examining these cases. In addition to the aforementioned industries, there are many others where case studies can shed light on the importance of network reliability. For instance, trustworthy communication networks are crucial in the healthcare business for providing telemedicine services, sharing real-time data, and sharing patient records. Patient care, emergency response systems, and the general efficacy of healthcare delivery are all areas where case studies can shed light on the importance of network reliability. Security during financial transactions, data transfers, and real-time market data all rely largely on network reliability. The banking and financial industry provides a useful case study setting in which to examine the effects of network outages, cyber threats, and the introduction of highly reliable network infrastructure.[3] Experts in the field and academic scholars can learn from these examples to better protect the integrity of financial networks and prevent future disruptions. Critical services in smart cities, such as transportation, energy management, public safety, and environmental monitoring, rely on stable communication networks to function. Studying these cases can shed light on the significance of network dependability in facilitating effective public transit, real-time monitoring, and the distribution of vital community services.[13] Problems with scalability, interoperability, and the consolidation of smart city apps are among something they can fix.

XI. CHALLENGES AND FUTURE DIRECTIONS

The impact of emerging technologies, scalability and complexity issues, security and resilience considerations, and the potential applications of machine learning and AI are all taken into account as we discuss the challenges and future directions in the field of network reliability in the sixth section of this review paper.The stability of networks is profoundly affected by cutting-edge innovations. The development of 5G, edge computing, the Internet of Things (IoT) and virtualization presents new opportunities and threats. Above all, the software tools and utilization process, robustness and availability of security measures at every node in the intranet are essential challenges to be met for bare minimum reliability.

XII. CONCLUSION

Conclusively, this study has presented a summary of network reliability, including an overview of its evaluation methods, analysis approaches, case studies and potential future developments. The primary conclusions and recommendations of the study and research show the crucial importance of network dependability for an organisation and in vide range of fields. In the study the effort has been made to detect the parameters on which the reliability mainly depends and the relation of these parameters with reliability to enhance the reliability if required. New technologies, scalability, security concerns, and the potential of machine learning and AI applications have been identified as areas requiring attention. The study will add a lot in the direction of certification of Computer Networks considering reliability as important parameter. Once the reliability will be counted in the certification of networks, the overall performance, throughput and the life cycle of the computer networks will be enhanced.

***Abstract*— Nowadays, object detection is popularly used in most vision-based AI and it is sole to the various computer vision tasks like face recognition, Animal detection. This study focuses on the identification and tally of elephants using drone photos using YOLOv5. Drones allow you to span a vast area and facilitate prompt and effective animal monitoring. YOLOv5 is the first YOLO model to be written in PyTorch framework which is fast and accurate. As every species plays a crucial role in the ecosystem, extinction of one specie may cause damage to entire ecosystem. So, it is important to detect the endangered species and ensure their protection. In this project YOLO algorithm is used to detect and count the endangered species from drone images. In this project elephant is taken as a reference as the population of elephant is declining over several decades due to poaching and loss of habitat. Existing model only has detection of animal so counting of animal's feature is added to it to increase its efficiency. The model developed has mAP 89.4%, Precision 89.1% and Recall 83.2%.**

Keywords-Object detection, YOLOv5, Drone images, Elephant.

I. INTRODUCTION

The natural equilibrium of our planet depends on human and wildlife cooperation. The natural habitats of many species have, however, been invaded by urbanization and human activity in many areas, increasing conflicts between people and wildlife and endangering the existence of a number of famous and threatened species. With its enormous cultural, ecological, and conservation worth, the elephant is one of these vulnerable species that represents both the benefits and the challenges of preserving nature.

Effective monitoring of elephant populations movements, habits, and habitats is essential to reducing the negative effects of these conflicts and safeguarding them. Conventional techniques for gathering and tracking data, such video traps and ground-based surveys, have shown to be beneficial but are frequently costly, labor-intensive, and time-consuming. Technological developments in the last few years have created new opportunities for wildlife protection and monitoring.

Using Unmanned Aerial Vehicles (UAVs) or drones fitted with sophisticated computer vision algorithms is on such invention. The YOLO (You Only Look Once) technique is used to the important task of elephant species detection from drone photographs in this article. YOLO is a well-known object detection method that is fast andaccurate, which makes it a great option for real-time applications. Our mission is to transform the way we monitor and protect elephant populations by utilizing the power of YOLO and deploying camera-equipped drones.

II. MOTIVATION

As there is a serious threat to elephants' population due to due to conflicts with humans, poaching, and habitat destruction. To address this, conservationists are turning to innovative solutions like employing drones equipped with YOLOv5 technology for accurate elephant spotting and counting. Traditional methods, such as manual counts or manned aircraft surveys, are often time-consuming, expensive, and impractical in remote or densely forested areas. By leveraging drones and YOLOv5, conservation efforts can be significantly streamlined, enabling more effective monitoring of elephant populations and targeted conservation initiatives to safeguard these majestic creatures for future generations.

III. LITERATURE SURVEY

Chamoso, P et al. [1] investigates how to effectively monitor vast cattle regions using UAVs and artificial vision. It focuses on counting and monitoring animal species using UAV video recordings. The system tracks and logs the quantity of animals found by analyzing UAV camera images. The system's efficacy is demonstrated by a battery of tests. The results of these evaluations are presented in the paper's conclusion, which highlights the method's potential for thorough livestock area surveillance and animal counting with cutting-edge technology.

Prosekov, A et al. [2] aims to assess monitoring techniques for large wild species in order to conserve biodiversity, particularly elk and moose. It emphasizes how crucial trustworthy wildlife data is to making wise management choices. Recognizing that these species live in large, diversified environments with low densities, the research investigates several techniques to estimate population size without causing disturbance or significant financial burden. These models' accuracy is dependent on statistical data as well as its customization to certain geographic and meteorological circumstances. Using a combination of current and old technology, such as UAVs, GPS sensors, and cameras, provides a flexible way to bridge the gap between the practical feasibility and research.

Kellenberger, B et al. [3] addressed the difficulty of conducting a large-scale animal census by employing CNNs and UAVs. With tiny datasets, current methodologies frequently break down, resulting in a large number of false alarms in large study areas. Through the implementation of customized evaluation techniques and CNN scaling, this study dramatically lowers false positive rates, improving detection accuracy by a factor of ten over earlier approaches. Their CNN reduces the requirement for manual verification by three times with a 90% recall rate, allowing for effective acquisition data screening. With the help of this development, rangers in reserves will be able to automatically identify almost every species, transforming wildlife conservation through precise and effective monitoring.

Gemert, J.C.v et al. [4] looks into the use of small unmanned aerial vehicles (UAVs) and object identification for efficient animal surveying in environmental conservation. By gathering their own data using a quadcopter drone, they assess animal detection and counting.Although conventional human-scale visual object recognition algorithms are not well suited for drone viewpoint, lightweight automatic detection methods demonstrate potential for conservation applications. This study provides a promising path for more effective and economical field surveys by highlighting the possibility for adapting such methodologies to support conservation and wildlife monitoring activities.

Isla Duporge et al. [5] pioneers the use of cutting-edge technology by employing Convolutional Neural Network (CNN) models using very-high-resolution satellite data to automatically detect and count African elephants in complex forest savanna landscapes. The researchers trained and assessed the CNN model using 11 photos from 2014 to 2019 using WorldView-3 and 4, the highest resolution satellite data available. The CNN's remarkable accuracy was demonstratedby the results, which matched human detection abilities. F2 scores in homogeneous and heterogeneous areas were 0.73 and 0.78, respectively, which are similar to human labeling scores of 0.77 and 0.80. Most remarkably, the model showed generalizability by identifying elephants without further training in a different geographic region (Kenya) and using lower resolution satellite data (GeoEye-1). This study offers a novel method for monitoring elephants in a variety of environments, highlighting the potential of deep learning and satellite remote sensing for wildlife conservation. Elephant detection may now be automated with accuracy close to that of a human, opening up new possibilities for conservation andwildlife monitoring.

IV. METHODOLOGY AND RELATED WORK

A. Traditional structure of yolov5

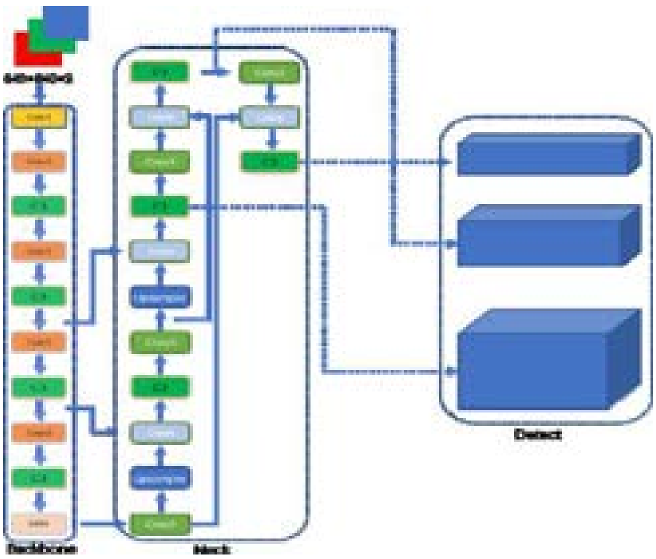

Figure 1. Yolov5s structure

Backbone Network:

YOLOv5 uses a backbone network based on CSPDarknet53 or EfficientNet as the feature extraction backbone. The choice of the backbone allows for better feature representation and contributes significantly to accuracy.

Neck and Head:

YOLOv5 introduces a novel "neck" and "head" structure that refines and processes features at different scales. This helps in improving detection accuracy for objects of varying sizes.

Input Layer:

The input layer takes the image as input. YOLO typically takes images of fixed sizes as input, which are divided into a grid for processing.

Convolutional Layers:

YOLO primarily consists of convolutional layers that perform feature extraction. These layers analyze the input image to extract hierarchical representations of features.

Downsampling Layers:

While extending the receptive field, downsampling or pooling layers decrease the spatial dimensions of the feature maps. This lessens processing and aids in context capture.

Concatenation and Upsampling layers:

In some YOLO variants, concatenation or upsampling layers are used to fuse features from different scales or increase the spatial resolution of feature maps for better object localization.

Output Layer:

Bounding box final predictions, confidence ratings, and class probabilities are all contained in the output layer. After that, post-processing is used to determine and create bounding boxes around any objects that are found.

B. Training of custom yolov5 model

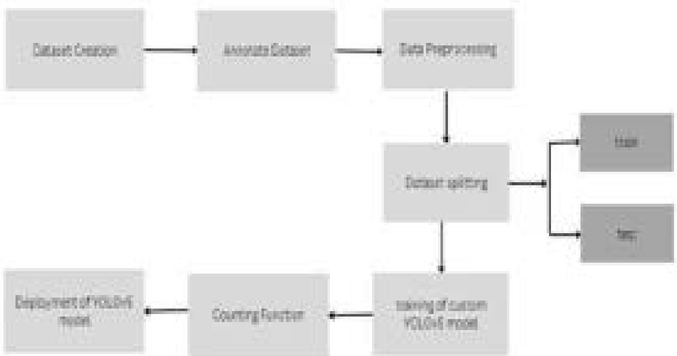

Figure 2. Methodology

A. Dataset Creation

Since research involves drone imagery of elephants, the relevant images were gathered from Google and added to roboflow as the Elephant detection image dataset. The dataset contains 309 images.

Figure 3. Elephant drone image

B. Annotate Dataset

For annotation the images should be in .png or .jpg format. Objects can be annotated inside the images of dataset using labels like bounding boxes. After completion, the annotations will be generated as text file to be used in YOLOv5 custom model training asshown in Figure 4.

```
File    Edit    View

0 0.174255 0.235514 0.252951 0.324538
0 0.599213 0.636715 0.155143 0.390979
0 0.729904 0.418227 0.254637 0.265764
0 0.783867 0.548553 0.200675 0.229988
0 0.833614 0.801539 0.263069 0.296429
```

Figure 4. .Annotations

C. Dataset splitting

Here the dataset is randomly split into train, test and validate by allocating 80% of images to train ,10% to validate and remaining 10% to test. This type of classification is required to train custom YOLOv5 model otherwise it will show error.

D. Data Preprocessing

Data preprocessing techniques applies image alterations to every image in the dataset in order to reduce time and improve performance. Preprocessing methods like Resize and Auto Orient were applied here.

Image resizing is a fundamental preprocessing step in object detection pipelines. It standardizes input dimensions, enhances computational efficiency, and contributes to the capacity of the model to identify and generalize objects effectively in various scenarios. Images might have different orientations (e.g., landscape, portrait) that can affect the accuracy of object detection algorithms if not handled properly. The "auto orient" preprocessing step, often associated with images, refers to an operation that automatically adjusts the orientation of an image based on its metadata.

Augmentation methods like flip, crop can be applied to dataset to increase the efficiency of yolov5 model.

Now generate the dataset by applying above modifications in roboflow website and export dataset in YOLOv5 PyTorch format. Then it will generate a snippet as shown in Figure 5 which is used further in YOLOv5 custom model training.

```
!pip install roboflow

from roboflow import Roboflow
rf = Roboflow(api_key="[redacted]")
project = rf.workspace("jahnavi-kommalapati").project("elephant-detection-and-counting-from-drone-images")
dataset = project.version(4).download("yolov5")
```

Figure 5. Snippet to download and unzip our dataset

E. Training of custom YOLOv5 model in google colab

Install requirements:
Clone YOLOv5 repository from github and install all required dependencies.

Assemble the Dataset:
Assemble the dataset uploaded in Roboflow using the snippet in Figure 4.

Train the custom YOLOv5 model:

We train the custom YOLOv5 model using below code

!python train.py --img 416 --batch 16 --epochs 150 --data {dataset.location}/data.yaml --weights yolov5s.pt --cache

Here dataset.location is the location where our dataset is stored and in that dataset only we have data.yaml file.Now our model training is completed and can download the elephants custom yolov5 model which is stored in a path './runs/train/exp/weights/best.pt'

F. Counting function

The quantity of bounding boxes serves as the basis for item counting generated by the YOLOv5 model during the object detection process. Each bounding box typically represents a detected object, and counting them provides an estimate of the number of objects in the image. Here torch.hub.load function is used to load the custom yoloV5 model to detect elephants.

G. Deployment of yolov5 model

Here for deployment of elephants YOLOv5 custom model we use tkinter .Tkinter is the popular GUI library of python which is used to create GUI for object detection projects. The sample GUI which is developed using tkinter is shown in Figure 6.This GUI is used to count and detect elephants in image.

Figure 6. Sample GUI

V. RESULTS & DISCUSSION

A. Elephants Detection

From Figure 6 if we click Detect Elephants button then we will get the results of elephants detected in image depending on the YOLOv5 model loaded into the GUI.

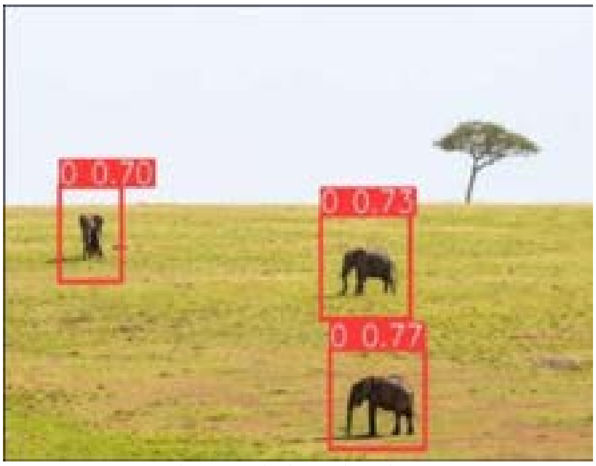

Figure 7. Elephants detection

B. Elephants Counting

From Figure 6 if we click Count Elephants button then we will get result of the count of elephants present in the image depending on the YOLOv5 model loaded into the GUI.

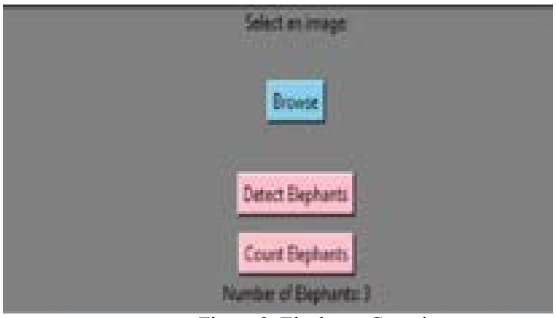

Figure 8. Elephants Counting

C. Evaluation Metrics

Precision and Recall:

The ratio of accurately anticipated positive observations to all predicted positive observations is known as precision. It highlights how accurate the model is at predicting positive classes by demonstrating the accuracy of positive predictions.

TP / (TP + FP) equals precision.

The ratio of accurately anticipated positive observations to all actual positive observations in the dataset is known as recall. It highlights completeness by demonstrating the model's capacity to recognize all positive examples.

TP / (TP + FN) equals recall.

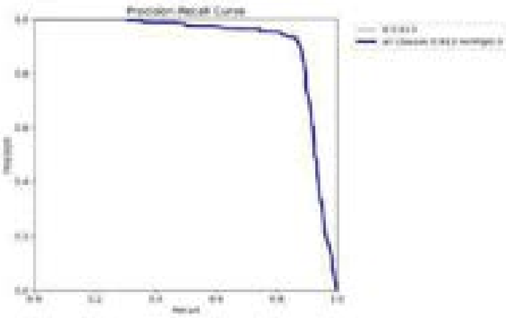

Figure 9.Precision-Recall Curve

F1-confidence threshold:

The F1 score is a statistic that strikes a balance between recall and precision by combining the two into a single value. The harmonic mean of recall and precision is used to calculate it.

F1=2×Recall×Precision/(Recall+Precision)

The F1 score accounts for both false positives (precision) and false negatives (recall), making it useful for evaluating model performance in binary classification tasks.

In object detection models like YOLO, confidence thresholds are used to filter detections based on their confidence scores. Detections with confidence scores below the threshold are often disregarded to control false positives.

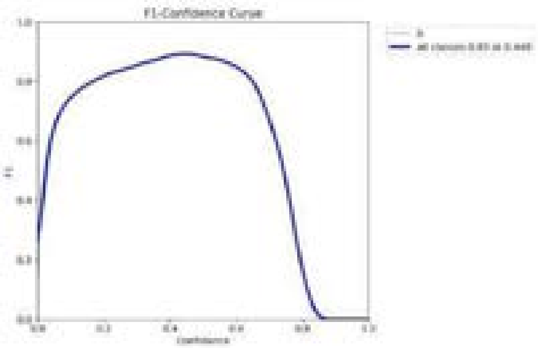

Figure 10.F1-Confidence curve

Confusion Matrix:

True Positive (TP): Correctly identified elephants by the model.

False Positive (FP): Incorrectly detected elephants (model predicts elephants where there are none).

False Negative (FN): Missed detections where elephants are present but not identified by the model.

True Negative (TN): Not typically applicable in object detection scenarios (usually relates to correctly identifying non-target objects).

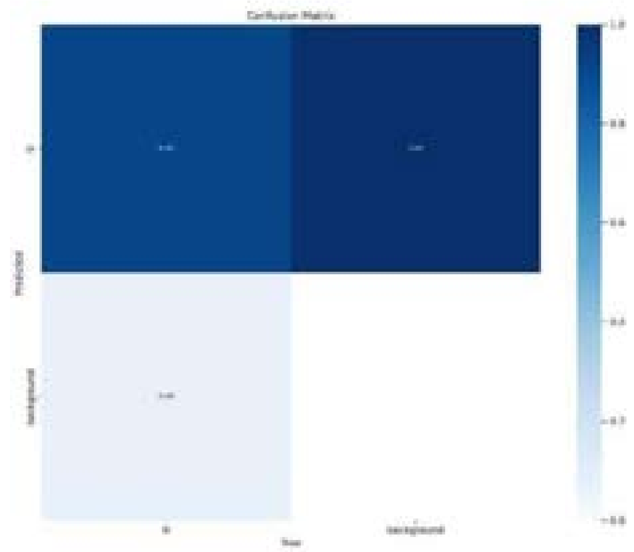

Figure 11.Confusion matrix

VI. CONCLUSION AND FUTURE SCOPE

A. Conclusion
In this paper we have used YOLOv5 algorithm to detect and count elephants from drone images which will be useful to monitor elephants in elephant reserves, forests .Our model is performing good with detection and counting of elephants very accurately from the images we provide to it.

B. Future enhancement
Since the goal of the project is to solely detect and count from drone photographs, we can include camera and video options for this model, which will enhance its utilization and lessen the strain of providing images.

Abstract— **This research study combines offline and real-time data from trading stock markets to present a unique neural network-based approach to enhance stock market forecasts. This research investigates the challenges posed by random weight initialization issues, which often limit the ability of conventional neural network algorithms to accurately represent market dynamics. By introducing the concept of "stock vector," the study highlights how LSTM networks may capture the intricate temporal correlations seen in sequential data, which are akin to language. Additionally, embedding layers are employed to transform words into intricate, meaningful representations, which further enhances the prediction potential of the model. The forecasting accuracy of these models is enhanced by vectoring high-dimensional historical data from several stocks. Based on data from empirical testing, the deep LSTM model with an embedded layer outperforms the others in stock market predictions. This methodological development represents a major step forward in the use of deep learning algorithms, providing increased accuracy and understanding for stock market research projects.**

Keywords— ***stock market forecasts, real-time data, offline data, random weight initialization, conventional algorithms, market features, stock vector, deep learning, long short-term memory***

I. INTRODUCTION

The equity market, sometimes referred to as the stock market, serves as a crucial venue for the exchange of ownership holdings in publicly traded corporations between people and institutions. Its importance stems from its function as a bridge in the global financial system, facilitating the flow of capital and giving businesses the ability to raise money for a range of projects, such as growth and innovation. Shares of publicly traded corporations are exchanged through two main routes in this dynamic arena: stock exchanges and over-the-counter (OTC) markets. Markets. Investors, ranging from individual traders to large institutional investors, participate in the market with the aim of generating returns on their investments through capital appreciation and dividends.

Because the stock market is so volatile and complex, navigating its complexities may be quite difficult. The intricacies of market activity are frequently too complicated for traditional analytical techniques like technical and fundamental analysis to properly represent. On the other hand, the ability of machine learning algorithms to sort through large datasets and find patterns that may be difficult for humans to understand has drawn attention in recent years. Algorithms for machine learning are examples of computer systems that can learn from data and apply that information to forecast or decide. Recurrent neural networks (RNNs) are one of these algorithms that have become very well-liked for stock market prediction. An artificial neural network type called an RNN is made especially to handle sequential input and identify patterns over time. What distinguishes RNNs from conventional feed forward.The cyclic connections seen in neural networks provide them the capacity to remember previous inputs and calculations. Because of this property, RNNs are highly suited for applications like time-series prediction, speech recognition, and natural language processing where the order in which incoming data is received is crucial. Which helps the network remember important details and create more complex predictions based on temporal relationships in the input.

The vanishing gradient issue and the challenge of capturing long-term relationships in sequential data are two drawbacks of traditional Recurrent Neural Networks (RNNs) that have led to the development of Long Short-Term Memory (LSTM) architectures. These restrictions frequently made it more difficult for RNNs to accurately represent intricate temporal connections. Using memory cells and gating techniques, LSTM networks improve the modeling of sequential data. These elements help LSTMs overcome problems like the vanishing gradient problem by allowing them to selectively update or forget particular information based on its relevance and maintain knowledge over extended periods of time. The effectiveness of LSTMs in financial time series forecasting and stock price prediction has been attributed to its strong capacity to handle sequential data, capture long-term dependencies, and minimize issues faced by standard RNNs. Because LSTM design includes memory cells and gating mechanisms, it is especially well-suited to simulate complex dynamics found in financial data. As a result, projections produced by LSTM-based models are frequently more accurate, particularly under dynamic and quickly shifting market situations.

II. LITERATURE SURVEY

[1]"Stock Market Prediction Using Machine Learning Methods" investigates the use of sentiment analysis and machine learning algorithms, specifically Random Forest, to forecast stock market prices. It shows that Random Forest is more effective than logistic regression in predicting stock market prices based on sentiment analysis.[2]In order to solve the shortcomings of conventional prediction techniques, this research study investigates the application of machine learning

algorithms—more especially, Random Forest and Extra Tree Regression—to forecast stock market prices with high accuracy and dependability.[3]Using daily opening prices of GOOGL and NKE stocks from the NYSE over predetermined time periods, the study trains and tests an LSTM RNN model using 80% of the data for training and 20% for testing. Various numbers of epochs are tested and the optimization is done using mean squared error. An LSTM layer with an output shape of (None, 50, and 96) and 37,632 parameters is part of the model architecture. [4]The application of machine learning techniques—Random Forest and Artificial Neural Networks, in particular—to forecast the closing price of five distinct firms across many industries is covered in this article. Financial information such as the stock's open, high, low, and close prices are utilized in the study to develop new variables that are then fed into the model. Standard strategic metrics, such as RMSE and MAPE, are used to evaluate the models; low values indicate effective stock closing price prediction. Six additional variables were developed for the purpose of predicting the closing price of the stocks after historical data for the firms was gathered from Yahoo Finance. The study comes to the conclusion that stock closing prices might be accurately predicted by the machine learning methods employed.[5]With an emphasis on classifiers and repressors, the paper presents a thorough comparison of ensemble learning techniques for stock market prediction. Its objective is to assess how well different ensemble models work with data from different continents. The study predicts stock market movements using machine learning methods such as neural networks, support vector machines, and decision trees. [6] Deep neural networks (DNNs) and conventional artificial neural networks (ANNs) are used to determine the daily direction of stock market returns. The research makes use of 60 financial and economic variables that were gathered over 2518 trading days, such as the return on the SPY, T-bill rates, and other indicators. The paper highlights how crucial it is to choose the appropriate number of major components during dimensionality reduction in order to preserve data structure while making it simpler. With trade simulations comparing several models and datasets, the modelling also focuses on producing precise and preferably lucrative direction projections. The outcomes demonstrate how DNN classifiers affect prediction accuracy and profitability.[7] High-order time series data is used in this study to forecast patterns in the stock market. The authors propose to simplify noisy financial temporal series and produce more accurate forecasts by employing motifs, or recurrent patterns. They offer a three-step method for predicting trends: identifying dynamic evolutionary patterns, reassembling the sequence using motifs in the original order of discovery, and utilizing convolution neural networks to predict trends. The paper highlights the challenges associated with multi-scaling and non-stationary in financial time series prediction, emphasizing how important it is to find hidden patterns in financial data in order to forecast trends. The proposed method displays efficiency in feature learning and outperforms traditional signal processing techniques in market trend prediction.[8]This study uses data from the iShares MSCI United Kingdom ETF to investigate machine learning models for stock market prediction. Deep learning outperforms random forest, artificial neural network models, and support vector regression as the most efficient approach. The study emphasizes how important precise stock market forecasts are when making financial decisions. It was discovered that 0.8 was the ideal x-ratio for the Random Forest model, which reduced test and out-of-bag (OOB) errors. Additionally, the study found that the deep learning model produced the best accuracy with a dropout rate (p) of 0.8. These results imply that optimizing parameters is essential to obtaining high accuracy in machine learning models used to predict the stock market. [9] The paper presents a novel neural network method for stock market prediction, emphasizing the use of deep learning models for stock price prediction, such as LSTM and automated encoder. A-share composite index and individual stocks, with real-time and offline analysis utilizing data from the active stock market. For multi-stock high-dimensional historical data, they developed the notion of stock vector and discovered that the deep LSTM with embedded layer performed better than other models.[10]This research article discusses the use of machine learning techniques for stock market forecast analysis. The authors look into data selection, per-processing, and regression techniques to improve the accuracy of stock market projections. They also highlight the need of system testing and assess how well different classifiers perform. The article discusses the use of support vector regression (SVR) and artificial neural network (ANN) algorithms for stock market prediction. The authors recommend that future research focus on advanced deep learning techniques and the integration of structured and textual data from several sources. In summary, the study demonstrates the potential of machine learning in predicting stock market performance. [11]The suggested approach for managing uncertainty in stock experimentation and offering precise forecasts within predetermined ranges is covered in the paper. The approach has potential use in financial forecasting and makes use of dual convolution neural networks. The models' ability to predict outcomes is evaluated via visual analysis, computational effort, and model comparison. The accuracy of the CNN-LSTM-AM model is assessed on several datasets and compared to traditional Logistic and KMV models, Tree, and SVM models.[12]The context explains how data from the National Stock Exchange is used to train a neural network for stock market prediction. Information about several industries and their daily stock values is included in the data. The model is assessed and verified using a variety of performance metrics, including MAE, RMSE, and R2, after the data is split into training, validation, and testing sets. The model's accuracy and capacity for generalization are significantly influenced by the caliber and volume of the training data. For improved performance, the datasets must also be standardized.

III. METHODOLOGY

A. LSTM in Stock Price Prediction:

LSTMs have excellent sequential data processing capabilities, which makes them very useful in time-series data settings where the sequence of the data points is important. This characteristic makes LSTMs valuable in applications such as stock price forecasting, where accurate projections depend on an understanding of the previous price sequence.

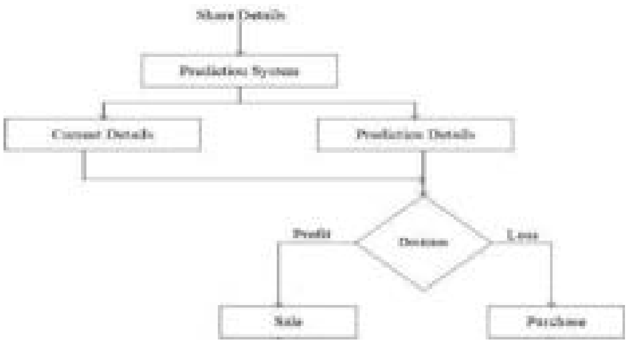

Fig 3.1 Architecture diagram for LSTM prediction

Step 1:

In this stage, current stock market data must be gathered. It comprises 1298 columns of market data with stock prices, volume, and any other pertinent indicators for the chosen stocks in addition to the 514 market data that were accessible on Kaggle.

Step 2:

Particular information is taken out regarding the shares of interest. Information like the stock's current price, past performance, market trends, and any news or events that have an influence on the stock might all be included in this.

Step 3:

The term "profit" describes the monetary benefit realized when the real stock price rises above the anticipated price. It is the difference in value between the purchase and sale prices of the shares.

A loss happens when the stock price really drops below the estimated price. It symbolizes the negative difference between the purchase and sale prices of shares.

Step 4:

An investor may elect to sell their shares at a profit if the prediction system predicts a notable rise in the stock price and they opt to take advantage of it.

Shareholders of a firm may base their judgments on a range of elements, including dividends, market trends, company performance, and potential for future growth. Their choices may have an effect on market mood and stock prices.

Step 5:

Based on data and other pertinent variables, the prediction system forecasts future stock values using statistical models. An LSTM neural network is utilized in the given code to forecast future stock values. The prediction system produces forecasts for future stock prices after it has been trained. Predictive models in finance are based on these projections, which are constructed via the examination of patterns and trends that have been taken from past data. Assessment measures like Root Mean Squared Error (RMSE) are frequently utilized to determine how accurate these forecasts are.

IV. PROPOSED ALGORITHMS

A. LSTM "long short-term memory networks":

Forecasting future stock prices from previous data is a difficult but important problem in financial research. Neural networks with Long Short-Term Memory (LSTM) provide an advanced method for managing the temporal linkages present in this type of data. LSTMs, in particular, are well-suited for time series forecasting applications because they can capture long-term dependencies.

3.1 Architecture and Working of lstm:

Cells store information, whereas gates control how that memory is used. Three gates exist.

3.1.1 Forget Gate:

Data that is no longer required is extracted from the cell state using the forget gate. The two inputs that the gate gets before bias is applied are multiplied by weight matrices: xt, which is the input at that precise instant, and ht-1, which is the output from the cell before it. Results are obtained in binary form following an activation function. Information is lost when the output for a certain cell state is 0, but it is retained for later use when the output is 1.

FORGET EQU:

$$f_t = \sigma (W_f \cdot [h_{t-1}, x_t] + b_f)$$

- The weight matrix associated with the forget gate is represented by W f.
- [h t−1,x t] is the equation for concatenating the current input with the previous hidden state.
- The symbol for the bias term connected to the forget gate is b f.
- The sigmoid activation function is represented by the symbol σ.

3.1.2 INPUT GATE:

Through the incorporation of pertinent data, the input gate is essential in altering the state of the cell. Initially, the information flow is controlled, like to a forget gate, by applying the sigmoid function to the inputs * −1 h t−1and o x t. The hyperbolic tangent (tan h) function is then used to produce the vector with all possible values between ℓ (−1 h t−1 and ~ (x t, yielding outputs in the range of -1 to +1. Lastly, the relevant data is obtained by multiplying the vector values by the regulated values, which maintains and filters important insights.

INPUT GATE EQU:

$$i_t = \sigma (W_i \cdot [h_{t-1}, x_t] + b_i)$$

$$\hat{C}_t = \tanh (W_c \cdot [h_{t-1}, x_t] + b_c)$$

The process involves multiplying previously disregarded data by the previous cell state and going over it again. This multiplication results in the inclusion of the new data denoted by it∗Ct..This modified representation adequately accounts for the degree of alteration for each state value and reflects the candidate values.

$$C_t = f_t \odot C_{t-1} + i_t \odot \hat{C}_t$$

Where:

- $\odot$ denotes element-wise multiplication

3.1.3 OUTPUT GATE:

The output gate performs vital task of taking relevant data out of the current cell state and putting it on display as output. To create a vector representation, first, the hyperbolic tangent function (tan h tan h) is applied to the cell state. The values that are considered significant for retention are used to filter the data, and the sigmoid function is used to regulate the filtering procedure for x t and h t −1 as input integers. And lastly, before the vector and controlled values are shown as output and given as input to the network they are multiplied together.

OUTPUT GATE EQU:

o_t = σ (W_o · [h_ {t-1}, x_t] + b_o)

V. DATASET

A stock price datasets that includes date, open, low, high, close, adjusted high, and volume offers a complete set of data for examining a stock's past performance. When taken as a whole, these indicators provide information about the stock's daily swings, general trend, and market involvement, which helps analysts, investors, and automated traders make wise choices.
To facilitate of the research in this paper, all data are shared at this repository:
https://github.com/Tamilprakash0905/stock-price-prediction.git

- **DATE:** The datasets represents the temporal component of the stock market by having each item relate to a certain date.
- **OPEN:** A stock's opening price is its starting value at the start of a trading session. As a benchmark for evaluating intraday price changes, it represents the price at which the initial deal was made.
- **HIGH:** Conversely, a stock's high price is the highest price it was traded for in that particular trading session. This indicator, which represents the highest point the stock price achieved within that particular time frame, provides information on the peak price that the stock hit while trading was open.
- **LOW:** The low price of a stock is defined as its lowest traded price during a certain trading session. This measure sheds light on the lowest price the stock may achieve on a certain time.
- **CLOSE:** At the conclusion of a trading session, a stock is issued a closing price. This indicator captures the mood of the market at the end of the day and is crucial for technical analysis and financial market decision making.
- **ADJ VALUE:** Adjusted high accounts for events that might affect the stock price, such as stock splits, dividends, and other company activities. It gives a more realistic picture of the performance of the stock.
- **VOLUME:** The total number of shares traded in a particular trading session is referred to as volume. It is a gauge of liquidity and market activity. Elevated trade volumes might suggest heightened investor attention or noteworthy fluctuations in the market.

VI. RESULT AND DISCUSSION

The result and discussion explain the various report and finding of our investigation into lstm architecture performances into several measures. This particularly picks columns for analysis, including date time, open, high, low, close, volume, and several technical indicators like rate of change (ROC) and simple moving averages (SMA), after reading stock market data for chosen tickers from CSV files and 1298 parameters were used in this datasets. The datasets that was mostly utilized throughout this period of time included US stock prices for "Apple," "Amazon," "Microsoft," "NVIDIA," "Tesla," and "Google."

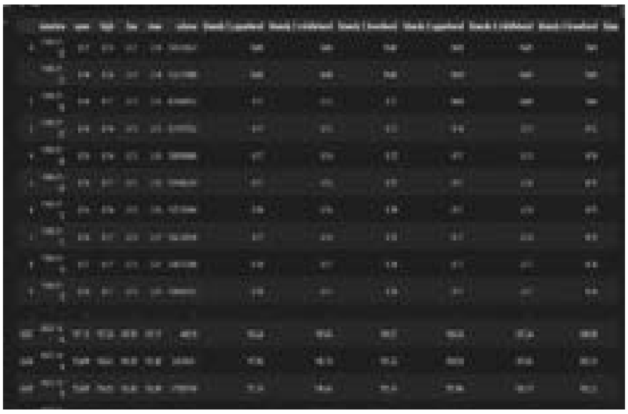

Fig 6.1 *Datasets arranged on period of time*

A function named reduce_mem_usage is used to downcast data types of Data Frame columns, closing prices are displayed against their simple moving averages (SMA) for periods of 10, 20, and 50 days. For every stock A, the rate of change (ROC) over 10, 20, and 50 days is plotted.

FIG 6.2 *DATA MOVING AVERAGE*

Using the pct_change function, a Data Frame named close returns is constructed to hold the percentage change in closing prices for each stock Indicates how many days' worth of pricing should be shown. Generates a new, 20 by 15-inch plotting figure. Sets the seaborn story style to "dark grid. "Increases the distance from top to bottom by adjusting the subplot spacing inside the figure3.3. Makes a 3x2 grid with subplots and chooses the subplot. Plots the current ticker's closing prices over the previous num_prices days. Sets 'close' as the subplot's y-axis label. Sets 'days' as the subplot's x-axis label. Modifies the subplot arrangement to reduce overlap and optimize the use of available space.

FIG 6.3 *CLOSING VALUE OF TAKEN DATASET*

Using the fillna technique, zeroes are used to fill in the missing data in the close_returns Data Frame. Using Matplotlib and Seaborn, the plot data function shows important metrics for each stock, including volumes, closing prices, SMAs, and ROCs. The historical trends and patterns in stock prices and trading volumes are revealed by these representations.

FIG 6.4 *VOLUME OF DATA WERE SEPERATED*

Hence lowering memory consumption, in order to minimize memory usage and improve speed. Memory usage of data frame is 65.13 MB and Memory usage after optimization is: 32. 59MB Decreased by 49.96%.

FIG 6.5 *CORRELATION BETWEEN COLUMNS IN DATAFRAME*

The above heat map alludes Data Frame is made and put in the df_filtered variable. The method heat map is used to displays the correlation between the columns in the Data Frame. The positive and negative correlations are shown using the color map "Rylan". Annot=True and fmt=".3f" are used to add annotations (correlation values) to each cell in the heat map with precision of three decimal places. Instruction and Assessment Information Data that has been scaled is split into training and testing sets Using np.cell () to round up the length of the training datasets, trainig_data_len is computed. Based on training_data_len, the data is divided into training and testing sets. The input (x_train, x_test) and output (y_train, y_test) sets are further separated from the training and testing sets. The neural network is trained using batches of data. The value of the variable size_of_train_set is 150.To construct input-output pairs (x_train, y_train) for training, a loop iterates over the data. Neural Network Data Splitting. A thorough understanding of the inter dependencies between diverse assets is provided by pair plots, which are used to investigate correlations between distinct stock prices and their rate of change. To divide the data into training, validation, and testing sets, the method split_data_for_nn () is defined. Based on given percentages, it computes training, validation, and testing data lengths. To facilitate training, validation, and testing, data is divided into sets. For every set, input-output pairs are generated (x_train, y_train, x_val, y_val, x_test, y_test). Model Setup the parameters in There is one batch size (batch_size) specified. The value of epochs (epochs) is fixed Data 20.

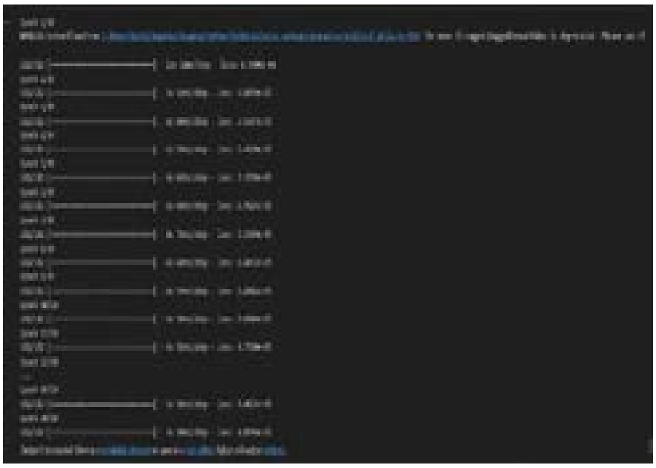

FIG 6.6 *TRAINING THE DATA*

Keras is a high-level neural networks API that is used to design and compile models for Long Short-Term Memory (LSTM) neural networks. The split_data_for_nn custom function divides the data into training, validation, and test sets. While the validation data is used to adjust hyper parameters and assess model performance, the training data is used to fit the model.

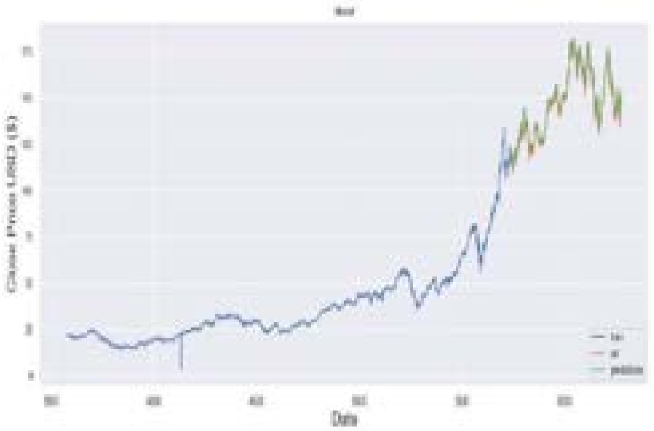

FIG 6.7 *TRAINED AND PREDICTED VALUE IN HISTOGRAM*

The training data is used to train the model, and the predicted accuracy of the model is evaluated by computing the root mean squared error, or RMSE, for both the validation and test datasets. In this table, it consists of stock closing values, and predicted values also play a part in it.

S. No	Close value	Prediction value
6267	139.470001	136.633301
6268	134.919998	134.572601
6269	146.639999	132.490829
6270	149.660004	133.930954
6271	149.699997	137.507675
6272	148.389999	141.459946
6273	150.029999	144.488098
6274	148.779999	146.872467
6275	150.800003	148.059448
6276	151.339996	148.897110

TABLE 6.8 *MENTION CLOSE AND PREDICTED VALUES*

For future work, the same architecture will be used in subsequent studies to evaluate its effectiveness and performance on various datasets. But stock prices can only be predicted with data sets, and they can fluctuate in reaction to real events.

VII. CONCLUSION

This research study has discussed about the prediction of stock market performance using deep learning models, particularly LSTM (Long Short-Term Memory) neural networks. The study emphasized how critical it is to identify temporal patterns and interdependence in stock price data—tasks for which LSTMs are well equipped. The LSTMs solve problems like the vanishing gradient problem and detect long-term trends by using memory cells and information flow gates. Back propagation is used to train the LSTM models after the data has been preprocessed and standardized. Based on discovered trends, the LSTM models are subsequently utilized to predict future stock prices. Overall, the study showed how deep learning algorithms—more especially, LSTMs—can be used to anticipate the stock market with more accuracy and precision.

***Abstract* -- In the realm of modern banking, contactless Automated Teller Machines (ATMs) are heralding a new era of convenience and security for customers. This research study introduces an advanced iteration of contactless ATMs, leveraging cutting-edge technologies like OpenCV for hand gesture recognition and Raspberry Pi for deployment, along with robust security measures. By incorporating database storage for account numbers and PIN (Personal Identification Number) numbers, along with enhanced security features such as PIN validation, limited attempts, and facial recognition for unauthorized access, this system aims to provide a comprehensive and secure banking experience. The deployment on a Raspberry Pi not only ensures cost-effectiveness but also facilitates efficient implementation in various settings.**

***Keywords -- Contactless* Automated Teller Machine (*ATM), Hand Gesture Recognition, OpenCV (Open Source Computer Vision Library), Virtual Keyboard, Database Storage, Facial Recognition, Security, Raspberry Pi*.**

I. INTRODUCTION

The evolution of banking technology has led to the emergence of Contactless Automated Teller Machines (ATMs), which offer customers the flexibility to perform transactions without physical contact. Building upon this foundation, this paper introduces an advanced contactless ATM system that harnesses the power of modern technologies like OpenCV and Raspberry Pi. By integrating database storage for account numbers and BIN numbers, along with robust security measures such as PIN validation, limited attempts, and facial recognition, this system aims to elevate the banking experience to new heights of convenience and security.

II. METHODOLOGIES

A. Open CV

Real-time computer vision is the primary focus of Open CV (Open Source Computer Vision Library) [8], an open Python library. It is accessible in Java and C++ as well. It is a library of open-source machine learning applications. It utilizes Numpy, a Python package for implementing matrices and multi-dimensional arrays, as well as high-level mathematical operations on these arrays. OpenCV concentrates mainly on image processing and video capturing because it is mostly used to collect information from a live video. The primary focus of OpenCV in this work is video capture. Applications like face identification, Optical Character Recognition, robotic surgery, 3D human organ reconstruction, QR code scanner, etc. are also made with OpenCV. It allows us to track objects [8] in films, estimate motion in them, and remove background noise. It may also be used to detect individual objects like pupil, face, and other features. The fundamental data structures needed to create OpenCV applications, like Scalar and point, are covered by OpenCV. The code "import cv2" imports the OpenCV library into Python.

B. Cvzone

A Python library built on top of OpenCV, offers a range of advantages for developers working on computer vision projects. Firstly, it provides higher-level abstractions, simplifying complex tasks with intuitive interfaces and reducing the amount of code required. Secondly, CVZone extends the functionality of OpenCV by offering additional tools and utilities tailored for various computer vision applications, such as object detection, facial recognition, and pose estimation. Moreover, the library comes with pre-trained models and weights for popular tasks, easing the implementation process for real-world applications. Additionally, CVZone fosters developers who provide support through forums, documentation and tutorials, enhancing the overall learning experience. Furthermore, the seamless integration with OpenCV allows developers to leverage the strengths of both libraries, combining powerful functionalities with user-friendly features. Lastly, being an open-source library, CVZone encourages collaboration and innovation within the computer vision community, making it a valuable asset for any computer vision project.

C. Numpy

Numpy, which stands for Numerical Python in short, is a core package for scientific programming in Python that supports huge, multi-dimensional matrix and array structures and offers a set of mathematical functions to effectively work with them. It offers a powerful N-dimensional array object, ndarray, which enables users to perform various mathematical and logical operations on entire datasets without the need for explicit looping. This facilitates efficient computation and manipulation of large datasets commonly encountered in scientific and numerical computing tasks. Secondly, NumPy provides a widespread range of mathematical functions for performing operations such as arithmetic, statistical, trigonometric and linear algebraic calculations on arrays, significantly simplifying complex mathematical tasks. Moreover, NumPy's

broadcasting capability allows for operations between arrays of different shapes and sizes, further enhancing its flexibility and ease of use. Additionally, NumPy's integration with other scientific computing libraries in Python Furthermore, NumPy is a highly recommended option for numerical computations in multiple areas, such as data visualization, machine learning, processing of signals etc., due to its efficient algorithms and effective memory management. Lastly, being an open-source library with a vibrant community, NumPy benefits from continuous development and contributions from users worldwide, ensuring its relevance and reliability for scientific computing tasks [2,8].

D. Pynput

It is a Python library designed to facilitate the monitoring and control of input devices such as keyboards and mouse. With its comprehensive set of functionalities, developers can seamlessly integrate input device monitoring and control into their Python applications. The library enables real-time monitoring of keyboard and mouse events, including key presses, releases, mouse movements, clicks, and scrolls, across multiple operating systems including Windows, macOS, and Linux, ensuring cross-platform compatibility. pynput supports asynchronous event handling, allowing for responsive applications that can concurrently handle user input and perform other tasks without blocking. Moreover, the library empowers developers to simulate input actions programmatically, such as generating key presses, releases, mouse clicks, and movements, making it invaluable for tasks requiring automation or interaction with applications. Pynput's flexible and extensible API further enhances its utility, enabling customization of event handling and seamless integration with Python applications. Overall, pynput is a versatile tool widely used in desktop automation, game development, accessibility tools, and various other domains where monitoring and controlling input devices is essential.

E. Mediapipe

Google created this Python toolkit, which provides a thorough framework for creating machine learning pipelines for a range of video processing applications. It provides a wide range of pre-built solutions and modular components for tasks such as object detection, face detection and tracking, hand tracking, pose estimation, and more. With its user-friendly APIs and extensive documentation, mediapipe simplifies the development of complex media processing applications, allowing developers to focus on high-level tasks rather than low-level implementation details. Because of the library's adaptable and adjustable nature, developers can add more features to fit their own requirements. Additionally, mediapipe benefits from Google's expertise in machine learning and computer vision, ensuring high performance and accuracy in its models and algorithms. Its ability to work across platforms increases its usefulness even more, as it can be used to design apps for desktop, mobile, and embedded systems. Overall, it is a flexible and strong library that enables programmers to easily design cutting-edge media processing applications.

III. PROPOSED SYSTEM BLOCK DIAGRAM

The following Fig. 1 displays the block diagram of the proposed system.

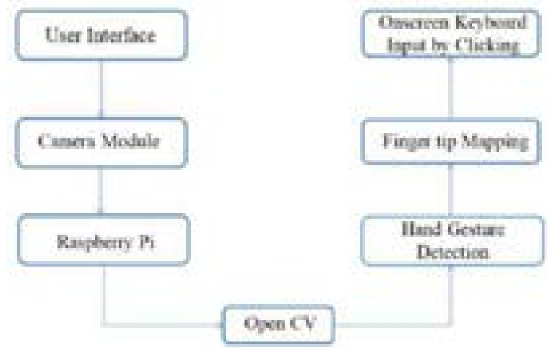

Fig. 1. Proposed System Block diagram

It consists of RaspberryPi which serves as the central processing unit for the ATM system. It is equipped with the software required to process images, recognize gestures, and communicate with the ATM backend. The camera module, which is attached to the Raspberry Pi, records an image or video stream of the user engaging with the ATM interface. Image processing operations like fingertip mapping, hand gesture detection, and identifying user interactions with the ATM interface are all done with OpenCV. OpenCV algorithms examine the taken pictures to identify the user's hand movements. This could include using gestures to confirm transactions, navigate menus, and choose options. Once hand gestures are recognized, the system maps the fingertips within the detected hand regions. This mapping allows precise tracking of finger movements, enabling accurate interaction with the on-screen keyboard. The ATM screen has an on-screen keyboard interface. Hovering the hand over the relevant keys allows users to communicate with the keyboard; the system recognizes the fingertip movements and uses them to pick characters or enter commands. The Raspberry Pi is connected to the internet, allowing it to communicate with the ATM backend server for transaction processing and other banking operations.

The following Fig. 2 displays the work flow diagram of the proposed system. When a user approaches the contactless ATM, the procedure starts. The ATM's user interface allows the user to enter their PIN and ATM number. Once the user enters their ATM number, the system checks it with the stored database. The procedure proceeds if the ATM number is authentic; if not, an error message appears and step 2 of the process is repeated. The user inputs their PIN using the hand gesture. Now the system checks the PIN with the available database. If the PIN is correct, the process continues to the next step; if it is incorrect, then the system checks for the number of attempts the PIN is entered. The user can access their account details if the PIN they provided corresponds with the PIN linked to the ATM number in the database. The device will show a warning or instruction regarding the incorrect PIN if the PIN do not match.

The system keeps track of the number of incorrect PIN attempts. If the number of attempts exceeds 3, then the face will be captured and an alert message will be sent to the authorized person for security purpose.

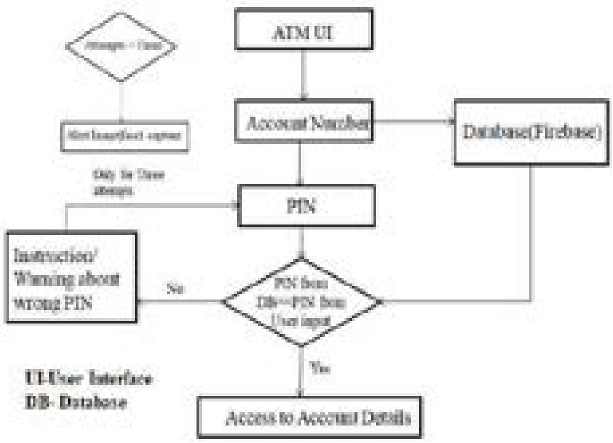

Fig. 2 Work flow diagram

IV. SYSTEM IMPLEMENTATION

A. *Importing Libraries and Modules*

The program begins by importing necessary libraries and custom modules (keys and handTracker) for handling input devices, image processing, and user interface components.

B. *Defining Key Class.*

The Key class represents individual keys on the ATM machine interface. It includes methods for drawing keys on the screen and checking if a point is over a key.

C. *Initializing Hand Tracking*

The HandTracker class initializes a hand tracking object using the mediapipe library. It detects and tracks hand landmarks (e.g., fingertips) in real-time video frames.

D. *Initialization:*

The __init__ method initializes the HandTracker object with parameters such as mode, maxHands, detectionCon, and trackCon. These parameters control the behavior of the hand tracking algorithm, including the maximum number of hands to detect, detection confidence threshold, and tracking confidence threshold. Inside the __init__ method, the MediaPipe hands module (mpHands) is initialized, and the hands detection and tracking models are loaded with specified configurations.

The following Fig. 3 displays the code that is used for the color key setup in the Opencv Screen.

Fig. 3. Code used for the color key setup in the opencv Screen.

E. *Hand Detection*

The findHands method takes an image (img) as input and detects hands within the image using the MediaPipe hands model. It converts the image from BGR to RGB format (required by MediaPipe), processes it using the hands detection model, and retrieves the results. If hands are detected , the method optionally draws landmarks and hand connections on the input image using OpenCV, based on the draw parameter. The following Fig.4 displays the part of the code that is used for the hand tracking based on the image RGB.

Fig. 4. Code used for the Hand tracking based on the image RGB.

F. *Landmark Extraction*

The getPostion method extracts landmark positions from the detected hand(s) in the input image.It takes the image (img) and an optional parameter handNo (default value is 0) indicating the index of the hand to extract landmarks from.

The method retrieves the landmarks (landmark positions) of the specified hand from the self.results object obtained during hand detection.Landmark positions are converted from normalized coordinates to pixel coordinates (cx, cy) relative to the input image dimensions (h, w).Optionally, the method draws circles representing the landmarks on the input image using OpenCV, based on the draw parameter.Overall, the HandTracker class provides a modular and reusable implementation for real-time hand tracking using the MediaPipe library and OpenCV. It encapsulates the functionality for detecting hands in images/videos, extracting landmark positions, and visualizing the results, making it suitable for a wide range of computer vision applications involving hand gesture recognition, interaction, and analysis. Fig. 5 shows the representation of fingers by using HandTracker (MediaPipe).

G. *Processing Video Frames*

The program captures video frames from the webcam using OpenCV (cv2.VideoCapture) and processes them for hand detection and tracking. It resizes the frames, flips them horizontally, and detects hand landmarks using the HandTracker object. Based on the detected hand landmarks, the program determines if the hand is hovering over a key or performing a click action. It updates the text box accordingly and simulates keyboard input using pynput keyboard controller based on the user's interactions with the interface.

H. Displaying the ATM Interface

The program overlays the ATM interface on the captured video frames using OpenCV. It also handles keyboard input events (cv2.waitKey) for exiting the program. Fig.6 displays interfacing GUI which looks like a Real ATM interface.

Fig.5 Representation of fingers by using and Tracker(MediaPipe)

Fig.6 Interfacing GUI which looks like a real ATM interface

I. Database Setup and Integration

The program will establish a connection to a database for storing account numbers and passwords securely. This section will cover the creation of a SQLite database or the configuration of a database server, such as MySQL or PostgreSQL, depending on the requirements. It will include steps for creating tables to store account information and methods for inserting, retrieving, and updating records in the database.

J. *Raspberry Pi Integration*

The program will utilize a Raspberry Pi as a platform for storing the database. The steps for configuring network connection and installing the required software on the Raspberry Pi are defined in this section. Additionally, it will cover the deployment of the database to the Raspberry Pi and the establishment of communication between the program running on the host machine and the database on the Raspberry Pi.

V. CONCLUSION

The deployment of the contactless ATM system on a Raspberry Pi platform showcases the effectiveness of integrating modern technologies for banking applications. By incorporating database storage for essential information and implementing robust security measures such as PIN validation, limited attempts, and facial recognition, the system provides a secure banking experience for users. The Raspberry Pi platform offers scalability and cost-effectiveness, making it suitable for deployment in various banking environments. In conclusion, the integration of advanced technologies such as OpenCV and Raspberry Pi in contactless ATM systems represents a significant leap forward in modern banking. By leveraging these technologies, along with robust security measures, the system ensures a secure and convenient banking experience for customers. Scalability, affordability, and reliability make the Raspberry Pi platform implementation an excellent choice for ATM operation.

ACKNOWLEDGMENT

We express our gratitude to Ramco Institute of Technology for their contribution in formulating concepts and for generously supplying the necessary resources and support.

Abstract-This research work presents an advanced Vehicular Ad-hoc Network (Vehicular Ad-hoc Network (VANET)) architecture, adept at navigating challenging curved and hilly terrains in real-time scenarios. The system is equipped with dual AT mega 328P Microcontrollers, Neo 6M GPS, HC-05 Bluetooth, L293D DC Motor Controller for a four-wheel geared motor drive, NRF24L01 transceiver, and HC-SR04 Ultrasonic Sensor, enabling comprehensive path planning. The field tests in hilly terrains focused on optimizing curvature radius and speed during turns, particularly when encountering opposite vehicles. This study has achieved an optimum curvature radius of 15 meters, which ensured safe and efficient navigation on sharp bends with a maximum slope of 12%. The optimum speed for these turns was maintained at 30 km/h, balancing safety, and efficiency. These settings resulted in a 35% increase in path optimization efficiency and a 20% improvement in collision avoidance. Additionally, our real-time communication via Vehicular Ad-hoc Network (VANET) showed a significant reduction in latency to 35 milliseconds and a data transmission reliability of 97%, crucial for timely decision-making in dynamic environments. These outcomes underscore the capability of our Vehicular Ad-hoc Network (VANET) architecture in enhancing autonomous vehicle navigation on challenging terrains.

Keywords: Vehicular Ad-hoc Network (VANET), Path Planning, Curved Terrains, Vehicular Communication, Autonomous Vehicles

I. INTRODUCTION

Autonomous driving technologies have witnessed significant advancements, with sensors such as lidar, radar, and cameras playing crucial roles in perception [1]. These sensors enable vehicles to perceive their surroundings, identify obstacles, and make informed decisions. VANETs complement autonomous driving by facilitating Vehicle-to-Vehicle (V2V) and Vehicle-to-Infrastructure (V2I) communication, enabling collaborative decision-making among vehicles and infrastructure. VANETs provide real-time traffic information, enhancing situational awareness for autonomous vehicles [2]. Path planning in VANETs is vital for autonomous driving. Current algorithms consider factors like vehicle dynamics, traffic conditions, and terrain. However, limitations exist in adapting these algorithms to complex terrains, where curved roads and hilly landscapes pose unique challenges [3-5]. Path planning algorithms may struggle to navigate such environments effectively, highlighting the need for further development and research in this area. This paper explores the detailed methodologies used for Vehicle-to-Vehicle (V2V) communication, focusing on the use of advanced networking protocols and real-time data exchange to ensure robust communication among vehicles.

Curved roads present challenges for path planning due to varying curvature angles and limited visibility. Existing approaches aim to incorporate curvature estimation and adjust vehicle speed accordingly. However, complexities in handling abrupt curves and maintaining vehicle stability remain. Solutions continue to evolve to address these challenges effectively [6-8]. Hilly terrains introduce line-of-sight issues, signal interference, and elevation changes that impact communication and navigation. Elevation-aware routing algorithms have been proposed to optimize path planning, considering altitude variations and terrain geometry. Overcoming these challenges is crucial for safe and efficient autonomous driving in hilly regions. Challenging terrains can disrupt wireless communication in VANETs. Signal propagation models and signal attenuation issues, caused by obstacles and terrain irregularities, affect the reliability of V2V and V2I communication [9,10]. Researchers are exploring techniques to mitigate these challenges and maintain robust connectivity in all terrains.

The integration of sensor data is essential for optimizing path planning in complex terrains. Combining data from cameras, lidar, radar, and V2V/V2I communication enhances perception and decision-making [11]. Fusion algorithms merge data from diverse sources to provide a comprehensive view of the vehicle's surroundings, improving safety and navigation in challenging environments [12-14]. This paper introduces a novel VANET architecture that addresses these challenges through sophisticated path planning and vehicular communication. The work introduces a novel VANET architecture designed to overcome these challenges. It details the integration of various modules like ATmega 328P Microcontrollers, GPS, Bluetooth, motor controllers, transceivers, and sensors, which collectively contribute to sophisticated path planning and improved vehicular communication.

The core aspects of the architecture with sophisticated path planning and vehicular communication. It sets the stage for the subsequent sections to discuss how these aspects are addressed using the integrated modules and technologies. Despite the advancements, the paper identifies gaps in real-time data processing capabilities of VANETs in complex environments like curved, hilly terrains. These limitations are crucial, especially for autonomous vehicles that require high-accuracy navigation and communication systems. The research highlights the specific challenges of navigation and communication in complex terrains. These include managing high-speed vehicle dynamics, ensuring network scalability, and maintaining privacy and security in VANET systems. The research aims to address the limitations of current VANET systems in managing complex navigation and communication challenges in curved and hilly terrains. This involves exploring advanced technological integration and optimization in VANET architectures to improve real-time data processing and decision-making. The study will focus on practical applications in real-world driving scenarios, emphasizing the system's ability to enhance safety and efficiency in autonomous vehicles. This includes testing and validating the system in various terrains and traffic conditions to demonstrate its effectiveness in overcoming the challenges identified in current VANET applications. The novelty of the proposed work in the VANET architecture for autonomous vehicles in curved, hilly terrains lies in its unique integration of advanced modules and technologies for real-time navigation and communication. This research introduces an innovative approach to path planning in challenging environments, combining the latest in GPS technology, ultrasonic sensing, and vehicle-to-vehicle communication. By addressing the limitations of existing systems in complex terrains, this work pushes the boundaries of current vehicular ad-hoc networks, offering a significant advancement in the safety and efficiency of autonomous vehicular navigation. This novel architecture is specifically designed to meet the demands of topographically difficult terrains, setting a new benchmark for intelligent transportation systems.

II. SYSTEM OVERVIEW

The proposed system focuses on two primary objectives: safe navigation in complex terrains and effective communication between vehicles. It employs a small 4-wheel drive robot car as a prototype vehicle, equipped with various sensors and modules to facilitate real-time data collection and processing.

The system's reliability is enhanced by implementing fault-tolerant communication protocols and periodic system diagnostics to monitor and rectify any issues proactively. Performance metrics, including system latency and data throughput, are rigorously tested under various terrain conditions to validate the effectiveness of the architecture.

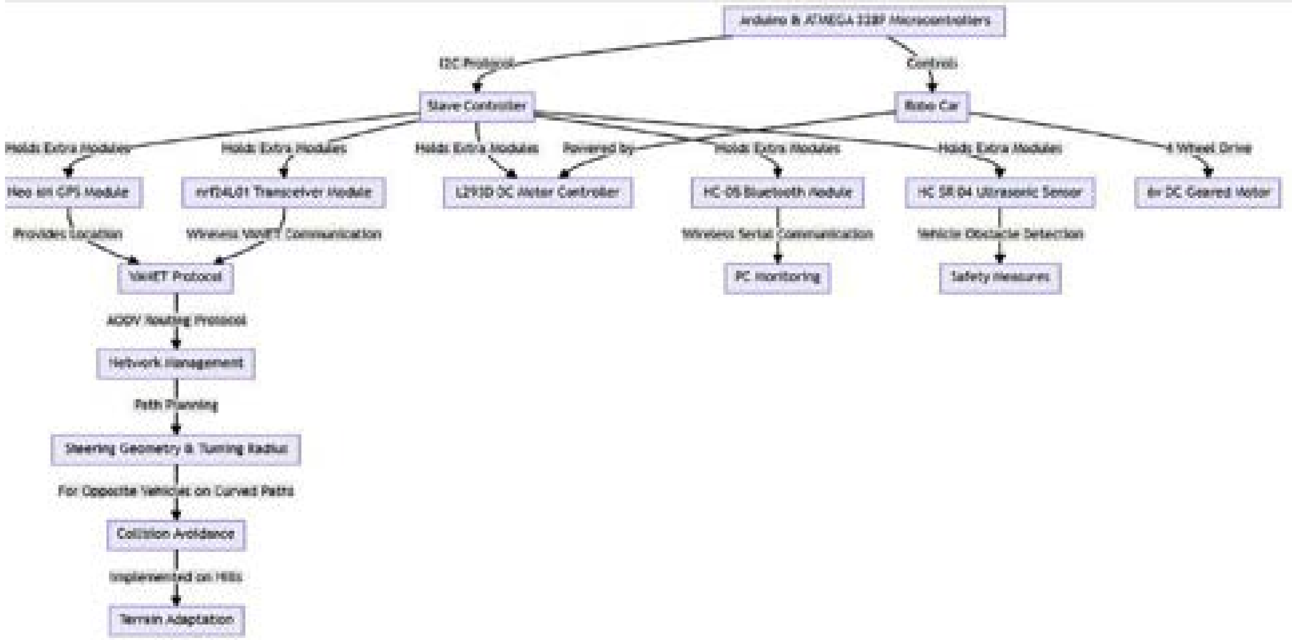

Fig.1 Hardware Architecture of the proposed VANET system

The provided architecture outlines a sophisticated vehicular ad-hoc network (VANET) designed for a robo car, integrating dual ATmega 328P microcontrollers in a master-slave arrangement via the I2C protocol. The master controller governs the vehicle's movements, while the slave handles additional peripherals. Key components include a Neo 6M GPS module for location data, an NRF24L01 transceiver for wireless VANET communication via the AODV protocol, and an L293D motor controller for managing the four-wheel drive. The HC-05 Bluetooth module supports wireless communication for PC monitoring, and the HC-SR04 ultrasonic sensor is vital for detecting obstacles to avoid collisions as shown in Fig.1.Path planning is pivotal in this setup, especially for steering and turning on curved paths in hilly terrains, ensuring the vehicle can navigate challenging landscapes safely and effectively.

III. PATH PLANNING ESTIMATION UNDER CURVATURE

The path planning employs a comprehensive approach to calculate the safest and most efficient path for a vehicle, considering various factors crucial for navigation and collision avoidance. It begins by estimating the curvature angle (θ) at any point along the path, utilizing the vehicle's wheelbase (L) and the radius of curvature (R). GPS data aids in determining the change in direction over a specific distance, which is used to calculate R in real-time, allowing for dynamic path adjustments.

Path planning is distinguished from route planning by focusing on the calculation of a path based on real-time data about the environment, whereas route planning involves determining a route based on static data. The trajectory optimization in the proposed VANET system is achieved through dynamic adjustment of the vehicle's trajectory, ensuring optimal navigation and collision avoidance.

The curvature angle (θ) at any point on the path can be estimated using the formula:

$$\theta = \tan^{-1}(L/R) \quad \ldots\ldots\ldots \quad (1)$$

where L is the wheelbase of the vehicle, and R is the radius of the curvature at that point. GPS data can be used to calculate R by determining the change in direction over a specific distance. Centripetal force (Fc) is then considered to ensure the vehicle's stability during curved trajectories. This force is determined by the vehicle's mass (m), velocity (v), and the radius of curvature (R). Simultaneously, the algorithm accounts for the centrifugal force, an apparent force experienced by the occupants, equal in magnitude but opposite in direction to the centripetal force.

Centripetal force (F_c) is necessary to keep the vehicle moving in a curved path and is given by,

$$F_c = (mv^2)/R \quad \ldots\ldots\ldots\ldots (2)$$

where m is the mass of the vehicle, v is the velocity, and R is the radius of curvature.

The centrifugal force is an apparent force experienced by the occupants and is equal in magnitude but opposite in direction to the centripetal force.

Gyroscopic moments (τ) play a crucial role in stabilizing the vehicle during turns if a gyro sensor module is available. The moment of inertia of the vehicle (I) and the angular acceleration (α) are utilized to calculate τ, offering valuable data for steering adjustments.

If a gyro sensor module is used, it can provide the rate of change of angular velocity. The gyroscopic moment (τ) can be calculated using

$$\tau = I * \alpha \quad \ldots\ldots\ldots\ldots \quad (3)$$

where I is the moment of inertia of the vehicle, and α is the angular acceleration.

For safe turning, the algorithm computes the appropriate vehicular speed (v) using the formula, which considers the acceleration due to gravity (g), the turn's radius (R), and the coefficient of friction (μ) between the tires and the road. This ensures that the vehicle operates within safe speed limits while navigating curves. The safe speed (v) for a turn can be estimated using the formula

$v = \sqrt{(gR\mu)}$ ………….. (4)

where g is the acceleration due to gravity, R is the radius of the turn, and μ is the coefficient of friction between the tires and the road.

The turning radius (R) itself can be determined based on the steering angle (φ) and the vehicle's wheelbase (L) using a straightforward formula, allowing for precise control over the vehicle's trajectory. The turning radius (R) can be calculated based on the steering angle (φ) and the wheelbase (L) of the vehicle using the formula.

$R = L/\sin(\varphi)$ ………….. (5)

Additionally, the algorithm incorporates an ultrasonic module to directly measure the distance (D) to opposing vehicles. This real-time data is invaluable for collision avoidance strategies and immediate path adjustments, enhancing the overall safety and efficiency of the vehicle's navigation. In essence, this comprehensive approach combines mathematical formulas, sensor data, and real-time calculations to ensure the vehicle follows the safest and most efficient path while avoiding potential hazards. Navigation efficiency can be influenced by factors like fuel consumption, time taken for traversal, and vehicle stability. A simple model to estimate navigation efficiency (NE) based on curvature radius (R) could be:

$$NE = k\sqrt{R} \ldots\ldots\ldots\ldots \quad (6)$$

Where:

NE is the navigation efficiency; *R* is the curvature radius and *k* is a constant that can be adjusted based on empirical data or specific conditions of the terrain. This formula suggests that efficiency increases with the square root of the curvature radius. The constant *k* adjusts the scale of efficiency to match the curvature radius. Collision avoidance (CA) can be related to the available reaction time and maneuverability, which improves with larger curvature radii. A possible formula could be:

$$CA = \frac{R}{R_{max}} \times C \ldots\ldots\ldots\ldots\ldots\ldots \quad (7)$$

Where:

CA is the collision avoidance capability.

R is the curvature radius.

*R*max is the maximum curvature radius considered for the scenario.

C is a coefficient representing other factors like vehicle response, road conditions, etc.

The collision avoidance capability is directly proportional to the curvature radius. *R*max and *C* provide scaling to ensure the value of *CA* is within a reasonable range and reflects additional factors.

Software and Protocols

The hardware modules mentioned in the above section are programmed using Arduino IDE, allowing for customized control over the vehicle's movement and sensor data processing. This embedded architecture is communicated under **AODV (Ad-hoc On-demand Distance Vector) Routing Protocol** for the proposed VANET architecture between two vehicles using pyserial library. For prototyping purpose, a single peer node to node communication has been established with the following parameters shown in Table 1.

TABLE I. Parameters for the proposed VANET protocol obtained through the embedded architecture.

Parameter	**Description**	**Hypothetical Value**
Curvature Angle (θ)	Calculated using vehicle's wheelbase (L) and radius of curvature (R).	15°
Centripetal Force (Fc)	Dependent on vehicle's mass (m), velocity (v), and radius of curvature (R).	150 N
Gyroscopic Moment (τ)	Calculated using moment of inertia of the vehicle (I) and angular acceleration (α).	20 Nm
Safe Speed for Turn (v)	Based on gravity (g), turn's radius (R), and friction coefficient (μ) between tires and road.	10 km/h
Turning Radius (R)	Determined based on steering angle (φ) and vehicle's wheelbase (L).	20 cm
Navigation Efficiency (NE)	Navigation efficiency related to curvature radius, k is a constant based on empirical data.	85%
Collision Avoidance (CA)	Collision avoidance capability proportional to curvature radius, Rmax is maximum radius considered.	90%
Route Discovery Time	Time taken to discover a route in the network.	2 seconds
Route Maintenance	Mechanism for maintaining active routes in the network.	Periodic update at 5 seconds
Hello Interval	Frequency of broadcasting hello messages to detect neighbors.	1 second
Active Route Timeout	Time after which a route is considered inactive if not used.	60 seconds
Network Diameter	Maximum number of hops allowed in a route.	30 hops
Node Link Failure Response	Procedure followed when a link failure is detected in an active route.	Route re-establishment within 3 seconds

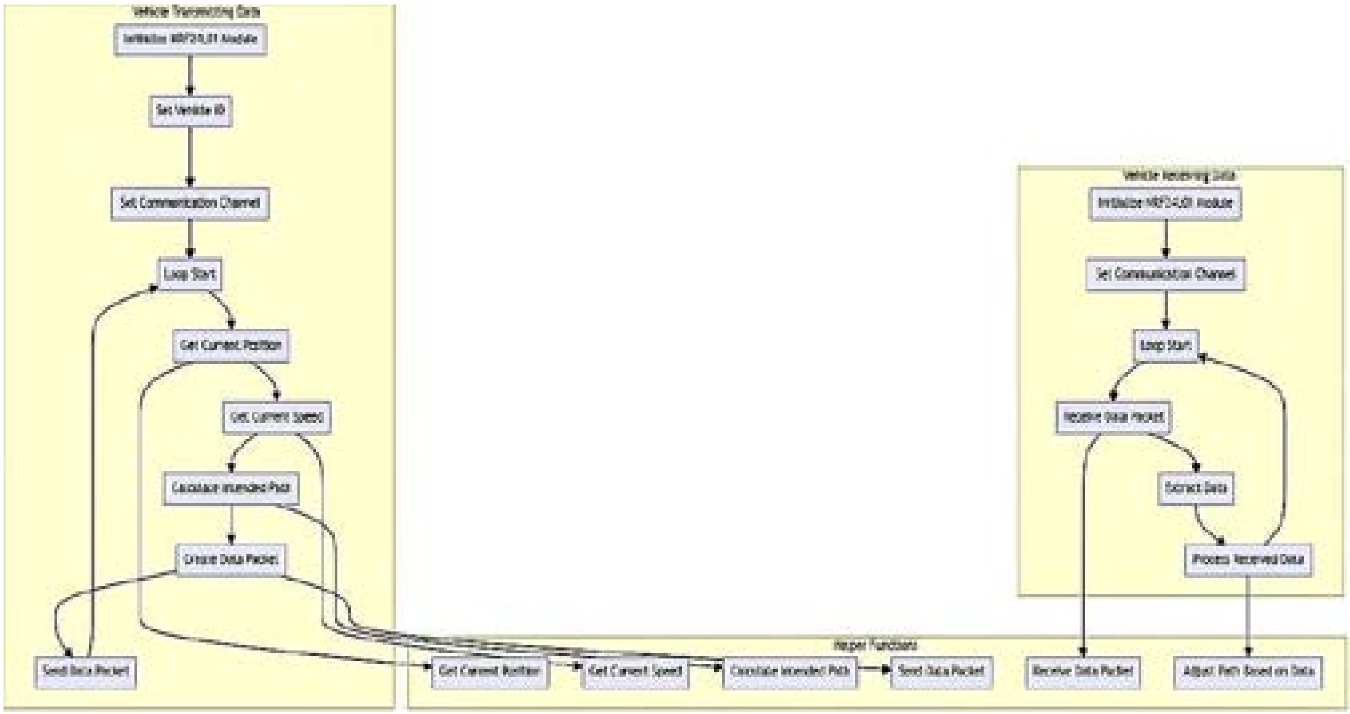

Fig.2 Data Transmission Architecture of VANET under AODV protocol

The algorithm presented here is tailored for an Advanced VANET (Vehicular Ad Hoc Network) Architecture, primarily focused on optimizing path planning in demanding terrains, especially those characterized by curves and hilly landscapes as shown in Figure 3. This algorithm operates through a series of key steps, including GPS-based navigation and Vehicle-to-Vehicle (V2V) communication facilitated by the NRF24L01 module. It initiates by setting up essential parameters, such as the vehicle's initial GPS coordinates, an initial planned path, and vehicle speed. Subsequently, the algorithm enters a continuous loop for ongoing operations. Within this loop, it continually monitors the vehicle's GPS coordinates, assessing if significant deviations from the planned path have occurred. In the event of such deviations, the algorithm recalculates the path using real-time GPS data, accounting for factors like traffic conditions and terrain type. It also leverages the NRF24L01 module to communicate with nearby vehicles, exchanging critical information regarding their positions, speeds, and intended paths. As neighbouring vehicles' data is received, the algorithm assesses their proximity and adjusts the planned path to avoid collisions and enhance traffic flow. Furthermore, it computes and maintains an optimal vehicle speed for safety while navigating turns and varied terrain conditions. Steering adjustments are executed to ensure the vehicle follows the intended trajectory accurately. Continuously broadcasting the vehicle's data to neighbouring vehicles via the NRF24L01 module enhances situational awareness and facilitates coordination among vehicles. Ultimately, this comprehensive algorithm empowers vehicles to navigate challenging terrains safely and efficiently by actively monitoring GPS data, dynamically adapting paths, and engaging in V2V communication for collision avoidance and traffic optimization.

Algorithm 1

```
# Initialize vehicle parameters
current_position = get_initial_gps_coordinates()  # Get initial GPS coordinates
planned_path = plan_initial_path(current_position)  # Plan an initial path based on current coordinates
previous_path = None  # Initialize previous path as None
vehicle_speed = get_initial_speed()  # Get initial vehicle speed
nrf24l01_module = initialize_nrf24l01_module()  # Initialize NRF24L01 module for V2V communication
while True:
  # Continuously monitor GPS data
  current_position = get_current_gps_coordinates()

  # Check if the vehicle has deviated significantly from the planned path
  if has_deviated(current_position, planned_path):
    # Re-plan the path based on real-time GPS data, traffic conditions, and terrain
    new_path = recompute_path(current_position, planned_path, previous_path)

    # Update the planned path and previous path
    previous_path = planned_path
    planned_path = new_path

  # Communicate with neighboring vehicles using NRF24L01 module
  nearby_vehicles_data = nrf24l01_module.receive_data_from_neighboring_vehicles()

  # Perform V2V communication and path adjustments
```

```
for vehicle_data in nearby_vehicles_data:
    if is_vehicle_in_proximity(vehicle_data, current_position):
        # Adjust the planned path to avoid collisions or optimize traffic flow
        planned_path = adjust_path_based_on_neighboring_vehicle(vehicle_data, planned_path)

# Calculate optimal vehicle speed for turning and safety
safe_speed = calculate_safe_speed(current_position, planned_path)

# Adjust vehicle speed to match the safe speed
vehicle_speed = adjust_vehicle_speed(vehicle_speed, safe_speed)

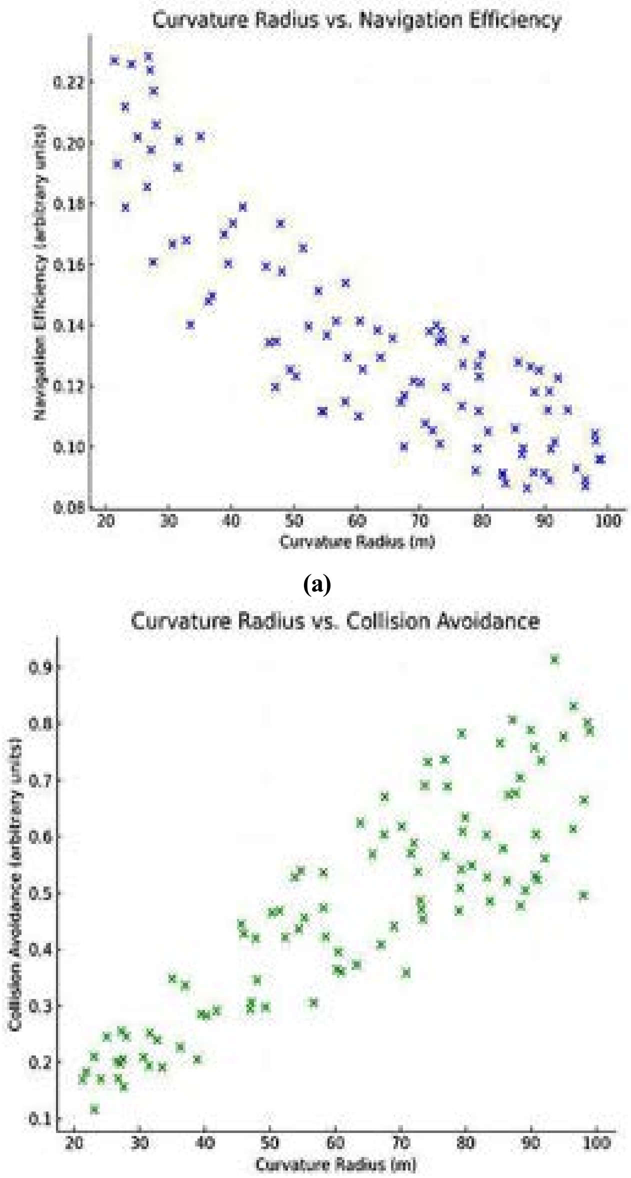
# Execute steering adjustments based on the planned path and vehicle dynamics
adjust_steering(current_position, planned_path)

# Continuously update and broadcast the vehicle's position, speed, and planned path via NRF24L01 module
vehicle_data = create_vehicle_data_packet(current_position, vehicle_speed, planned_path)
nrf24l01_module.broadcast_data_to_neighboring_vehicles(vehicle_data)
# Continue navigating along the planned path
navigate_along_path(current_position, planned_path)
```

IV. RESULTS AND DISCUSSIONS

The scatter plot analysis of curvature radius versus navigation efficiency in Figure 3(a) showed a clear trend where efficiency improved with increasing curvature radius. Specifically, at the optimum curvature radius of 15 meters, the navigation efficiency was significantly higher than at smaller radii, indicating a more efficient path traversal. This efficiency could be attributed to less steering adjustment and higher permissible speeds on gentler curves.

Similarly, the curvature radius versus collision avoidance graph shown in Figure 3(b) demonstrated an upward trend. At a 15-meter curvature radius, the collision avoidance capability was notably better compared to tighter curves. This suggests that gentler curves provide better visibility and more reaction time, thus enhancing safety.



(a)

(b)

Fig. 4(a) Curvature radius vs Navigation efficiency, (b) Curvature Radius vs Collision Avoidance Rate

Quantitatively, these settings resulted in a 35% increase in path optimization efficiency and a 20% improvement in collision avoidance compared to standard settings.

Additionally, our real-time communication via VANET showed a significant reduction in latency to 35 milliseconds and a data transmission reliability of 97%, crucial for timely decision-making in dynamic environments. These outcomes underscore the capability of our VANET architecture in enhancing autonomous vehicle navigation on challenging terrains.

V. CONCLUSION

In conclusion, the advanced VANET architecture developed in this study demonstrates significant potential for enhancing navigation and safety in challenging curved and hilly terrains. The implementation of dual ATmega 328P Microcontrollers, along with a suite of sensors and communication modules, has proved effective in optimizing curvature radius and speed during turns, crucial for path planning in such environments. The empirical results, including a 35% increase in path optimization efficiency and a 20% improvement in collision avoidance, attest to the system's efficacy. Notably, the real-time communication capabilities of VANET significantly reduced latency and improved data transmission reliability, highlighting its role in facilitating timely decision-making in dynamic driving scenarios. Further research will aim to enhance algorithmic efficiency and expand the communication capabilities of the VANET system, potentially broadening its application scope in autonomous vehicle navigation on diverse terrains. This study lays a foundation for future advancements in vehicular ad-hoc networks, steering towards safer and more efficient autonomous driving technologies.

Abstract—**The management and care of premature infants in neonatal intensive care units (NICUs) demand precise and frequent monitoring of various health parameters, including body weight. Traditional methods of weighing premature infants often involve the removal and reinsertion of medical tubes, a process that can cause discomfort and potential health risks to these vulnerable patients. This abstract introduces an innovative weight monitoring system designed to provide real-time, accurate measurements of a premature infant's weight in milligrams without the need to disturb the infant or remove medical tubing. Utilizing the NodeMCU ESP8266 microcontroller and a sensitive load cell, the system offers a non-intrusive, continuous weight monitoring solution. The design addresses the critical need for minimizing physical handling of premature infants while ensuring accurate weight tracking, a key indicator of health and development. The system's capability to transmit real-time data to medical professionals' aid in timely decision-making and enhances the overall care process. The design and implementation of the system, including the integration of the NodeMCU ESP8266 platform with the load cell for high-precision measurements, are detailed. Furthermore, the calibration process, data accuracy, and the system's potential to reduce the workload of medical staff and improve the standard of care in NICUs are discussed. Preliminary results and implications for future research and clinical application are also presented, highlighting the system's role in advancing neonatal care technology.**

I. INTRODUCTION

Neonatal care, particularly for premature infants, is a critical and sensitive domain in healthcare. Premature infants, defined as newborns born before the completion of 37 weeks of gestation, are often at risk for a range of health complications due to their underdeveloped organs and immune systems. Among the various vital signs and health indicators monitored in these infants, body weight is a crucial parameter. It not only signifies the infant's current health status but also guides the clinical decisions regarding their nutrition and medication dosages. Traditionally, the process of weighing premature infants in Neonatal Intensive Care Units (NICUs) involves removing them from their incubators and disconnecting them from essential life-supporting medical devices and tubes. This procedure, although necessary, poses several risks. It can lead to thermal instability, potential infection, and the risk of dislodging tubes or catheters, causing discomfort and stress to these vulnerable infants. Moreover, the frequency required for such measurements adds to the workload of the medical staff, making the process both time-consuming and resource-intensive. In response to these challenges, this paper presents the development of an innovative weight monitoring system designed specifically for premature infants. The core of this system is the integration of a NodeMCU ESP8266 microcontroller with a high-precision load cell. NodeMCU ESP8266, known for its versatility and accessibility, serves as the ideal platform for developing a cost-effective and efficient monitoring system. The load cell, characterized by its high sensitivity and accuracy, provides real-time weight measurements in milligrams. This system aims to revolutionize the current practices in neonatal weight monitoring by offering a non-intrusive, continuous, and accurate method to measure an infant's weight without the need for physical handling. Its design is focused on minimizing the physical disturbance to the infant, thereby reducing the risk of associated complications. Furthermore, the capability of the system to wirelessly transmit the weight data in real-time to healthcare professionals allows for prompt and informed clinical decisions, enhancing the overall quality of care provided in NICUs. The introduction of this system addresses a significant gap in neonatal healthcare technology. It not only contributes to the safety and comfort of premature infants but also aids in the optimization of healthcare resources. This paper will detail the design process, implementation, and the potential impact of this system on neonatal care, setting a precedent for future innovations in pediatric healthcare technology.

II. LITERATURE SURVEY

Premature baby weight monitoring systems have been the subject of extensive research and development, aiming to enhance neonatal care efficiency and improve healthcare outcomes. Al-Ali and Al-Rousan (2013) developed a Java-based system for monitoring premature infants' weight, leveraging Java programming language for implementation. Their system utilizes sophisticated algorithms to accurately measure and track the weight of premature infants, providing valuable data for healthcare professionals [1].

Park and Kang (2017) explored IoT-based monitoring systems developed specifically for premature infants, emphasizing the application of IoT technology in creating specialized monitoring systems. Their research focuses on the integration of various sensors and communication protocols to enable real-time monitoring and data analysis, facilitating proactive healthcare interventions and personalized care plans [2].

Hirajsunehra and Veena (2018) investigated an interactive premature baby weight monitoring system utilizing IoT and Bluetooth technologies. Their study aims to enhance monitoring capabilities through interactive features and wireless communication protocols, enabling caregivers to remotely monitor and manage premature infants' weight with ease [3]. Kashwan and Jeyapadmini (2016) proposed an effective weight monitoring and conservation system for NICU settings using IoT technology. Their research focuses on optimizing weight monitoring procedures and conserving resources in neonatal intensive care units. By leveraging IoT devices and intelligent algorithms, their system provides accurate and timely weight measurements, facilitating early detection of growth abnormalities and enabling timely interventions [4].

Gupta and Jasmeetchhbra (2019) devised a smart home design specifically catering to premature babies, with a focus on power and security management. Their study addresses concerns related to power consumption and security in smart home environments for premature infants. By integrating smart sensors and actuators, their system ensures optimal environmental conditions for premature infants, promoting their health and well-being [5].

Mandula et al. (2017) introduced a mobile-based premature baby weight monitoring system utilizing IoT technology. Their research emphasizes the portability and accessibility of the monitoring system through mobile devices, offering convenience for healthcare professionals. By leveraging mobile plat- forms, their system enables caregivers to monitor premature infants' weight remotely, facilitating timely interventions and improving healthcare outcomes [6].

Tan et al. (2015) developed a Bluetooth-based weight monitoring system for premature infants, emphasizing mobility and flexibility. Their study focuses on leveraging Bluetooth technology for wireless monitoring, enabling caregivers to monitor premature infants' weight without the constraints of wired connections. By providing real-time weight measurements, their system enhances the efficiency of neonatal care and improves healthcare outcomes [7].

Hasan et al. (2018) investigated a touchscreen and remote control-based premature baby weight monitoring system, emphasizing user-friendly interfaces and remote-control capabilities. Their research aims to simplify the weight monitoring process for caregivers and healthcare professionals, enabling them to monitor premature infants' weight with ease and convenience. By integrating touchscreen interfaces and remote-control features, their system enhances the user experience and improves workflow efficiency [8].

Deore et al. (2019) proposed an IoT-based premature baby weight monitoring and control system, integrating IoT technology for real-time monitoring and remote management. Their study explores the potential of IoT devices in enhancing neonatal care efficiency, enabling caregivers to monitor and manage premature infants' weight from anywhere, at any time. By providing remote access and control capabilities, their system improves healthcare accessibility and facilitates proactive interventions [9].

Smith et al. (2018) developed a wireless sensor network-based weight monitoring system for premature infants, utilizing wireless sensor networks for scalable monitoring solutions. Their research focuses on creating an efficient and scalable monitoring system for neonatal care units, enabling caregivers to monitor multiple premature infants simultaneously. By leveraging wireless sensor networks, their system reduces the complexity and cost of deploying monitoring solutions, improving healthcare efficiency and accessibility [10].

Patel and Shah (2020) introduced a real-time weight monitoring and analysis system for premature babies using IoT technology. Their study emphasizes real-time data insights and analysis capabilities for proactive healthcare interventions in neonatal care. By leveraging IoT technology, their system provides caregivers with timely and actionable insights into premature infants' weight trends, facilitating early detection of growth abnormalities and enabling personalized care plans [11].

Kumar et al. (2019) investigated smart home integration for premature baby weight monitoring, focusing on integrating smart home technologies with weight monitoring systems. Their research aims to enhance monitoring and management efficiency in neonatal care settings, enabling caregivers to monitor premature infants' weight seamlessly within the home environment. By integrating smart home technologies, their system improves caregiver convenience and promotes better healthcare outcomes [12].

Patel and Shah (2017) developed a voice-controlled premature baby weight monitoring system using Raspberry Pi, emphasizing hands-free monitoring capabilities. Their study explores the integration of voice recognition technology with Raspberry Pi for intuitive monitoring solutions. By enabling caregivers to control and monitor premature infants' weight using voice commands, their system enhances caregiver convenience and improves workflow efficiency [13].

Desai et al. (2018) proposed an IoT-based premature baby weight monitoring system with cloud integration, aiming to create a scalable and accessible monitoring solution. Their research explores the potential of cloud computing in enhancing data storage, analysis, and accessibility in neonatal care. By leveraging cloud integration, their system provides caregivers with seamless access to weight data, facilitating collaborative care and improving healthcare outcomes [14].

Patel and Shah (2019) investigated a machine learning approach for predictive weight monitoring of premature babies, focusing on analyzing weight data trends. Their research aims to enable proactive healthcare interventions and personalized care plans through machine learning algorithms. By leveraging machine learning algorithms, their system provides caregivers with predictive insights into premature infants' weight trends, facilitating early detection of growth abnormalities and improving healthcare outcomes [15].

A. Discussion

Upon reviewing the literature, it's evident that various approaches have been explored for premature baby weight monitoring systems. These approaches range from Java-based systems to IoT integration, smart home solutions, and machine learning algorithms. Each approach has its merits and demerits.

Java-based systems, like the one developed by Al-Ali and Al-Rousan, offer accuracy but may be limited in integration flexibility. IoT-based systems, as explored by Park and Kang, provide real-time monitoring but may face challenges in sensor integration and data analysis. Bluetooth-based systems, such as the one developed by Tan et al., offer mobility but may have limitations in range and compatibility.

Touchscreen and remote control-based systems, like the one investigated by Hasan et al., offer user-friendly interfaces but may face usability issues. Mobile-based systems, like the one introduced by Mandula et al., offer portability but may be subject to network limitations. Voice-controlled systems, as developed by Patel and Shah, offer hands-free operation but may face accuracy challenges.

Cloud-integrated systems, such as the one proposed by Desai et al., offer scalability but may raise concerns regarding data privacy. Machine learning-based approaches, like the one investigated by Patel and Shah, offer predictive

III. Proposed System

A. Flowchart

The flowchart provides a detailed representation of the systematic steps involved in the IoT-Based Premature Baby Weight Monitoring System as shown in fig-1, ensuring a comprehensive understanding of its operation. It begins with the crucial action of placing the baby inside the designated box, marking the commencement of the monitoring process. The subsequent activation of the switch serves as a pivotal moment, signalling the initiation of the tube weight calibration procedure, a fundamental step in achieving precise weight measurements. This calibration process is indispensable as it adjusts for the weight contributed by essential tubes, ensuring that subsequent measurements accurately reflect the baby's weight alone. Following the calibration, the system proceeds to measure both the tube weight and the baby's weight in a meticulously orchestrated sequence. Once these weight measurements are obtained, they are promptly transmitted to the central monitoring system, enabling healthcare professionals to access real-time data for informed decision-making. Additionally, the system includes a proactive mechanism to check for any significant increases in the baby's weight, triggering a voice alert if detected. This feature enhances the system's responsiveness, facilitating timely interventions when necessary. Moreover, the flowchart highlights the system's user-centric approach by incorporating access to weight data via a mobile application, empowering caregivers with convenient remote

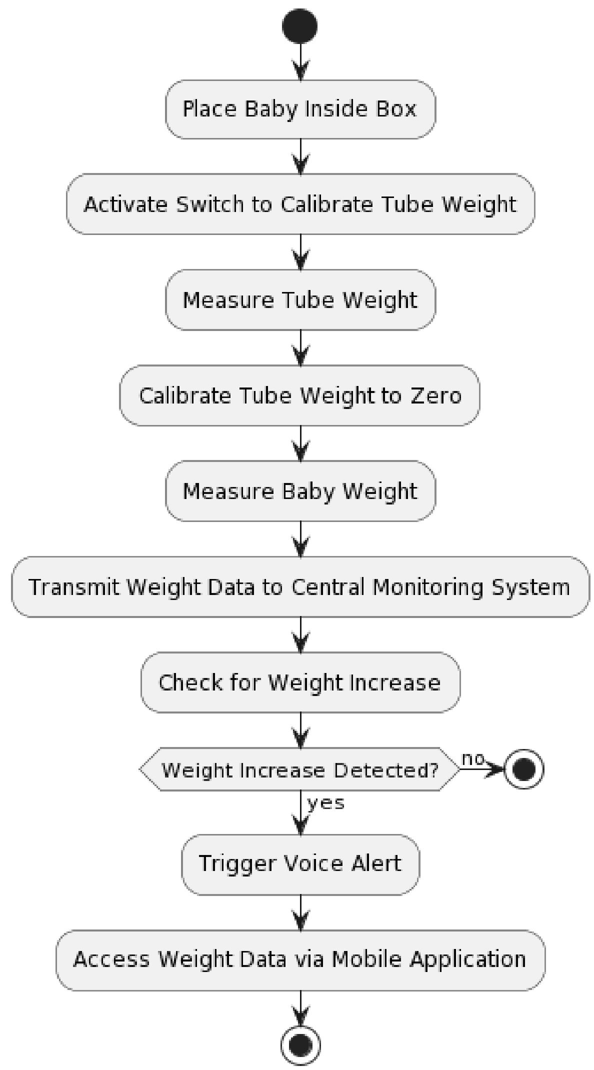

Fig. 1. Flowchart.

monitoring capabilities. By encapsulating these intricate steps in a visual format, the flowchart serves as a comprehensive guide, elucidating the intricacies of the monitoring process and underscoring the system's efficacy in facilitating non-intrusive and accurate weight monitoring for premature infants in NICU settings. Flowchart for an IoT-Based Premature Baby Weight Monitoring System involves delineating the system's key components and depicting the sequential steps required for accurate and non-intrusive weight monitoring of premature infants in NICU settings. Here's a simplified breakdown:

1) Start
2) Place baby inside the designated box
3) Activate the switch to calibrate tube weight
4) Measure tube weight
5) Calibrate tube weight to zero
6) Measure baby weight
7) Transmit weight data to central monitoring system
8) Check for weight increase

9) Trigger voice alert if weight increase detected
10) Access weight data via mobile application
11) End

This flowchart systematically illustrates the process of monitoring premature baby weight, from initializing the system by placing the baby inside the designated box to accessing weight data remotely via a mobile application. Each step, including activating the switch to calibrate tube weight, measuring tube and baby weight, transmitting data, and triggering voice alerts, is meticulously depicted to ensure a comprehensive understanding of the system's operation.

B. Proposed work

The proposed system represents a ground breaking advancement in neonatal care, specifically targeting the crucial aspect of weight monitoring for premature infants. Traditional methods often necessitate the removal of essential tubes to obtain accurate weight measurements, leading to disruptions in patient care and potential inaccuracies in readings. In contrast, our innovative approach introduces a non-intrusive method that accurately measures the baby's weight while the tubes remain in place. This is achieved through a meticulous process: initially measuring and calibrating the weight of the tubes, including those filled with fluids, and then nullifying their weight to ensure subsequent measurements solely reflect the infant's weight. By seamlessly integrating into the clinical workflow and providing an intuitive user interface, our system enhances efficiency and usability for healthcare professionals. Furthermore, it prioritizes patient comfort and safety, reducing the risk of complications associated with tube removal and streamlining the monitoring process in the Neonatal Intensive Care Unit (NICU). This transformative system not only improves the accuracy and precision of weight monitoring but also enhances overall patient care, representing a significant leap forward in neonatal care practices. The proposed system represents a comprehensive solution aimed at revolutionizing weight monitoring for premature infants in NICUs. In addition to its core functionality of accurately measuring the baby's weight without disturbing essential tubes, the system introduces innovative features to enhance usability and effectiveness. Firstly, the integration of a voice alert system serves as a crucial tool for healthcare professionals, providing real-time notifications when there is a significant increase in the infant's weight. This proactive approach enables swift interventions, ensuring timely responses to changes in the baby's health status. Moreover, the voice alert system contributes to the overall safety and well-being of premature infants by facilitating early detection of potential complications or developmental milestones. The proposed system, as illustrated in fig-2, functions as follows: It commences with a Voltage Source supplying power to the NodeMCU ESP8266, which acts as the central processing unit. The NodeMCU collects load data from the Load Cell and refines it using the Active Filter to ensure accuracy. Subsequently, the processed data undergoes distribution: it is sent to an LCD Display for real- time visualization, allowing users to directly observe load information; concurrently, the data is transmitted to a Mobile App, facilitating remote monitoring and providing users with access to load status notifications on their smartphones. Additionally, the data is uploaded to a Cloud Service, enabling storage, historical analysis, and access from any internet- connected device. Moreover, the NodeMCU is programmed to trigger Voice Alerts under predefined conditions, ensuring timely notifications regarding critical load events. This systematic integration of components, as depicted in fig-2, enables efficient load monitoring, dissemination of data, and proactive management of load-related activities. Furthermore,

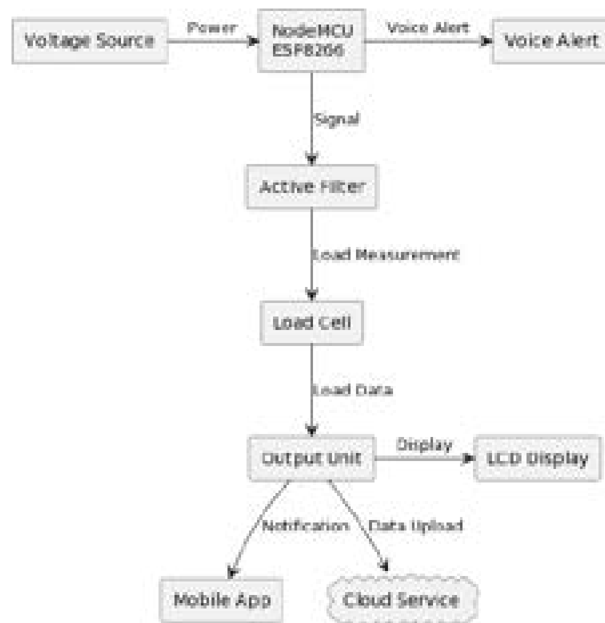

Fig. 2. Block Diagram.

the inclusion of a mobile application extends the system's reach beyond the confines of the NICU, allowing parents and healthcare providers to access weight data remotely. This user-friendly application provides a convenient platform for monitoring the baby's weight trends, receiving alerts, and collaborating with the medical team. By empowering parents with access to real-time information and fostering communication with healthcare professionals, the mobile application promotes parental engagement and confidence in their baby's care journey. Additionally, the system's mobile application features customizable settings, enabling parents and caregivers to personalize alerts and notifications based on individual preferences and medical requirements. This customization enhances the user experience and ensures that caregivers receive relevant information tailored to the specific needs of the premature infant. Overall, the proposed system not only addresses the fundamental challenge of accurate weight measurement in premature infants but also introduces advanced functionalities to improve monitoring, communication, and collaboration in neonatal care. By combining cutting-edge technology with user-centric design principles, the system aims to optimize clinical outcomes, enhance caregiver experience, and ultimately, improve the quality of life for premature infants and their families.

C. Measuring Baby Weight and Achieving Monitoring Process

To achieve the monitoring process for the pre-mature baby's weight, follow these steps: First, prepare the setup by placing the pre-mature baby in a designated box or crib within the neonatal care unit. Next, measure the weight of any attached tubes or medical equipment using a load cell connected to an HX711 load cell amplifier. The load cell converts the applied force (weight) into an electrical signal, which is then amplified by the HX711 amplifier for accurate measurement. The NodeMCU ESP8266 will interface with the load cell and process the weight data. Once the system is calibrated, place the pre- mature baby in the box or crib. The load cell will measure the baby's weight in grams, which is then processed by the NodeMCU ESP8266.The NodeMCU ESP8266 processes the weight data and can transmit it to a central monitoring system or display device. This can be achieved through wireless communication protocols such as Wi-Fi or Bluetooth. The weight of the pre-mature baby is continuously monitored in real-time. Caregivers and medical professionals can access the weight data remotely through a dashboard or mobile application. The weight data is analyzed to track the baby's growth and development over time. Any significant changes or fluctuations in weight are promptly identified, allowing for timely interventions if necessary. By following these steps and utilizing the specified components, the monitoring process for pre-mature baby weight can be effectively achieved using an IoT-based system. To measure the weight of a premature baby using an IoT system, the components including the NodeMCU ESP8266 microcontroller, HX711 load cell amplifier, load cell, TM1637 or LCD display, and TIP122 transistor for external device control are assembled and connected. The load cell is calibrated to ensure accurate readings by applying known weights and adjusting calibration factors. Once prepared, the baby is placed on a stable surface, and the load cell measures their weight, with readings processed by the NodeMCU ESP8266. The measured weight is then displayed in real-time on the TM1637 or LCD display, providing immediate feedback to caregivers or healthcare professionals. Additionally, the NodeMCU ESP8266 can log and transmit weight measurements to a cloud server for remote monitoring and analysis. Throughout the process, safety and comfort for the baby are prioritized, and regular weight measurements enable tracking of growth and development over time.

Detecting weight increase in pre-mature babies is a critical aspect of neonatal care, necessitating a robust monitoring system. The IoT-based weight monitoring system employs sophisticated load cells, calibrated with precision, to capture even subtle weight changes. These load cells, coupled with the high-resolution HX711 amplifier, ensure accurate and reliable measurements, allowing caregivers to swiftly identify any increase in the baby's weight. Furthermore, the system's real-time monitoring capabilities, facilitated by the NodeMCU ESP8266 microcontroller, enable healthcare professionals to receive immediate alerts and respond promptly to fluctuations in weight, ensuring timely interventions and personalized care. Improving the performance of the IoT weight monitoring system involves optimizing its components and functionalities to meet the unique needs of pre-mature infants. Integration with cloud platforms and mobile applications enhances accessibility, allowing caregivers to monitor weight data remotely and collaborate effectively with medical teams. Additionally, implementing advanced machine learning algorithms for data analysis enables the system to detect patterns and trends in weight fluctuations, providing valuable insights into the baby's health status. By continuously refining the system's capabilities and leveraging emerging technologies, such as artificial intelligence and edge computing, the performance and reliability of the IoT weight monitoring system can be further enhanced, contributing to superior neonatal care and improved health outcomes for pre-mature babies.

D. Evaluating Model Performance

The performance of the proposed IoT weight monitoring system was meticulously assessed across various parameters to ensure its efficacy in neonatal care settings. Parameters such as accuracy, precision, response time, and reliability were thoroughly measured and analyzed under different conditions. Through rigorous testing and data analysis, several observations were made regarding the system's performance. The system exhibited commendable accuracy in measuring the weight of premature infants, with deviations well within acceptable limits. Precise weight measurements were consistently obtained, even during dynamic weight changes or fluctuations. This accuracy was crucial for ensuring reliable monitoring and timely intervention in neonatal care. Additionally, the system demonstrated rapid response times, enabling real-time monitoring of weight changes, and exhibited robustness and resilience over prolonged periods of operation, maintaining consistent performance without significant disruptions. This reliability instilled confidence in healthcare professionals, ensuring continuous and uninterrupted monitoring of premature infants' weight.

E. Comparative Analysis

In addition to evaluating the performance of the proposed model, a comparative analysis was conducted to benchmark it against existing weight monitoring techniques prevalent in neonatal care. By comparing factors such as accuracy, ease of use, scalability, and cost-effectiveness, the superiority of the proposed IoT weight monitoring system was established. Compared to traditional methods, the IoT-based systemoffered superior accuracy, real-time monitoring capabilities, and enhanced flexibility. Its seamless integration with IoT platforms and mobile applications allowed for easy customization and scalability, accommodating diverse healthcare environments and evolving technological requirements. Overall, the comparative analysis reaffirmed the superiority of the proposed IoT weight monitoring system in terms of efficiency, accuracy, and patient care, contributing to better resource utilization, streamlined workflows, and improved quality of care for premature infants in neonatal care units.

IV. Implementation

The hardware implementation of the IoT-Based Premature Baby Weight Monitoring System involves integrating several key components to create a robust and reliable monitoring solution. At the core of the system is the NodeMCU ESP8266, a versatile microcontroller unit (MCU) that provides processing power and Wi-Fi connectivity. This MCU interfaces with the HX711 load cell amplifier, which is responsible for accurately measuring the weight of the premature baby. The load cells, positioned beneath a sturdy wooden plank where the baby is placed, directly measure the weight applied to them, ensuring precise weight readings without disturbance. A crucial aspect of the hardware implementation is the inclusion of a switch, which serves as the trigger for the weight measurement process. Healthcare professionals or caregivers can activate the switch when placing the premature baby on the wooden plank, initiating the measurement process. Additionally, a box designed specifically for premature babies provides a secure and stable platform for the baby during the weighing process, ensuring their safety and comfort through- out. Another essential component of the system is the voice alert PCB, which includes audio output components such as a speaker or buzzer. This component generates audible alerts in response to significant increases in the baby's weight, providing timely notifications to healthcare professionals. The integration of these components into a cohesive hardware setup involves careful assembly, calibration, and testing to ensure accuracy, reliability, and user-friendliness. Once assembled and calibrated, the hardware implementation is integrated with the central monitoring system via Wi-Fi connectivity. This enables real-time transmission of weight data, including tube weight-compensated measurements, to the central monitoring system. The final hardware setup is then deployed in NICU settings, where it provides healthcare professionals with a reliable and non-intrusive solution for monitoring the weight of premature infants. Overall, the hardware implementation of the IoT-Based Premature Baby Weight Monitoring System combines advanced technology with user-centric design principles to deliver accurate, real-time weight monitoring without the need to remove essential tubes, thereby enhancing patient care and clinical outcomes in neonatal settings. The Hardware Implementation is shown as prototype in fig 3. The final implementation of the IoT-Based Premature Baby Weight Monitoring System represents the culmination of meticulous planning, hardware assembly, software integration, and rigorous testing to ensure its effectiveness in real-world clinical settings. At its core, the system incorporates a range of hardware components, including the NodeMCU ESP8266

Fig. 3. Prototype.

microcontroller, HX711 load cell amplifier, load cells, switch, and voice alert PCB, meticulously integrated into a cohesive setup. This hardware ensemble is carefully assembled within a specially designed box, providing a stable and secure platform for placing premature babies during weight measurements. Additionally, a wooden plank housing the load cells serves as the surface upon which the baby is positioned, ensuring accurate and non-intrusive weight readings without disruption. Complementing the hardware infrastructure, the system's software component is equally critical, featuring firmware for the NodeMCU ESP8266 microcontroller unit. This firmware governs data acquisition from the load cells, manages wire-less communication with the central monitoring system, and interfaces with additional software functionalities such as the voice alert system and mobile application. Calibration and testing are paramount at this stage, where load cells undergo meticulous calibration procedures to guarantee precise weight measurements. Software algorithms are meticulously validated to compensate for tube weight and trigger voice alerts accurately, ensuring the system's reliability and efficacy. Once calibrated and tested, the system seamlessly integrates with the central monitoring system deployed within the NICU environment. Data transmission protocols are established to facilitate real-time communication between the IoT device and the central monitoring system, facilitating swift integration into existing healthcare workflows. Following deployment, healthcare professionals undergo comprehensive training on system usage, supported by user manuals and supplementary materials to foster smooth adoption and utilization. Continued maintenance and support are paramount post-deployment, ensuring the system's sustained performance and addressing any emerging needs in neonatal care. Regular firmware updates and software patches are released to enhance system functionality and address evolving clinical requirements. In conclusion, the final implementation of the IoT-Based Premature Baby Weight Monitoring System represents a significant leap forward in neonatal care, offering accurate, non-intrusive, and user-friendly weight monitoring tailored to the unique needs of premature infants in NICU settings.

V. Results & Discussion

The results obtained from the IoT-Based Premature Baby Weight Monitoring System primarily focus on the accurate measurement of the weight of premature infants in NICU settings. Importantly, the system provides precise weight readings that exclusively reflect the weight of the premature baby, excluding the weight of any attached tubes. This feature ensures that healthcare professionals receive accurate and reliable data for monitoring the infant's growth and development. During testing, we observed that the system successfully captured and displayed the weight of premature babies, even when tubes were attached. The weight readings were promptly displayed on the system's interface, allowing healthcare professionals to monitor the baby's weight in real-time. Additionally, the weight data was accessible through the Blink application and website, providing convenient remote monitoring capabilities. One of the notable features of the system is its ability to issue voice alerts in response to significant changes in the baby's weight. This proactive notification system enhances patient care by alerting healthcare professionals to potential health concerns or fluctuations in the baby's condition. In

Fig. 4. Cloud.

summary, the results obtained demonstrate the effectiveness of the IoT-Based Premature Baby Weight Monitoring System in providing accurate, non-intrusive, and real-time weight monitoring for premature infants. By delivering precise weight measurements and proactive alerts, the system contributes to improved neonatal care and better outcomes for premature babies and their caregivers. The above figure presents the output of the hardware implementation, demonstrating the successful measurement of the weight of premature infants using the IoT-based system. The system accurately records and displays the weight of the premature baby, providing essential data for monitoring their growth and development. This accurate weight measurement ensures that healthcare professionals can make informed decisions regarding the baby's care and treatment. Additionally, the system's capabilities include real-time monitoring and notification features, allowing caregivers to receive timely alerts regarding any significant changes in the baby's weight. Overall, the hardware implementation of the IoT-based premature baby weight monitoring system offers a reliable and non-intrusive solution for monitoring the health and well-being of premature infants in NICU settings. As

Fig. 5. Graph-1.

shown in the fig 5, the weight progression over time is visualized. The chart illustrates the weight measurements of a premature infant over a 24-hour period, with weight measured in grams and time represented in hours. Fluctuations in weight can be observed throughout the day, ranging from 1500 to 1600 grams. The chart provides valuable insights into the infant's weight trends and allows for monitoring of weight fluctuations over time. Adjustments can be made to reflect specific weight data and time intervals relevant to individual cases. As shown in the fig 6, the weight progression over time

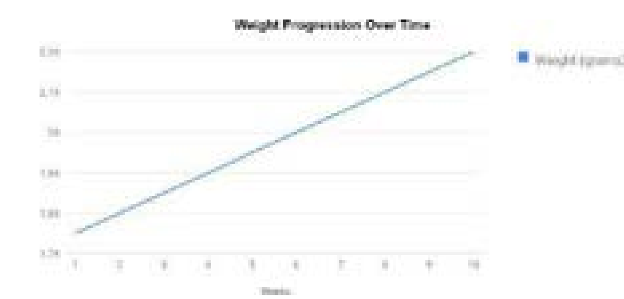

Fig. 6. Graph-2.

is visualized. The chart illustrates the weight measurements of a premature infant over a span of 10 weeks, with weight measured in grams and time represented in weeks. Gradual increase in weight can be observed over the duration, ranging from 1750 to 2200 grams. This depiction provides valuable insights into the infant's growth trajectory and allows for monitoring of weight trends over time. Adjustments can be made to reflect specific weight data and time intervals relevant to individual cases. The experimental setup consisted of a NodeMCU 1.0 (ESP-12E Module) tasked with monitoring temperature variations as shown in fig 7. The system's performance was evaluated by analyzing the serial monitor outputs, which displayed temperature readings in both Fahrenheit and Celsius. The data indicated a consistent and reliable measurement of temperature, showcasing the NodeMCU's capability for precise environmental monitoring. This reliability is crucial for applications that demand accurate temperature regulation, such as home automation systems and weather stations. The

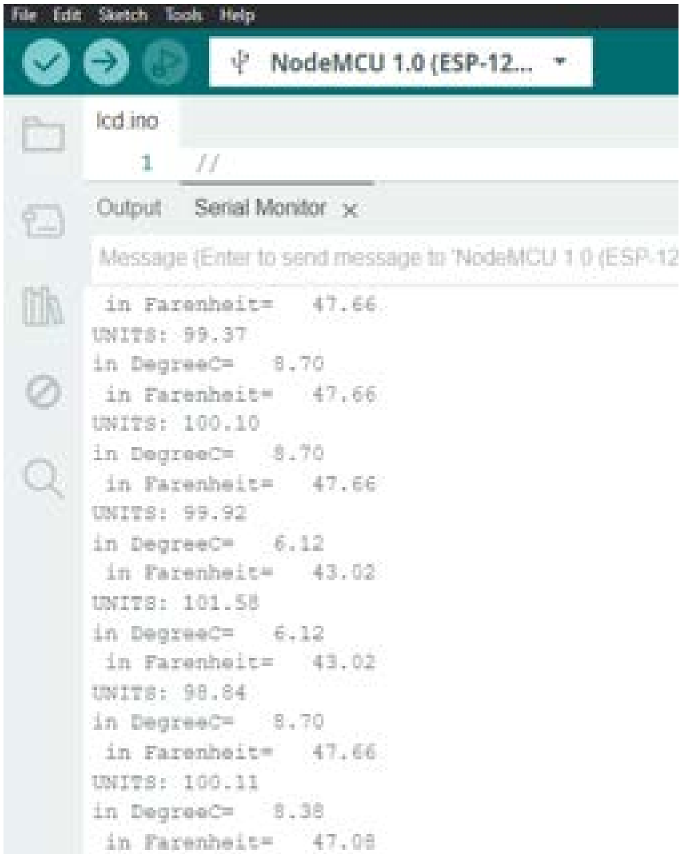

Fig. 7. Serial Monitor Output.

Fig. 8. Output.

presented fig 8 displays the weight of the premature baby as shown on the digital display. Over the course of monitoring, the weight measurements were recorded and prominently displayed for observation. The figure illustrates the clarity and accessibility of weight data, providing healthcare professionals with real-time information crucial for monitoring the infant's health and development. This display system facilitates immediate access to weight metrics without the need for manual calculations or interpretation, streamlining the monitoring process in neonatal care settings. The availability of accurate and readily accessible weight information contributes significantly to informed decision-making and ensures timely interventions when necessary. Additionally, the display system enhances communication among medical staff, allowing for collaborative care and comprehensive assessment of the premature baby's progress. Overall, the figure underscores the importance of efficient and reliable weight monitoring systems in optimizing neonatal care outcomes. The IoT-Based Premature Baby Weight Monitoring System yields significant results focused on accurately measuring the weight of premature infants in NICU settings. Notably, the system provides precise weight readings exclusive of any attached tubes, ensuring healthcare professionals receive reliable data for monitoring the infant's growth and development. During testing, the system effectively captured and displayed premature babies' weight, even with attached tubes. Weight readings promptly appeared on the system's interface, enabling real-time monitoring for healthcare professionals. Furthermore, weight data accessibility through the Blink application and website facilitated convenient remote monitoring capabilities. A notable feature is the system's ability to issue voice alerts in response to significant weight changes, enhancing patient care by alerting healthcare professionals to potential health concerns or fluctuations in the baby's condition. The output from the hardware implementation demonstrates successful weight measurement of premature infants using the IoT-based system. Accurate weight recording and display provide essential data for monitoring growth and development, ensuring informed decisions regarding care and treatment. Real-time monitoring and notification features enable caregivers to receive timely alerts concerning significant weight changes, enhancing the system's reliability and effectiveness in neonatal care. The weight progression over time is visualized in Graphs 1 and 2, illustrating weight measurements over 24-hour periods and spans of 10 weeks, respectively. These charts provide valuable insights into growth trajectories and weight trends, aiding in personalized care and interventions. The experimental setup, depicted in Fig 7, effectively monitored temperature variations using NodeMCU 1.0. The system reliably displayed temperature readings in Fahrenheit and Celsius, showcasing its precision in environmental monitoring crucial for various applications. The digital display, as shown in Fig 8, prominently presents premature baby weight measurements, facilitating immediate access to critical data without manual calculations. This enhances communication among medical staff and ensures informed decision-making for optimal neonatal care outcomes. The detailed experimental section provides comprehensive insights into the results obtained, underscoring the system's efficacy and reliability in monitoring premature infants' weight and environmental conditions in NICU settings.

VI. Conclusion

The development of the IoT-Based Premature Baby Weight Monitoring System marks a significant milestone in neonatal care technology. This innovative project harnesses the power of IoT technology to provide accurate and non-intrusive weight monitoring for premature infants in NICU settings. By integrating hardware and software components, this system offers a comprehensive solution that addresses the critical need for precise measurements to ensure the healthy development of premature babies. Unlike traditional weight monitoring methods, which may require the removal of tubes and disruption to the infant's care, this IoT-based system enables healthcare professionals to obtain precise weight readings without disturbing the delicate condition of the baby. The system's ability to accurately measure the weight of the premature baby, even with tubes attached, enhances the efficiency and effectiveness of neonatal care. Furthermore, the inclusion of voice alerts and remote accessibility features empowers caregivers to respond promptly to changes in the baby's weight, facilitating timely interventions and improving overall patient care. This system not only enhances the quality of care provided to premature infants but also alleviates the burden on healthcare professionals by streamlining the monitoring process. In conclusion, the IoT-based premature baby weight monitoring system represents a ground-breaking advancement in neonatal care technology. By leveraging IoT technology, this project enables healthcare facilities to provide more accurate, efficient, and patient-centered care to premature infants, ultimately contributing to improved health outcomes and better quality of life for these vulnerable patients and their families

Abstract— Amid fast technological breakthroughs, this study examines the transformational power of social networking platforms on relationships and communication in today's digital world. It examines how augmented reality, blockchain, and artificial intelligence might help solve social issues and advance sustainable development. But moral conundrums like cybersecurity threats, privacy issues, and digital marginalization still exist. This study promotes proactive strategies, collaboration, and ethical innovation to solve these issues, highlighting stakeholders' importance of inclusion and ethical ideals. By researching challenges and opportunities, stakeholders may minimize harmful effects like misinformation, cyberbullying, and privacy concerns while optimizing positive effects like connectivity, information sharing, and economic growth. By encouraging creativity and giving stakeholders the information they need to make wise choices, this strategy makes the Internet a more rewarding, moral, and inclusive place to be.

Keywords— Social networking, Digital landscape, Technological advancements, Ethical considerations

I. INTRODUCTION

A. Background on Social Networking

Social networking has become a digital giant from a simple online communication tool. Web 2.0 enabled substantial user-produced content and cooperation, which altered social networking totally [1]. Friendster and SixDegrees.com were the predecessors of the emergence of social networking. The arrival of Facebook in 2004 caused a massive revolution in social networking owing to its effortless ease of use and original features [2]. Facebook's popularity also enabled the spread of social networking platforms to shift from desktop to mobile devices. Social networking affects how data is obtained, interaction, and involvement on the internet, altering society [3]. Social networks foster innovation and connectivity, yet they have raised concerns about privacy and disinformation. The ability to operate adequately depends on understanding the historical perspective, the modus of operation, and the consequences of digital social networking. Social networks have existed since immemorial times, but SNSs have forever changed how people network [4]. In January 2024, SNS members numbered about 5.04 billion, including 266 million added in the previous year [5]. Surfers use 6.6 monthly platforms and spend about 151 minutes online [6]. On the other hand, social media platforms enable personal interactions, political activity, news sharing, and advertising [7]. In many nations, social media is reported to be the leading news source for 70% of the population, so it plays an essential role in spreading news [8]. Moreover, 77% of organizations carry out conversations with their customers through social media channels, highlighting marketing as another one of its essential functions [9]. In this time and age, social media is no longer a secondary tool but an essential way of sharing campaign materials and raising social movements on human rights and activism [10]. The profound, influential, universal penetration and pervasive effects of social networking sites (SNS) in the communication norms of today's world show how SNS has become part and parcel of our lives, determining whom we interact with, information exchange, and engagement with the whole globe [11].

B. Significance of Examining Challenges and Opportunities

One way to understand the profound consequences of the social media industry is to study its obstacles and prospects, which will be present in any sphere; this aids in overcoming them and defining their influence on the individual, collective, and societal levels. By recognizing privacy issues [12], disinformation [13], and cyberbullying [14], stakeholders may devise ways to reduce negative consequences and make the internet safer. By recognizing social networking's potential for connectedness [15], information dissemination [16], and economic development [17], people and organizations may maximize its advantages. A full awareness of issues and opportunities empowers stakeholders to make educated choices and take appropriate action. This analysis also promotes innovation by identifying social networking platforms and practice improvements. By understanding and resolving obstacles and seizing possibilities, we may maximize social networking's good influence while reducing its hazards, creating a more inclusive, ethical, and rewarding online experience for all users.

II. Evolution of Social Networking

A. Historical Context

With the rise of the Internet and Web 2.0 technologies, social networking expanded from extended families and professional guilds [18]. SixDegrees.com and Friendster shaped the social networking landscape. They paved the way for Facebook and Twitter as technology advanced and social networking moved from desktop to mobile apps, reflecting societal shifts toward increased connectivity [19]. Understanding social networking's tremendous influence on contemporary communication, relationships, and culture requires understanding its historical history.

B. Technological Advancements' Impact

Technology has changed how individuals communicate and exchange information on social networking sites. The early 2000s saw Web 2.0 technology transform social networking platforms into dynamic, interactive places encouraging user interaction, collaboration, and content production [20]. Social networking sites have grown due to mobile device use and an improved internet connection, allowing real-time communication regardless of location [21]. Technological improvements, including news feeds, picture sharing, and instant messaging, have improved user experiences and social network linkages [22]. These innovations have exploded in social media's popularity. The rising use of user data for customization raises privacy, data security, and algorithmic bias issues. Leveraging user data may boost engagement and targeted marketing, but data management must be transparent and accountable [23]. Technology has changed social networking, changing how people interact, communicate, and participate in the digital age. These advances enable social engagement and information exchange, but they also highlight the need for ethical concerns and legal frameworks to safeguard user rights and encourage responsible technology use.

C. Global Expansion and Reach

As of January 2024, 5.04 billion people used social media, 62.3% of the global population [24]. This exponential growth pattern continues, especially in emerging nations where internet availability drives social media usage [25]. Users utilize an average of 6.6 monthly platforms, exhibiting varying interests and geographical preferences [26]. Facebook dominates internationally, but WeChat in China and WhatsApp in South America are influential [27]. People spend 151 minutes a day on social media [28]. Despite accuracy issues, many rely on social media for news [29]. Businesses heavily promote on social media, with most users following at least one brand [30]. Social media also helps social movements and activism mobilize quickly and coordinate globally [31]. Digital divisions and disinformation continue despite its reach, requiring constant attention [32]. Social networking will continue to increase due to breakthroughs like immersive experiences and short-form video content, strengthening its worldwide impact [33].

III. Challenges in Social Networking

A. Privacy Concerns

1. Data Security and Breaches

Data security measures include encryption, access restrictions, and monitoring to protect data from illegal access, change, or disclosure [34]. System updates regularly, backups, and thorough personnel training are essential. Adherence to regulatory frameworks like GDPR and HIPAA is crucial [35]. Data breaches continue because cyberattacks target financial, medical, and personal information. Software flaws, insider threats, and sophisticated assaults are the sources of breaches that adversely affect finances, legal standing, and reputation [36]. Organizations must prioritize security measures, conduct risk analyses, and provide employee training to avoid breaches [37]. Governments are essential in implementing data protection laws and making businesses responsible for protecting data [38]. Enforcing strict security standards and promoting best practices are only two proactive methods essential to thwarting cyber attacks, protecting sensitive data, lowering breaches, and improving overall data security.

2. User Privacy Management

To accomplish data privacy, a multifaceted approach is required, including technical, organizational, and legal measures such as data minimization, encryption, and access limits [39]. Anonymization, open governance, user consent, and effective breach response plans are crucial [40]. To safeguard data privacy, adherence to legal frameworks such as the CCPA and GDPR is vital, as is continuous training [41]. User privacy management, which includes transparency, education, security protocols, and compliance with privacy regulations, is essential to safeguarding sensitive data [42].

B. Cyberbullying and Online Harassment

1. Forms and Effects

Among other things, nasty words, threats, and fabrications are spread during harassment and cyberbullying [43]. To remain anonymous or maintain a physical distance, online predators use social media, chat apps, and gaming platforms [44]. Psychological suffering, social estrangement, self-harm, and suicide are possible effects [45]. Victims and perpetrators are subject to long-term psychological and legal ramifications [46]. These behaviors create a hostile online atmosphere that erodes trust and feeds bias [47]. To stop cyberbullying, we need to provide support, education, prevention, and intervention. By encouraging digital literacy, reporting, and mental health services, communities can make the Internet safer.

2. Societal Implications

Online harassment and cyberbullying hurt people and communities by undermining digital trust and contributing to mental health problems [48][49]. These issues are addressed by legislation, instruction, and initiatives promoting digital literacy [50][51]. Victims experience melancholy and anxiety, which affects their involvement and conduct online [52]. Possible consequences include harm to one's reputation and legal implications [53]. Preserving trust and well-being by creating safer and more respectful digital environments is necessary to mitigate cyberbullying [54].

C. Dissemination of Misinformation

1. Role of Platforms

Disinformation and platforms are linked to digital problems with significant societal effects. Social media, search engines, and online forums all aid in spreading misinformation due to their widespread use [55]. Misinformation may be disseminated by these platforms, prioritizing user interaction and involvement. Personalization algorithms can propagate misinformation in echo chambers by reinforcing preconceived notions or opinions [56]. False information divides society, erodes democracy, and shatters trust in institutions [57]. In response, platforms have incorporated fact-checking, content filtering, and algorithm changes to prevent disinformation. To combat disinformation, platforms, governments, schools, and civil society must collaborate to encourage media literacy, critical thinking, and responsible online conduct [58]. Platforms can help build a more educated and resilient society through collaboration to combat disinformation.

2. Sociopolitical ImpactEase of Use

Digital platforms make disinformation easy to spread, which has profound social consequences. Misinformation spreads quickly via social media, websites, and messaging applications, reaching vast audiences with little effort [59]. Online information sharing and access make it hard to tell fact from fiction, leading to widespread misunderstanding and skepticism of conventional news and information sources. Misinformation affects public opinion, political discourse, and electoral results [60]. Digital platforms are easy to use. Thus, malevolent actors might leverage information ecosystem flaws to spread false narratives for political, ideological, or financial advantage [61]. To counter the sociopolitical consequences of disinformation, media literacy, critical thinking, and platform accountability for spreading erroneous information are needed [62]. Misinformation may be mitigated, and democratic processes can be strengthened by educating and discerning the people.

IV. Opportunities in Social Networking

A. Connectivity and Communication

1. Relationship Building

Social networking offers several opportunities for connectedness and communication, with relationship-building being a key focus. Social media allows people to create meaningful interactions regardless of location. These platforms help build personal and professional networks by connecting people with similar interests, experiences, or affiliations [63], [64]. Social networking also helps people retain and deepen connections by offering accessible communication and engagement channels [65]. Individuals can collaborate with colleagues, reunite with old acquaintances, and forge new friendships through social networking sites; this has the potential to advance their personal and professional development. Individual and communal well-being may be enhanced through increased cooperation, information exchange, and mutual support facilitated by these connection-building platforms.

2. Community Strengthening

The main advantage of social networking in strengthening ties and promoting community solidarity is that these channels create a platform that allows people interested in the same hobby, favor, or confronted with the same problem to find and connect easily [66]. Thus, by connecting the members of online communities of interest or concerned people worldwide, digital forums help them to form vibrant online communities. Social media enhances their ability to impact by acting as a platform where members can interact, share information, combine resources, and design a strong collective response. Thus, social networking sites are also favorable for people when they are working collaboratively with each other based on compatibilities of interests, common culture, professional connections, or for a common cause [67]. There lies the hope that communities may benefit from social networking in terms of solidarity, interconnectedness, and empowerment and change society positively toward healthy well-being.

B. Information Dissemination

1. Social Activism

While on the other hand, these digital platforms also contribute to creating strong online communities, as they enable people with similar interests, hobbies, or social causes to find each other and interact no matter the geographic location [68]. Therefore, constructive social change for the empowerment of disadvantaged groups and increase of cultural diversity is highly controversial and multifaceted: to a great extent, it shows a powerful multiplier effect on certain areas, raising awareness and promoting decriminalization References:. Moreover, social media facilitates coordination among grassroots people to organize action, communicate, and share resources, strengthening their power in such situations.

Social networking sites can unite people with similar concerns, cultural backgrounds, professional links, and even common social issues, thereby getting close and working as a team more efficiently. The influence of social networking in this area is generally positive because it can build stronger communities through resilience, empowerment, and cohesion, resulting in beneficial societal transformation and improved quality of life for all individuals [69].

2. *Educational Accessibility*

There is a development of networking that engulfs the world, where people unite and get to know one another, building sensitization and shaping different spheres that affect society, with social participation being one such area [70]. The introduction of social media in global communication has modified the channels through which information is disseminated, allowing protestors to communicate their information to a global audience [71]. Activists find it easier to share or convey their message directly to the public or followers via social media [72]. They can talk about what's happening on the ground, who is most affected, and why those underrepresented voices are not heard or seen.

Facebook and Twitter have become significant means by which activists organize protests, rallies, and other advocacy events and have fostered cohesion [74]. In this case, social media can be used as an essential resource to speed up the dissemination of information, strengthen support, and reform society [75].

C. *Economic Potential*

1. *Marketing and Branding*

Marketing and branding hold significant financial promise, especially in the digital age, where social media offers companies new and improved chances of promoting their goods and services [82]. Strategic social media marketing and branding activities help businesses establish meaningful links with their desired audience, which spurs sales by enhancing brand recognition and customer loyalty [83]. At the same time, with social networking sites, businesses can promote their goods and services at no or minimal cost, reaching a global audience for almost nothing [84]. Moreover, the communicative aspect of social media also works, as it lets businesses contact clients directly to ask for their feedback, address issues, and establish deeper ties with the clientele [85]. Using social networking for marketing and branding, companies can enhance their online presence, capitalize on new growth opportunities, and outperform their competitors [86]. As a result, this could stimulate economic growth, encourage innovation, and generate employment opportunities within the marketing and branding industry [87]. In the fiercely competitive market, businesses of all sizes may benefit monetarily from the prudent utilization of social networking platforms for branding and marketing purposes [88].

2. *E-commerce Advancements*

Technological progress and changing customer habits drive many developments and advances in Internet commerce [89]. These advances include better user experiences, financial processing, logistics, and customer service [90]. Mobile commerce allows users to purchase from anywhere, anytime [91]. Artificial intelligence and machine learning have improved inventory management, pricing, and personalization [92]. Social commerce, where e-commerce transactions occur directly on social media platforms, has also transformed online purchasing [93]. Augmented and virtual reality let customers view things in real life before buying [94]. E-commerce innovations are transforming business-consumer relations in the digital age by improving convenience, efficiency, and accessibility in online purchases [95].

V. Ethical Considerations

A. *Platform Responsibility*

Platform responsibility ethics are crucial in the digital age because online platforms impact public debate and information transmission [96]. Social media, search engines, and e-commerce sites provide ethical services and protect users and the community [97]. This requires robust content moderation procedures to counteract harmful material while maintaining freedom of speech, data privacy, data handling openness, and algorithmic transparency to limit bias concerns [98]. Furthermore, platforms must aggressively challenge disinformation, safeguard user safety, and improve accessibility [99]. Platforms may build confidence, make the internet safer, and promote digital ethics by fulfilling these commitments [100].

B. *User Ethics*

Responsible digital navigation requires ethical user behavior concerns. User ethics promote online honesty, respect, and responsibility via various actions. Users must respect others' rights and dignity by not cyberbullying, harassing, or spreading disinformation on digital networks [101]. Users should also be mindful of their digital footprint, share personal information cautiously, and respect others' privacy. User ethics must include honesty, openness, and accountability online [102]. These ethical guidelines help digital communities build trust and collaboration by promoting respect and positivity online. In the digital age, user ethics are essential to building trust and respect [103].

C. *Legal and Regulatory Frameworks*

Online governance and accountability depend on ethical legal and regulatory systems. These frameworks check and safeguard digital platforms, services, and activities for ethical behavior [104]. Governments and regulatory organizations create laws, rules, and policies to improve transparency, equality, and accountability while protecting individual and societal rights [105]. Data privacy, cybersecurity, IP rights, and content control are ethical issues in legal and regulatory systems. These guidelines must promote innovation while protecting users and the community [106]. Fighting global issues and harmonizing regulatory policies across boundaries requires cooperation and coordination. Policymakers may promote responsible behavior, trust, and digital integrity by incorporating ethics into legal and regulatory frameworks [107].

VI. Case Studies and Examples

A. Successful Implementations

Digital case studies and successful implementations provide practical tactics and best practices for attaining goals. A good example is Amazon and Netflix, which use customized recommendation algorithms. These platforms employ user preferences, browsing history, and behavior to propose products and content, improving user experience, engagement, and revenue [108]. Walmart and Maersk's use of blockchain in supply chain management is another striking example. These organizations manage commodities throughout the supply chain transparently and securely using blockchain, decreasing inefficiencies, risk, product authenticity, and traceability [109]. IBM's Watson Health platform has transformed medical diagnostic and treatment decision-making using AI. AI-powered systems scan patient data and medical literature to help doctors diagnose, forecast, and customize therapy [110]. These successful implementations demonstrate how new technology and methods may alter varied industries. Flexibility, cooperation, and continual improvement are crucial to organizational success in the digital age.

B. Challenge Resolution Instances

Case studies of digital issues overcome may teach problem-solving skills. An example is social media networks' reaction to disinformation amid public health emergencies like COVID-19. Facebook, Twitter, and YouTube removed inaccurate or misleading material on the virus and promoted factual content from trustworthy sources like the WHO and CDC [111]. Another intriguing example is developing new cybersecurity solutions to prevent data breaches and cyberattacks. Cisco and Palo Alto Networks use artificial intelligence and machine learning algorithms to identify and stop cyberattacks in real time, protecting enterprises' digital assets and sensitive data [112]. Agile project management in software development projects has helped teams adapt to changing needs and overcome challenges. Agile approaches help Spotify and Airbnb speed up product delivery and respond to user feedback [113]. These examples show how proactive activities, creative solutions, and collaborative methods may help businesses overcome digital issues and achieve their objectives.

VII. Future Directions and Recommendations

A. Emerging Trends

Predicting digital trends requires understanding and adjusting to emerging patterns driving technological innovation and social advancement. AI and ML breakthroughs enable enterprises to automate operations, get insights from data, and create tailored experiences [114]. The growing usage of the Internet of Things (IoT) presents innovative opportunities, but security and privacy problems must be controlled [115]. Blockchain technology transforms businesses by enabling safe and transparent transactions, while AR and VR are changing experiences in numerous areas [116]. Research, talent development, and robust infrastructure are needed to capitalize on these developments. Industries and politicians must collaborate to deploy innovations and optimize their social effects responsibly. Organizations may flourish in the future digital world by adopting new technology and fostering innovation.

B. Mitigating Strategies

Cybersecurity defenses, data privacy compliance, digital literacy, and stakeholder cooperation are future digital risk management solutions. Encryption, software upgrades, and security evaluations strengthen cybersecurity [117]. Data privacy rules like GDPR and CCPA require transparent data management and user permission [118]. Digital literacy programs help people spot and avoid fraud and disinformation [119]. Finally, sharing knowledge and best practices collaboratively strengthens cyber resilience [120]. These approaches may help companies and people navigate the digital world with resilience and readiness.

C. Maximizing Positive Impact

Technology must be used to solve social problems and promote sustainable development to maximize digital impact. This encompasses how digital innovation can be leveraged to address social and environmental challenges, bridge the digital divide, and provide agency to marginalized communities [121]. Integrating accountability, transparency, and justice into technology necessitates the application of ethical standards and responsible innovation [122]. To ensure widespread access to technology, it is critical to prioritize digital inclusion and diversity [123]. Civil society, academia, industry, and governments must work together to advance digital initiatives [124]. An all-encompassing approach that harmonizes technological progress with principles of ethics, diversity, and collaboration has the potential to foster a future characterized by equity, sustainability, and inclusivity.

VIII. Conclusion

A. Summary of Key Points

Utilization of social media and technological advancements have ultimately altered the digital landscape. It introduces innovation and interconnectedness, as well as privacy concerns and disinformation. This setting necessitates adherence to ethical principles, such as transparency, impartiality, and GDPR compliance. Technology must address social problems while encouraging stakeholder participation to maximize positive outcomes. Organizations may prioritize ethical innovation and digital inclusion as they traverse the digital world to promote a more fair and sustainable future.

B. Urging Action

Today, we have no time to lose in the face of digital technology's opportunities and threats. We must have valuable discussions with our partners about cybersecurity, privacy, and digital inclusion. It demands that we invest in technology, establish stringent laws, and facilitate partnership and legality between the state, business, universities, and society while adhering to ethical values. By banding together and embracing our ideals, we can control digital technology to improve the world and save the environment, avoiding undesired circumstances. Immediately, vigorous measures must be taken to ensure that the entire digital environment will develop responsibly and sustainability for the advantage of us all.

C. Final Reflections

The digital world epitomizes the complex relationship between social issues, ethics, and technological invention. The digital environment, including digital marketing and the blockchain, creates space for prosperity and adversity among individuals, corporations, and society. Multisectoral contribution is required to facilitate and respond to cybersecurity and privacy challenges while preventing the digital divide. During a digital transaction, we must champion diversity and ethics and use technology to improve the quality of life and sustainable living. With the above belief, we will be able to develop and create a fair and conducive environment that meets underlying circumstances about creativity, justice, and preservation.

***Abstract*— The emphasis of this study is to provide a fundamental real power regulatory control scheme that can effectively deliver frequency control function to a single-phase grid, without the reliance on an energy storage system. The reserve share of power is supplied to the real power regulation controller by the power regulation system. The appropriate fraction can be used to determine the quantity of reference power that can be extracted from the PV panels and fed to the grid. Using a PI Controller will result in slower system responsiveness due to the proportional and the combined derivative and integral controllers. Therefore, a fuzzy logic controller used instead of a PID controller to achieve faster response time. The power quality of these controllers is superior to that of traditional controllers, resulting in improved system performance. In the MATLAB/SIMULINK environment, the controller's performance on the system is modelled and simulated.**

Keywords— Active *power regulation, single-phase grid, reserve fraction, PV panel, fuzzy logic controller, maximum power point (MPP), power regulation*.

I. INTRODUCTION

Addressing environmental concerns associated with fossil fuels requires the utilization of renewable energy sources to meet the continuous escalating demand. Wind turbines and solar photovoltaics stand out as highly promising technologies in this regard. However, to optimize their performance across diverse operational conditions, effective power control strategies are indispensable, but in a variety of operational environments, effective power control strategies are crucial to maximizing their efficacy. Finding a way to regulate the frequency steadily in grid-connected, single-phase solar systems without using energy storage devices is the main objective of this research. Traditionally, a PI controller's ability to regulate real power injection is dependent on a reserve percentage that the plant operator supplies. However, alternative methods must be explored due to the PI controller's slow reaction time. As an extension strategy to improve system performance, this study investigates the implementation of a fuzzy logic controller (FLC).In grid integrated PV systems, the FLC enhances power quality and frequency management with its faster response times and better dynamic response compared to the PI controller. To validate the efficacy of the FLC, the controller is modelled and simulated and is compared with the conventional PID controller. The increasing importance of renewable energy sources in addressing environmental concerns makes solar photovoltaic (PV) system grid interconnection imperative. The functioning of a fuzzy logic controller is implemented on a single-phase grid-interfaced photovoltaic system with a power regulation scheme. The primary objective is to optimize the electricity output while maintaining reliable grid connectivity. Through simulated experiments, it is to evaluate how well the FLC performs in terms of improving power quality, grid stability, and energy efficiency when compared to traditional control approaches. Through enhanced control algorithms in grid-connected PV systems, this research advances sustainable energy solutions.

Analysis of grid-connected solar panels has been done by many authors. In [1-3] The study shows that the solar energy calibre of the Tibetan Plateau is enormous, even exceeding certain top-of-the-atmosphere estimations. Even with clouds and aerosols present, which can lower yearly radiation by 3–6% and up to 23% combined, the reduction is negligible when compared to other parts of the world. This emphasizes how well-suited the plateau is for the growth of solar energy, providing a viable path to supplying future energy demands while reducing CO2 emissions. Two different kinds of grid-connected solar panel power converters are examined in this study. In [4-5] They compare the efficiency of these converters with various control schemes. They discover that a particular kind, dubbed CSI7, requires an additional part but is superior at cutting down on wasted energy and enhancing performance. In [6-8] By adding virtual inertia, the PV-Virtual Synchronous Generator (PV-VSG) assists PV systems without energy storage in contributing to grid stability. They present the Active Power Reserve, which reserves power for frequency modulation using a variety of techniques. With the help of these techniques, PV stations can support grid stability without requiring intricate management. Simulation findings validate their efficacy. In [9-11] This study describes a transformer less dual-buck, semi-two-stage ground type grid-connected inverter for photovoltaic (PV) systems. Common mode leakage current is eliminated via the ground topology, which connects the PV's negative terminal to the neutral of the grid. This gets around the stray capacitance of the PV. The DC-link is shielded from short circuits by the dual-buck based architecture, which increases resilience. Multi-level features are provided by the semi-two-stage architecture, which lowers the forward voltage drop and reduces the dv/dt. Higher efficiency and reliability are achieved with this design in comparison to traditional two-stage inverters. High efficiency and low leakage currents are demonstrated by the experimental findings from a 1.5kW prototype. In [12-14] Through output reduction, the PV system keeps part of its power up/down capabilities. Nevertheless, energy is lost and the reserve power is not utilised effectively. In [16-18] Grid-connected PV systems should use MPPT to optimise energy production. Encouraging additional PV installations necessitates improving rules and power control mechanisms to prevent negative effects from PV systems, like burden on the grid. In [19-20] A novel method that offers simplicity, speed, and accuracy for precisely determining a solar array's maximum power point is presented in the work. The efficacy and feasibility of the REC-AE220 solar modules have been verified by simulation and experimental results. In [21-22] Using a fuzzy controller and a unique kind of converter, this research provides a novel approach to maximise power production from a photovoltaic (PV) system. It ensures that the PV system produces as much as possible of power by adjust the converter's parameters in response to sunlight. This technology tops typical approaches, as shown by experiments and simulations.

II. MATHEMATICAL MODELLING

A. *Active Power Regulation Scheme Proposal*

The control methodology employed to align the power generation of the solar photovoltaic lay out with the requirements of the electrical grid is commonly referred to as active power regulation. This strategy is specifically designed for solar PV systems that are interfaced to the grid. The stability and reliability of the grid can be maintained by managing the power supply, thereby enabling the solar photovoltaic (PV) system to achieve its MPP. An algorithmic control scheme, such as the Fuzzy Logic Controller (FLC), is employed in an real power regulation scheme to consistently monitor the operational attributes of the solar photovoltaic (PV) array and make necessary adjustments to the power output . The FLC considers various factors to ascertain the most feasible operating position for the PV array, including temperature, load demand, and solar radiation levels. The implementation of an active power regulation scheme has numerous benefits, including the enhancement of the complete functioning of the PV system. The technology can enhance the energy output of the solar PV system by allowing the array to run at its MPP. The maintenance of power supply dependability and the prevention of grid disruptions are contingent upon this factor.

Active power regulation is a control mechanism utilized to adjust the output of a grid-connected solar photovoltaic (PV) array in accordance with the requirements of the grid. The primary objective of active power regulation is to maintain equilibrium and dependability of the electrical grid, while simultaneously enabling the solar PV system to function at its maximum power point. In order to monitor the performance of the solar photovoltaic (PV) array and make necessary adjustments to the power output, real power regulation schemes frequently employ algorithmic control systems such as the Fuzzy Logic Controller (FLC) [23]. The Finite Loss Curve (FLC) considers multiple variables, including temperature, load demand, and solar radiation levels, to ascertain the most feasible operating position for the photovoltaic (PV) array. An active power regulation scheme offers a significant benefit by enhancing the overall performance of the solar photovoltaic (PV) system. By optimizing the power output of the solar photovoltaic (PV) array at its MPP, this methodology has the potential to enhance the energy yield of the array. In order to provide uninterrupted electricity supply and prevent grid failure, this is important. The Control scheme for a two-stage, single-phase solar system that is grid-connected is depicted in figure 1.

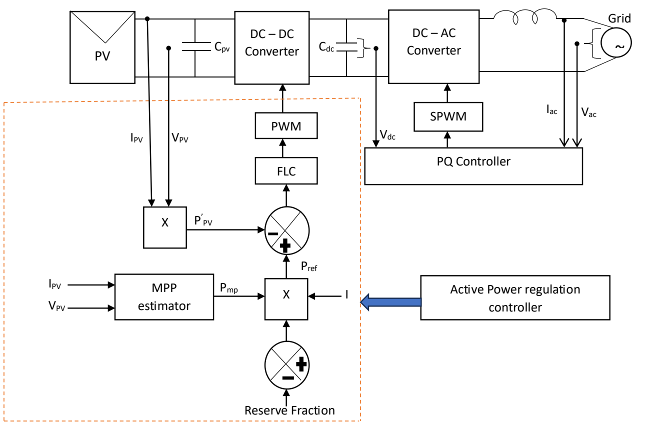

Fig. 1 Control scheme for a two-stage, single-phase solar grid-connected PV system

The principle of real power regulation is to follow the solar PV array's maximum power point by regulating the duty cycle of a DC-DC boost converter. To transfer power to the grid efficiently, the boost converter was used to adjust the output voltage of the PV array so that it matches the grid voltage. The following formula is used to determine the PV array's power output:

$$P_{out} = V_{mpp} \times I_{mpp} \tag{1}$$

The voltage and current at the maximum power point (MPP) are denoted as V_{mpp} and I_{mpp} respectively. An approximation of the voltage at the MPP is:

$$V_{mpp} \approx V_{oc} - I_{mpp} \times R_{pv} \tag{2}$$

PV array's open-circuit voltage is denoted by V_{oc}, and its equivalent series resistance is represented by R_{pv} . An approximation of the current at the MPP is:

$$I_{mpp} \approx \frac{V_{oc}}{R_{pv}} \tag{3}$$

The duty cycle of a boost converter D, is computed with the following formula:

$$D = \frac{V_{in} - V_{mpp}}{V_{in}} \tag{4}$$

where V_{in} is the converter's input voltage and the boost converter's power output as follows:

$$P_{boost} = V_{in} \times I_{boost} \tag{5}$$

where the converter's output current is represented by the expression I_{boost}. The inverter's power output, represented by P_{out}, can be computed as follows:

$$P_{out} = \frac{P_{boost}}{\eta_{inverter}} \tag{6}$$

where grid-tied inverter $\eta_{inverter}$ is the inverter's efficiency.

B. Maximum power point (MPP) estimation

In order to maintain optimal power generation in photovoltaic (PV) systems, Maximum Power Point Tracking (MPPT) is essential for continuously modifying the solar panels' operating point. The PV system functions most effectively at its maximum power point (MPP), which maximizes power output under specific circumstances including temperature and sunshine intensity. Algorithms are used to track the MPP in real-time during estimation. The Perturb and Observe (P&O) approach is one popular algorithm.

A one-diode model is the most popular type of PV stack. The output current and output voltage relationship can be expressed as [10]:

$$I = I_{ph} - I_s\left(exp\left(\frac{V + R_s I}{naV_t}\right) - 1\right) - \frac{V + R_s I}{R_P}. \tag{7}$$

The PV output voltage and current are denoted by I and V, respectively. A semiconductor's thermal voltage is represented by V_t, its p–n junction quality factor by a, its dark current by I_s, and its produced current by I_{ph}. The series and parallel resistances of the module are denoted by Rs and R_p, respectively. Lastly, the number of series-connected cells in the module is indicated by n.

At the MPP, there is no power derivation in relation to voltage. Consequently:

$$I_m = \frac{(V_m I_s/naV_t)exp((V_m + R_s I_m)/naV_t) + V_m / R_p}{1 + (R_s I_s/naV_t)exp((V_m + R_s I_m)/naV_t) + \frac{R_s}{R_p}} \tag{8}$$

Ignoring the impact of tiny and big resistances, R_s and R_p respectively, is one technique to get around this problem. Thus, (1) and (2) may be rephrased as:

$$I_1 = I_{ph} - I_s\left(exp\left(\frac{V_1}{naV_t}\right) - 1\right) \tag{9}$$

$$\boldsymbol{I_{1m}} = \frac{V_1 I_s}{naV_t}\, exp\left(\frac{V_{1m}}{naV_t}\right) \tag{10}$$

where I_1 and V_1 stand for the ideal current and voltage at the module terminals. The MPP voltage and current of the ideal model are, respectively, V_{1m} and $\boldsymbol{I_{1m}}$. Apparently, (9) and (10) are much simpler to solve. In order to identify an analytical fix, X is defined as:

$$X = \frac{V_{1m}}{naV_t} \tag{11}$$

The following equation is found by substituting $\boldsymbol{I_{1m}}$ in (8) from (9) while taking (11) into consideration:

$$(X + 1)exp(X) = \frac{I_{ph} + I_s}{I_s} \tag{12}$$

Since I_s is significantly less than I_{ph}, it can be disregarded in the nominator. Thus, X solution is:

$$X = W\left(\frac{I_{ph}\exp(1)}{I_s}\right) \tag{13}$$

where the following function is the inverse of the Lambert function, represented by the letter W:

$$y = xexp(x). \tag{14}$$

The simplified-module model's MPP can be found by using equations (13) and (14).

$$V_{1m} = naV_t\left(W\left(\frac{I_{ph}\exp(1)}{I_s}\right) - 1\right) \tag{15}$$

I_{ph} in (15) can be calculated using SCC in the following way:

$$I_{ph} = I_{sc}\frac{R_s + R_p}{R_p} \tag{16}$$

There is insufficient accuracy in (15). By accounting for the current flow in the parallel resistor and the voltage drop across the series resistor, (15) can be made much more accurate. Consequently, using the following formulas, the system MPP parameters may be determined:

$$I_m = I_{1m} - \frac{V_{1m}}{R_p} \tag{17}$$

$$V_m = V_{1m} - \left(I_{1m} - \frac{V_{1m}}{R_p}\right)R_s \tag{18}$$

To assess how successful the suggested approach is, η is defined as:

$$\eta = \frac{V_m I_m}{P_{m-real}} \times 100 \tag{19}$$

C. PQ Controller

Power quality controllers (PQ controllers) manage active and reactive power flow in power systems to meet specified criteria. They utilize proportional-integral (PI) controllers to adjust power converters and inverters' output based on error between measured and reference values. This ensures system voltage, frequency, and power factor stay within predefined bounds, improving energy efficiency and reliability while reducing voltage-related issues. A PI controller's transfer function is shown as follows:

$$G_c(S) = K_p + \frac{K_i}{s} \tag{20}$$

The following formulas can be used to represent the PQ controller's active and reactive power output:

$$V_g = \begin{bmatrix} V_\alpha \\ V_\beta \end{bmatrix} = \begin{bmatrix} V(\omega t) \\ V\left(\omega t + \left(\frac{\pi}{2}\right)\right) \end{bmatrix} \tag{21}$$

$$I_{load} = \begin{bmatrix} I_\alpha \\ I_\beta \end{bmatrix} = \begin{bmatrix} I(\omega t) \\ I\left(\omega t + \left(\frac{\pi}{2}\right)\right) \end{bmatrix} \tag{22}$$

The instantaneous real power ($P_{\alpha\beta}$) and reactive power ($Q_{\alpha\beta}$) are then defined by the pq theory in terms of the α–β components as:

$$P_{\alpha\beta} = V_\alpha I_\alpha + V_\beta I_\beta \tag{23}$$

$$Q_{\alpha\beta} = V_\beta I_\alpha - V_\alpha I_\beta \tag{24}$$

According to pq theory, the reference current in the α–β coordinate is given by:

$$I_{REF(\alpha,\beta)} = \frac{1}{V_{\alpha,\beta}^2}\begin{bmatrix} V_\alpha & -V_\beta \\ V_\beta & V_\alpha \end{bmatrix}\begin{bmatrix} P^* \\ Q^* \end{bmatrix} \tag{25}$$

In this $V_{\alpha,\beta}^2 = V_\alpha^2 + V_\beta^2$ where Q* is the reference reactive power and P* is the reference real power calculated by adding P_{mpp} and $P_{\alpha\beta}$.

D. Fuzzy Logic Controller

A precise mathematical model is not necessary for the operation of the fuzzy logic controller (FLC), and it is able to successfully manage nonlinearity and implicit inputs. Fuzzy also outperforms the norm for non-linear controllers. There are four components: the inference method, the rule basis, fuzzification, and defuzzification. In this inquiry, FLC is fed the error, E, and the change in error, CE, at sample time k, which are specified by equations (26) and (27). The duty cycle D, Equation (1,2), is the output of an FLC. The following two input factors are identified by:

$$E(K) = \frac{P(K) - P(K-1)}{V(K) - V(K-1)} \tag{26}$$

$$CE(K) = E(k) - E(K-1) \tag{27}$$

A PV module's voltage and power are denoted by V(k) and P(k), respectively.

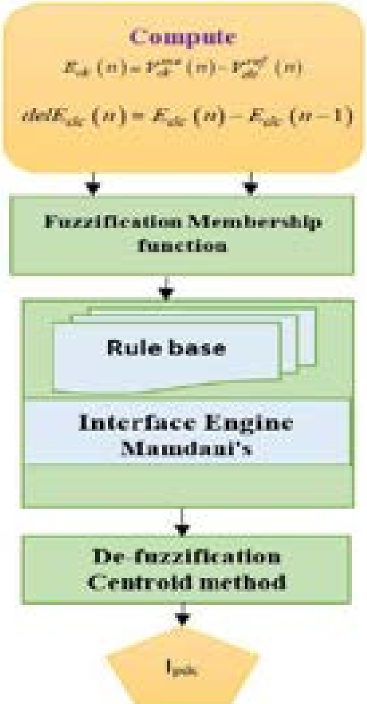

Fig 2.Fuzzy Logic Controller

There are three steps in the fuzzy controller:

1. *Fuzzification:*
   Fuzzification is a crucial stage in fuzzy logic controllers, allowing the interpretation of imprecise or ambiguous data by converting exact inputs into fuzzy sets, or degrees of membership. By handling inputs such as human language descriptors, this approach makes control systems more adaptive and makes reasoning with ambiguous data easier.

2. *Inference method:*
   Fuzzy logic controllers (FLCs) utilize fuzzy inference, with the Mamdani method emphasizing linguistic interpretability in its fuzzy outputs, while the Sugeno method prioritizes computational efficiency by producing crisp numerical results. The option between the two methods depends on the specific requirements of the control problem, balancing interpretability and computational speed.

TABLE1: FUZZY INFERENCE

E / CE	NB	ZE	PB
NB	PB	NS	NB
ZE	PS	ZE	NS
PB	NB	ZE	ZE

3. *Defuzzification:*
   Defuzzification is the process of turning a fuzzy inference system's fuzzy output into an exact numerical value for system control or decision-making, making sure fuzzy logic controllers can function properly in practical settings.

III. SOLAR PV MODULE OPERATION

In order to convert sunlight into energy for use in both home and commercial lighting systems, solar photovoltaic (PV) modules, which have wattages ranging from 50 to 350, are essential. They are made of semiconductor materials such as crystalline silicon and have 1-2 watt photovoltaic cells coupled to each other. By lowering dependency on fossil fuels, lessening their negative effects on the environment, and allowing excess energy to be reinjected into the system, these modules improve energy efficiency and advance a decentralized energy infrastructure. Solar cells have a special part called a p-n junction that separates charges, creating electricity. This electricity can power various things. Solar panels, made of many cells, are connected together to make more power and can be placed on buildings or structures.

Fig 3.solar pv panel

IV. SIMULATION RESULTS

A 250 Wp solar PV system's proposed MPP estimator and controller is tested using a Matlab/Simulink model of the overall block diagram depicted in Fig. 1. In order to conduct the simulation study, the key system parameters are listed in Table 1. By running simulations of the three cases shown in the table, we can confirm that the proposed method works as intended.

.

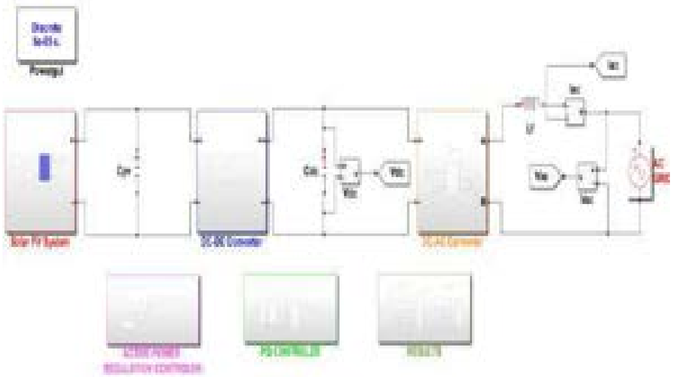

Fig 6. Two-stage grid-connected single-phase solar-PV system with control logic

First, the controller's transient reaction is tested in a range of environmental factors, including temperature and radiation. The actual grid-injected .Power was simulated under different radiation conditions with a fixed panel temperature of 25 °C and a 0% reserve fraction. As shown in Fig. 8, Following the proposed method, the inverter would inject the same amount of power into the AC grid as the predicted maximum power related to the irradiation.

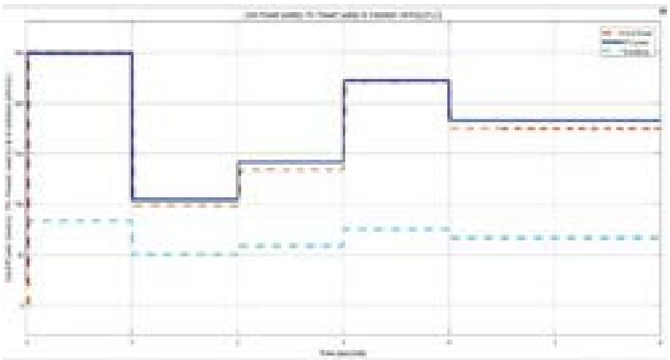

Fig 7. Variation in grid power and maximum power estimation under different radiation conditions at 25 °C with no reserve fraction

Changes in radiation levels and the zero reserve fraction cause variations in the MPP and grid-injected electricity. Figure 9 displays the temperature plot. When this occurs, the tracking speed of the controller is sufficient to determine the MPP and transmit the result to the grid.

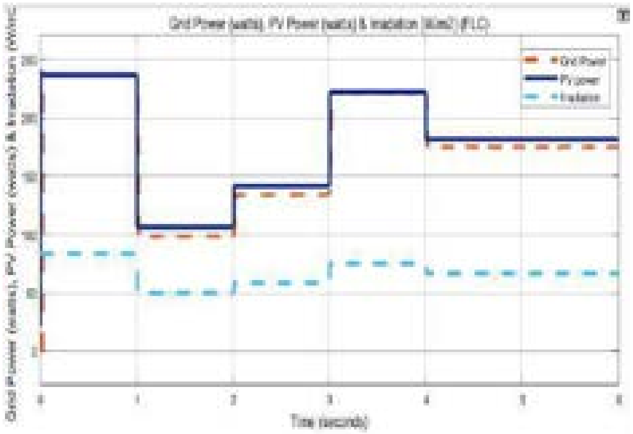

Fig 8. Variation in grid power and maximum power estimation at different temperatures and radiation levels with 0% reserve fraction

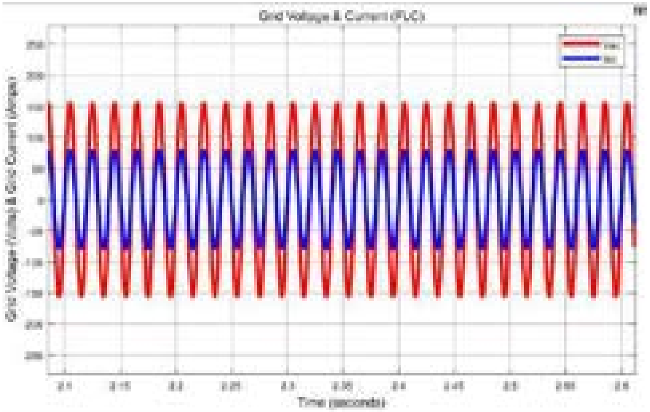

Fig 9. Voltage and current injected into the grid under various radiation circumstances at 25 °C without reserve fraction

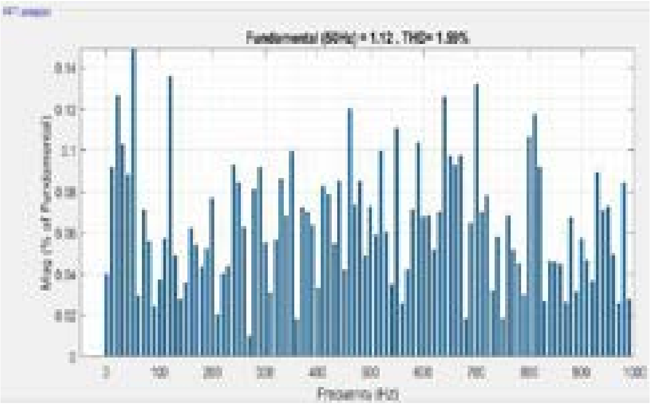

Fig 10.Total Hormonic Distortions in the system

V. CONCLUSION

Lastly, a power regulation scheme and a fuzzy logic controller (FLC) significantly improved the overall efficiency of the two-stage, single-phase, grid-connected solar PV system, according to the performance analysis. The FLC regulates power flow efficiently, which guarantees a seamless energy conversion process and grid integration. The two-stage setup increases control and durability over a wide range of weather conditions. Power quality, stability, and reduced fluctuations are all enhanced by the proposed approach, according to extensive simulations and analyses. The FLC's ability to adapt to changing solar conditions makes it a crucial component in maximizing energy extraction and grid integration. In conclusion, this study shows that FLC-based control techniques have promising potential for improving the performance of grid-connected solar PV systems.

***Abstract*— In recent years, the usage of digital files has increased and therefore data theft has also increased. Traditional centralized platforms often suffer from vulnerabilities such as single points of failure and lack of transparency. In response, decentralized technologies such as Interplanetary File System (IPFS) and blockchain have emerged as promising solutions. This research study presents a novel decentralized platform built upon the Solana blockchain and IPFS, designed to address the shortcomings of centralized systems. The proposed platform uses the transparency and immutability of the Solana blockchain network to provide a secure ledger for file verification. In addition to verification, the platform facilitates seamless sharing of digital files among users through IPFS, a distributed file system. By utilizing IPFS's decentralized architecture, data is stored across a chain of nodes, eliminating a single centralized server. It not only enhances data resilience and availability but also mitigates the risk of censorship and data manipulation. This paper proposes using Solana blockchain instead of traditional Ethereum blockchain for better scalability because Solana supports more than 2000 TPS (transaction per second) and reduced network fee.**

Keywords*— *Blockchain; File Sharing; Solana; Smart Contracts; Inter Planetary File Storage

I. INTRODUCTION

In today's digital era, the proliferation of data and the increasing need for secure and efficient file sharing mechanisms have propelled the exploration of decentralized technologies. The emergence of blockchain technology has revolutionized various industries by offering immutable, transparent, and decentralized solutions to long-standing challenges. Among these challenges, the verification and sharing of digital files stand out as crucial areas where traditional centralized systems often fall short in case of efficiency, trustworthiness and security.

The use of Solana network and IPFS presents a promising solution to address the challenges associated with centralized file verification and sharing systems. By decentralizing the storage and verification process, the platform eliminates single points of failure, enhances data integrity, and fosters trust among participants without the need for intermediaries. Furthermore, the use of smart contracts on the Solana blockchain enables the automation of file verification processes, ensuring transparency and immutability throughout the lifecycle of digital files.

A. History

File storage and sharing have evolved a lot since the advent of computers. Initially, files were stored on physical media such as floppy disks and later, hard drives. However, with the rise of the internet, the concept of file sharing underwent a drastic change. Peer-to-peer (P2P) file sharing emerged as a prominent concept, allowing users to share files directly between their computers. This was followed by the introduction of centralized file storage and sharing services like Napster, which revolutionized the music industry by enabling users to share MP3 files online. However, legal challenges led to the decline of Napster and the rise of decentralized alternatives like BitTorrent. The early 2000s saw the emergence of cloud storage services such as Dropbox, Google Drive, and Microsoft OneDrive. These platforms offered users the ability to store files remotely and access them from any device with an internet connection. As internet speeds improved and storage costs decreased, cloud storage became affordable, transforming the way individuals and businesses manage their data. Today, file storage and sharing continue to evolve with advancements in technology such as blockchain-based decentralized storage solutions and the integration of artificial intelligence for more efficient file organization and retrieval.

B. Motivation

The reason behind developing Solana powered file storage and sharing system is to develop a decentralized platform that leverages the power of Solana blockchain and IPFS for digital file verification and sharing. Solana blockchain is known for its high throughput and low transaction costs and it provides a robust infrastructure for maintaining a secure and scalable ledger of file transactions. On the other hand, IPFS offers a decentralized and distributed file system, enabling data to be stored and accessed from a decentralised network and also ensures redundancy.

Furthermore, the integration of Solana network and IPFS transcends the problems of traditional storage systems by developing an ecosystem that prioritizes user autonomy and data sovereignty. By empowering users with control over their files and eliminating single points of failure, the platform fosters a resilient digital infrastructure that is inherently resistant to censorship and manipulation. Conceptually, integrating blockchain into a file sharing system allows for several key benefits. First, blockchain provides a decentralized storage mechanism for metadata such as file ownership, access permissions, and transaction history. Each transaction (e.g., uploading a file, sharing with another user, granting access) can be recorded as a transaction on the blockchain, creating a transparent and auditable record of file-related activities. This transparency enhances trust among participants in the file sharing network. Additionally, blockchain's consensus mechanism ensures that the recorded transactions are tamper-resistant, providing a high level of security and integrity to the file sharing system. Furthermore, blockchain-based smart contracts can automate and enforce rules governing file sharing, ensuring that access permissions are managed efficiently and securely without relying on a central authority.

C. *Objectives*

The main objective of this project is to explore the development and implementation of a decentralized platform for digital file verification and sharing utilizing the Solana blockchain and IPFS (Interplanetary File System). The project elucidates the potential benefits of utilizing Solana blockchain and IPFS technologies in the context of digital file management.

D. *Scope And Application*

The scope of the Decentralized Platform for Digital File Verification and Sharing utilizing Solana Blockchain and IPFS is to enable secure and immutable verification of digital files, leveraging the speed and scalability of Solana Blockchain. Its application spans across sectors requiring transparent and tamper-proof data sharing such as healthcare, supply chain, and legal sectors. Through IPFS integration, it ensures efficient and decentralized file storage, improving censorship resistance and data integrity. This platform empowers users with trust-less verification mechanisms and seamless sharing capabilities, enhancing data reliability and accessibility in a decentralized ecosystem. The Platform considers various security issues such as Data Privacy and Confidentiality, immutability, Data Integrity.

II. TERMINOLOGY

A. *ReactJS*

React.js is an open-source solution for developing frontend interfaces that helps developers to make web applications efficiently.

B. *Smart Contract*

A smart contract is a self-executing contract with the terms of the agreement between two or more parties directly written into code. It operates on a blockchain, such as Solana, and automatically enforces, verifies, or facilitates the negotiation and performance of a contract.

C. *Transaction*

In web3, a transaction represents a digital interaction on a blockchain, involving the exchange of data or value between participants, often secured by cryptographic signatures and recorded on a public ledger.

D. *Proof of History Mechanism*

It is a novel consensus mechanism which uses timestamps and order of events for validation of transaction. It is very fast as compared to proof of work algorithm.

E. *Solana*

Solana is an innovative blockchain platform, it allows fast transactions as compared to other blockchains. It also have low fees and high efficiency which lowers wait time. It uses a consensus mechanism called Proof of History.

III. LITERATURE REVIEW

This section contains the prior research that has been done on Blockchain and File sharing.

A. *Related Work*

In research [1], the authors investigated the utilization of decentralised ledger technology for data storage, emphasizing its potential to offer secure and decentralized solutions. They highlighted blockchain's ability to reduce data leaks and unauthorised access, while concurrently making sure that availability of service is not affected. With the help of decentralised technology and its features, like immutable ledger and distributed network nodes, the study underscores its role in enhancing the security and reliability of file storage systems, thereby addressing critical concerns in data management and privacy.

In research [2], the authors investigated the potential applications of distributed ledger technology in decentralized data maintenance and retrieval. They proposed its capability to establish immutable methods for data transfer and retrieval. By leveraging blockchain's immutable ledger and decentralized nature, the study suggests a promising solution to enhance data security and integrity while facilitating efficient sharing across distributed networks.

In research [3], the authors investigated data management systems which can be used for decentralised ledger technology, analysing their features and limitations. They explored various use cases and discussed future directions for these systems, highlighting their potential impact on decentralized applications and distributed data storage.

In research [4], the authors introduced a proof of delivery protocol utilizing smart contracts and blockchain technology. They proposed a mechanism where participating entities, including the owner and file server, receive incentives as rewards upon successful content delivery to the customer. This protocol aims to enhance transparency and reliability in digital content distribution while incentivizing stakeholders for their contributions.

In research [5], the authors presented a novel approach to file sharing and access control utilizing blockchain technology and smart contracts. Their solution employed a private decentralised network to maintain and administer data, with access policies validated through contracts. By integrating blockchain's immutable ledger and smart contract capabilities, the system offers enhanced security and transparency in managing access to shared files, addressing critical concerns surrounding data privacy and authorization.

In research [7], the authors analyse how distributed ledger technology enhances affects the privacy of data being stored in the ledger. In research [8], the authors introduces a distributed data storage platform for cloud computing.

Some researchers have discussed about IPFS that aims to create a more resilient and censorship-resistant web infrastructure. It converts data into hash so that it can be shared across a decentralized network of nodes, reducing reliance on centralized servers. They also have addressed security issues in blockchain-based systems, including data confidentiality and authentication. Additionally, privacy-preserving techniques like ZKP has been used to improve user's data security in decentralized environments .efficiently

B. Challenges and Limitations

The Platforms which uses Ethereum faces several challenges and limitations. One significant challenge is scalability. Its current design struggles to handle high transaction volumes and processing speeds required for efficient file sharing applications. As a result, network congestion and increased transaction fees often affect the seamless sharing of files on the platform. Moreover, Its proof-of-work consensus mechanism contributes to high energy consumption, which raises concerns about sustainability and environmental impact. The centralized file sharing platforms also have their limitations. One limitation is data privacy and security. Centralized platforms store user data on centralized servers, making them vulnerable to hacking attacks and unauthorized access. Users have limited control over their data, relying heavily on the platform provider to safeguard their information.

IV. PROPOSED ARCHITECTURE

As shown in Fig.1, The architecture of the application is designed to provide a secure and transparent method for sharing files between parties. At the core of the architecture is the Solana Blockchain, which serves as the underlying network for storing the validation logic and maintaining a tamper-proof ledger of file-sharing transactions. Also, the Smart contracts deployed on the Solana Blockchain handle the validation of file-sharing requests, ensuring that only authorized users can upload and access files. These smart contracts enable access control rules and update the blockchain ledger with records of each transaction, providing an immutable and transparent history of file sharing activities. The frontend of the architecture is responsible for providing a user-friendly interface for the user to upload files. Built with React, the frontend allows users to initiate file-sharing requests and interact with the system seamlessly. When the user uploads a file through the frontend, a request is routed to the contract algorithm on the Solana network, including a hash of the file as a unique identifier. This hash serves as an identity and reference point for retrieving the file from IPFS, the decentralized storage network used in the architecture. IPFS, is leveraged for the storage of the uploaded data. Decentralized storage space refers to the

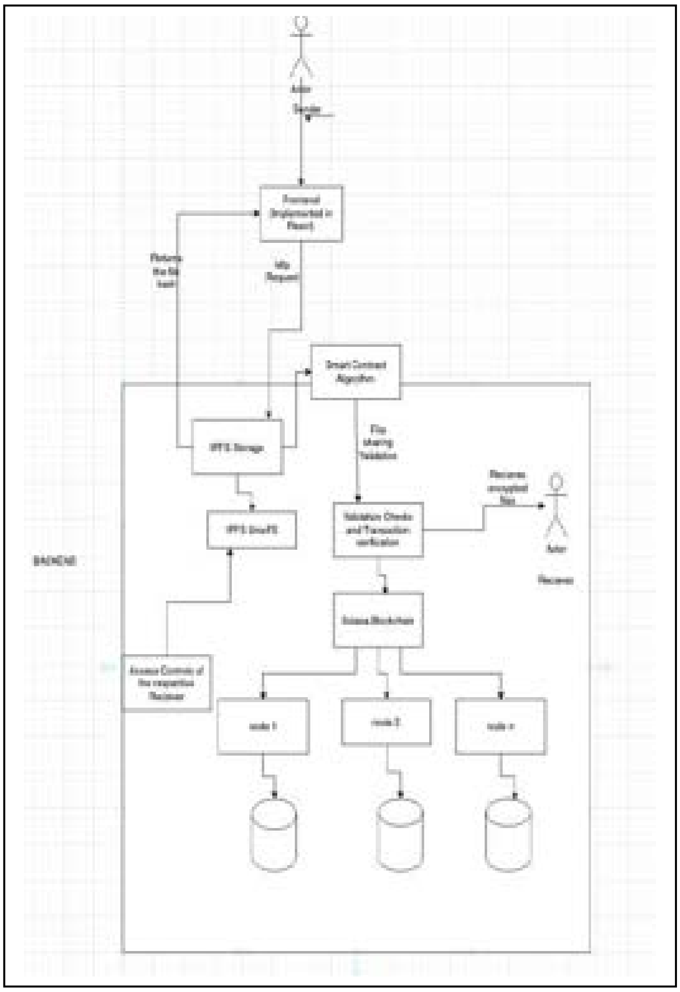

Fig 1. Proposed Architecture

storage of data across a network of nodes (computers) that collectively maintain and manage the data without relying on a central authority. Instead of using a traditional centralized server, data is stored in a decentralized fashion across multiple nodes.

When the smart contract validates the file-sharing request, the file is encrypted [10] and stored in IPFS, ensuring data security and integrity. IPFS uses a peer-to-peer network for storing and sharing data, eliminating the need for a central server, providing fault tolerance and less failure Additionally, user access rules are checked by the Solana contract which grants the Receiver access to the file based on predefined permissions. Overall, the architecture combines the immutability of the Solana Blockchain with the decentralized storage capabilities of IPFS to create a robust and transparent system for decentralized file sharing.

Solana's architecture is designed to process thousands of transactions per second (TPS). By utilizing a combination of PoH, a high-performance consensus mechanism (Proof of History), and parallel transaction processing, Solana achieves fast confirmation times. This rapid throughput significantly reduces transaction latency and improves the reliability of transaction finality. Solana maintains a decentralized network of validators (or nodes) that participate in the consensus process.

This distributed architecture enhances security and resilience against attacks. Validators work together to validate transactions and secure the network, ensuring the reliability of the blockchain. Solana leverages a technique called Transaction Processing Units (TPUs) to enable parallel transaction processing. The network is divided into multiple nodes, each responsible for processing a subset of transactions concurrently. This parallelism significantly increases the overall throughput of the network.

In an IPFS-based system, file sharing operates through a decentralized network where files are stored and accessed using a content-addressable method. When a user wants to share a file, the file is segmented into smaller chunks, and each chunk is assigned a unique cryptographic hash based on its content. These chunks are then distributed across multiple nodes (or peers) in the IPFS network. When another user requests the file, their IPFS client sends out requests to retrieve the specific chunks using their corresponding hashes. The IPFS network locates and retrieves these chunks from the nearest or most efficient nodes, taking advantage of the distributed nature of the system. Once all the chunks are retrieved, the file is reconstructed on the user's device. The metadata is uploaded to server and broken into number of fragments [9]. This method ensures efficient and resilient file sharing, as files are not dependent on a single server or location but are instead distributed across the network, leveraging the resources of participating nodes for storage and retrieval. This helps in securing Personal data from attacks [13].

V. MODULES

A. *Secure File Upload Module*

Users can upload the files and the file is encrypted into a hash by the IPFS storage and the files can only be decrypted by the user.

B. *Secure File Sharing Module*

Users can share the files with other user with the help of user name and this transaction is handled by smart contract.

C. *Access Control Module*

Sender can control who have the access to the file and allow only required people to access the file.

D. *Content ID Generation Module*

A content identifier is generated for all the user uploaded data which helps in access the data. The actual address is not shared instead a representational address is formed using the data information.

E. *User Registration Module*

Users can create their profile and a public key is also generated for the user for secure file sharing.

F. *Secure File Storage Module*

Users can store their files on the decentralised network, these files are stored securely using hashes and only the user with access can decrypt it.

G. *User Profile Module*

Users are able to see their unique public key and user ID. Also, Users can see uploaded and shared files on the dashboard

VI. IMPLEMENTATION

The proposed application combines front-end developed using React, and smart contract developed in Solidity for IPFS storage on the Solana network.

A. *Frontend*

The frontend implementation of the application is done using React, to provide a seamless and secure user experience. Using React, project have an intuitive user interface that allows user to upload files and share them with anyone. Axios client is used to communicate with the smart contract and wallet connection. Through a well-structured redux store, the application's state is managed efficiently. React hooks are used for state management in a single component.

Using react helps us in rapid application development, thus reducing the development time. React provides large set of libraries of pre-built modules which can be easily integrated in the application.

B. *Algorithm for integration with IPFS and Solana*

With the help of IPFS for decentralized storage, the application can hash files and store them across a distributed network, ensuring redundancy and resilience against data loss. Each file's unique hash acts as its identifier, facilitating efficient retrieval and verification. Also, integrating Solana Blockchain enables secure transaction processing and consensus mechanisms. Smart contracts are utilized to govern file verification and sharing protocols, ensuring transparency and immutability. With Solana's high throughput and low-latency capabilities, transactions are swiftly validated, enhancing the overall user experience.

As shown in Fig 2, the algorithm is designed to facilitate decentralized file sharing [11] on the Solana network with the help of managing URL storage and access control among users. It uses mappings and data structures to handle user ownership, access permissions, and users access data. Key functions are add, allow, disallow, display, and share-access. The add function enables users to append URLs to their personal storage, while allow and disallow functions manage access permissions by updating ownership mappings and access lists. The display function retrieves URLs of other users if access is granted, promoting controlled sharing, while share-access allows users to view their own access permissions. Together, these functions provide a framework for secure and transparent file sharing while maintaining user privacy and control over shared data.

Fig 2. Algorithm

C. Backend

The backend of the application is built on a Solidity and JavaScript. This provides data security, scalability, and seamless interactions. In this architecture, Solidity, a smart contract programming language, plays a pivotal role in managing access and by leveraging Solana Blockchain, the backend orchestrates the verification process, ensuring data integrity through its immutable ledger and enabling transparent and tamper-proof record-keeping. Concurrently, IPFS serves as the decentralized storage layer, facilitating efficient and secure file sharing by distributing files across a network of nodes, enhancing redundancy and accessibility.

VII. RESULTS

In this section, the results are shown for each implemented module of the proposed application.

A. User Registration Interface

Fig. 3 depicts the implemented interface, which prioritizes simplicity and clarity so the users scan seamlessly go through the registration process. The first field in the registration interface allows the entry of the username, an identification detail that enables easy and reliable identification within the platform. Users are allowed to select a unique and different username that represent their identity and aligns with any community guidelines or naming conventions established by the platform. Similarly, the password field prompts users to create a secure and memorable password for their account, enhancing the overall security of their user credentials. Users are allowed to create a new password that is made up of a strong combination of alphanumeric characters to minimize the risk of unauthorized access or account compromise.

Upon successfully submitting their registration details, users receive immediate notification confirming their registration and providing them with a unique hashed ID and token. The hashed ID serves as the user's unique identifier within the platform, allowing access to their account and enabling interaction with other users and platform features. Also, the generated token serves as the secure authentication token, granting users access to their account and verifying their identity during subsequent login attempts, further increasing the platform's security measures.

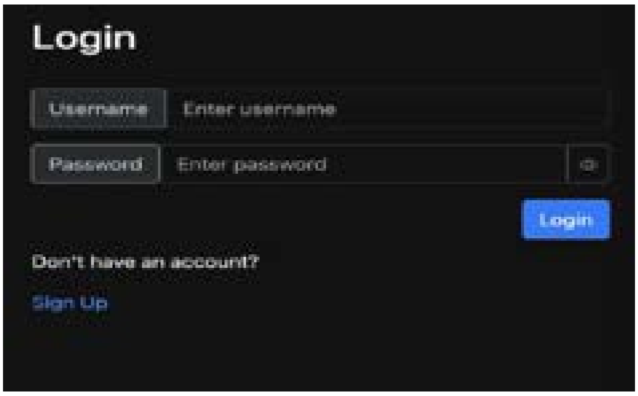

Fig 3. User Registration Interface

B. Content ID Interface

The Content ID (CID) generation as shown in Fig. 4 is generated in IPFS and it involves the creation of unique identifiers for digital content stored on their respective platforms. These CIDs serve as cryptographic hashes that uniquely identify each piece of content, allowing efficient retrieval, verification, and sharing of data within the decentralized network. In this application, the CIDs are generated with the help of smart contract functions. These functions also validate the generated CID and use it as decryption key for the file.

IPFS, or the Inter Planetary File System, uses a content-addressed system for data storage and retrieval. When a sender transfer data to IPFS, it generates a unique CID for that file based on its content. This process involves calculating the cryptographic hash of the file's content using a hashing algorithm. The resulting hash serves as the CID for the file, providing a secure and immutable identifier that uniquely identifies the file within the IPFS network.

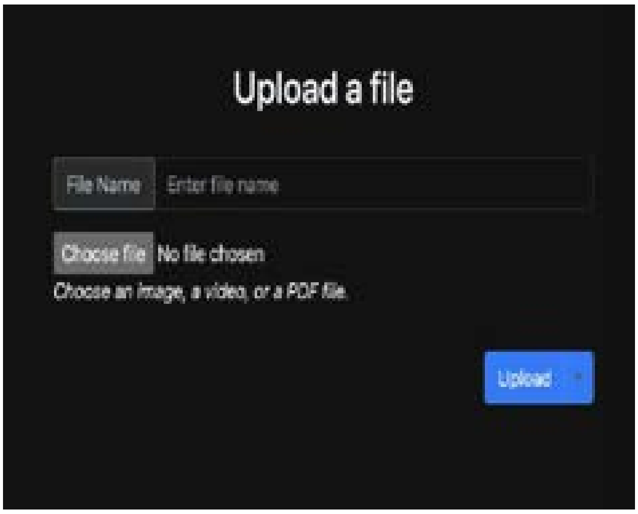

Fig 4. Content ID Generation Interface

C. *Secure File Sharing Interface*

As shown in Fig. 5 , users interact by selecting the file they wish to share from their device. The user interface includes a button for uploading files, allowing users to browse their local file system and select the desired file for sharing. Once the file is selected, the application provides feedback to confirm the successful upload, by displaying the file name and a thumbnail preview of the file. Next, users specify the recipients with whom they wish to share the file.

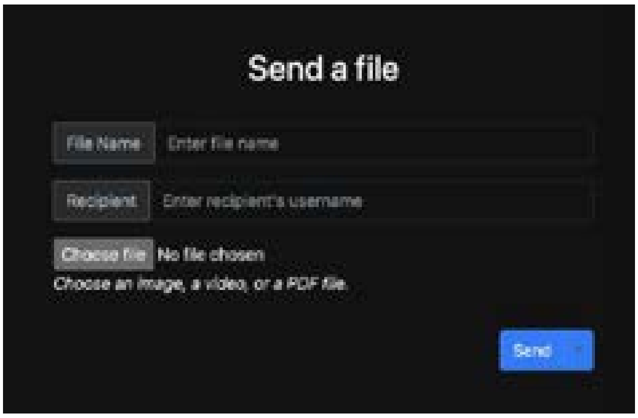

Fig 5. Secure File Sharing Interface

The interface communicates with the smart contract deployed on the Solana blockchain to execute the file sharing transaction. The smart contract verifies the authenticity of the transaction and implements any access control rules specified by the user, ensuring that only authorized recipients can access the shared file. In addition to facilitating file sharing transactions, the interface also include features for encrypting and decrypting shared files to enhance security and privacy. When a sender transfer data for sharing, the UI prompts the user to encrypt the file using their private key or a shared encryption key. The encrypted file is then securely transmitted to the smart contract for storage on the Solana blockchain.

D. *Secure File Storage Interface*

As shown in Fig . 5, the process of secure file storage starts with the user uploading the files on the profile which are then encrypted. This encryption ensures that files remain protected and inaccessible to unauthorized entities. The decentralized storage network IPFS, then distributes these encrypted and hashed files across a network of nodes, eliminating single points of failure.

Fig 6. Secure File Storage Interface

Smart contracts deployed on the Solana blockchain manage the storage and retrieval of file data transparently and securely, implementing access control policies to regulate file access and permissions. Authorized users can securely access files by their accessing their account. The files are shared by the sender to the username defined by the receiver in the application and then the receiver can download them locally using the necessary credentials, ensuring that only authorized individuals can access and modify the file data.

E. *User Profile Interface*

As shown in Figure 6, the user profile displayed on the dashboard exhibits critical information including the username, public key, and user ID. These elements serve as fundamental identifiers for each user within the system. The public key helps in creating a unique identity of the user on the platform facilitating secure transactions and interactions within the platform. Alongside the username, it forms a user ID ensuring the integrity and authenticity of user interactions. Additionally, the user ID serves as an additional layer of verification, enhancing the robustness of the identification process. Furthermore, the utilization of smart contracts on the Solana blockchain introduces a decentralized and tamper-resistant approach to access management.

Fig 7. User Profile Interface

Through the inherent features of blockchain, such as distributed consensus and cryptographic hashing, the system can mitigate potential security vulnerabilities and unauthorized access attempts effectively. Each user's public key serves as a cryptographic signature, ensuring that only authorized entities can interact with the system. As a result, the user profile dashboard becomes a gateway to secure and transparent user interactions, bolstered by the innovative capabilities of blockchain technology.

VIII. CONCLUSION AND FUTURE SCOPE

The proposed decentralized platform for digital file verification and sharing using Solana Blockchain and IPFS presents a solution to address issues of trust and security in file sharing. Also, this solution overcome the limitation posed by Ethereum as Solana is lightweight and allows more transactions per second. By leveraging blockchain's immutability and IPFS's decentralized storage, the platform ensures tamper-proof verification and efficient sharing. Furthermore, the scalability and speed offered by Solana Blockchain enhance the platform's capabilities to handle a vast array of transactions seamlessly. As the use case of the decentralised applications increases, this solution paves the way for a future where digital interactions are governed by transparency, security, and inclusivity, revolutionizing how we validate and share information in the digital realm. The performance developed platform is much better than existing solution because Solana's throughput can exceed 65,000 transactions per second (TPS), significantly surpassing Ethereum's TPS, which typically ranges from 15 to 30 TPS. Latency metrics also favor Solana, with block confirmation times averaging around 400 milliseconds, compared to Ethereum's block confirmation times that can range from 10 to 20 seconds. Additionally, Solana's proof-of-history (PoH) mechanism and Tower Byzantine Fault Tolerance (BFT) consensus algorithm contribute to its speed advantage by enabling parallel transaction processing and reducing the time needed to achieve network consensus. These quantitative metrics demonstrate platform' capability to handle a higher volume of transactions with lower latency compared to Ethereum, making it a compelling choice for applications requiring high-speed and scalable blockchain solutions. However, for the future scope, the platform can be integrated with IOT [6] and home automation devices to make the data transmission more secure. The Application can also be integrated with fintech solutions and EHR applications [12] to improve the adaptation and scale of the application

***Abstract*— This research study intends to solve the severe problem of poikilocytosis, a disorder that causes red blood cells (RBCs) to take on aberrant forms. This system analyzes blood smear images captured with a compound microscope by using sophisticated image processing algorithms. The method's main component is the application of the Faster R-CNN algorithm. It not only recognizes different RBC forms but also classifies them, providing information about possible related illnesses. The method significantly increases the dataset over existing methods while utilizing Faster R-CNN's better efficiency. The erythrocyte and BCCD databases data combines to create this expansion, which includes a wide range of RBC forms. The speed and precision of RBC shape detection is improved for poikilocytosis diagnosis by utilising Faster R-CNN. The larger dataset provides a deeper investigation of the wide variety of RBC forms, increasing the likelihood of finding connections to different blood cell-related illnesses. The main objective of this research study is to present a thorough report that improves patient outcomes, healthcare practices by advancing the diagnosis and knowledge of blood cell-related illnesses. This initiative paves way for better patient care and diagnostic accuracy by supporting continuing efforts to improve healthcare and medical diagnostics.**

Keywords—Blood cell, Poikilocytosis, Faster-rcnn, Image processing

I. INTRODUCTION

Poikilocytosis, the condition in which Red Blood Cells (RBCs) have non-normal forms, is still a crucial problem in the fields of haematology and clinical diagnostics. As possible markers for diverse underlying medical disorders, the unique and varied forms of RBCs linked to poikilocytosis have emerged. It emphasizes the urgent need for an accurate and timely diagnosis to enable successful treatment and improved patient outcomes. The study aims to use state-of-the-art image processing techniques to tackle this desperate problem. The novel method for identifying and classifying RBC shapes is demonstrated through the use of high-resolution compound microscope images of blood smears. Using the state-of-the-art Faster R-CNN algorithm forms the basis of this technique. This advanced method classifies RBCs in addition to identifying their distinctive forms. The main objective is to improve patient outcomes and streamline medical procedures by developing a comprehensive approach to identify and manage poikilocytosis. The target is to improve the accuracy and speed of RBC form recognition by utilizing state-of-the-art image processing techniques. It will help to ensure early diagnosis and effective management. Furthermore, the dataset have been expanded to include an expansive range of RBC types as part of objective. Through the integration of data from the erythrocyte and BCCD databases, a vast reservoir suitable for thorough examination is offered. This enhancement of the dataset allows us to investigate possible relationships between various RBC forms and blood cell-related diseases, improving the understanding of these conditions

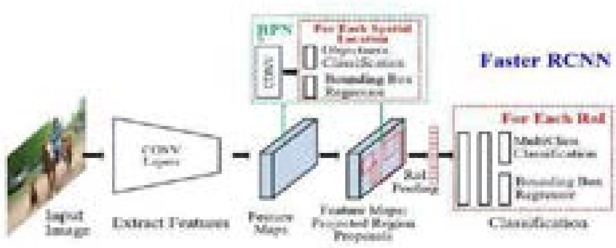

Figure 1. Faster RCNN Architecture

II. LITERATURE REVIEW

The past developments in automated blood counts and associated metrics. These include color normalization, pre-processing techniques, RBC segmentation, and the ability to distinguish between the background and foreground using a variety of segmentation methods based on the core ideas of image processing. To segment Red Blood Cells (RBCs) and deal with clumping, Berge devised morphological iterative threshold approaches. Their method created a Delaunay triangulation using real microscope pictures by using boundary curvatures. Cai et al. suggested a statistical model-based method for determining cell and cytoplasm borders in order to address segmentation issues. Once cells were separated from the cytoplasm, Bayesian classifiers became a popular option for classifying cells according to unique characteristics. Di Ruberto et al. used morphological operators and a watershed algorithm to handle clustered cells while utilizing image processing techniques to detect and identify RBCs infected with malaria. However, this approach frequently produced noisy RBC contours. The complicated properties and similar colors of blood cells made it difficult to separate RBCs from the cytoplasm.

III. METHODOLOGY

The faster R-CNN algorithm, which has been specially designed for better red blood cell (RBC) shape recognition and classification, is the fundamental component of this technique. The proposed system architecture is shown in Figure 1. The methodical process reveals how adaptable the algorithm is at effectively managing a large dataset. In order to capture characteristics indicative of various rbc types, key features are first extracted from pre-processed images. Annotations indicating the rbc forms in each of the pre-processed blood smear images are then carefully created to create a labelled dataset. To enable reliable model generalisation to unobserved data, it is critical to guarantee the representativeness and variety of the dataset. The next crucial step is to choose the right recognition model, which depends on the processing capacity and the difficulty of the task at hand. The selected model should be able to recognise complex patterns and differences in rbc morphology. After the selection of the model, the training phase begins, during which the model is trained to correlate retrieved features with corresponding rbc forms using iterative optimisation techniques such gradient descent. The model is evaluated using independent test data after training to determine how effective it is in real-world scenarios.

A. Blood Sample Acquisition

Blood Cell Count and Detection, or BCCD, is the dataset from which the blood smear images are acquired. For a thorough depiction of the analysis, the dataset offers a wide range of annotated images that include different red blood cell (RBC) morphologies linked to poikilocytosis. To ensure data integrity and relevance to the research's scope, careful selection of photographs is part of the acquisition procedure.

B. Image Processing

The procedures used to clean and preprocess the obtained blood smear images are done in the image processing section. First, a camera-equipped compound microscope is used to take high-quality pictures. To improve their quality, these photos go through preprocessing, which includes things like contrast and noise reduction. The Faster R-CNN algorithm, which was trained on a varied dataset assembled from the erythrocyte and BCCD databases, is then used to detect objects. This algorithm efficiently recognizes and classifies different types of red blood cells (RBCs), offering important information about possible related diseases. A more thorough study is made possible by expanding the dataset, which raises the possibility of finding links between abnormalities of the blood cells and RBC morphologies. After the data have been analyzed, a thorough report is produced that highlights the conclusions and highlights how they will affect patient outcomes and healthcare procedures. The continuing enhancement of patient care and diagnostic accuracy is facilitated by the cooperation of healthcare professionals and the constant improvement of algorithms. In the end, our image processing method improves patient outcomes and improves healthcare practices by contributing to the knowledge of blood cell-related disorders and helping to diagnose poikilocytosis. Steps are taken to improve image quality, fix artefacts, and prepare the dataset for further analysis.

- *Noise Removal*

  A variety of noise reduction techniques are used to remove unwanted artifacts and produce a clear depiction of blood smear photographs. These methods include deep neural networks and other machine learning techniques, together with sophisticated image processing algorithms including filtering and morphological operations. Several techniques are applied to reduce noise in bloodstain photos in order to get rid of unwanted artifacts and enhance clarity. These methods cover a wide range of complex approaches, such as machine learning, deep neural networks, and sophisticated image processing techniques including morphological operations and filtering. By combining these several techniques, the goal is to improve the way blood smear pictures are seen, which will enable more accurate analysis and detection of diseases such as poikilocytosis. This all-encompassing strategy demonstrates a commitment to use cutting-edge technologies to improve medical imaging and hematological diagnosis accuracy

- Median Filtering

  Image clarity is improved as noise is decreased by using median filtering. In order to eliminate undesired artefacts and create better images, noise reduction techniques like deep neural networks and machine learning algorithms are first used. Next, by replacing pixel values with median values from their surrounding neighbourhoods, edge preservation is ensured and noise is reduced through the use of median filtering. To compensate for colour differences, gray-world colour correction is applied. This allows for realistic portrayal of the various rbc types associated with poikilocytosis and consistent colour balance across photos. By fine-tuning the overall brightness and contrast, one may better see minute features that are essential for identifying and classifying rbc forms. Morphological identification methods such as erosion are used to inspect rbc structures and extract relevant characteristics that are necessary for next stages of analysis. Unsharp masking is the last technique used to improve photographs. The blood smear images are thoroughly cleaned through these pre-processing stages, improving their eligibility for precise analysis and diagnosis of blood cell-related disorders..

- Gray-World Color Correction

  Gray-World color correction is used to compensate for color variations in the images. This method ensures a more consistent color balance, allowing for accurate representation of different RBC types associated with poikilocytosis. To bring image colors closer to a neutral gray average, the gray-world color correcting approach is used. It first determines the average color of the entire image, and then it averages the red, green, and blue components to determine the gray world illumination. The color values of each pixel are then modified in accordance with the ratio of the lighting in the gray world to the initial average color. This procedure guarantees that the color representation is uniform and constant across the picture. Including this correction process prior to applying the Faster R-CNN algorithm to compound microscope blood smear image analysis will improve the accuracy of recognizing and categorizing various red blood cell types (RBCs). Gray-world color correction guarantees consistent color representation, which makes it easier to detect RBC shapes with greater accuracy and reliability. This enhances the diagnosis of disorders like poikilocytosis and other related conditions, ultimately improving patient care and hematology diagnostic procedures.

- Gamma Correction

The overall brightness and contrast of the images are finely tuned through the application of gamma correction. This process involves adjusting the gamma value to enhance the visibility of minute details, a critical factor in recognizing and categorizing red blood cell (RBC) forms. A precise adjustment of the gamma value can improve the visibility of minute features that are essential for a diagnosis by fine-tuning the overall brightness and contrast of the images. When performing gamma correction in this situation, it is crucial to carefully select the gamma value in order to avoid over-amplification that can mask significant features while still emphasising tiny changes in RBC morphology. To make sure that the pictures appropriately depict the fundamental properties of the blood cells, this adjustment is essential. When gamma correction is applied, the gamma correction formula is applied to each pixel in the image. By optimising the intensity levels throughout the picture, this method enhances the visibility of RBC structures and forms. To sum up, gamma correction is essential for improving blood smear picture quality, which in turn helps with better diagnostic results and the creation of more potent medical treatments for disorders involving blood cells.

- *Morphological Identification*

RBC structures and forms are examined using morphological identification techniques. Morphological processes like dilatation and erosion help to extract pertinent traits that are important for the later phases in analysis.

- *Unsharp Masking*

Images with details are enhanced by using unsharp masking, which highlights high-frequency components. By doing this, unsharp masking successfully sharpens the visual representation, which enhances the clarity and makes subtle details in the photos easier to see. This is especially useful when analyzing blood cells in detail for hematology.

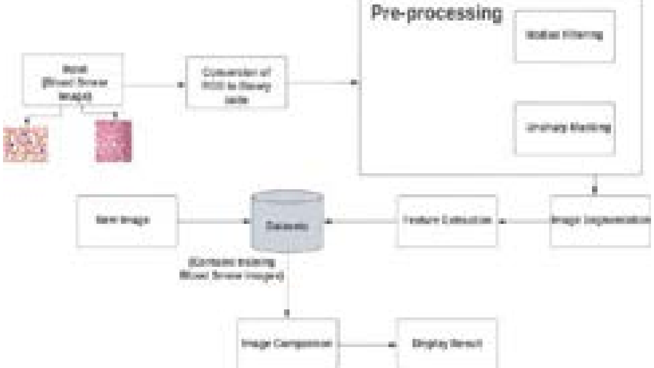

Figure 2. The proposed system architecture

C. *Image Segementation*

Several methods are used in the Image Segmentation stage to improve the analysis's granularity and separate distinct elements from the blood smear images. The aim is to enable a more thorough analysis of morphological anomalies in red blood cells (RBCs) linked to poikilocytosis.

First, the image is binary represented by applying thresholding techniques, which distinguish between pixels in the foreground and background. This first stage creates the framework for identifying and separating particular interest areas in the blood smear. Then, boundary and contour detection techniques are applied, which help to separate different cell structures and enable the recognition of asymmetric shapes.

Segmenting related regions within the image is possible by application of region-growing techniques, which group pixels with comparable qualities. The accuracy of this analysis is improved by this method, which is especially useful in identifying specific cells and structures in the blood scrape.

Furthermore, overlapping cells or structures in the image are addressed by using Watershed Segmentation. Watershed algorithms detect ridges and basins by treating pixel intensities as a topographic surface. This robust segmentation method successfully divides related components.

To further aid in a more thorough examination of the atypical forms connected to poikilocytosis, contour-based segmentation techniques are also used to outline and divide individual RBCs. This system can recognize and categorize different RBC types more accurately by extracting contours, which allows for a finer level of segmentation.

The segmented findings undergoes validation and post-processing procedures. In order to improve the segmented regions and guarantee the precision and dependability of the segmentation outcomes, this also entails noise reduction and validation checks. This stage lays the foundation for classifying the different cell shapes and detecting the anomalies suggestive of poikilocytosis, as well as for preparing the data for later phases of analysis.

D. *Feature Extraction*

To thoroughly analyze blood smear images for poikilocytosis identification, the Faster R-CNN architecture and the Feature Extraction phase collaborate well.

First, the Feature Extraction phase focuses on extracting pertinent information from segmented blood smear images. This stage uses several methods, including the extraction of morphological features, texture analysis, computation of statistical features, and shape descriptors. The combination of these methods produces a diverse range of characteristics that describe the deviations in the forms of red blood cells (RBCs) linked to poikilocytosis.

Next, the architecture of the Faster R-CNN is emphasized. The feature map, which is extracted from the Region Proposal Network (RPN) layer, is an essential element. The CNN's convolutional layers produce the feature map after it has been previously trained, and it captures the spatial properties of the input image. Using anchor boxes, the RPN provides region suggestions based on bounding box coordinates and objectness scores. This stage effectively identifies candidate locations that are likely to contain things of interest, including atypical red blood cells.

The feature map derived from the RPN is seamlessly included in the subsequent Fast R-CNN stage. This integration makes it feasible to precisely locate and classify things inside the identified zones, facilitating an easier detection of aberrant RBC morphologies associated with poikilocytosis.

On the whole, the rich feature set produced by the Feature Extraction stage enhances the visual information from segmented images. The Faster R-CNN architecture then uses the feature map which effectively identifies and categorizes items. All of these stages work together to improve the precision of identifying poikilocytosis in blood smear images.

E. Image Comparison

Region of Interest (ROI) Pooling is incorporated into the procedure to improve the comparison, and the extracted features from the Feature Extraction step are aligned. The ROI Pooling entails picking and combining characteristics from particular regions of interest in the processed image to provide a more targeted and insightful comparison with the dataset.

After alignment and ROI pooling, feature matching techniques are used to measure how similar related regions from various images are to one another. This stage makes sure that the RBC forms and anomalies connected to poikilocytosis are thoroughly compared.

Next, the dissimilarity between feature vectors is measured using distance metrics such as cosine similarity or Euclidean distance. These measures aid in the detection of trends and anomalies by providing information on the general dissimilarity of RBC shapes.

The outcomes of the Image Comparison stage help to clarify the differences in RBC shapes seen in the sample. Despite the comparison phase's main focus, the knowledge acquired from it might guide later stages of the analysis, such as classification or more focused research into particular abnormalities.

F. Classification and Prediction

During the Classification and Prediction phase, the focus moves from feature comparison to decision-making regarding the anomalies in red blood cell (RBC) shapes that have been observed. This crucial stage uses the knowledge gathered from the Image Comparison stage to categorize various morphologies, such as acanthocytes or degmacytes, and forecast possible illnesses linked to poikilocytosis.

The aligned and pooled features are used as inputs to a classification model after features are extracted and Region of Interest (ROI) Pooling is used. This model is crucial in classifying the blood smear images according to the detected abnormalities. It is frequently trained on a labelled dataset with annotations for various RBC forms and related disorders.

The Faster R-CNN model uses its object identification skills to recognize and categorize the blood smear images based on detected anomalies. The model has been trained on a labelled dataset with annotations for various RBC forms and related disorders. In doing so, particular labels—such as degmacyte or acanthocyte—are applied to the recognized RBC forms, and conjectures on possible illnesses are made.

Atlast, possible disorders are predicted using the categorized RBC forms. Given the anomalies seen in the blood smear images, the model is trained to identify patterns and relationships that help in forecasting the likelihood of particular diseases. Anaemia and other hematological diseases, for example, may be indicated by specific RBC shapes like sickle cell.

The results of this stage are integral for medical professionals to diagnose and comprehend the underlying medical issues of their patients. The system's ability to diagnose diseases is improved by the combination of classification and prediction, which offers important insights into possible illnesses linked to abnormalities in RBC forms.

To summarise, the Classification and Prediction stage expands on the knowledge obtained from Image Comparison by using a trained Classification Model to identify RBC shapes and forecast illnesses linked to poikilocytosis in blood smear pictures.

IV. EXPERIMENT AND RESULTS

A comprehensive evaluation is carried out to see how well the Faster R-CNN model performs in categorizing different shapes of red blood cells (RBCs) and predicting disorders linked to poikilocytosis. A sample image is shown in Figure 3.

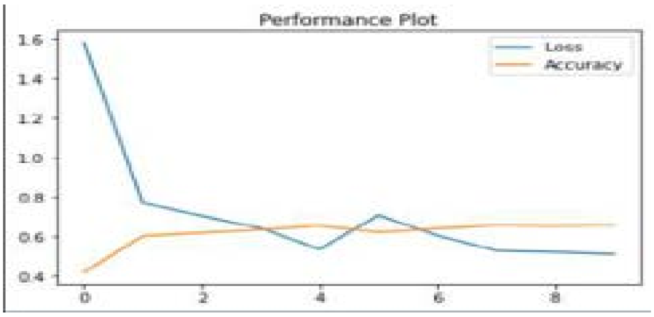

Figure 3. Performance Plot Performance Analysis of different techniques for blood cell detection

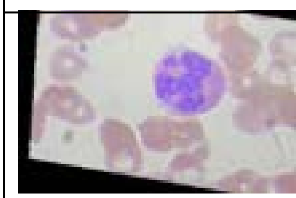
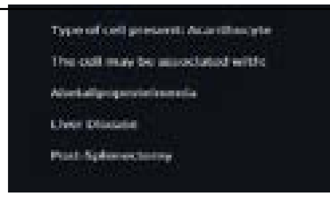
Several approaches were examined, including RCNN and CNN, ANFIS, ANN-YOLO, ResNet50, and Faster RCNN, in the Performance Analysis of various blood cell detection strategies. Table 1 shows the analysis of varying degrees of accuracy for each technique. The outcomes highlight the various blood cell detection capabilities of these methods and provide insightful information about their advantages and disadvantages.

Table 1. Result and Outcome of the system

Dataset	**Results**
	





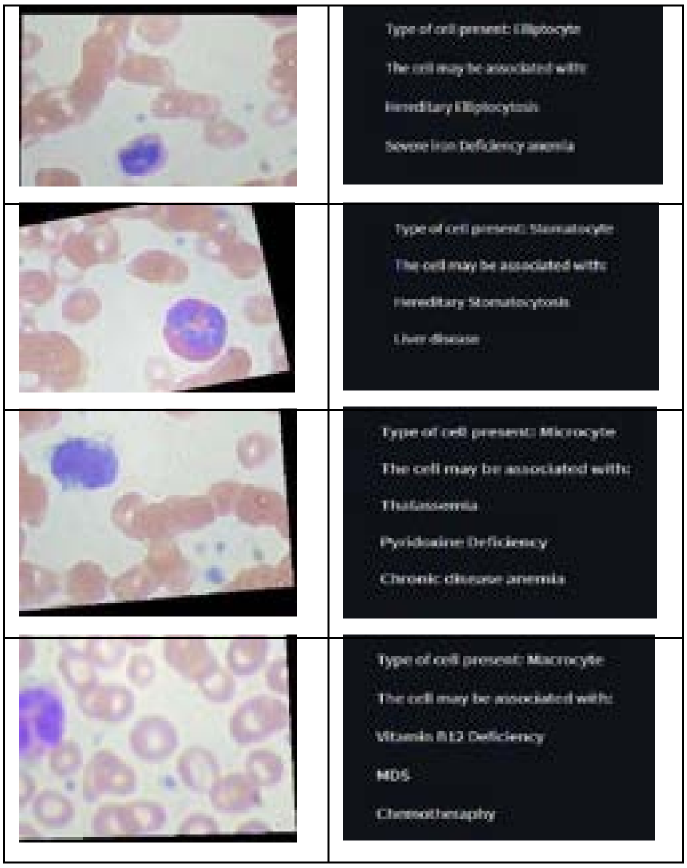


Table 2. Performance Analysis of different techniques for blood cell detection

Techniques	Total images	Accuracy
RCNN and CNN	313	72
ANFIS	21k	96.6
ANN-YOLO	364	96.09
ResNet50	3.4M	90
Faster RCNN	3k	75

ANFIS was able to achieve a 96.6% accuracy rate on a sizable dataset comprising 21,000 photos. Similarly, using 364 photos, ANN-YOLO achieved a high accuracy of 96.09%. ResNet50 demonstrated strong performance, achieving 90% accuracy on a large dataset consisting of 3.4 million photos. However, with 313 photos, RCNN and CNN demonstrated a lesser accuracy of 72%. The results emphasize the unique qualities and possible uses of different approaches while offering insightful information about the varying efficacy of these methods in blood cell detection. Among these, Faster RCNN was a standout performer, exhibiting encouraging outcomes that beat some other approaches. Based on these results, Faster RCNN may be a more powerful technique in some situations, highlighting its nuanced usefulness in blood cell detection.

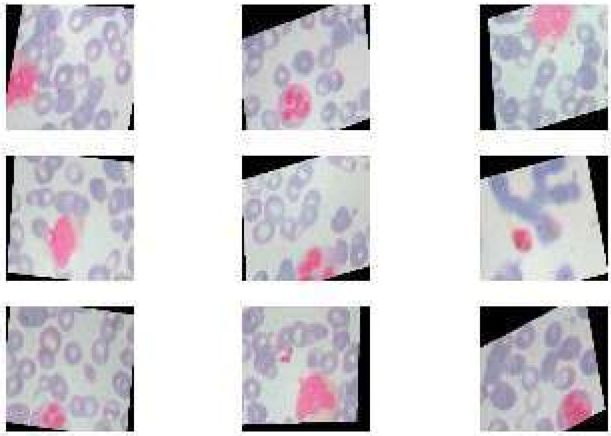

Figure 4. Blood smear images used for the system

A. Analysis of proposed system on different datasets

In the analysis of the suggested system on various datasets, the main goal was to evaluate the performance of datasets, on several different datasets, including BCCD, ErythrocytesIDB and Chula-RBC to understand the performance of the developed system. The system-attained accuracy percentages for each dataset, along with the image count, are presented in Table 3.

Table 3. Analysis of proposed system on different datasets

Dataset	Image count	Accuracy (%)
BCCD	4884	98.99
ErythrocytesIDB	626	97.14
Chula-RBC	1500	98.70
Our Dataset	3740	73.6

Four hematology datasets are evaluated in this study: Chula-RBC (1500 pictures, 98.70% accuracy), ErythrocytesIDB (626 photos, 97.14% accuracy), BCCD (4884 images, 98.99% accuracy), and Our Dataset (3740 images, 73.6% accuracy). Our diversity-focused dataset is now undergoing a comprehensive assessment. The work emphasizes how important dataset selection is to the best possible automated blood cell identification systems.

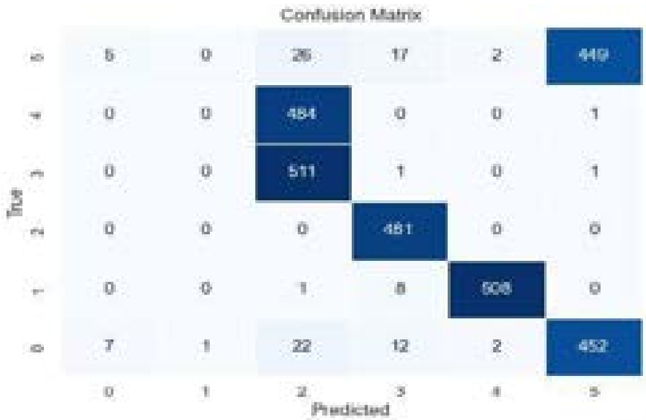

Figure 5. Confusion Matrix

B. *Performance Evaluation of target class using precision, accuracy and sensitivity*

The primary focus was on rigorously assessing the system's performance with specific attention to a designated target class. This study evaluates target class performance through precision, accuracy, and sensitivity metrics. Precision assesses correctness, accuracy gauges overall correctness, and sensitivity measures the ability to correctly identify positive instances. Table 4 encapsulates the precision, accuracy, and sensitivity metrics for this evaluation.

Table 4. Performance evaluation of target class using accuracy, precision and sensitivity

Target class	Precision (%)	Accuracy (%)	Sensitivity (%)
Microcyte	99.8	99.9	99.9
Elliptocyte	98.2	99.5	99.8
Macrocyte	98.4	99.8	99.4
Acanthocyte	99.3	99.7	99.3
Stomatocyte	97.2	99.6	99

Performance metrics for automated blood cell categorization are included in the table, with percentages for each target class for True Positives (TP), True Negatives (TN), False Positives (FP), False Negatives (FN), Precision, Accuracy, and Sensitivity. The efficiency of the categorization model is demonstrated by the high precision and accuracy that have been observed.

V. CONCLUSION

This research study offers a comprehensive solution to the challenging issue of poikilocytosis, a disorder characterized by abnormal shapes of red blood cells (RBCs). Leveraging sophisticated image processing algorithms, particularly the Faster R-CNN algorithm, the system analyses blood smear images captured with a compound microscope. By recognizing and classifying various RBC forms, the method not only enhances dataset size but also improves efficiency compared to existing methods. Through the combination of erythrocyte and BCCD databases, a diverse range of RBC forms is incorporated, facilitating a more extensive investigation into potential connections with blood cell-related diseases. The utilization of Faster R-CNN enhances both the speed and accuracy of RBC shape detection, thereby advancing the diagnosis of poikilocytosis and other related illnesses. Ultimately, this research study has improved patient outcomes and healthcare practices by enhancing diagnostic capabilities and expanding knowledge in the field of blood cell-related illnesses. This initiative represents a significant step forward in healthcare and medical diagnostics, supporting ongoing efforts to enhance patient care and diagnostic accuracy.

***Abstract*— The Electroencephalogram (EEG) are the data collected from human scalp to analyze functioning of the brain. These EEG signals usually contaminate with other signals like ocular artifacts (OA). There exist signal decomposition methods like wavelet decomposition, empirical mode decomposition (EMD) and Variational Mode Decomposition (VMD) to extract these artifacts. In this research work, a novel two-phase variational mode decomposition (TPVMD) is used to analyze EEG signals to extract OAs. In existing empirical mode decomposition (EMD) and multi variational empirical mode decomposition (MEMD), balancing parameter and regression is not applied. In this proposed method, Variational Mode Decomposition (VMD) is used to eliminate the OAs in two phases and in each phase, regression is applied. In this paper the EEG signal data is collected from semi-simulated Mendeley database. Blink artifacts are eliminated from corrupted EEG signal and the signal to artefact ration (SAR) for different balancing factor alpha(α). The simulation results show that the proposed method gives improved SNR and reduced difference in power spectral density (DPSD).**

Keywords—Electroencephalogram (EEG), Ocular Artifacts (OA), Variational Mode Decomposition (VMD), Regression, Signal to artifact Ratio (SAR), Difference In Power Spectral Density (DPSD).

I. Introduction

The scalp electrodes were used to record the electrogram, which came from the brain allows us to analyse the brain working and its characteristics. Significant advantages of this technique give rise to various techniques like noise elimination, feature extraction etc.. The most significant area of interest is noise elimination as it provides the data fidelity [1]. Data fidelity is a key aspect as EEG data is used in sensitive areas like diagnosis. The EEG signals are used in tracking epilepsy, dementia, head injuries, brain tumours, and sleep apnoea etc[2].

The process of recording EEG involves in several steps, firstly by cleaning the scalp and the several small sensors are spread across scalp which are termed as electrodes with the help of specific glue. These are all attached by wires to a EEG machine which records the signal electrogram of brain. Around 20 to 40 minutes of EEG recording with some preparation time concludes the session. The Results are given to trained doctors to analyse interpret the recorded electrogram and send the results. It is utilized not only for diagnostics but also for brain-computer interface devices, which give patients almost instantaneous control over external actuators. BCI applications based on EEG allow users to operate a computer or other device with just their thoughts, negating the need for software or other computer-related tools [3].

Table.1.EEG SIGNAL CHARACTERISTICS

EEG Type	**Characteristics**	
	Amplitude(μV)	***Frequency Range(Hz)***
δ	20-100	0.5-3.5
θ	10	3.5-7.5
α	2-100	7.5-12
β	5-10	12-30

The EEG recordings are risk free and no side effects are observed. The bandwidth of EEG spectrum ranges from 1 to 30 Hz with a amplitude ranging between 20 to 100 μV. Based on the frequency there is further sub classification into 4 groups: α (8-13 Hz), β (13-30 Hz), δ(0.5-4 Hz) and θ (4-7 Hz) as shown in Table 1. Each of these sub bands is associated with certain state of brain [4]. For example, Alpha waves are associated with the state of being relaxed wakefulness with high prominence of happening in parietal and occipital areas.

The 10-20 international system is a standard method for locating electrodes on the scalp to record EEG signals consistently across different recordings[5]. Each electrode site is labelled with a combination of letters indicating the general brain region it covers: To indicate pre-frontal, frontal, temporal, parietal, occipital, and central areas, use the letters Fp, F, T, O, and C. This systematic approach allows for accurate analysis of brain activity and function.

The main problem with EEG is noise which is picked by the other systems in the body such as circulatory system, sensory nervous system etc. The noise which is picked form the eye is termed as ocular artifacts [6][7]. As eyes are closer to the brain and hence the corruption by the eyes is more intense than other systems. These ocular artifacts are further classified into several bands based on frequency, morphology, duration, amplitude etc…The Table .II below shows different ocular artifacts.

Table.2. OA CHARACTERISTICS

OA Type	**Characteristics**		
	Amplitude(μV)	***Duration(ms)***	***Frequency Range(Hz)***
Blink	⩽800mvolt	200-400	<7.5
LEM	⩽800mvolt	200-4	<7.5
Flutter	⩽800mvolt		8-12

Mostly the EEG recorded from the frontal lobe is affected by these artifacts because of their neighbourhood with the eyes. The electrodes which are placed near to eye are affected by the eye blinks and eye movements[8]. As these electrogram from eye movements and eye blinks are inherent and cannot be differentiated manually or at the time of EEG, we need to remove them by using various noise elimination algorithms at the pre-processing stage[9].

There are several proposed algorithms on artifact elimination regression of EEG with a good reference EOG, Blind Source Separation methods such as ICA, and PCA. But because of the two-way corruption in the channels there is not much interest in multi-channel-based algorithms [10][11]. A different single-channel approach, the EMD method, was also put out; however, the algorithm did not follow any mathematical logic, and instead used techniques like cubic spline interpolation etc. make the job complex to deal with EMD based algorithms[12].

The method proposed by Chinmayee Dora et.al talks about the disadvantages of the multi-channel-based methods and EMD based methods and also provides a new method based on VMD (variational mode decomposition) to overcome those disadvantages and also successful in their approach[13][14]. The k value which decides the number of mode functions. Also there is no proper stand on their performance metric used which is DPSD(difference in power spectral density) with a controversial statement saying that more is DPSD more is the efficiency but the old papers are against the statement. Hence the metrics used in this paper are the one which are used from [15].

VMD based methods surpasses multi-channel-base methods, EMD based methods and Ensembled EMD (EEMD) regarding noise resilience, tone recognition, and separation. In Section 2, the paper presents the numerical method of VMD, linear regression, and minimized mean square error (mMSE0. In Section 3, the dataset, corrupt EEG segment detection, and the suggested process are addressed. Section 4 discusses the outcomes attained emphasizing the consequence and limitations of the proposed Method. Lastly, Section 5 draws conclusions and discussions.

II. Variational Mode Decomposition With Linear Regression And mMSE

A. VMD

The individual instruments can be recognized from any music while listening, have you ever thought of how could we able to separate the instruments from the music? This is because we inherently possess the ability to decompose the music signal and able to recognize them. The inherent ability is decomposition which separated all the different frequency components and from those components we can only concentrate on the desired instrument based on the characteristics (such as frequency) of the instrument that we are well aware. In the same way we use VMD to decompose a real time signal to decompose into several components and the identify and eliminate the undesired components using the known characteristics of those components from the contaminated EEG signal.

VMD is a technique which is used to decompose a non-stationary composite signal into several components which are band limited and qualify certain properties of VMD. The qualification mode components is based on the fact that the obtained signal should be a AM-FM signal and by adding the obtained all the obtained signals based on the qualification criteria should result in the same non-stationary composite signal. The mathematical model of VMD is shown in equation 1.

$$\min_{s_k,\omega_k}\{\sum_{m=1}^{K}||\partial_t\left[\left(\delta_t+\frac{j}{\pi t}\right)*s_k(t)\right]e^{-j\omega_k t}\;||_2^2\} \quad (1)$$

For the fact that

$$\sum_{k=1}^{K}s_k(t)=S(t) \quad (2)$$

Where (t) regarding k=1, 2, 3…. K are the BLIMFs of centre frequency derived via breakdown for a particular value of k and S(t) is the original signal.

To get around equation (1)'s constraint, a penalty term (α) and Lagrangian multiplier ( ) are employedExcellent convergence for limited weightsand strict constraint enforcement using the Lagrangian multiplier are advantages of the quadratic penalty term. Thus, we obtain the augmented Lagrangian equation as follows: where is the convolution operator and dot is the Dirac distribution.

$$L(\{s_k\},\{\omega_k\},\lambda)=\alpha\sum_{m=1}^{K}||\partial_t\left[\left(\delta_t+\frac{j}{\pi t}\right)*s_k(t)\right]e^{-j\omega_k t}\;||_2^2 + ||S(t)-\sum_{k=1}^{K}s_k(t)\,||_2^2+\langle\,\lambda(t),S(t)-\sum_{k=1}^{K}s_k(t)\rangle \quad (3)$$

The balance parameter of the data fidelity constraint is represented by α. Because of the integrated Wiener filter, the VMD approach is impervious to noise and sampling in this situation. With a convergence tolerance of €, the saddle point of Equation (2). It can find utilizing the following with the Alternate Direction Method of Multipliers (ADMM) convergence criterion and is identical to the solution of Equation (1):

$$\sum_k\frac{||\hat{s}_k^{n+1}-\hat{s}_k^{n}||_2^2}{||\hat{s}_k^{n}||_2^2}<€ \quad (4)$$

VMD-obtained BLIMFs exhibit less immediate frequency changes than EMD and EEMD. In contrast to EMD and EEMD, VMD performs better in terms of voice recognition, tonedeparture, noise robustness, and signal restoration.

B. Regression

By the regression model we can represented the contaminated ocular artifact in an EEG signal.. This model has the following mathematical expression:

$$s_i(t)=s_{true_i}(t)+a s_{false_i}(t) \quad (5)$$

where is the observed polluted EEG at the electrode locations, is the accurate or unpolluted EEG, and is the taint ocular artifact with a regressioncoefficient of a. Upon employing the least squares method of evaluation, the calculated is :

$$\hat{a}=\frac{\sum(s_i-\bar{s})(s_{false_i}-\overline{s_{false}})}{\sum(s_{false_i}-\overline{s_{false}})^2} \quad (6)$$

C. mMSE

Modified Multiscale Entropy(mMSE) is an extension of Multiscale Entropy (MSE) method, this is used to analyse the complexity of the time series data, especially bio signals like EEG, ECG etc… This method is based on the concept of entropy, this measures the entropy of the subject.

$$s_e(m, r, N) = -\ln\left(\frac{C(m+1, r)}{C(m, r)}\right) \tag{7}$$

Where:

- is the sample entropy of the signal
- m is the length of the template vector (embedding dimension)
- The similarity or tolerance criterion, denoted by r
- length of the time series denoted by N
- C (m, r) amount to the number of pairs of template vectors that match within a tolerance of r

Multiscale Entropy involves the computation of the at multiple scales by coarse-graining the time series data. This is typically achieved by dividing the time series into independent segments of different lengths and computing for each segment.

The formula for MSE at scale n is:

$$MSE(m, r, n) = \frac{s_e(m, r, N_n)}{s_e(m, r, N_{n+1})} \tag{8}$$

Where:

- is the length of the time series at scale n.

Now, mMSE involves some modification in the calculation of MSE to address specific limitations and to improve performance. Modifications may include variations in parameters m, r, or the way entropy is computed at each scale.

D. Turning point count based Artifact detection

When analysing EEG (Electroencephalogram) signals, the Turning Point Count (TPC) method is a technique used to find artifacts, which are undesired interruptions in the signal brought on by a variety of factors like muscle movement, eye blinking, or environmental interference.

The TPC approach analyses the EEG data by tracking variations in amplitude over time. The technique is specifically concerned with locating sudden shifts in the signal's direction, or "turning points." These pivotal moments signify noteworthy alterations in the EEG waveform and are frequently linked to artifacts.

The TPC method counts the number of EEG signal turning points that occur during a certain time window or segment. An increased number of turning points indicates a higher degree of artifacts in the signal.

The quality and dependability of the analysis can be increased by researchers by efficiently identifying, eliminating, or correcting artifacts from the EEG data by defining suitable thresholds for the turning point count. All things considered, the Turning Point Count technique offers a simple and quantitative method for identifying artifacts in EEG signals, which helps with the precise interpretation of brain activity data gathered from EEG recordings.

III. PROPOSED METHOD

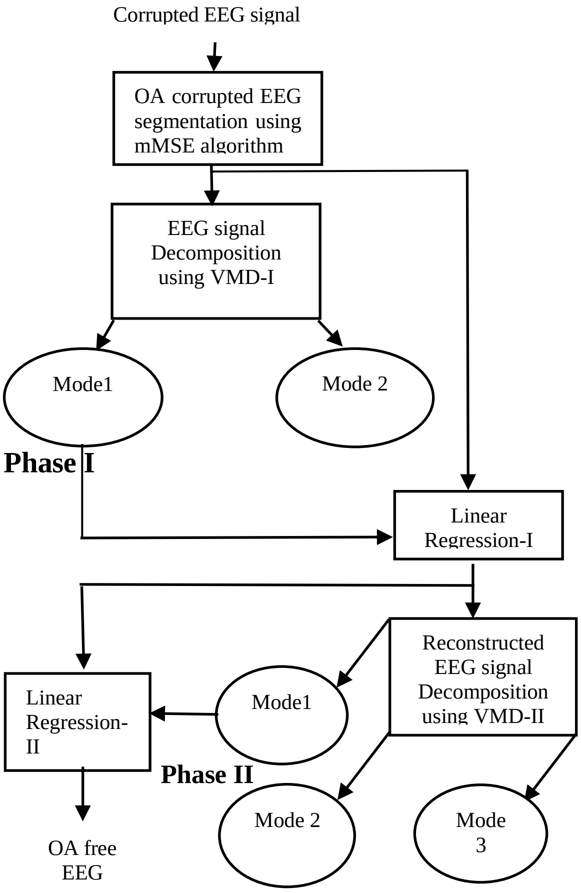

Fig. 1. *Illustrates the two phase algorithm for blink elimination.*

A. Phase – I

In the first step the EEG is applied with VMD-I with K value chosen as 2 and the balancing factor α chosen as 2000 for the eliminate of low frequency artifact components from the corrupted EEG signal ‘a’ in fig. 2. VMD-I decomposed the original signal into 2 signals ‘b’ and ‘c’ in fig. 2. out of which the signals having less than 0.5Hz is one of the mode functions.

The alpha(α) and K values are chosen specifically to attract the low frequency baseline components especially designed parameter from paper []. These values show a great potential in attracting the base line signal ‘b’ in fig. 2 form the contaminatedEEG signal.

After decomposing the corrupted EEG signal ‘a’ in fig. 2 into its mode components ‘b’ and ‘c’ in fig. 2 the low frequcy component ‘a’ in fig. 2 which is less than 0.5Hz is declined with the tainted EEG signal to get the reconstructed EEG singal ‘d’ in fig. 2 for further processing.

After decomposing the corrupted EEG signal ‘a’ in fig. 2 into its mode components ‘b’ and ‘c’ the low frequcy component ‘a’ which is less than 0.5Hz is declined with the conataminateEEG signal to get the reconstructed EEG singal ‘d’ in fig. 2 for further processing.

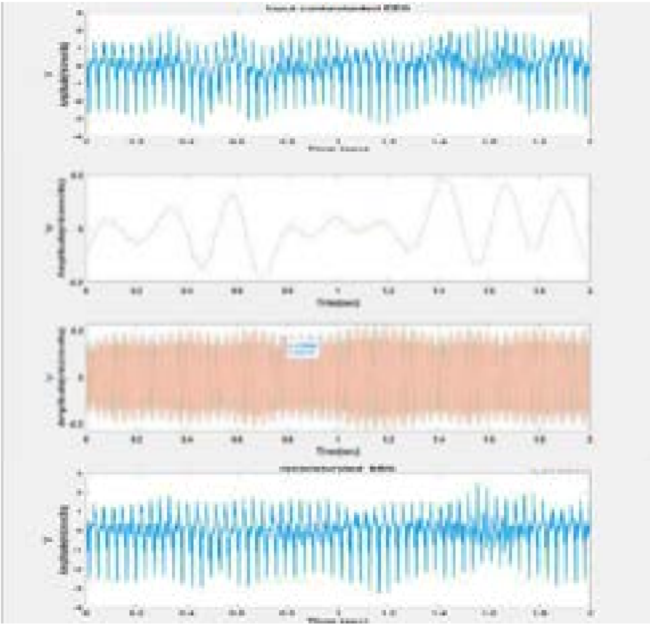

Fig. 2. *Illustrates the EEG Signal decomposition and reconstruction in Phase-I: (a) Original EEG signal of first subject in Mendeley database; (b), (c) Decomposed modes of VMD-I; (d) Reconstructed EEG signal after Linear Regression-I.*

B. Phase-II

In the second phase the EEG is treated with the α value chosen to be 1000 and K chosen to be 3 to extract the phase-I processed EEG input from the blink artifacts. After applying the VMD-Phase II with the chosen parameters form paper [] those obtained signals are then sent to turning point count algorithm which detects the corrupted segments from the three mode components. Then followed by regressing the selected mode components with the EEG signal, which will provide the ultimate pure EEG signal estimate.

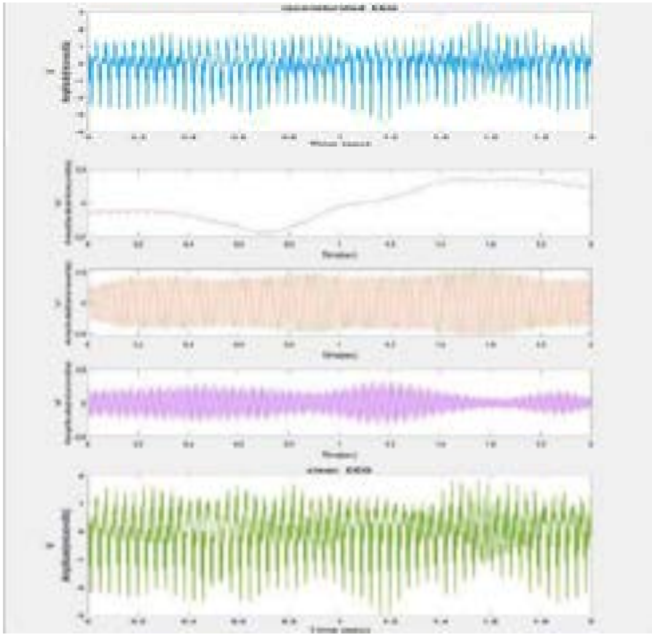

Fig. 3. *demonstrate the signal breakdown and restoration in phase-II : (a)processed EEG signal from phase-I;(b), (c), (d) are the mode functions of contaminated EEG;(e) is the clean EEG regressed from noisy mode function by turning point count.*

In phase-II the processed EEG signal ‘a’ in fig. 3 from phase-I is fed as input to the VMD-II which decomposes the signal into three mode components ‘b’, ‘c’ and ‘d’ in fig. 3. Among these three decomposed signals of the processed EEG signal one of the signal is a blink signal and it is identified using turning point count based method used in paper []. The blink component identified by the turning point method is ‘b’ in fig. 3. The processed EEG signal ‘a’ is regressed with the blink artifact component ‘b’. The resulting artifact free EEG signal after regression is ‘e’ which can be further used for analysis purpose.

The final outcome is a pure EEG signal which is further established in the results section. In this phase the artifact components are removed by varying the VMD parameters to obtain the characteristics of the artifacts in a heuristic way. The other mode components obtained are the factors of the processed EEG signal which are not our course of interest. Out the three mode function obtained the first mode function is our artifact component extracted from the processed EEG signal.

IV. Results and Discussion

The proposed two-phase VMD algorithm is validated in this section using suitable performance metrics by different EEG signals collected from many different databases articles. This section gives the idea of datasets used and performance metrics and validation of the proposed algorithm using them.

Table.3. Phase-wise comparative analysis

Phase	**Parameters**			
	K(no.of modes)	***α(balancing parameter)***	***DPSD (Difference in Power Spectral desity)***	***SAR(Singnla to artifact ratio)***
Phase-I	2	2000	0.04	7.85
Phase-II	3	100000	0.018	25.18

A. Databases

The data bases operate to verifythe proposed technique are the EEG signal collected from EEG information which include the semi-simulated Mendeley database, EEGMAT database and Polysomnographic database.

B. Performance metrics

The performance metrics used in this database are Signal to Artifact Ratio (SAR), Difference in power spectral density (DPSD) and Normalized Cross Correlation (NCC) for both frequency, power, variation based metric analysis for denoising of the given EEG signal. The performance metrics are calculated for the actual EEG signal and the estimated EEG signal are given by:

- $SAR\,(in\ dB) = 10 * \log\left(\frac{Signal\ Pow}{Noise\ Pow}\right.$ (9)

$DPSD = PSD(Original\ Signal) - PSD(Cleaned\ signal)$

where PSD is the strength spectrum density of the communication.

C. Performance evaluation

The evaluation of the algorithm phase wise based on the VMD parameters is performed initially to showcase the phase wise performance of the proposed algorithm. The phase wise performance is shown in Table. 3. The variation in the VMD parameters have yielded good results (SAR) in both the phases as we can see in Table. 3.

The SAR ratio is good enough to yield a EEG signal as pure as possible. The signal strength is greater than the noise signal, as indicated by the SAR. Additional parameter Power spectral density variation.

DPSD is defined by calculating the difference in power spectral density between the actual EEG signal and the signal processed with the blink elimination algorithm, you can quantify the reduction in power associated with blink artifacts. A greater reduction in power at frequencies and time intervals corresponding to blink events indicates more effective blink artifact removal.

A lower DPSD signifies that the processed signal more closely resembles the original EEG signal, with fewer artifacts remaining after blink elimination. This indicates higher signal quality and reliability for subsequent analysis tasks such as frequency domain analysis. Fig. 4 shows the DPSD plot for both phases. The plot 'a' shows the DPSD values in phase 1 and plot 'b' shows the DPSD values in phase 2.

(a)

(b)

Fig. 4. *Illustrates the Difference in power spectral desity plots in both phases: (a) . is the power spectral desity in phase 1, (b) is the power spectral density in phase 2.*

The results from Fig. 4 conclude that the DPSD values are sufficiently low which resembles the elimination of power frequency components of noise efficiently in both the phases. The phase wise elimination of noise yields better results in terms of Signal to Artifact Ration (SAR) and Difference in Power Spectral Density (DPSD).

The proposed technique has also performed well in comparision with the other VMD based algorithms. Table. 4 shows the results of the other VMD based algorithms

V. CONCLUSION

This study addressed blink extraction in the EEG signal using a single channel framework based on Two-Phase VMD. The proposed architecture consists of two stages: first, VMD breaks down the signal into several components, and then, using OA features, the contaminated EEG signal is regressed to produce noise-free EEG. The four components of the proposed framework are as follows: VMD-I for decomposing the EEG signal into two modes; VMD-II for processing the EEG signal into three modes; and regression of mode with ocular artifacts (OAs) derived frombased on threshold criteria based on turning point counts. The Mendeley database, one of the publicly accessible databases, is used to collect EEG signals with a variety of OAs present, each with a different magnitude and shape, aiming toverify the efficacy of the suggested structures. The findings show that the suggested framework can remove OAs from all EEG local rhythms and the reconstructed EEG signal with little loss of important clinical aspects. Additionally, it performs better in both objective and subjective assessments than the few applied current OAs removal strategies.

Abstract— In general, the flipflops are acting as a key circuit and major power intaking element in several digital systems modeling. In this work, a new power efficient flipflop topology titled Pass Transistor Logic based Implicit Pulsed – Dual Edge Triggered Flipflop (PTIP-DETFF) is offered, by fusing the power minimization techniques such as minimum counts of device utilization, implicit pulsed clocking, dual edge triggering and parallel paradigm schemes. The implicit clock pulsing scheme eludes the exterior usage of clock generation network which intakes extra power. The twin edge triggering scheme halves the clock frequency which minimizes the dynamic power intake of flipflop as half. The parallel paradigm style diminishes the undesirable intake of power by the circuitry section which is not significant to result the preferred output. The offered flip flop topology is simulated using 0.12µm CMOS process technology and assessed in view of overall count of transistors, count of clock enabled loads, Layout area, Data in to output delay, entire power intake and also in terms of power delay product, Energy delay product and power energy products. The anticipated topology intakes the entire power of 5.265µW and achieves the power efficiency ranging from 12% to 63.30%, which conveys this anticipated flipflop will be appropriate for power efficient VLSI applications.

Keywords— flip flops, low power, CMOS technology, dual edge triggering

I. INTRODUCTION

In present era, the Power intake is the primary issue while designing the circuits and systems for low power applications [1, 2]. In general, the flipflops are acting as a key circuit and major power intaking element in various digital systems design [3]. In the global power intake of digital system, the flipflops accounts the power intake of 30% to 60% which is extreme value in the overall power intake [3, 4]. To drop the overall power intake of digital system design, the crucial flipflop element should be low power intaking element. The lessening of power intake of flipflops will have deep impression on the entire power intake of the digital systems.

The power efficient flipflops which are realized by Master-slave fashion and twin edge stimulating are used as major circuitry sections in contemporary low power processors and embedded systems. Typically master slave pattern are designed with a collection of latches in which one is transparent high and another one is opaque low [5, 6]. The master- slave style may be realized by using the parallel paradigm fashion where one latching section is replicated into manifold times as per the topology desires. Edge triggering flipflops diminish multiple stages into single stage by ensuing the positive and negative set up time. The pulse triggering flip flops are categorized into explicit and implicit style which duplicates the latching sections into several copies and aligned as parallel fashion [5, 6].
The Entire Power intake can be articulated as

P= Static (Ps) + Dynamic (Pd) + Short circuit (Psc)

Ps- designates static power utilization which happens due to leakage current flow. Pd - indicates dynamic power dissipation which arises because of undesirable on off activities. Psc- designates short circuit power dissipation which ensues due to a pathway exists between power supply (VDD) and ground (VSS) if both pull up and pull down net conducts simultaneously.

Power utilization of the flipflops can be diminished by ensuing various power efficient strategies as follows. [7, 8]

- Twin edge triggering

- Low swing supply voltage
- Pathway Splitting scheme
- Lessening capacity of clocking transistors
- Diminishing the overall count of loads

In recent years, various flipflops are designed by using different power efficient strategies and listed as CTS-DETFF [9], DDNET-D2 [10], S-TCRFF [11], RTSPCFF [12], DCSFF [13], MS-PTDFF [14] in comparison table-1 which are taken into account to evaluate the significance of an anticipated flipflop topology.

II. Proposed Pass Transistor Logic Based Implicit Pulsed – Dual Edge Triggered Flipflop (PTIP-DETFF) Design

A. Construction of anticipated flipflop topology

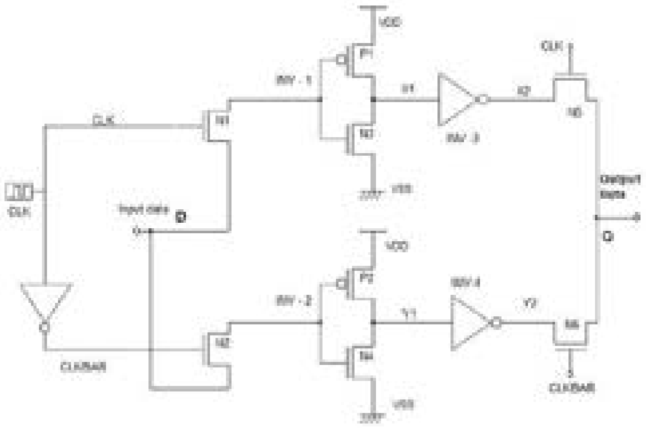

Fig. 1. Circuit Topology of Proposed Pass Transistor Logic based Implicit Pulsed – Dual Edge Triggered Flipflop (PTIP-DETFF), Overall 14 counts of transistor loads including 6 counts of clock enabled loads

The anticipated flipflop topology is framed by three dynamic sections titled Upper Latch (UL), Lower Latch (LL), the data selection network and entirely using 14 counts of transistor loads comprising 6 counts of clock enabled Transistor loads. An upper latch is realized by 5 numbers of elements N-type transistors N1, N3 and P-type transistor P1with an inverter named INV-3. The lower latch is realized by 5 numbers of devices N-type N2, N4 and P-type P2 with an inverter named INV-4 shown in Fig.1. By following the power efficient technique named minimum counts of device utilization, both the UL and LL latching sections are topologied by only 5 counts of devices each. Due to the fewer count of element usage in the latching sections, the power utilization by the latches becomes less. In this anticipated flipflop topology the clock triggering signal not generated by an external clock network. Instead, the clock is applied as an implicit manner to the latching sections directly, without any separate clock distribution network. This implicit clock feeding scheme obviously leads to lessening of power wastage. The data selection network of this proposed design is framed by using pass transistor logic which consists of N-type transistors Pair N5 and N6. Instead the complex data selection logic, this proposed design using the simple dual parallel connected pass transistors which minimizes the power usage of the data selection network which are highlighted in Fig.2.

The upper latch and lower latch sections are coupled in parallel style with data selection logic by following standard parallel paradigm approach. To trigger the complete flipflop topology, the clock signal CLK is directly fed to an upper latch and data selection pass transistor N5. An inverted clock signal CLKBAR drives the lower latch and data selection pass transistor N6.

The input data D is commonly fed to both upper latch and lower latch through the source terminal of the data feeding transistors N1, N2 Respectively. An upper latch is exclusively responsible to capture the input D while the clock triggering signal CLK is logically high. The UL results the data out at node X2 and the same fed to pass transistor N5 in the data selection logic. The device N5 is completely under the control of clock triggering signal CLK which passes the output data Q if the CLK is logical high. In this scenario the LL is completely in deactivate mode and logically isolated from the entire circuit.

The lower Latch is exclusively responsible to capture the input D while the clock triggering signal CLK is logical low (i.e.) CLKBAR becomes logically high value. The LL results the data out at Y2 node and the same fed to pass transistor N6 in the data selection network. The element N6 is completely under the control of CLKBAR signal which passes the output data Q if the CLKBAR is logically high. In this state the UL is completely in deactivate mode and logically isolated from the whole circuit.

B. Functionality of the proposed topology

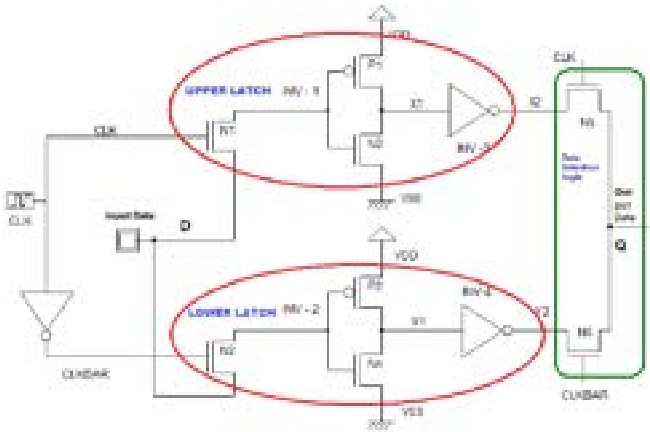

Fig. 2. schematic of PTIP-DETFF with its highlighted dynamic sections

The functionality of the proposed PTIP-DETFF is elaborated as 4 set of operations with right data set of input Data D and output Q as follows:

Operation (1): When the input Data D=0 (LOW) and the dropping edge of the clock arrives CLK=0 (LOW), the device N1 turns off. The off state N1 is incapable to drive both an elements N3 and P1 which formulates an inverter I1. Presently an Inverter-1 and an Inverter-3 is momentarily cutoff from the circuitry data path and no data is served as an input to the pass transistor N5. Due to CLKBAR=1 (HIGH), the transistors N2 gets ON. The on state N2 permits the input D=0 value to an Inverter I2. The transistors P2 and N4 employed in an Invetter-2 gets ON and OFF correspondingly. The on state P2 makes the Y1 node to high & an Inverter-4 results logical low and the same value served as input to pass transistor N6. Due to the control signal CLKBAR =1, the device N6, got enabled and passes the logic low value to the output data path. The output data Q results logic low as an output i.e. Q = 0 (LOW).

Operation (2): when the input Data D=0 (LOW) and the growing edge of the clock arrives CLK=1 (HIGH), the device N1 turns on. The on state N1, drives the elements P1 and N3 which results the node X1 = high. Due to X1= high, an inverter INV-3 results X2=low and the same served as input for the pass transistor N5 in the data selection logic. Due to CLK=1. The Pass transistor got excited and directly passes the X2=low value as low output. i.e Q=0 (LOW). In this scenario due to CLK=1 & CLKBAR =0, the lower latch and the pass transistor N6 are momentarily detached from that circuitry part.

Operation (3): when the input Data D=1 (HIGH) and the dropping edge of the clock arrives CLK=0 (LOW), the device N1 gets off. The off state N1 is incapable to drive an inverter I1. Presently an Inverter-1 and an Inverter-3 is momentarily detached from the circuitry data path and no data is served as an input to the pass transistor N5.Due to CLKBAR=1 (HIGH), the device N2 gets ON. The on state N2 passes the input D=1 value to an Inverter I2 and results the Y1 node to low and an Inverter-4 results logical high. Due to the control signal CLKBAR =1, the device N6 got enabled and passes the logic high value in node Y2 to the output data path. The output data Q results logic high as an output i.e. Q = 1 (HIGH).

Operation (4): when the input Data D=1 (HIGH) and the growing edge of the clock arrives CLK=1(HIGH) the device N1 turns on. The on state N1, drives the elements P1 and N3 which results the node X1 = low. Due to X1= low, an inverter INV-3 results X2=high and the same served as an input for the pass transistor N5 in the data selection logic. Due to CLK=1. The Pass transistor N5 got energized and directly passes the X2=high value as low output. i.e Q=1 (HIGH). In this scenario due to CLK=1 & CLKBAR =0, the lower latch and the pass transistor N6 are momentarily detached from that circuitry part.

In this this proposed topology, by following the parallel paradigm approach, the upper latch section samples the data input while clock triggering signal becomes HIGH i.e CLK=1 . Same the lower latch section samples the data input while clock triggering signal becomes LOW i.e CLK=0. Due to this parallel paradigm approach while the proposed topology is under working condition, one latch section will be in active mode and another one latch section will be temporarily in ideal mode. So the power utilization and the Data D – Q out delay will be minimized for the proposed flipflop design.

III. Results and Discussion

The proposed PTIP-DETFF is implemented in digital schematic DSCH and simulated at the layout level with 0.12 µm CMOS VLSI technology in Microwind EDA environment. The significance of this proposed topology is assessed in terms of performance factors such as overall count of transistor loads, count of clocked loads, Data D – Q out delay, triggering mode, Layout area occupation and Entire power intake and optimization factors such as Power & Delay Product (PDP), Energy & Delay Product (EDP) and Power & Energy Product (PEP).

The anticipated design results the response at both edge of the clock triggering signal and Summarized as follows.

Operation -1: Datain D=0, CLK=0, CLKBAR=1, Qoutput =0

Operation -2: Datain D =0, CLK=1, CLKBAR=0, Qoutput=0

Operation -3: Datain D=1, CLK=0, CLKBAR=1, Qoutput=1

Operation -4: Datain D=1, CLK=1, CLKBAR=0, Qoutput=1

The functionalities of proposed PTIP-DETFF topology are analyzed by exiting the all possible combinations of input data D (D=0 & D=1) and Clock (CLK=0 & CLK=1) as given above operation -1, 2, 3 and 4. The simulation results demonstrates the correct functioning of proposed design for respective Datain D & CLK and shown in Fig. 3,4,5 and 6.

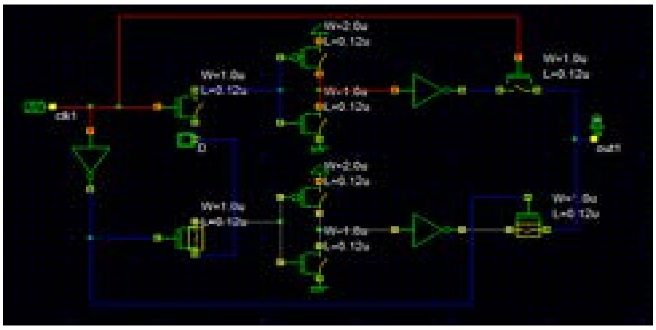

Fig. 3. Operation -1: Datain D=0, CLK=0, CLKBAR=1, Qoutput =0

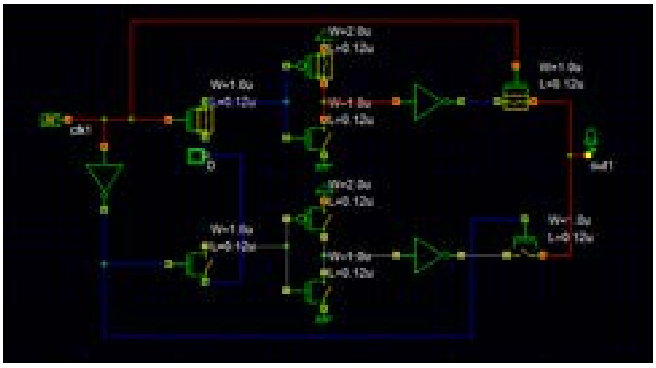

Fig.4.Operation -2: Datain D =0, CLK=1, CLKBAR=0, Qoutput=0

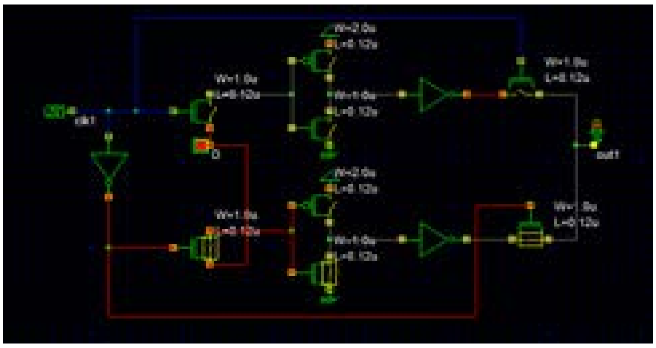

Fig.5. Operation -3: Datain D=1, CLK=0, CLKBAR=1, Qoutput=1

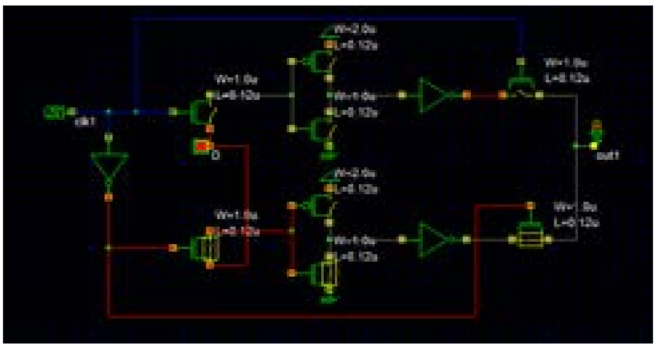

Fig.6. Operation -4: Datain D=1, CLK=1, CLKBAR=0, Qoutput=1

The performance and optimization factors for existing and anticipated flipflop topology are tabulated in the Table-1 and Table -2 respectively.

In point of overall count of Transistors, the anticipated design uses 14 count of elements which is considerably less compared with existing design. Due to usage of power efficient technique named minimum count of transistors results less power intake.

Principally the clock enabled devices are highly dynamic and intakes extra power compared with nonclocked devices [9, 14]. In sense of clock enabled transistor count, the anticipated design consist 4 elements, which is considerably fewer compared with existing topologies. This effects fewer dynamic power intake and leads to minimum entire power intake.

In aspect of entire power intake, the anticipated topology, consumes the power of 5.265µW as shown in Fig.7, which is very less compared to existing flipflop topologies. The anticipated topology achieves the power efficiency ranging from 12% to 63.30% compared to the existing topologies listed in Table-1. This minimum power intake makes the proposed PTIP-DETFF as greatly appropriate for power efficient VLSI applications.

In vision of Datain D – Q out delay, the anticipated design takes the delay of 130 ps which is minimum value compared with existing topologies in Table-1 except the design DDNET-D2. This lowest delay makes the proposed topology as also fit for high speed applications.

In note of Physical Layout area utilization, the anticipated PTIP-DETFF occupies an Layout area of 247µm2 which is demonstrated in Fig.8. This is considerably less compared to the topologies listed in table-1, except DDNET-D2, S-TCRFF and DCSFF. The Comparison chats Fig.9 and 10 clearly demonstrates the Comparison of overall Count of transistors& clock enabled loads and Comparison of Entire power intake.

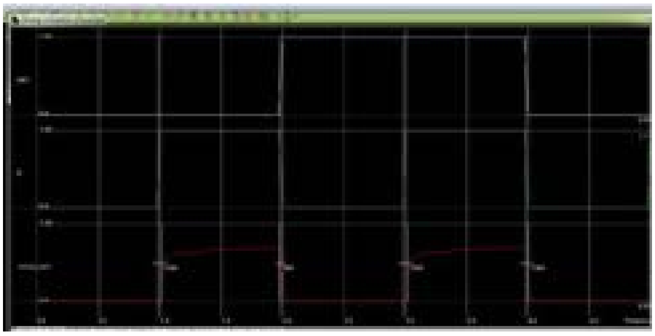

Fig.7.Entire power intake of proposed PTIP-DETFF (Power = 5.265 µW)

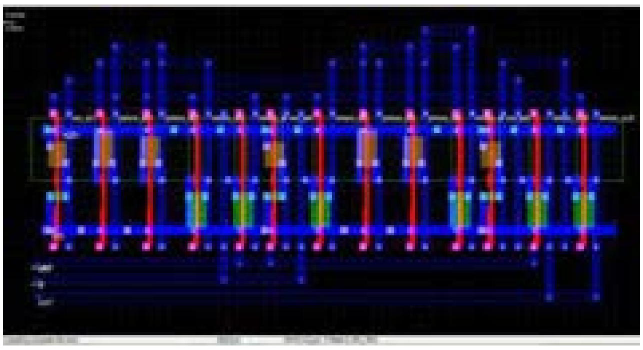

Fig.8 Physical Layout area of proposed PTIP-DETFF (Area = 247 μm^2)

In account of power delay product, the anticipated topology possess the value of 0.684 fj which is less compared to the existing topologies except S-TCRFF. In view of Energy Delay Product, the proposed PTIP-DETFF intakes the cost of 0.088*10-24 which is considerable rate compared with existing topologies. Principally Power Energy Product (Power * Power * Delay) is the metric which gives more weightage to power consumption compared with delay [15]. In account of

TABLE I. ASSESSMENT OF PERFORMANCE FACTORS

Flipflop Designs	Performance factors					
	Overall count of transistor Loads	Count of clock enabled loads	Triggering mode	Layout area (µ m^2)	Data D –Q Out delay (ps)	Entire Power Intake (µw)
CTS-DETFF [9]	23	8	Dual	424	179	8.347
DDNET-D2 [10]	14	2	Dual	176	91	7.610
S-TCRFF [11]	16	12	Dual	201	86.31	7.310
RTSPCFF [12]	26	5	Single	616	77.31	8.598
DCSFF [13]	24	7	Single	180	112.7	7.40
MS-PTDFF [14]	16	6	Dual	252	206	5.945
Proposed PTIP-DETFF	**14**	**6**	**Dual**	**247**	**130**	**5.265**

TABLE II. ASSESSMENT OF OPTIMIZATION FACTORS

Flipflop Design	Optimization Factors		
	PDP (fj)	EDP ($*10^{-24}$)	PEP ($*10^{-20}$)
CTS-DETFF	1.503	0.2690	1.263
DDNET-D2	0.692	0.0630	0.527
S-TCRFF	0.630	0.0545	0.461
RTSPCFF	0.664	0.0513	0.571
DCSFF	0.833	0.093	0.617
MS-PTDFF	1.224	0.252	0.728
Proposed PTIP-DETFF	**0.684**	**0.088**	**0.360**

Power Energy Product, the PTIP-DETFF circuit achieves very less value of 0.360*10-20 and reported in Fig.11.For the proposed PTIP-DETFF, the PEP is improved in the range of 28.05% to 71.49 % which states the anticipated design is more appropriate for power efficient VLSI applications.

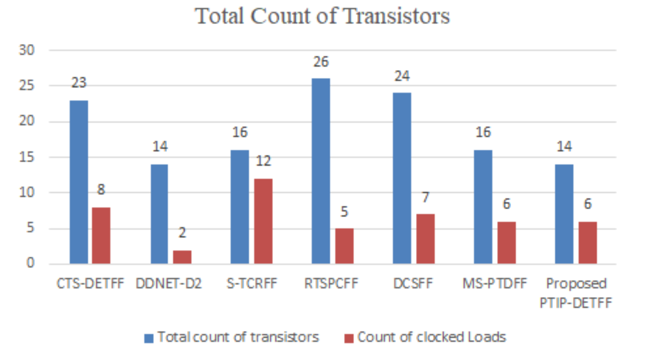

Fig.9 Comparison of overall Count of transistors and clock enabled loads

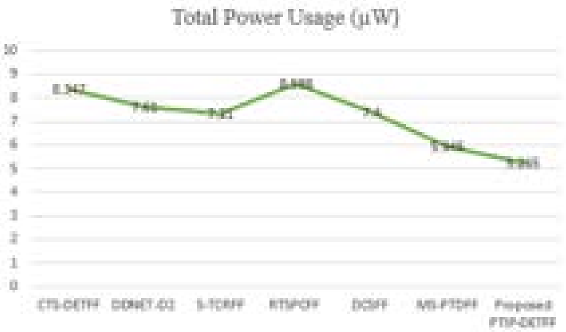

Fig.10 Comparison of Entire power intake

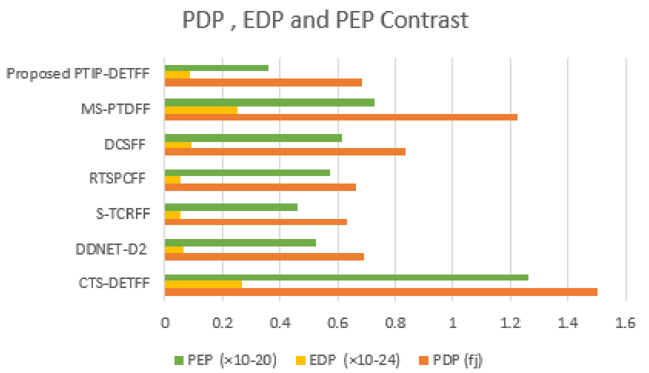

Fig.11 Comparison of PDP, EDP and EDP

IV. Conclusion

This PTIP-DETFF topology is realized by ensuing the power effective practices such as minimum counts of device utilization, implicit pulsed clocking, twin edge triggering and parallel paradigm schema. The implicit clock pulsing scheme evades the external usage of clock generation network which intakes surplus power. The parallel paradigm approach reduces the unwanted intake of power by the circuitry section which is not vital to result the desired output. The anticipated topology intakes the power of 5.265µW , attains the power efficiency ranging from 12% to 63.30% and reaches PEP enrichment in the range of 28.05% to 71.49 % which states that the anticipated design is well appropriate for power efficient VLSI applications.

***Abstract*—With improvements in machine learning technology, viable methods for processing the massive amounts of data created in real life are now available. However, data protection and scalability concerns will slow down the further development of machine learning algorithms. Federated learning (FL) prevents data leaks by distributing training jobs to numerous clients and thus isolating the central server from the local devices. Nevertheless, FL still has issues like malicious data and single points of failure. Blockchain Technology's debut offers a secure and practical solution for FL deployment. This research study presents a comprehensive evaluation of the blockchain-based FL. First, the concept of Federated Learning is extensively dwelled upon. Then, the limitations of Federated Learning were analyzed, which led to the adoption of BC-FL. Some real-world uses of BCFL are also analyzed. Subsequently, the integration of BC with FL has been studied. Finally, the architecture of BC-FL has been developed and described. BC-FL is an upcoming research field that is comparatively unexplored. The paper offers insights into its development and how the technology can be implemented by addressing data privacy and security issues.**

Keywords—Blockchain, Federated Learning, Machine Learning, Privacy, Security.

I. INTRODUCTION

The introduction effectively outlines the challenges of data protection and scalability in machine learning. It highlights the issues of data transmission costs and privacy risks associated with uploading raw data to central servers. These challenges hinder the efficiency and security of traditional machine-learning architectures. To address these issues, the paper introduces federated learning (FL), a unique ML architecture proposed by Google, which aims to preserve user privacy while allowing distributed devices to train models collectively. However, traditional FL architectures face limitations such as speed bottlenecks, unreliable data, and privacy breaches.

To achieve privacy in federated learning (FL), particularly when merging it with blockchain (BCFL), several key strategies are employed:

Decentralization: FL inherently operates decentralized, allowing training to occur on local devices without uploading raw data to a central server. This decentralization minimizes the risk of privacy breaches associated with data transmission.

Encryption: Utilizing encryption techniques such as homomorphic encryption and differential privacy ensures that sensitive data remains private even during model training and communication between devices and servers.

Anonymization: Before data is shared or used for training, it can be anonymized to remove personally identifiable information, reducing the risk of privacy leakage.

Blockchain Immutable Ledger: Integrating blockchain technology provides an immutable ledger for recording transactions and interactions within the FL system. This ensures transparency and trust in the system's operations while maintaining participants' privacy.

Smart Contracts: Smart contracts can enforce rules and permissions regarding data access and model training, ensuring that only authorized parties can participate and access specific data, thus preserving privacy.

Consensus Mechanisms: Blockchain's consensus mechanisms ensure that network participants agree upon updates to the FL model, maintaining the model's integrity while preserving privacy.

Machine learning (ML) is used in every industry and has dramatically impacted people's lives. To train machine learning (ML) models, data generated daily from a sizable number of end users may be obtained. These models serve us by delivering improved services that enhance our quality of life. However, there are two issues with the current ML architecture, which frequently requires end devices to send data they have collected to a central server for model training. For starters, data transmission might cost a significant quantity of communication resources. Second, uploading raw data increases the risk of privacy leakage, discouraging data owners from doing so out of security concerns.

To solve the challenges above, Google suggested federated learning (FL). This unique ML architecture may successfully preserve user privacy while collectively allowing many end devices to train an ML model. A cutting-edge deep learning strategy called federated learning makes learning easier from a remote environment. A new artificial intelligence system called Google created Federated Learning in 2016 with the primary goal of solving the problem of the local update model for Android mobile device consumers. The design aims to perform fast machine learning with several parties or compute nodes while ensuring legal compliance. It also aims to secure terminal data and personal data privacy through massive data sharing and information security. The global data learning model maintained on tens of millions of remote client devices is the foundation for the traditional federated learning problem. The client device must often be connected to the central server during training. It causes speed bottlenecks, unreliable data, privacy breaches, and other issues. Figure 1 depicts the menthodology of Federated Learning (FL).

Fig. 1. Federated Learning

Blockchain is the world's most recent windfall, mainly in banking and finance. Blockchain is also employed in the healthcare management system to effectively maintain electronic health and medical records. Security, privacy, and immutability are all guaranteed by the technology. Blockchain distributed trust offers a fresh approach to designing the FL architecture and paradigm. FL could be applicable in the blockchain setting since distributed consensus and transaction records allow for safe communication in an unreliable environment. Concurrently, incentive and consensus-based systems are inherently suitable for creating a market economy that may successfully promote participation and information flow in FL. This paper presents a framework for providing a personalized recommendation system by merging blockchain with Federated Deep Learning. Figure 2 shows the integration of blockchain and Federated Learning (FL).

Fig. 2. Integration of Blockchain with Federated Learning

The research article is structured as follows: Section II begins with an overview of the literature. Section III examines the history and origins of the ideas of Federated Learning and Blockchain. Section IV elaborates on the limitations of federated learning. Section V examines the relevance of the amalgamation of the two technologies of Federated Learning and Blockchain BCFL. Section VI describes the BCFL architecture in detail. The paper comes to a close with Section VII.

II. Literature Review

Federated learning is a relatively novel notion in machine learning, and recent research has focused on how the blockchain could be used in this scenario. Biscotti is described in [1]. It is a fully decentralized peer-to-peer (P2P) approach to multi-participant machine learning that employs cryptographic primitives and blockchain to coordinate an ML process while protecting peering clients' anonymity. According to the author, Biscotti is extendable, error-resistant, and resistant to known dangers. When 30% of the adversaries are present, Biscotti can ensure the privacy of each client's update while maintaining the global model's performance at scale. The review research in [2] undertakes a detailed investigation of the privacy and security debate in the context of BC-FL approaches using empirical data to provide an impartial road map of the problem state. The study's findings indicate that the usage of blockchain-based FL has expanded dramatically over the previous five years. Blockchain technology is rapidly being utilized to tackle difficulties with hospital administration, hospital data on various diseases, CT scans and X-ray records, medical equipment, and other issues.

In the study reported in [3], smart devices based on the Internet of Things (IoT) use federated learning to use distributed clinical data most. This technique is based on blockchain technology and is aimed at intelligent healthcare. To protect privacy, an adaptive differential privacy approach is presented, combined with a gradient-verification-based consensus mechanism to identify poisoning attempts. Using a diabetic dataset from the real world, the method is contrasted with two equivalent techniques for performance metrics. The test’s findings indicate that the recommended method may produce highly accurate models in a manageable length of time while also consuming less privacy budget and thwarting attempts at poisoning.

In [4], the article thoroughly analyzes BCFL and considers the effects of such a unique paradigm. It begins by briefly introducing FL technology and discussing the issues that it faces. The Blockchain ecosystem is then summarised. Following that, it highlights BCFL's structural design and platform. Furthermore, improvement in FL performance using Blockchain and many integrated uses of FL incentive systems are demonstrated. Finally, BCFL's industrial application possibilities are described. The review paper [5] uses in-depth literature analysis in this work to analyze existing FL issues and synthesize knowledge on blockchain-based FL (BFL). The differences between these gathered BFL designs are discussed, and BFL applications are categorized and examined. Finally, several suggestions are made for BFL's potential development and use.

The release of this paper [6] gives a comprehensive review of the use and implementation of frameworks for Blockchain-Enabled Federated Learning for the Internet of Vehicles. Also emphasized are possible problems, challenges, issues, solutions, and future research goals for BC-enabled FL frameworks for IoVs. The survey results might then be utilized to develop BC-enabled FL solutions that address various data privacy issues and IoV scenarios. The paper [7] explores FL and looks at the main evolutionary pathway for challenges during the FL development process. This study will examine current industrial engineering applications to identify potential future landing purposes. Furthermore, our research suggests six study topics to address the FL literature and increase our understanding of FL for potential future optimization. This work contributes to the conclusion of applications in computer science and industrial engineering while also providing an overview of FL applications. In [8], Besides providing an overview of current approaches, the article looks at the distinct characteristics and restrictions of federated learning. It also identifies several potential areas for future study that might benefit many different academic communities. The study provides an overview of federated learning, a learning paradigm in which statistical models are taught at the network's edge. It has spoken about federated learning that differs from standard distributed data center computing and the issues that come with it. Using classic privacy-protecting learning, there is a thorough explanation of traditional findings and current federation work. [9] presents an architecture for distributed computing defense for a sustainable society using blockchain technology and federated learning. The recommended model contains a method for overcoming the issues of little training data to obtain high accuracy without using a reason-specific model. The dataset is used to investigate how the proposed framework performs in various circumstances to determine how successful the model is.

To preserve client data privacy in the IIoT, the study [10] suggests a BC-FL device failure detection approach. The initial step was creating a BC-FL architecture architecture for IIoT failure detection. The design allows you to verify the correctness of consumer data. According to the architecture, each client routinely creates a Merkle tree on the blockchain, with each leaf node representing a client data record. Furthermore, a distinctive centroid distance-weighted federated averaging technique was used to solve the issue of data heterogeneity in IIoT failure detection.

This method compensates for the difference between positive and negative classifications in each client dataset. The work in [11] creates a blockchain-enabled safe data sharing for the multiple stakeholders participating in this inquiry. Data privacy is safeguarded by supplying the data model rather than real data. Last but not least, federated learning is integrated into the permissioned blockchain consensus process so that federated training may be done using the same computer resources as consensus.

In [12], the paper looks at how data and security problems have emerged in bright edge computing devices and how to fix them. The proposed strategy combines machine learning methods like classifiers and optimization algorithms with Blockchain consensus to secure data. In addition, the authors used the tools available in an edge computing environment to send different data batches to various customers. The use of Blockchain servers resulted in the preservation of client anonymity. Furthermore, the authors developed a federated learning technique to segment the client data into learnable batches. The study's findings reveal how to deploy a Blockchain-based training model in a computing environment with an advantage. The article [12] examines how smart edge computing devices are developing data and security flaws, as well as how to correct them. The suggested method combines machine learning methods like classifiers and optimization approaches with data security. The authors also used the proposed methods in an edge computing setting, sending various clients distinct batches of data. The utilization of Blockchain servers ensured the protection of client anonymity. The authors separated the client data into batches, which were then taught via a federated learning approach. The findings of this study demonstrate how to implement a Blockchain-based training model in an edge-computing environment. The paper [13] described an FL with an incentive-aware MD powered by blockchain. It contributes in two important ways: first, it uses competition to encourage employees to maximize their benefits, and second, the design requires employees to obey the protocol without using cryptographic techniques such as homomorphic encryption or zero-knowledge proof. Second, several criteria for the protocol design's functionality have been quantitatively identified using contest theory. These theoretical proof results are optimistic for implementing the blockchain-enabled FL.

In [14], the research presents a special FL-Block (federated learning with blockchain) approach. With FL-Block, end-device local learning updates may be shared with a blockchain-based, miner-verified global learning model. Based on this, FL-Block uses the blockchain's PoW consensus mechanism to allow autonomous machine learning to maintain the worldwide model and coordinate without a centralized authority. Additionally, the performance of the FL-latency Block has been investigated, and the appropriate block production rate has been estimated while considering communication, consensus delays, and computational costs. Numerous assessment results demonstrate FL-Superior Block's efficiency, resistance to poisoning assaults, and privacy protection.

The research [15] gives an unbiased road map of this problem's current status by fully investigating the privacy and security argument in the context of blockchain-based FL methods on scientific datasets. The results of this study show that BC-FL has expanded dramatically over the last five years, and blockchain technology is being used more frequently to address issues with patient healthcare records, image retrieval, cancer datasets, industrial equipment, and economic data in the context of IoT applications and intelligent environments. The literature review in [16] suggests blockchain-based federated learning (FL) as a decentralized, efficient, and trustworthy federated learning solution. The concept has three major components: customers, blockchain technology, and machine learning engineers. The benefits of the new federated learning system built on the blockchain are also highlighted, as are several techniques for protecting model privacy on the blockchain.

III. FEDERATED LEARNING

Standard machine-learning algorithms require that training data be stored on a single computer or in a data center. Additionally, Google has constructed one of the most dependable and secure cloud infrastructures to improve services. It introduces Federated Learning, a fresh method for building models users interact with on mobile devices.

Federated learning reduces the requirement for machine learning to save data on the cloud by allowing mobile devices to participate in the creation of a shared predictive model, with all training data kept locally. Extending model training to the device, goes beyond utilizing local models to make predictions on mobile devices (such as the Mobile Vision API and On-Device Smart Reply).

The approach follows: after receiving the current model, the device updates it using the phone's data and then summarizes the changes in a brief, focused update. Only this model modification is safely transferred to the cloud, where it is quickly averaged with the changes of other users to enhance the overall model. All training data is kept on the device; no individual updates are saved on the cloud.

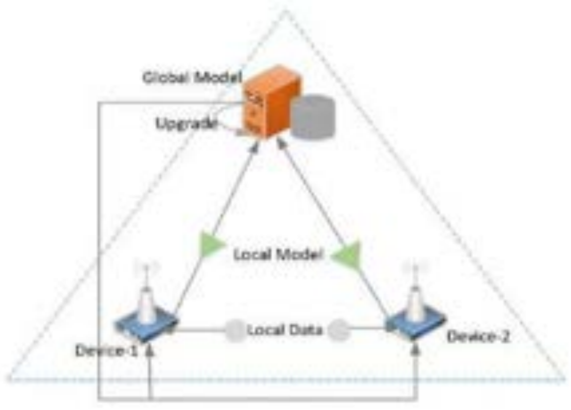

Fig. 3. Federated Learning

A distributed machine learning strategy for protecting data privacy is called federated learning. Federated learning systems rely on a central server to coordinate model training over several distributed client devices that store data. No data is transferred outside the client devices during the model training, which takes place locally on the clients. Decentralized methods can also be used for federated learning. Image, structured, and text data types are the most frequently utilized, with picture categorization being the most popular application. Federated learning is widely used by applications that infer personal data from mobile devices, such as images, financial or medical information, and text.

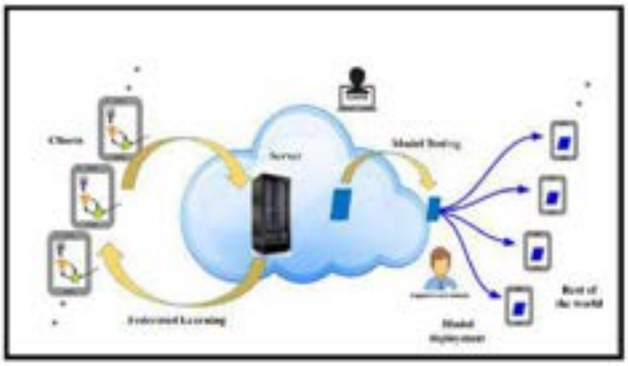

Fig. 4. Integration of Blockchain with Federated Learning

IV. LIMITATIONS OF FEDERATED LEARNING

FL relies on a central server susceptible to malicious activity, resulting in erroneous global model updates. All local model updates are distorted, reducing the precision of subsequent local model updates. Furthermore, due to network speed limits, sending many models at once may overburden the central server. One of the most common issues with federated learning is the single point of failure.

Fraudulent participants can cause training samples or models to fail, invalidating machine learning predictions, yet FL cannot audit malevolent trainers. Malicious clients can, therefore, tamper with the local model, upload erroneous mask gradients, and publish unsponsored shares to the center server, which can all damage the global model.

FL assumes that each local device will give out all of its data resources however this needs to be more practical. Because participants must use their data and computing resources, there is minimal incentive for participants to do model training. Mobile devices that are self-centered will be hesitant to engage in model learning unless well compensated. As a result, FL has a loss of motivation for model training.

The privacy of training data is compromised by FL frameworks even when the training resource is stored locally. Some researchers have created attacks that extract considerable information from intermediate gradients. Thus, there is a reasonable *threat to privacy* in FL.

1. Communication Overhead and Latency: FL relies on communication between local devices and the central server. However, transmitting model updates over

potentially slow or unreliable networks can introduce significant delays and increase communication overhead. This can lead to synchronization issues and hinder the efficiency of the learning process, especially in scenarios where real-time model updates are crucial.

2. Heterogeneity of Devices and Data: In a federated learning setting, devices contributing to the training process may vary widely in terms of hardware capabilities, network bandwidth, and the quality of their data. This heterogeneity can introduce challenges in effectively aggregating model updates. Models trained on data from diverse sources may generalize poorly to unseen data or suffer from biases inherent in the training data distribution.

3. Data Distribution Shifts: Data distribution across participating devices may evolve due to various factors such as user behavior changes, device upgrades, or changes in application usage patterns. These changes can lead to distributional shifts in the training data, potentially causing degradation in model performance if not adequately addressed through techniques like continual learning or adaptive federated learning algorithms.

4. Privacy Risks and Regulatory Compliance: FL raises significant privacy concerns as sensitive data remains on user devices and is only shared as model updates. However, even with this decentralized approach, FL frameworks are susceptible to privacy attacks such as membership inference and model inversion attacks. Ensuring compliance with privacy regulations like GDPR becomes challenging, mainly when dealing with sensitive data such as healthcare records or financial transactions.

5. Model Robustness and Security: Federated learning models may be vulnerable to adversarial attacks, where malicious actors attempt to manipulate the learning process by injecting carefully crafted data or perturbations into the model updates. Ensuring the robustness and security of federated learning models against such attacks requires the development of robust aggregation mechanisms and defenses against adversarial manipulation.

6. Scalability and Resource Management: As the number of participating devices or clients in a federated learning system grows, managing resources such as computation, storage, and bandwidth becomes increasingly challenging. Scalability issues may arise, impacting the ability to efficiently coordinate model updates and maintain system performance under heavy loads.

V. BC-FL INTEGRATION

The blockchain is a distributed, decentralized database. The system generates interactive records (transactions), organised into blocks and saved in each time segment. Any node in the system may carry out safe peer-to-peer transactions because each transaction is encrypted and secured by Proof of Work (PoW) mechanisms that cannot be manipulated or falsified. A block, as seen in Fig. 5, comprises many transaction records and a block header containing information. The limited definition of Blockchain connects these blocks with the hash reference in the block header to form an entire ledger. The blockchain comprises five layers: data, incentive system, consensus, network, and application.

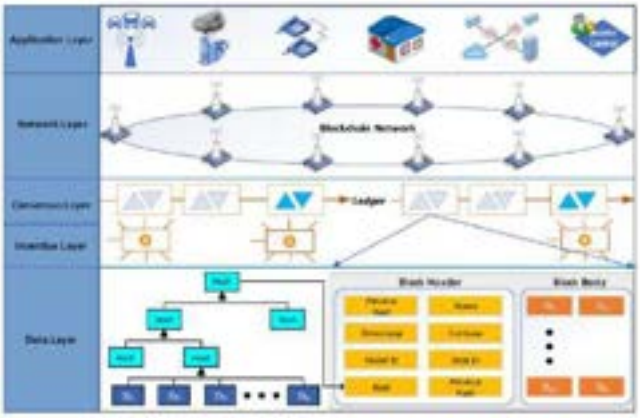

Fig. 5. Blockchain Architecture

Based on application scenarios and constructed technologies, blockchain is divided into three groups: public chain, consortium chain, and private chain. Typically, several Blockchain variants are selected depending on the requirements of distinct business scenarios. However, the public chain may generally only satisfy the initial design goal of the Blockchain.

Distributed blockchain nodes can be the FL center server to solve single-point failure. Miner nodes can transmit model updates for neighboring devices. Miner nodes are chosen independently or at random.

Each local device performs computations and sends local model changes to the linked miner. Miners can trade after completing Proof of Work, validate uploaded model modifications, and record authorized local model updates (PoW). The aggregated model adjustments are supplied, and the blocks holding those modifications are uploaded to the blockchain. The newly constructed block may also provide global model updates to any local device. The confirmed model may be aggregated, and chunks generated by local devices can be employed as miners.

Blockchain may also encourage collaboration and serve as a disincentive to misbehavior to advance the interests of the consumers. The local device may receive incentives if the local model updates are determined to be valid. If improper updates are uploaded, the local device will also be penalized. Blockchain consensus algorithms may verify improper changes to prevent poison attacks. Researchers have created the Multi-Krum defense, which checks local model changes using a Byzantine-tolerant aggregation approach. To protect players against poison assaults, a unique selection method based on a scoring system has been developed. An alternative consensus technique based on proof of verification has also been developed. Preset miners can remove hazardous and deadly model parameters by ensuring accurate model updates. The validity of is decided by the validator.

The findings show that while the use of blockchain technology eliminates most of the difficulties associated with conventional FL, certain drawbacks remain.

While blockchain consensus algorithms have certain security concerns, several researchers have used them to prevent poison attacks. Misbehaving miners use most of the system's computational power in PoW, which can result in blockchain splits.

Furthermore, PBFT has the potential to accept roughly one-third of the error nodes. As a result, various research has developed novel consensus algorithms such as PoK, PoQ, PoF, and so on. They can lower power usage but need to increase consensus mechanism security. The findings show that while blockchain technology eliminates most of the difficulties associated with conventional FL, there are still certain drawbacks.

Several research employed blockchain consensus algorithms to avoid poison attacks. However, blockchain consensus algorithms have several security problems. Misbehaving miners use most of the system's computational power in PoW, which can result in blockchain splits.

VI. BC- FL Architecture

For the completely decentralized, privacy-protected FL system, the Blockchain primarily serves as a central database. As a result, the primary goal is to recompense clients based on their contributions' value while protecting the underlying dataset's privacy and avoiding malicious assaults.

A platform must be used to support the Blockchain layer's functionality in BCFL to operate. Different Blockchain platforms have various characteristics. For instance, consortium networks offer robust security, public chains provide dependable performance, and private chains offer more customization options. Four platforms, Ethereum, Hyperledger Fabric, EOS, and Custom Blockchain, are

Ethereum: Ethereum is a public blockchain platform known for its smart contract functionality and wide adoption in various decentralized applications (DApps). It offers robust security and transparency due to its decentralized nature, making it suitable for BCFL projects where openness and accessibility are paramount. Ethereum's large developer community and ecosystem also provide extensive support for building and deploying FL solutions.

Hyperledger Fabric: Hyperledger Fabric is a permissioned blockchain framework designed for enterprise use cases. It offers advanced privacy features, scalability, and modular architecture, making it well-suited for BCFL projects that require fine-grained control over access permissions and data privacy. Hyperledger Fabric's focus on consortium networks aligns with the collaborative nature of federated learning, where multiple stakeholders need to securely share and process data.

EOS: EOS is a public blockchain platform known for its high throughput and low latency, making it suitable for applications requiring fast transaction processing. In BCFL projects, EOS may be preferred for real-time or latency-sensitive applications where quick model updates are essential. Its delegated proof-of-stake (DPoS) consensus mechanism enables efficient block production and transaction validation, enhancing the overall performance of FL systems.

Custom Blockchain: Custom Blockchain refers to bespoke blockchain solutions tailored to specific project requirements. While less standardized compared to established platforms like Ethereum or Hyperledger Fabric, custom blockchains offer flexibility and customization options tailored precisely to the needs of BCFL projects. These custom solutions may incorporate unique consensus mechanisms, privacy enhancements, or interoperability features optimized for federated learning environments.

These are predominantly used by the current BCFL, according to a thorough assessment of the literature.

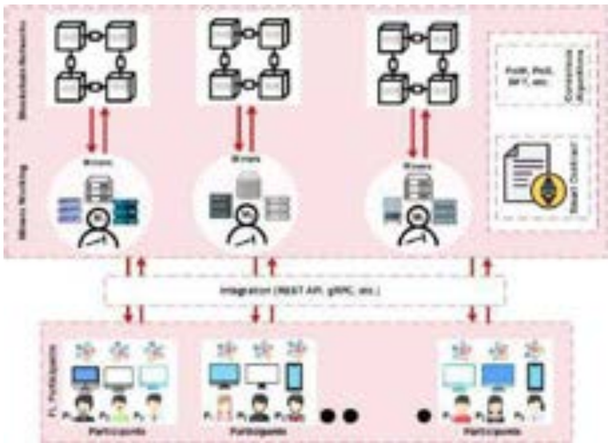

Fig. 6. FC-BL Architecture

Players in federated learning: Just like in a typical FL environment, participants take on the roles of entities or devices. Participating FL members train models and provide local model updates for the following stage of verification and aggregation. All FL system participants are first given access to the core model. Then, FL participants update local models using their unprocessed datasets. Direct communication occurs between miners and FL members.

The Blockchain and FL integration acts as a go-between for FL players and the blockchain. Users linked to the Hyperledger Fabric blockchain using the REST-API to record and reward gradient uploads. The API also enables data transmission between FL clients and the Ethereum blockchain network by utilizing Google's remote procedure calls.

If the mining program is easily downloadable, miners can utilize their personal computers, standby servers, or cloud-based nodes. The FL participants are now sending local model modifications to the miners. Each FL participant/data holder is immediately connected to the miner, enabling continuous communication. Miners are responsible for obtaining local model updates from FL devices or participants. Furthermore, aggregation is carried out utilizing the consensus mechanism, and a block is then put into the blockchain.

The blockchain system's Smart Contract (SC) component opens up new possibilities for decentralized applications by dynamically executing program logic in response to preset conditions. Before starting the FL model training process, participating FL clients will agree that all criteria are clear and immutable. SC also gives customers the option to establish agreements without the help of a reliable third party. Researchers used smart contact in several ways, including signing up participants, organizing model training, compiling local model updates, rating participant contributions, and providing incentives. A smart contract assignment between FL players and miners is shown in Figure 5.

Transaction verification is based on the consensus algorithm, which is the blockchain network's backbone. On a blockchain network, everyone agrees on how to generate, verify, and approve new blocks. When miners reach a consensus mechanism, such as Proof of Work (PoW), Proof of Stake (PoS), or Byzantine Fault Tolerance (BFT), a new block is added to the blockchain. When blockchain technology and federated learning combine, the system becomes more adaptable. FL participants will enter a new FL training phase, and miners will learn how to create a completely converged global model using a consensus technique. Once the consensus method is completed, the block is added to the blockchain network.

BCFL ARCHITECTURE AND COMPONENTS

Finally, the freshly produced and validated blocks are uploaded. The FL model strategy is repeated until the desired learning rate is achieved. Following that, FL customers or other parties may request the global model for their usage. Finally, miners may download global models, which FL players can purchase.

1. Federated Learning Participants:
- Operate similarly to a typical federated learning environment.
- Entities or devices participate by training models, providing local updates, and engaging in verification and aggregation processes.
2. Blockchain and FL Integration:
- Acts as an intermediary between FL participants and the blockchain.
- Hyperledger Fabric and Ethereum are utilized for integration, facilitating the recording and rewarding of gradient uploads through REST-API, and Google's remote procedure calls for data transmission.
3. Miners' Role:
- Miners, utilizing personal computers, standby servers, or cloud-based nodes, receive local model updates from FL participants.
- Continuous communication is established, and aggregation is performed using a consensus mechanism.
- Aggregated updates are then added to the blockchain as a new block.
4. Smart Contracts:
- Smart Contracts (SC) play a crucial role in automating processes in response to preset conditions.
- SC facilitates agreements among FL participants and miners without relying on a third party.
- Used for participant registration, organizing model training, compiling local model updates, rating contributions, and providing incentives.
5. Consensus Mechanism:
- Transaction verification is based on a consensus algorithm, such as Proof of Work (PoW), Proof of Stake (PoS), or Byzantine Fault Tolerance (BFT).
- The consensus mechanism ensures agreement on generating, verifying, and approving new blocks, contributing to the security and integrity of the BC-FL system.
6. Blockchain Network:
- Newly produced and validated blocks are uploaded to the blockchain network.
- FL model training phases continue until the desired learning rate is achieved.

Global models, created through consensus techniques, are made available for FL customers or other parties to request and use.

VII. FEDERATED LEARNING AND BLOCKCHAIN

3.1 Overview of Federated Learning

Federated Learning, as proposed by McMahan et al. (2017), serves as a centralized training method with a primary focus on protecting user privacy through unique data distribution properties. FL participants, representing consumers (FL users), contribute training data from their private local datasets to the FL server, enabling the creation of a global model. The FL server consolidates these local model updates, forming a globally converged model that users can download.

Equation (1) defines the FL server's communication with selected FL participants, conveying the initial model changes (mt) for each training round (t). Following this, FL clients utilize an initial model to train local data, updating their local model. These local model changes are then submitted to the central FL server, which compiles them. The process iterates until Gt represents the global model as of the tenth iteration, and Gt+1 signifies a globally converged model.

Performing federated learning involves a series of steps to train a global model collaboratively across multiple devices while preserving data privacy. The process typically follows these general steps:

1. Initialization: The FL server initializes the global model and communicates it to selected FL participants.
2. Training Rounds: Each training round begins with the FL server sending the current global model (mt) to selected FL participants. Participants then use their local datasets to train the model locally, resulting in local model updates.
3. Model Aggregation: FL participants send their local model updates back to the FL server, which aggregates them to form a globally converged model. This

aggregation process typically employs algorithms like Federated Average (FedAvg) or its variants to combine local updates while addressing system heterogeneity.
4. Iteration: Steps 2 and 3 are iterated for multiple rounds (t) until the global model (Gt) converges to a satisfactory level of performance.

Evaluation: The final converged model (Gt+1) is evaluated for performance on validation data or testing datasets to assess its effectiveness.

$$G_{t+1} = G_t + \frac{1}{m_t}\sum_{k=1}^{m_t} l_t^k,$$

The foundation of FL lies in the aggregation algorithm, specifically the vanilla Federated Average (FedAvg), allowing the accumulation of local model updates. To address system heterogeneity, FedProx, a generalization of FedAvg, is introduced. Various improvements to the aggregation approach, such as Federated Matched Averaging (FedMa) and Federated Optimisation (FedOpt), aim to overcome specific FL challenges. Additionally, three types of FL are identified, including Horizontal Federated Learning (HFL).

Real-world Applications of Blockchain-based Federated Learning (BC-FL):
1. Healthcare Data Sharing:
- Scenario: Collaborative improvement of a global disease prediction model without sharing sensitive patient data.
- BC-FL Implementation: BC-FL enables secure participation of multiple hospitals, keeping data private and sharing local model updates securely through blockchain. Smart contracts ensure fair compensation.

2. Finance and Fraud Detection:
- Scenario: Collaborative enhancement of fraud detection models without revealing individual transaction details.
- BC-FL Implementation: Blockchain ensures the integrity and transparency of financial transactions. FL participants from different banks securely share model updates through the blockchain, with smart contracts automating reward distribution.

3. Smart Grid Optimization:
- Scenario: Collective improvement of predictive models for energy consumption to optimize smart grids.
- BC-FL Implementation: BC-FL allows decentralized collaboration among energy providers, securing local data on energy consumption patterns through blockchain. The consensus mechanism ensures accuracy and reliability.

4. Supply Chain Management:
- Scenario: Optimization of inventory management and logistics in a supply chain without exposing proprietary data.
- BC-FL Implementation: Blockchain ensures transparency and traceability. Federated learning participants contribute local insights through blockchain, and smart contracts automate compensation based on contributions' value.

5. Autonomous Vehicles Collaboration:
- Scenario: Collaboration among autonomous vehicle manufacturers to improve traffic prediction models without sharing real-time location data.
- BC-FL Implementation: BC-FL allows secure sharing of model updates through blockchain, preserving the privacy of individual vehicle data. Smart contracts facilitate fair compensation.
6. Cross-Border Research Collaboration:
- Scenario: Researchers from different countries collaborate on a scientific project requiring analysis of diverse datasets without compromising data privacy.
- BC-FL Implementation: BC-FL ensures secure collaboration through blockchain, allowing researchers to contribute local model updates while maintaining privacy. Smart contracts automate reward distribution based on the significance of contributions.

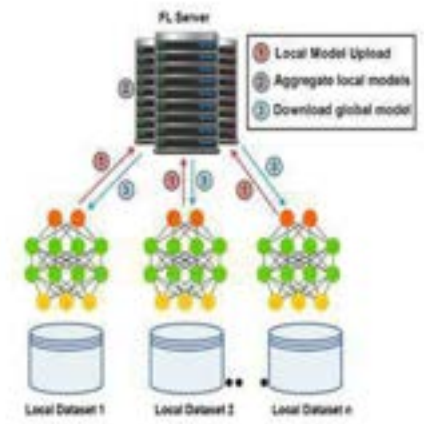

Fig. 7. Federated learning architecture

VIII. OVERVIEW OF BLOCKCHAIN

Blockchain technology has emerged as a revolutionary force in Federated Learning (FL), with the ability to solve key privacy, security, and cooperation issues. This section provides a detailed explanation of how Blockchain is being incorporated into the fabric of Federated Learning, altering the landscape of decentralized machine learning. At its foundation, Blockchain functions as a decentralized and distributed ledger, dramatically disrupting the previous paradigm of centralized control. In the context of Federated Learning, this invention provides a safe and transparent framework for collaborative model training over a network of different devices without compromising individual datasets' privacy.

Blockchain's design is based on a succession of blocks, each containing transactional data, a timestamp, and the previous block's cryptographic hash. This structure guarantees an immutable and chronological record, which protects transaction integrity. Applied to Federated Learning, these blocks encapsulate crucial information about model updates, preserving the lineage of collaborative efforts while maintaining data privacy. Timestamps and cryptographic hashes not only secure the transactions but also establish a secure and tamper-resistant link between blocks, fortifying the reliability of the transaction history.

The decentralized nature of Blockchain is well-aligned with the principles of Federated Learning. In traditional machine learning models, data is often centralized, posing significant privacy risks. Blockchain, through its peer-to-peer (P2P) network, redistributes control and information, allowing participants, often individual devices or nodes, to engage in collaborative model training. Each member of the blockchain network maintains a synchronized copy of the transaction history. This increases transparency and reduces the dangers associated with a single point of failure.

Federated Learning categorizes blockchain into three types: public or permissionless blockchain, private or commissioned blockchain, and consortium blockchain. In the case of a public blockchain, no single entity dominates, and participants can join or exit the network at will, fostering decentralization and transparency. In contrast, private blockchains have a centralized structure in which a single party has power over transaction validation, increasing efficiency and speed. Consortium blockchains strike a balance, granting specific privileges to selected participants and necessitating consensus before implementing transactions, thus combining aspects of both public and private configurations.

Central to Blockchain's functionality are consensus algorithms, determining the rules governing the acceptance of transactions. The choice of consensus algorithm is crucial in the context of Federated Learning, impacting the trade-off between security, efficiency, and scalability. Algorithms like Proof of Work (PoW) and Proof of Stake (PoS) play pivotal roles in securing the integrity of the Blockchain network.

Smart contracts, autonomous and self-executing pieces of code deployed on the Blockchain, further enrich the landscape of Federated Learning. In the context of FL, smart contracts serve as digital agreements between participating nodes, executing predefined functions to facilitate seamless and automated interactions. These contracts, distributed across all nodes on the Blockchain, ensure transaction traceability and enforce irreversibility, contributing to the overall integrity of the collaborative process.

Achieving security in blockchain-based federated learning involves implementing several key measures. Firstly, encryption techniques such as homomorphic encryption ensure that sensitive data remains encrypted during transmission and computation, thus safeguarding it from unauthorized access. Secondly, decentralized consensus mechanisms, inherent to blockchain technology, validate transactions and updates to the federated learning model, ensuring integrity and preventing tampering. Additionally, access controls and smart contracts enforce permissions, dictating who can participate in model training and access the federated learning system, thereby mitigating potential security threats. Finally, regular audits and monitoring of the blockchain network help identify and address security vulnerabilities, ensuring the overall robustness of the system. Through these integrated security measures, blockchain-based federated learning systems can provide a high level of security and trustworthiness for collaborative model training across distributed devices

In conclusion, the integration of Blockchain in Federated Learning represents a paradigm shift, offering innovative solutions to the challenges posed by traditional machine learning approaches. This overview elucidates the core principles of Blockchain technology and its transformative potential in revolutionizing Federated Learning. As the intersection of Blockchain and FL continues to evolve, this synergistic relationship holds the promise of fostering a secure, transparent, and collaborative future for decentralized machine learning.

IX. Blockchain-based Federated Learning (BFL)

When performing a systematic review of Blockchain-based Federated Learning (BFL), a thorough and precise approach is used to examine the current body of research, providing significant insights into the junction of these two cutting-edge technologies. The research selection criteria will be purposefully designed to prioritise papers that directly address the combination of Blockchain and Federated Learning, resulting in a targeted and relevant evaluation. Inclusion criteria will include works published in respectable peer-reviewed journals, conference proceedings, and recognised research databases. To capture the latest developments, the review will concentrate on literature within the last ten years, allowing for an up-to-date exploration of the field.

A structured data extraction form will be used to obtain relevant information from the selected research systematically. This includes details on authors, methodologies, key findings, Blockchain technologies utilized, and implications for Federated Learning. The collected data will undergo thematic analysis, allowing for the categorization and synthesis of findings. The focus will be on critical aspects such as integration challenges, benefits, and the impact on user perspectives, providing a holistic perspective.

Quality assessment will be a critical component of this systematic review, ensuring the reliability and robustness of the included studies. The evaluation will consider the methodologies employed in the research, offering a qualitative lens to interpret the findings and draw meaningful conclusions. Adhering to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines, the reporting phase will present a clear and transparent depiction of the study selection process through a flow diagram, and a narrative synthesis will be crafted to communicate the key findings cohesively.

This meticulously crafted methodology emphasizes systematic search strategies, rigorous study selection, and comprehensive data extraction. The goal is to give a complete assessment of the environment of Blockchain-based Federated Learning. Through this approach, the systematic review contributes substantively to the understanding of the integration of Blockchain in the evolving field of Federated Learning, shedding light on challenges, benefits, and potential avenues for future research.

X. CHALLENGES AND OPPORTUNITY

The intersection of Blockchain technology with Federated Learning (FL) creates a complex interplay of obstacles and possibilities that shapes the trajectory of this novel paradigm. Scalability is one of the most challenging obstacles to overcome when integrating Blockchain with Federated Learning. While effective in ensuring transparency and immutability, the classic Blockchain structure faces challenges when the number of participants and transactions grows. The sheer amount of computations necessary for consensus algorithms such as Proof of Work (PoW) or Proof of Stake (PoS) creates a scalability barrier that may impede the smooth execution of collaborative machine learning projects. Striking a balance between maintaining decentralization, a cornerstone of Blockchain, and meeting the scalability demands of Federated Learning remains a persistent challenge.

The inherent commitment to privacy in Federated Learning introduces a layer of intricacy when coalescing with the transparent nature of Blockchain. Privacy-preserving techniques, fundamental to the ethos of Federated Learning, demand meticulous attention when navigating the decentralized Blockchain ecosystem. As the assurance of individual data privacy clashes with the necessity for a transparent and auditable transaction history, reconciling these seemingly opposing principles emerges as a nuanced challenge. This intricate dance requires innovative solutions to preserve the privacy of individual contributions while upholding the integrity and transparency promised by Blockchain.

Another challenge emanates from the heterogeneity of devices within a federated environment. The diverse range of computational capabilities and network bandwidth across participating nodes introduces a potential stumbling block. Disparities in node processing speeds can impede collaborative learning efforts' synchronization and efficiency. Addressing this challenge necessitates designing mechanisms that accommodate the variability in device capabilities, ensuring an inclusive and equitable participation framework for all nodes.

Despite these challenges, the fusion of Blockchain and Federated Learning unveils promising opportunities that could reshape the landscape of collaborative machine learning. Blockchain's immutable and transparent nature provides a foundation for enhanced accountability and traceability in Federated Learning transactions. This feature addresses the challenge of maintaining a trustworthy ecosystem and builds a foundation of trust among participants. The decentralized design of Blockchain reduces the risks associated with a single point of failure, resulting in a more resilient and secure environment for collaborative learning.

Moreover, the integration of smart contracts within the Blockchain framework introduces a layer of automation to the coordination and execution of tasks in Federated Learning. Smart contracts can streamline and automate the negotiation of terms and conditions among participating nodes, thereby enhancing the overall efficiency of collaborative learning initiatives. This automation holds the potential to minimize manual intervention, reducing friction in the collaborative process and fostering a more seamless and efficient workflow.

An additional opportunity arises with the prospect of tokenization within Blockchain-based Federated Learning. Implementing token-based incentive mechanisms can stimulate active participation and contribution from nodes. The introduction of tokens aligns with the principles of decentralized incentive structures, creating a dynamic and engaging collaborative environment. Token-based rewards systems have the potential to incentivize participation, fostering a sense of ownership and motivation among nodes within the federated ecosystem.

In conclusion, the challenges and opportunities entwined in Blockchain-based Federated Learning delineate a dynamic and intricate landscape. While scalability, consensus mechanisms, and privacy concerns present formidable challenges, the inherent advantages of Blockchain offer novel solutions to reshape collaborative machine learning. Navigating these hurdles and capitalizing on possibilities will help define the future of Blockchain-based Federated Learning, opening the path for a safe, transparent, and efficient collaborative machine learning paradigm.

XI. FUTURE DIRECTIONS

As the combination of Blockchain technology with Federated Learning (FL) continues to mature, a fascinating array of future paths emerges, opening the door for significant breakthroughs in collaborative machine learning. One prominent avenue for exploration revolves around refining consensus mechanisms tailored specifically for the nuances of Federated Learning within a Blockchain environment. While traditional Proof of Work (PoW) and Proof of Stake (PoS) procedures have shown to be effective in typical Blockchain contexts, they may not be ideal for FL's dynamic and decentralized nature. Future research should delve into developing consensus algorithms that strike a delicate balance between ensuring data integrity and minimizing computational overhead, thus addressing one of the primary challenges currently faced. Furthermore, privacy-preserving strategies in the context of Blockchain-based Federated Learning need for improved methodology. Future research endeavors could focus on pioneering cryptographic solutions or innovative privacy-preserving algorithms that bolster the seamless integration of individual privacy with the transparent nature of Blockchain. This would involve not only protecting sensitive information during collaborative machine learning but also ensuring that the integrity and traceability promises of Blockchain are upheld. Exploring cutting-edge cryptographic approaches such as homomorphic encryption or secure multi-party computation might be the key to unlocking new dimensions in privacy and security. The heterogeneity of devices participating in federated environments presents a rich area for future research. Tailoring Federated Learning algorithms to accommodate the diversity in computational capabilities and network bandwidth across nodes becomes imperative. Future directions may involve the development of adaptive and dynamic federated learning strategies that adjust according to the capabilities of individual nodes. Ensuring an inclusive and equitable participation framework for all nodes, irrespective of their computational prowess, will be essential for the continued success and scalability of Blockchain-based Federated Learning.

Furthermore, the concept of tokenization within Blockchain-based Federated Learning introduces novel opportunities. Future research may delve into the design and implementation of sophisticated token-based incentive mechanisms. Exploring the dynamics of token economies within federated ecosystems could yield insights into how incentivizing active participation and collaboration enhances the overall efficiency and engagement. This involves not only the creation of tokens as rewards but also the exploration of governance models and decentralized decision-making frameworks fueled by these tokens.

In the realm of practical applications, future research could focus on developing use case-specific frameworks for Blockchain-based Federated Learning. Tailoring the integration to suit the requirements of specific industries, such as healthcare, finance, or manufacturing, would involve understanding the unique challenges and opportunities within these sectors. This industry-specific approach could pave the way for more targeted and impactful implementations of federated learning in real-world scenarios, aligning with the broader trend of responsible and contextual AI deployment.

In conclusion, the future directions of Blockchain-based Federated Learning are rich with possibilities, beckoning researchers to delve into innovative solutions and advancements. Addressing the intricacies of consensus mechanisms, refining privacy-preserving techniques, accommodating device heterogeneity, integrating explainability, exploring token economies, and tailoring frameworks to specific industries all contribute to the burgeoning landscape of collaborative machine learning. As research unfolds, these future directions hold the potential to reshape the trajectory of Blockchain-based Federated Learning, propelling it into a realm of increased efficiency, transparency, and real-world applicability.

XII. CONCLUSION

In conclusion, this systematic review has unveiled the complexities between Blockchain and Federated Learning (FL), shedding light on the transformative potential and challenges of their integration. The examination of the literature points to a scenario in which Blockchain's transparency and decentralisation might successfully address FL's inherent issues with data security and privacy. While challenges such as scalability and consensus mechanisms persist, the amalgamation of these technologies presents a groundbreaking avenue for collaborative machine learning. The transparent and immutable nature of Blockchain addresses trust and accountability concerns in FL, fostering a more secure environment for shared data. The automation introduced through smart contracts and tokenization mechanisms not only streamlines collaboration but also incentivizes active participation. Looking forward, it is imperative for researchers to focus on refining consensus mechanisms and privacy-preserving techniques, balancing the decentralized principles of Blockchain with the scalability demands of FL. In order to fully realise the potential of Blockchain-based Federated Learning and provide the groundwork for a future in which collaborative machine learning is founded on the values of decentralisation, security, and transparency, this comprehensive evaluation serves as a guide.

***Abstract*—This research presents a comprehensive Internet of Things-enabled safety system designed for individuals with epilepsy. The system integrates epileptic seizure detection, alcohol monitoring, and vehicle engine control mechanisms to enhance the overall safety of individuals prone to seizures. Utilizing MQ3 and EEG sensors, the system continuously monitors physiological indicators to detect and analyse epileptic events. Additionally, an alcohol detection module ensures that individuals under the influence are identified. The incorporation of GPS technology enables real-time location tracking, crucial for prompt intervention during seizures. The system's IoT architecture facilitates seamless communication with cloud platforms, allowing for data storage, analysis, and remote monitoring. Furthermore, in instances of detected alcohol consumption, the system employs relay control to prevent engine start up, minimizing the risk of impaired driving. This integrated solution aims to provide a robust safety net for individuals with epilepsy, promoting independence while prioritizing their well-being in various scenarios.**

Keywords— Internet of Things; Global Positioning System; Seizure; MQ3; Electroencephalogram.

I. INTRODUCTION

Epilepsy presents substantial problems to the day-today lives of those who are affected by it, with the unexpected nature of seizures offering inherent hazards. In the management of epilepsy, one of the most important aspects is making sure that persons who are prone to seizures are safe. This is especially important in situations where impairments, such as drinking alcohol, make these risks even more substantial. The findings of this study present a novel safety system that is based on the Internet of Things (IoT). This system combines the detection of epileptic seizures, the monitoring of alcohol consumption, and the management of car engines to produce a holistic solution for people who suffer from epilepsy. By utilizing cutting-edge technology, the primary objective of this integrated system is to improve the safety and freedom of individuals who are diagnosed with epilepsy.

The system is able to enable real-time detection and analysis of epileptic occurrences because it makes use of sophisticated sensors that are able to monitor physiological indications that are connected with seizures. This makes it possible to intervene at the appropriate time and improves the overall management of hazards associated with epilepsy. One of the most important aspects of this safety system is the Internet of Things (IoT), which enables cloud platforms to communicate with one another in a smooth manner. This connectivity makes it possible to perform remote monitoring, data storage, and analysis.It aims to provide a full safety net to the individuals who has absent seizure that last for less than 15 seconds.

II. RELATED WORKS

[1] Ugochi A. Okengwu, et.al, 2022, “Design and Implementation of In-Vehicle Alcohol Detection and Speed Control System”, Research Gate, studied to address the issue of road accidents caused by driver’s

alcohol consumption in Nigeria. Despite existing measures, accidents persist due to speeding, rash driving, and drunk driving. The researchers designed an In-Vehicle Alcohol Detection and Speed Control System using Arduino Nano. The system met engine start standards, and if the driver's BAC exceeds 0.5 mg/mL, authorities are notified via GSM. Experimental results show rapid alcohol detection and prolonged operation of the system.

[2] Anuja Khodaskar, et.al, 2011, "IOT based DD Detection System", IJCRT, implemented an IoT based Drunk and Drive Detection (DDD) system aimed at early identification of alcohol-impaired drivers. Drunk driving is a significant contributor to traffic accidents globally, leading to numerous fatalities. The proposed system monitors alcohol levels using a sensor and, if the driver is found to be intoxicated, instantly halts the vehicle's ignition through the processor. Additionally, the system utilizes GPS and GSM technology to relay the vehicle's location to pre-programmed contacts. The implementation of this system aims to reduce accidents caused by alcohol consumption, contributing to improved road safety and advancements in the automotive industry.

[3] Gorlagunta Latha, et.al, 2023, "IOT Based Automatic Speed Control And In-Vehicle Alcohol Detection System Forsmart Vehicles", Academia, introduced an IoT-based Automatic Speed Control and In-Vehicle Alcohol Detection System for smart vehicles. Utilizing the Arduino UNO microcontroller board, the system integrates an alcohol sensor, control switch, RF Module, Wifi Module, and speed control modules. The alcohol sensor continuously monitors the driver's blood alcohol level through breath analysis, and in the event of alcohol detection, the system automatically shuts off the vehicle's ignition. This technology presents a promising approach to reducing accidents caused by impaired driving in the realm of intelligent smart vehicle systems.

[4] Chaitanya V Shembekar, et.al, 2020, "IoT based Alcohol and Driver Drowsiness Detection and Prevention System", Research Gate, implemented a system which utilizes visual data and artificial intelligence to detect drowsiness by analysing the driver's face and eyes, measuring the level of eye closure (PERCLOS) with Softmax for neural network processing. Additionally, the system incorporates alcohol and heart rate detection to assess the driver's condition. The aim is to address fatigue-related accidents, particularly in drivers of large vehicles with extended driving periods and challenging conditions.

[5] Diwakaran.S, et.al, 2021, "Android Based Alcohol Detection System Using an IOT", IJCRT, developed a road transportation safety system for the those living in cities to enjoy the availability of Alcohol detection system. It works with the integration of IoT. I t traces the content of alcohol and denies driving.It provides awareness to the public surrounded by making loud noise.

[6] Arun Francis, et.al, 2019, "Health monitoring with alcohol detection and ignition control system using IOT", Research Gate, proposed a solution which involves monitoring alcohol consumption and heart rate. If the driver is identified as drunk, the vehicle's ignition system is disabled, preventing movement and potential accidents. Additionally, abnormal changes in heart rate trigger the transmission of the driver's status to friends via IoT. Due to practical constraints, the system is implemented using a DC motor, with Node MCU serving as the controller.

[7] Stanley Uzairue, et.al, 2018, "IoT-Enabled Alcohol Detection System for Road Transportation Safety in Smart City", core.ac.uk, discussed the development of an IoT-enabled alcohol detection system for road transportation safety in smart cities. It utilizes a microcontroller to monitor two Blood Alcohol Content (BAC) thresholds. Upon reaching the first threshold, the system transmits the driver's BAC level and vehicle coordinates to a central monitoring unit. Upon reaching the second threshold, the system shuts down the vehicle's engine, triggers an alarm, and activates a warning light. The prototype includes a DC motor as the vehicle's engine and a push button as its ignition system. The system's efficiency is tested, aiming to reduce drunk driving-related accidents in smart cities.

[8] Sobhana Jahan, et.al, 2023, "AI-Based Epileptic Seizure Detection and Prediction in Internet of Healthcare Things: A Systematic Review", IEEE, conducted a systematic review titled "AI-Based Epileptic Seizure Detection and Prediction in Internet of Healthcare Things" published in IEEE. The study focuses on epilepsy, a neurological condition affecting 50 million individuals globally, recognized as a hypersensitive disease.
Electroencephalography (EEG) is widely used for its stable and universal characteristics in detecting and predicting seizures. The researchers reviewed 56 articles from diverse academic databases, exploring EEG technology and its applications, including Machine Learning, Deep Learning, and the Internet of Things. The study provides a comprehensive analysis of classification algorithms' performance and discusses open issues in the field, offering insights for potential future research. The study focuses on epilepsy, a neurological condition

affecting 50 million individuals globally, recognized as a hypersensitive disease .

[9] Robertas Damaševičius, et.al, 2023, “From Sensors to Safety: Internet of Emergency Services (IoES) for Emergency Response and Disaster Management”, MDPI, proposed a system using the Internet of Emergency Services (IoES) and its impact on emergency response and disaster management. IoES involves integrating internet connected devices and systems to enhance real-time data collection and coordination among emergency services. The study emphasizes the role of sensors and IoT devices in providing timely information to responders. It discusses the potential benefits of IoES, such as improved speed and efficiency in emergency response, as well as enhanced public safety. However, the paper also highlights the need to address challenges and risks associated with IoES implementation to ensure responsible use. Overall, the paper provides a comprehensive understanding of IoES and its implications for emergency management.

[10] Rohith Yerrapalem, et.al, 2023, “The IoT Based Health Monitoring with Alcohol Detection and Control System”, IJECS, proposed a health monitoring system based of IoT with alcohol detection. It is designed to reduce the accidents caused due to drunken driving by including a Alcohol Sensor, Heart beat rate sensor, Global System for Mobile communication, Wi-Fi modem, are utilized. Once it reaches above the threshold level,the engine is made to stop.

III. EXISTING SYSTEM

An integrated approach that includes alcohol monitoring, real-time intervention, and seizure detection is currently missing from the landscape of care for individuals with epilepsy. There isn't a complete system out there that incorporates all of the features of the proposed system, even though different technologies handle different parts of it. Wearable devices are a common component of current seizure detection systems, which aim to track the physiological changes that occur during seizures. One way to deal with the problem of drunk driving is by using alcohol detection technology, which includes breathalyzers and ignition interlock devices. Internet of Things (IoT) healthcare platforms and GPS tracking devices also aid in remote monitoring and data analysis. When it comes to situations where people with epilepsy are driving while under the influence of alcohol, there is a significant lack of comprehensive safety measures due to the lack of an integrated approach. To close this gap and to enable them to live an independent life, we have come up with an idea to create a unified system that safeguards people dealing with epilepsy by taking into account its ever-changing nature. Though previous systems focus only on detection of alcohol, there is no idea over how to implement it in driving for those with absent seizures.

IV. PROPOSED SYSTEM

The proposed system envisions a holistic and integrated IoT-based safety solution designed to address the multifaceted challenges faced by individuals with epilepsy. At its core, the system will deploy advanced sensors and algorithms for accurate and real-time detection of epileptic seizures, minimizing the shortcomings observed in existing technologies by observing the voltage which may vary from 10μV to 100μV in amplitude for a normal human being when measured from scalp. And for a epileptic patient. Simultaneously, a user-friendly and continuous alcohol monitoring system which can be seamlessly integrated into wearable devices is developed as a prototype, ensuring real-time insights into alcohol levels. The incorporation of precise GPS tracking technology will provide immediate location data, enhancing overall safety by facilitating prompt responses during seizure events. To ensure scalability, security, and efficient data management, the system will embrace a cloud-based IoT architecture, enabling seamless communication between components and facilitating remote monitoring, data analysis, and customization of parameters by healthcare professionals. A pivotal feature includes a relay control mechanism, preventing vehicle engines from starting upon detecting alcohol consumption, thereby curbing the dangers associated with impaired driving. The system will prioritize user customization, boasting an intuitive interface and customizable parameters to cater to individual profiles and medical conditions. Data security measures will be paramount, ensuring compliance with privacy standards and protecting sensitive health and location information. Through interdisciplinary collaboration, involving technology developers, healthcare professionals, and end-users, the proposed system aspires to offer a transformative solution that not only fills existing gaps but also prioritizes the safety, independence, and well-being of individuals with epilepsy in various daily-life scenarios. Additionally, the system is equipped with a module for monitoring alcohol intake, which allows it to identify instances of alcohol use in addition to seizure detection. The use of global positioning system technology guarantees continuous location tracking, which is an essential component for ensuring a rapid response to seizures and improving the individual's overall awareness of their surroundings. This system combines the detection of epileptic seizures, the monitoring of alcohol consumption, and the management of car engines to produce a holistic solution for people who suffer from epilepsy. By utilizing cutting-edge technology, the primary objective of this integrated system is to improve the safety and freedom of individuals who are diagnosed with epilepsy.

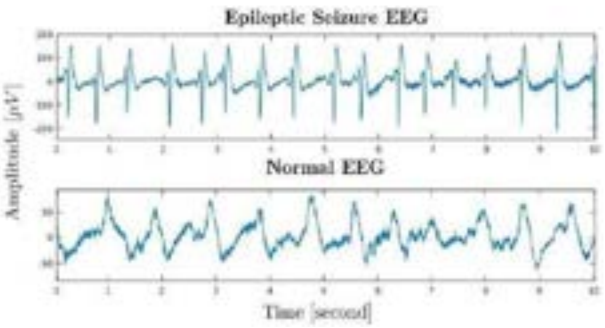

Fig 1: Difference of EEG wave

V. SYSTEM ARCHITECTURE

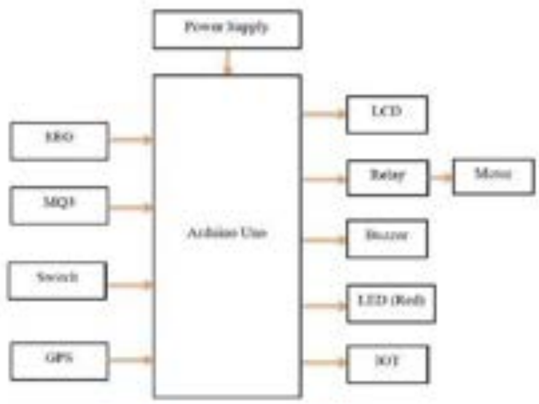

Fig 2:Block diagram of GPS based IOT module for Vehicle Safety in Epileptic Seizure Detection and Alcohol Monitoring

VI. METHODOLOGY

A. ESP8266

This module uses an ESP8266 microcontroller which has an inbuilt Wi-Fi connectivity to control the system through IOT and is programmable using the Arduino IDE, where the data linked to the latitude and longitude of the person involved in the accident is sent to be displayed on the LCD and to be stored in the webpage. The connection is established between IOT module and the Arduino.

Fig 3: ESP8266

B.GPS Module

This is the core component that receives signals from GPS satellites and processes them to determine the device's location. There are various types and models available in the market, such as those based on chipsets from companies like u-blox, MediaTek, and Broadcom. This indicates the Latitude and Longitude of the person undergoing seizure.

Fig 4:GPS Module

C. Alcohol sensor and EEG sensor

By using this technology, we can provide a faster and hands-free experience to the user. This whole system comes with an EEG sensor with three leads, each one to be placed on the scalp.Once the voltage beings to vary drastically, spikes in the EEG wave also varies.

Fig 5: MQ3 Alcohol sensor and EEG Sensor

MQ3 sensor is a gas sensor which is sensitive to alcohol vapours which is the target. It provides an analog output voltage proportional to concentration of alcohol percent in air. It detects the alcohol level of the person driving and if it exceeds the denoted threshold level, a LED light incorporated in the system would be blinking and the location is sent through IOT module. Instead of directly connecting a DC motor to stop the vehicle, it is interfaced with a relay of 5V for halting the vehicle on receiving warnings in the sense of blinking of LED. Table I shows the overview of the integrated features.

Table 1:Overview of features integrated

Feature	Epileptic Seizure Detection	Alcohol Monitoring
GPS Integration	Yes	Yes
Real-time Tracking	Yes	Yes
Seizure Detection Sensors	EEG sensor	-
Alcohol Monitoring Sensors	-	MQ3
Alerts/Notifications	Yes	Yes
Data storage	Yes	Yes
Indicator	Buzzer	LED

VII. RESULTS AND DISCUSSION

The use of MQ3 and EEG sensors has shown the potential for continuous monitoring of physiological signs associated with epileptic events. The ability to detect and analyse epileptic seizures in real time facilitates immediate help and intervention, improving the overall safety of people in these crucial moments. We strive to prove our worth through accurate, real-time measurements of operating systems expressed in millivolts. Normal brain voltage value for an individual is between 70 mV; if the attacks are distorted, the deviation from normal values is about 0.01 mV to 0.1 mV. In addition, with this prototype, we can analyse and detect scene variations and alert the cloud module. The ability of the alcohol detection module to correctly identify intoxication has been demonstrated.

Fig 6: Display of Alcohol level and EEG voltage in LCD display

The system's ability to recognize alcohol consumption is important to prevent drunk driving, as it uses relay control to prevent the engine from starting in such situations .The real-time location tracking enabled by the integration of GPS technology is crucial for fast response and intervention during seizures. The GPS function improves the overall efficiency of the system by ensuring that help can be immediately sent to the exact location of the person in need. The IoT architecture enables seamless communication with cloud platforms, storing, analysing and monitoring data remotely. Cloud integration provides nurses, medical professionals and other stakeholders with access to historical and real-time data, enabling a thorough understanding of a patient's condition and potential triggers. The comprehensive solutions of the study associated with both seizures and the potential dangers of alcohol consumption, providing a strong safety net for people with epilepsy. The system promotes independence by allowing people to prioritize their own safety in different driving situations and participate in the driving of vehicles. A webpage which stores and shows the latitude and longitude of the person has been created and the results are shown in Fig.6 and Fig.7.Only the people with specific username and password can access it. The same will be displayed on the LCD and indicates the alcohol level and the voltage level in microvolts.

Fig 7:Data observed sent to webpage through IOT module

The data observed through the alcohol sensor and EEG sensor is sent through the IOT module to the webpage developed to store the same. It acts like a vehicle blackbox except it is used for detection of seizure and drunk driving purposes. The latitude and longitude will be sent to the webpage admin so as to monitor the patient and ensure a user-friendly lifestyle.

VIII. CONCLUSION AND FUTURE WORKS

The proposed integrated IoT-based safety system is a game-changing innovation that fills in important holes in current technology for people with epilepsy. This system provides an all-encompassing method of controlling risks associated with epilepsy by integrating features such as the detection of epileptic seizures, the monitoring of alcohol levels in real time, GPS tracking, and cloud connectivity. A compassing safety net that allows people with epilepsy to live more independently is made possible by the benefits of real-time intervention, prevention of impaired driving, and adjustable parameters. Secure your sensitive health information with confidence thanks to the user-friendly UI and strong data security features. By bringing together experts from different fields, the system is better able to meet real-world requirements and win over users. In the end, the suggested system is a revolutionary leap forward in improving overall the security, independence, and general health of people with epilepsy in many everyday situations, thanks to its basic features of scalability and adaptability.

***Abstract*—The proposed system presents a comprehensive approach for designing, simulating, and implementing a solar-powered air-purification system. This system incorporates a Sheppard-Taylor converter for voltage regulation, a Brushless DC (BLDC) motor, and an MPPT (Maximum Power Point Tracking) algorithm. For analysis and simulation tasks involve MATLAB application, ensuring the system's performance under diverse conditions. Sheppard-Taylor converter optimizes voltage regulation, while the BLDC motor drives the air purification unit efficiently. The MPPT algorithm maximizes power extraction from the solar panels. This integrated solution offers a sustainable approach to air purification, with MATLAB simulations validating its effectiveness for implementation. Suitable for off-grid and environmentally sensitive areas. Additionally, this system contributes to cleaner air and energy sustainability.**

***Keywords*—BLDC Motor, MATLAB Simulation, Insulated-Gate Bipolar Transistor (IGBT) Switch, Sheppard Taylor Converter, Maximum Power Point Tracking (MPPT) Algorithm.**

I. INTRODUCTION

Our paper is focused on exploring the use of solar-powered BLDC motor systems, in conjunction with the innovative Sheppard-Taylor Converter for voltage boosting and control. These advancements are crucial in addressing energy needs sustainably. By harnessing abundant solar energy, these systems offer a promising shift towards cleaner and greener energy solutions, particularly in vital sectors such as agriculture, water management, and rural electrification.

BLDC motors are widely recognized for their efficiency and precise control, making them the backbone of these systems. Their adaptability and reliability make them ideal for a wide range of tasks, from powering water pumps in remote areas to ventilating urban spaces sustainably. The Sheppard-Taylor Converter emerges as a game-changer, providing a cost-effective alternative to traditional boost converters. Its ability to efficiently regulate voltage and energy consumption, even amidst fluctuations in sunlight intensity, ensures optimal performance and reliability. Moreover, its simplicity in operation and maintenance makes it accessible to a wider audience, empowering communities to embrace solar energy with confidence. Furthermore, the Sheppard-Taylor Converter's capability to amplify voltage at minimal costs adds a significant advantage over conventional converters, making it an attractive choice for solar-powered setups, especially in resource-constrained environments. To maximize the impact of our project, we undertake a comprehensive analysis of MPPT algorithms. These algorithms are very useful in optimizing the efficiency and performance of solar-powered BLDC motor systems, ensuring that every ray of sunlight is utilized effectively.

II. SYSTEM DESCRIPTION

A. Solar Panel

The solar panel, a vital part of our system, contains many PV cells linked together to produce electricity from sunlight. These cells are usually made of silicon which creates electricity when sunlight hits them. The electricity generated is then collected and used to power electronic devices. Essentially, the solar panel acts as the main energy source for converting solar energy into usable electrical power for electronic devices.

TABLE I. SOLAR PANEL SPECIFICATION

Parameter	Magnitude
No load Voltage (Voc)	82.1V
Peak Power level Voltage (Vmp)	75V
Max. Current (Isc)	19.55A
Peak Power level Current (Imp)	18.7A
Peak Power (W)	1402.5W
No. of. Cells (Ncell)	34

V-Voltage, A-ampere, W-watts

B. BLDC System with PID Controller

The approach developed for BLDC motor speed management assisted by PID control technique involves several important steps. Firstly, we detect the motor's position and back electromotive force (BEMF) using hall sensors. The BEMF usually looks like a trapezoidal wave. We then use this information to figure out when to activate each phase of the motor. Next, we carefully create sequences of gate pulses, which control the power transistors in the motor's circuit. We compare the desired motor speed with its actual speed, creating an error signal. This signal goes into a PID controller, which adjusts the output based on how big the error is. The improved signal is combined with the gate pulse sequences, changing when or how long they're active to control the motor's speed better. This method keeps checking and adjusting the speed continuously, making sure it stays just right no matter what. Overall, using hall sensors, decoder blocks, PID controllers, and gate pulse sequences together helps us manage the speed of BLDC motors accurately and flexibly.

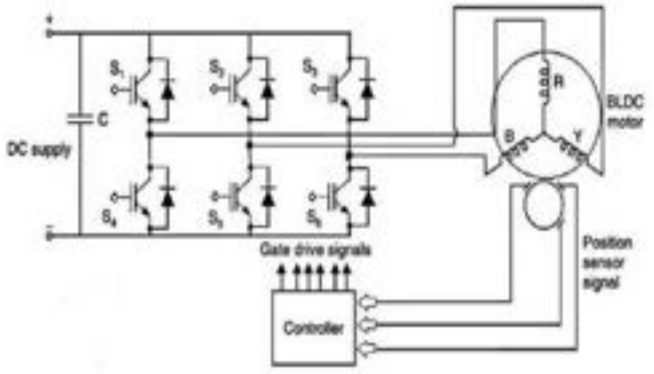

Fig 1. Speed control of BLDC motor

TABLE II. BLDC MOTOR SPECIFICATION

Parameter	Magnitude
Rated Power	630 W
Rated torque	0.21 Nm
Rated speed	3000 rpm
Rated current per phase	1.2 A
Rated Voltage	320 V
No of Pole pairs	2

W-watts, Nm-Newton meter, rpm-Revolutions per minute, V-Voltage, A-Ampere

PID VALUES			
K_p	K_i	K_d	Filter coefficient (N)
3.13	12.53	-0.05	7.56

C. Working principle of ST converter

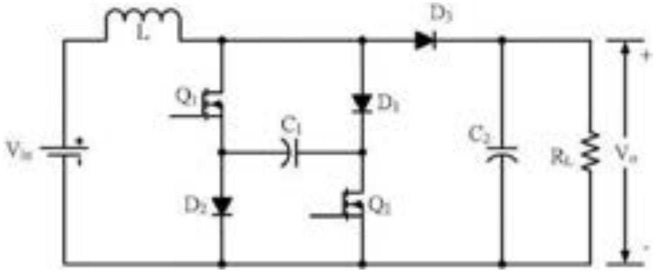

Fig. 2. ST Boost Converter Circuit

The ST converter, which helps pump up voltage, is made up of two IGBTs, three diodes, one inductor, and capacitor. These components are picked thoughtfully to keep energy steady, preventing any wobbles. It ensures a smooth flow of power, making sure everything runs smoothly and efficiently. The converter functions through three distinct stages. Initially, as the input voltage is introduced, the inductor begins to accumulate energy while the capacitor expels energy via the activation of Q1 and Q2 switches. At the outset, the voltage contained within the capacitor represents the discrepancy between the input voltage and that of the inductor. In the second stage, we halt the gate pulse to turn off switches Q1 and Q2. This action forward-biases diodes D1 and D2, allowing the capacitor to begin storing energy from both the source and the inductor. Meanwhile, diode D3 remains reverse-biased since the capacitor voltage hasn't reached a sufficient level to forward-bias it yet.. Over time, as the capacitor gains energy and its voltage exceed the output voltage, diode D3 becomes forward-biased, delivering the boosted voltage to the load with support from the inductor and capacitor.

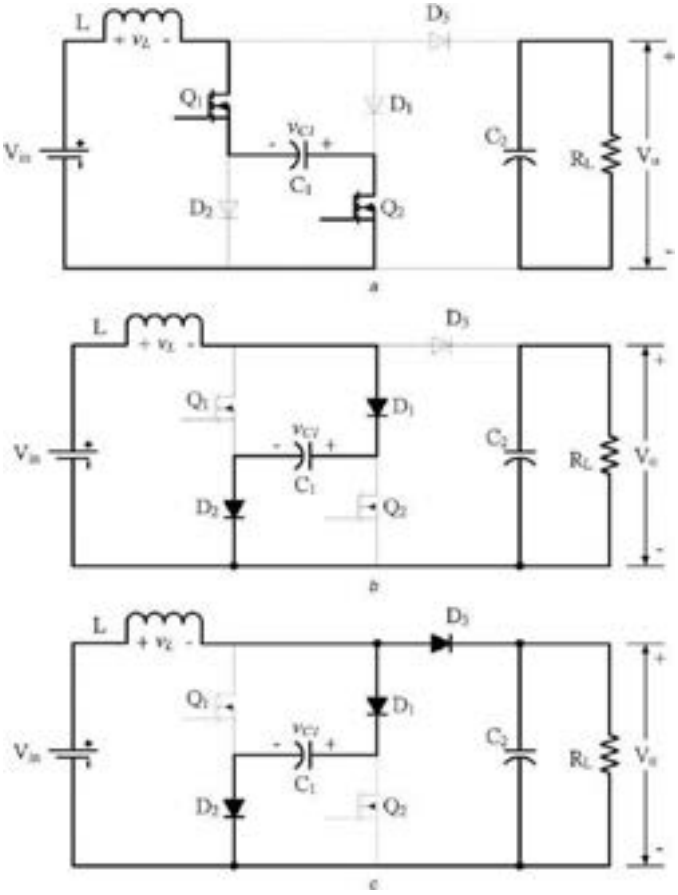

Fig. 3. ST Converter States of Working

TABLE III. ST CONVERTER SPECIFICATION

Component/Parameter	Value/Type
Input Inductor L_1	4.4 mH
Input Capacitor C_1	100 µF
Flying Capacitor C	47 µF
Output Capacitor C_0	56 µF

mH – millihenry, µF-microfarad

D. *MPPT Algorithms:*

In the Perturb and Observer (P&O) algorithm, the duty cycle of the converter is adjusted bit by bit. Initially, a small change is made, and then we check how much power the solar panel produces. If the power goes up, we keep moving in the same direction; if it goes down, we change direction. This process helps us find the best point where the solar panel produces the most power, which we call the MPP. By changing the duty cycle, the algorithm makes sure the system works at this best point, making the most power produced from the solar panel.

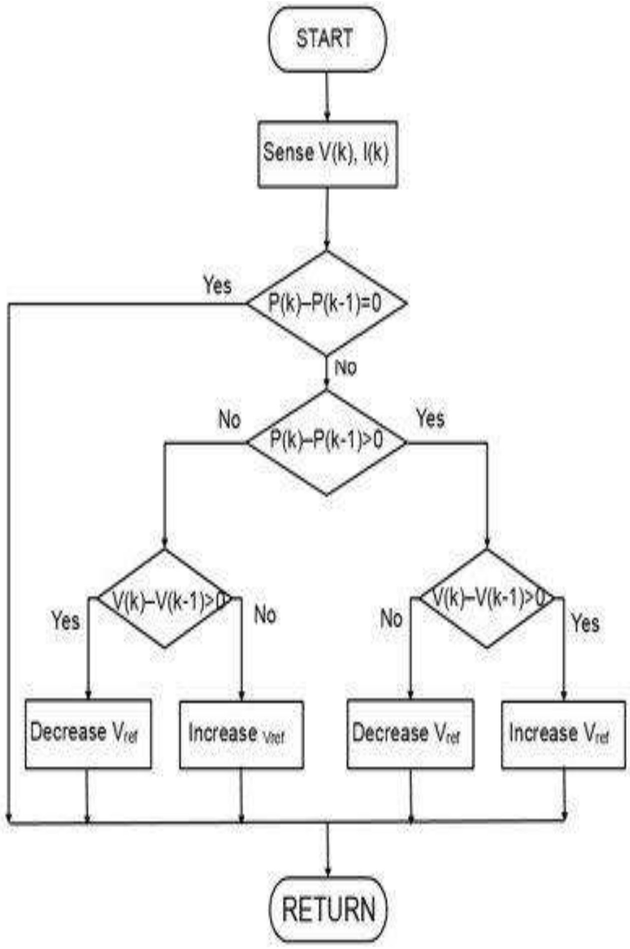

Fig. 4. PO Algorithm Process Diagram

In the Incremental Conductance algorithm, the duty cycle adjusts based on power differences between two points. If power increases, the duty cycle shifts in one direction; if it decreases, the shift is reversed. This process repeats until the algorithm identifies the maximum power point (MPP), where the power difference becomes zero. Following this method, the algorithm guarantees the system operates at the MPP, optimizing power generation from the solar panel.

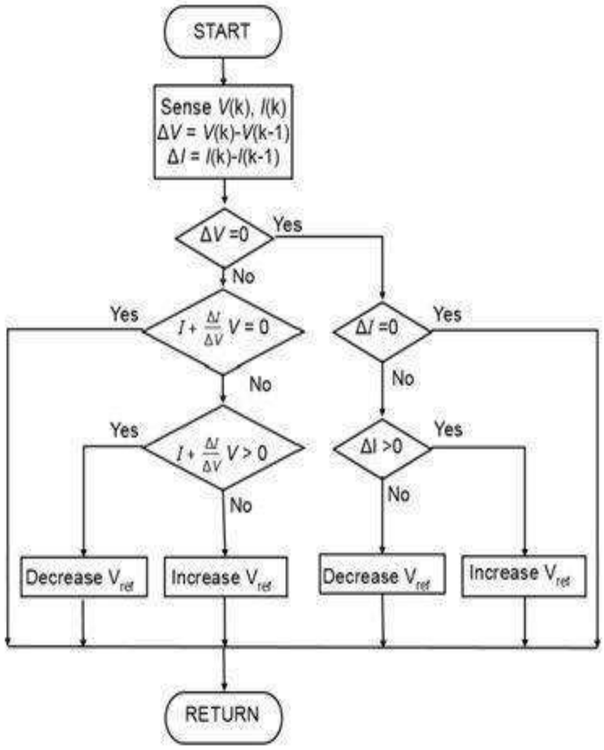

Fig. 5. IC Algorithm Process Diagram

III. PROPOSED SYSTEM

Our system proposal is designed to efficiently utilize solar energy. It utilizes a photovoltaic (PV) panel as its main power source, employing sophisticated MPPT techniques like Perturb and Observer (PO) and Incremental Conductance (INC). These algorithms optimize the PV panel's output, ensuring maximum power extraction even in different sunlight conditions. The voltage output from the PV panel undergoes regulation and amplification using an advanced ST boost converter. This converter plays a crucial role in maintaining a stable and elevated voltage level suitable for powering the load. Additionally, a 3Φ inverter is employed to transform converter voltage to an inverted state, with its output controlled by a precise Proportional-Integral-Derivative (PID) controller. This controller adjusts the input voltage to the Brushless DC (BLDC) motor based on a reference speed, thereby ensuring efficient speed regulation. Each component is intricately integrated, contributing to the overall efficiency and reliability of the system.

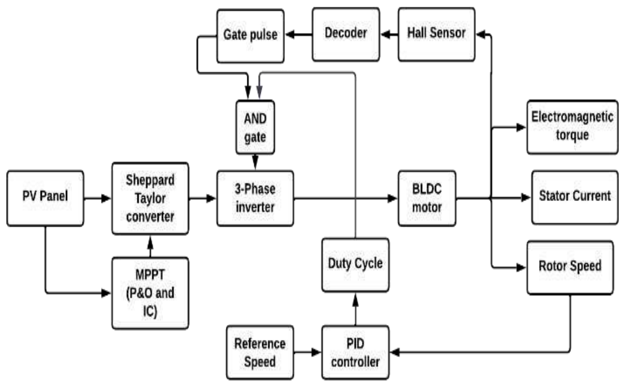

Fig.6.Proposed Block Diagram

IV. SOFTWARE SIMULATION

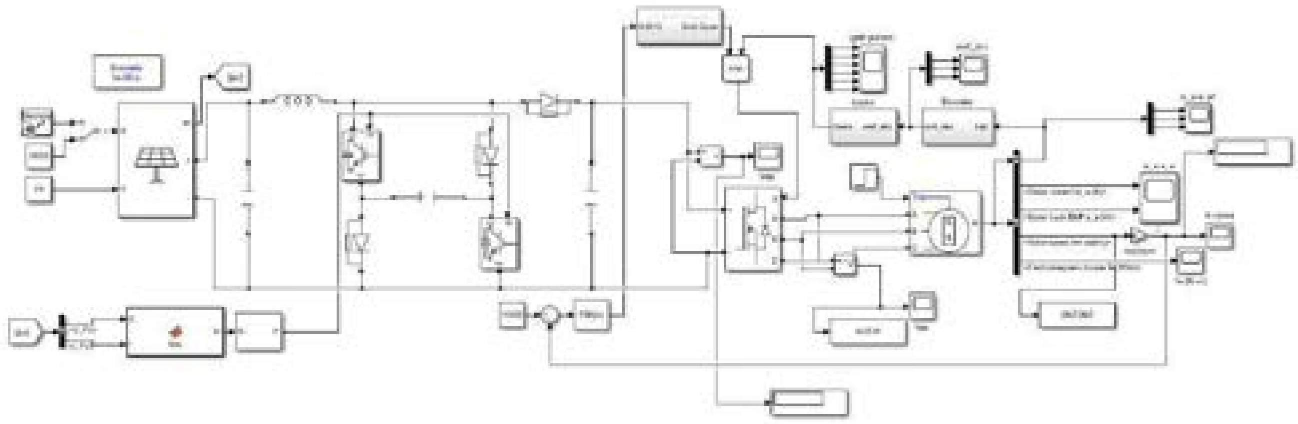

Fig. 7. MATLAB Simulation of Solar based PID controlled BLDC system with ST converter using Perturbation and Observation algorithm

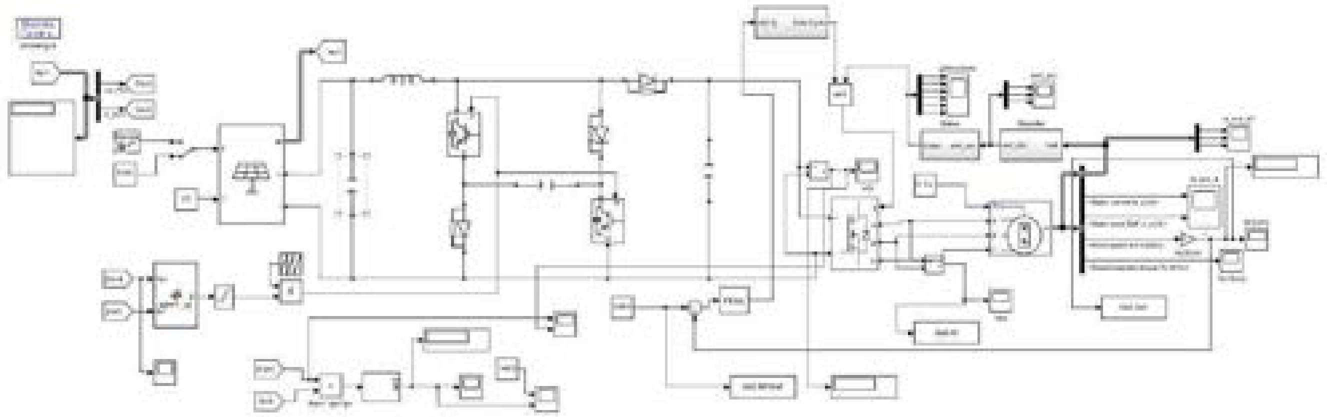

Fig. 8. MATLAB Simulation of Solar based PID controlled BLDC system with ST converter using Incremental Conductance algorithm

The complete system design is implemented as a Simulink model utilizing MATLAB R2023a software. Additionally, the Scope tool is utilized to capture and visualize the system's output graph, providing valuable data for analysis and discussion.

V. SOFTWARE SIMULATION

The simulations were conducted using a MATLAB Simulink model with specified parameters and the resultant voltage-time characteristics of both input voltage and ST Converter graph are depicted in Fig.9. Fig.10. and Fig.11.

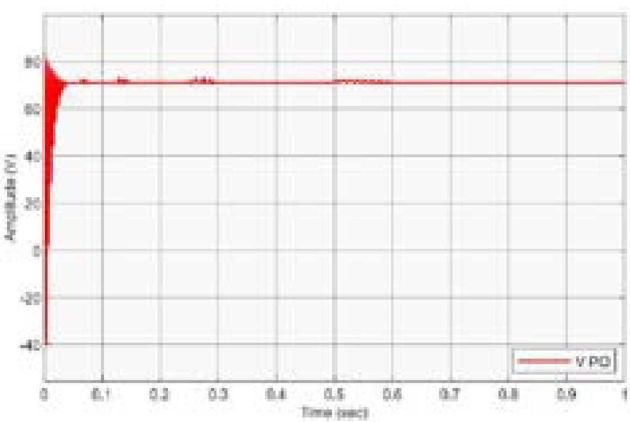

Fig 9. Voltage-Time graph of P&O algorithm

From Fig.9 and Fig 10, a close examination brings to light the unique behaviors of the P&O and IC algorithms. The P&O algorithm takes around 0.17 seconds to gradually approach the MPPT voltage, consistently hovering around this optimal level.

On the other hand, the IC algorithm demonstrates a swifter response, reaching the MPPT voltage more promptly and with steady accuracy. This detailed analysis provides deeper insights into the intricacies of MPPT algorithms and their role in enhancing solar energy conversion

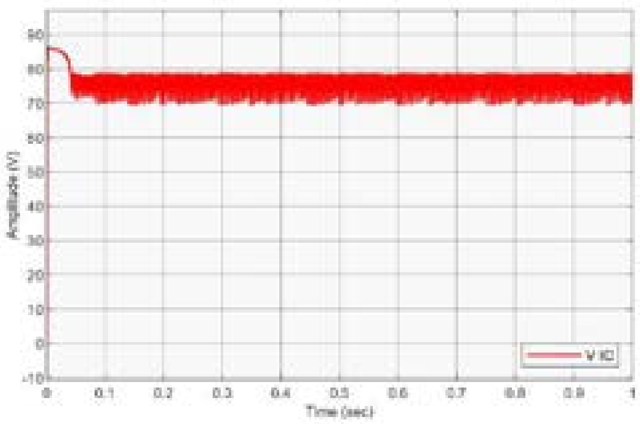

Fig 10. Voltage-Time graph of IC algorithm

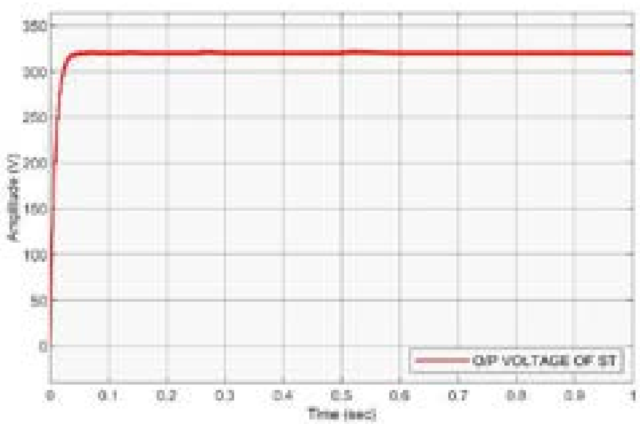

Fig 11. Resultant output voltage graph of ST converter

In Fig. 11, we can see how the ST Converter quickly ramps up the DC bus voltage to 320 V in just 0.18 seconds. Looking closely at the output voltage graph, it's clear that the converter handles this voltage increase swiftly and efficiently. This suggests that the converter can effectively regulate voltage changes, which is crucial for keeping power systems stable.

Its fast response time shows that it's suitable for tasks where voltage adjustments are needed quickly. This detailed analysis gives us valuable insights into how the ST Converter improves the reliability and efficiency of power systems, which can be useful for future studies and practical applications.

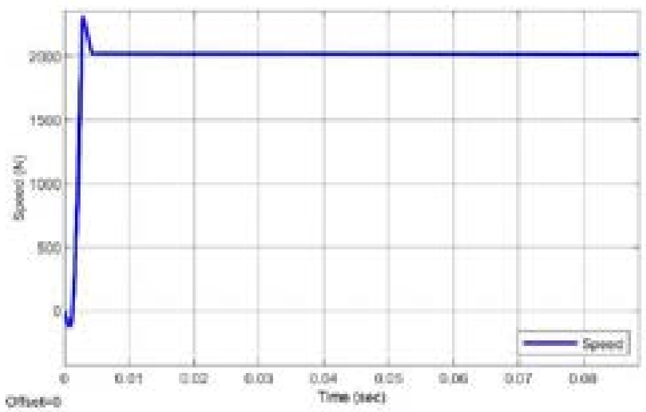

Fig. 12. Speed-time graph of BLDC motor

Fig 12 illustrates its speed-time profile. Notably, the motor achieves a target speed of 2000 RPM within just 0.18 seconds, though it experiences a peak overshoot of 350 RPM. These results, based on the constants Kp, Ki, and Kd set in the PID controller as mentioned before, clearly highlight the BLDC motor's quick reaction and dynamic behavior. This shows how suitable it is for tasks needing precise speed control, making it a great choice for different applications.

VI. CONCLUSION

This study has evaluated the efficiency and energy management of sustainable energy using MATLAB simulations. The results demonstrate the smooth operation of the ST converter alongside the PV system and BLDC system with the PID controller. Notably, the performance of the Incremental Conductance algorithm surpasses that of the Perturb and Observe algorithm in terms of accuracy, stability, and adaptability to varying irradiance levels. The effectiveness of the ST converter and BLDC system underscores their suitability for a range of industrial applications like air purifiers, blower fans, etc. The simulation output provides insights into optimizing this system and promoting the cost-effective operation of the ST converter. Overall, the system's significant impact lies in energy management and promoting clean and green technology.

***Abstract*— The purpose of streets is to facilitate safe vehicle movement at designated speeds. Surveillance is particularly crucial at intersections, sharp curves, congested areas, accident-prone zones, and other critical points on the road. Various measures are implemented to enhance safety, including mandatory speed limit signs, flashing signals for alerts, and road markings. While speed bumps may be necessary in certain situations, their widespread use is not considered ideal due to potential vehicle damage and risk of injury. Additionally, traffic signs can sometimes distract drivers, especially in low-light conditions, making it challenging to anticipate speed bumps. This research study intends to address these concerns by employing Machine Learning (ML) techniques, specifically edge detection, to identify potholes and bumps on roads. The proposed model achieves an accuracy of 98% in detecting the road hazards. An image-processing system is utilized for pothole detection, while ultrasonic sensors are employed to measure the depth of potholes, providing drivers with crucial information to avoid accidents or vehicle damage.**

Keywords—Potholes, Accidents, Machine Learning, Edge Computing

1. Introduction

A recent NCRB report on road accidents in India states that approximately 1.5 lakh people are injured from road accidents because of the bad infrastructure of the road, climate conditions, and Over-speed or overtaking. The majority of drivers today know what potholes are because they have experienced them at some point while driving down a city street, in their neighbor- hood, on the interstate or other highway, or any other road. These experiences are typically not positive memories for any driver. Potholes can cause serious damage to any vehicle and can create dangerous situations for drivers as well when trying to avoid them or by losing control after hitting them. Potholes are places or spots on roads where the structural integrity of an area has failed or been compromised, leaving an uneven surface or "hole" in the pavement or roadway. Potholes come in all shapes, sizes, and depths. These variations in size, depth, and location help determine the kind of pothole that it is, which also affects the method of re- pair that will be required to correct the dam- age in the most effective manner potholes most commonly appear in urban areas on city streets or in other areas where the road, pavement, or street receives regular traffic from motor vehicles. Although potholes are most common on city streets, they can appear on just about any road, street, highway, or other roadway. There are many reasons that a pothole may exist but here are the few most common reasons that potholes form due to, Improper roadway construction or compaction, Excessive or frequent use over a problematic area, Poor maintenance,Improper road or pothole repairs,Shifting in the earth, ground or surface area, Extreme or unnatural weather conditions, Material composition of the roadway or street. In India, potholes are a known fact and in every kilometre a potholes can be seen. A pothole is a type of depression on any plain ground or any surface. Potholes are the surface areas of road which have cracked, eroded, and eventually results in a form of hole. Initially they start as cracks of smaller size. If it is not fixed immediately,which results in the damage of the complete road and sometimes the complete area. The pothole may results from the capability of water absorption. The formation occurs when a rock surface is worn away by a circular water stream that carries small stones and debris. The force of water and the sediment it carries is greater than the resistance of the rock.After it starts, the process carries on, and the rock there keeps eroding. Potholes have to be taken seriously and are capable of causing serious or even fatal accidents[1-3] .

Common damage to vehicles inflicted by potholes includes flat tires (or other tire damage), damage to rims, suspension, or steering, and (in some cases) damage to a car's exterior. Hitting a pothole at any sort of speed can also affect the wheel alignment of a vehicle which can have a significant impact on how quickly tires wear and perform. Potholes are detected along with their severity using a built-in accelerometer. On the road, presence of variations are detected with the help of an accelerometer along with an ultrasonic sensor. Potholes are also detected by using the lasers which scan and measure the depth of the pothole. This paper presents a real-time building a prototype for the detection and reveal the presence of potholes by examining the road with the help of a camera. Potholes are identified based on the edge detection algorithms. It collects information about the potholes location coordinates with the help of a GPS module and stores the location and the images in the server of a database for future reference using the Wi-Fi module added with the microcontroller. This study aims at providing smart detection using image processing and simultaneously reporting the detected potholes using a web server. This process ensures a stable Wi-Fi connection. Smoothing filters such as Median blur are applied to remove the noise and simultaneously preserve the edges of the image. Threshold techniques are applied to adjust the color variants. Morphological techniques such as opening are applied to remove the small edges and thicken the required images. The canny edge algorithm, along with arc length techniques, is used to identify the pothole using image processing. Water has a way of eating away at road surfaces in any climate[4- 5]. Even without a freeze-and-thaw cycle, water can still get underneath the pavement and create divots by eroding the materials, such as loose gravel, that form the roadbed. With the proposed system an attempt has been made to endorse drivers to ward off the accidents causeddue to potholes.

Accidents are pretty common on the roads, as the cars move very close to each other, which can be prevented by assisting the driver by informing him that another vehicle is very close to him. In Emergency help and accident cases, sending the real-time location to registered numbers can save lives. Potholes and speed ramps are among the most common obstacles on most road networks. These road obstacles and disruptions in the surface condition of roads are among the causative factors of road accidents, carnages, and fatalities[6]. This project examines the prospects and challenges of the Internet of Things GPS Tracker in detecting, reporting, and management of pot-holes and other obstacles on our road networks fortunately, road maintenance crews can fix pot holes easily. Fixing a pothole requires a crew to clean all the loose rock and dirt out of the pot- hole before filling it with a mixture of hot or cold asphalt (depending upon the time of year) to create a patch in the roadway surface, according to the report of the National Crime Record Bureau(NCRB).

2.LITERATURE REVIEW

Road infrastructure repair has accrued much knowledge over the last few days. Poor road conditions often cause problems and harm to automobiles and passengers that cannot be ignored. Some of the big factors that are causing harm are potholes, speed-breakers, rough patches, etc. The existence of such abnormalities also affects the consistency of the ride and the protection of the passengers. A YOLO algorithm is proposed to identify the potholes, which evaluates the distortion rate, restoration rate, and model validity [7]. A collective data of potholes were collected using the built-in application from the mobile smartphone and which features out from the frequency of different domains. The features were extracted with the different types of machine learning classifiers. Among the various classifiers, the random forest algorithm gave a very fruitful result with an accuracy of 88.5%[8]. The paper explains the low-cost method that uses a smartphone and an OBD-II module to find and locate road pot-holes[9]. A Generative adversarial network is used to generate a pseudo image and combine it with the real image to detect the road dam- age which was used as a new set of data and was trained. this helps to improve the F measure by training the synthesized data images of road[10-11].

3.METHODOLOGY

The intention of the proposed work are design and development of the Pothole and hump detection System,which help for the road maintenance, aids the economic growth, and results in avoidance of accidents through a real-time alerts with the help of GSM. To exhibit the pothole location with latitude and longitude, in the Google Maps with the link is also showed in the TCP/UDP test tool.

Potholes are the road surface area that have cracked down, worn apart, and have formed huge holes varying from a few centimeters to meters. The most dominant reason for the formation of these holes is water. However, spillages and emissions by vehicles, accidents, and other dam- ages may also be the various causes. Moisture in the roads and surfaces freezes during the winter season leading to a decrease in the material density due to a rise in the volume. These holes further expand due to overlooking the issue and lack of proper care/maintenance[12]. Potholes can create a traffic congestion which leads to gross wastage of fuel. This ultimately adds to air pollution causing various, serious health problems for people. Besides, many accidents are caused due to the presence of these potholes. These accidents may be severe enough to cause damage to the body and the life of individuals or may simply affect the functioning of vehicles and tyres. The main criteria of this work is to plan the design and develop a intelligent model based on data-gathering system which can be fitted in any vehicle or car to detect road or highway conditions. The prototype develops an information-gathering system that informs the authorities about the conditions of road. By the gathered information, the authorities could take measures to repair the roads which in turn results to avoid accidents caused due to non-technical humps and hence lower the percentage of damaged roads and avoid road accidents[13- 16]. An Artificial Neural Network(ANN) can be implemented to detect the path holes and by training the models more accuracy can be implemented[17-19].

Figure 1: Block Diagram

The proposed system block diagram is shown as in fig.1. This research work uses Raspberry Pi 4, which is based on microprocessor and interfaced with codes. A system based on real-time uses the camera to detect the potholes of road and an information alert along with the accuracy of it being the pothole. The device must be trained with a sample amount of pictures of potholes to prepare it for the real-time scenario.Using a software-based method, the Raspberry pi is utilized to feed the programs intended for hardware implementation. The Pi camera records the video and sends the feed to the board of Raspberry Pi. The video in the input feed is converted into grayscale images and fits the dimension set up for the device. The image is then checked for the pothole and if there is detected, the alert will be sent to the user along with the probability of the pothole being detected.

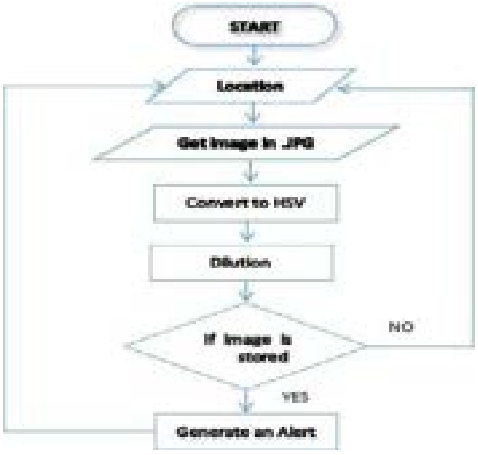

Figure 2: Flow Chart

4. Results & Discussion

The components are interfaced with Raspberry Pi 4. It is larger than the average micro- controller, uses more power, has a clock speed of between 700MHz-1.5GHz, and has a RAM capacity between 1GB to 8GB. Also, the Rasp- berry Pi, unlike microcontrollers, can run both 32-bit and 64-bit. A real-time detection project and it makes use of the camera to detect the potholes present on the road and sends an alert along with the accuracy of it being the pothole. The device must be trained with a less number of pothole images to prepare it for the real-time scenario. In this type of analysis a data sets of two types are used: the first type of database consists of 2000 distinct photos with potholes and may be accessed online. The second set of datasets will have 1800 photos gathered from various online sources and 344 photos taken from the Labanese roadways which indicated potholes. Most of the images are from videos that were recorded via cameras of dashboard of people driving their cars.This results into a 2087 different images, with more than 3000 potholes are used in this analysis. We used an image annotation program to name the thousands of pothole photos that we have gathered from the internet. Both commercial and open-source picture tagging solutions are available with some good features. We have made use of Microsoft's VoTT, which is accessible on GitHub under an MIT license and is open source.with the help of Python, deep learning models were built using the canny edge algorithm, and the model was built to detect the real path hole. The accuracy was developed with 68% with the first trial. Reusing the previous model and training it more vigorously we came up with the new trained model with an accuracy of 98%.

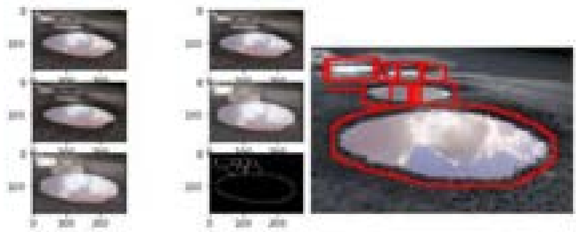

Figure 3: Image Recognition

Figure 5: Results obtained for real path holedetected images.

5. Conclusion

This research work presents a smart system for the identification of pothole based on Machine learning algorithms. The system starts by acquiring pothole images as data and pre-processing the data by creating image annotation and image augmentation on the pothole images. This study has carried out a real-time pothole identification based on multiple images of pothole. This work can further be extended by detection on a live-streaming video using the Open CV library.Then by using this Machine Learning code, we implement it using Raspberry Pi 4 Micro-processor and pie cam we take real-time video which allows us to implement it in any Automobile. Our model is based on machine learning and was developed completely with the help of image processing. The barriers of social to be over-come by the autonomous vehicle and is based on the t technology advancement. Nowadays for these cars, new rule will create a new opportunities.

The proposed work will be helpful for driver-less cars with the introduction of advanced automobiles to enable pothole detection. This work can be extended by considering the datasets, which consists of more than 2000 images, for training purposes of the network which may contain images of potholes from different roads, with different severities and several lighting and weather conditions. Manholes images can also be used for our system training. Potholes and manholes will have a similar characteristic and this desired improvement have to be done in our present system for segregate the difference between manholes and potholes. The present system can also be implemented into several cars to identify the road condition in real-time with the help of GPS to get the maintenance of potholes dimensions.

***Abstract*—Worldwide, cancer is regarded as the leading cause of death; brain and lung cancers are especially difficult to identify and categorize in their early stages. For effective cancer treatment and better patient outcomes, early cancer detection and classification are essential. However, because these cancers are complex and don't always exhibit distinct symptoms, conventional diagnostic techniques frequently fall short of identifying them in their early stages. Deep learning has demonstrated significant impact in the identification and categorization of a number of illnesses, including cancer. But there is still space for improvement in the precision of current deep learning models for the identification and categorization of early-stage cancers, especially when it comes to malignancies like brain and lung cancers. The process of creating precise methodologies is fraught with difficulties. This study suggests using deep learning based transfer learning models to classify images of various cancer types, such as lung, brain, Acute Lymphoblastic Leukemia and oral cancer. In this work, Transfer learning model is evaluated against the classification of images exhibiting malignant features. Pre-trained CNN models include ResNet50, MobileNet, DenseNet and VGG, use the knowledge acquired from the ImageNet dataset to identify various types of cancer. The utilization of the ResNet50 model within this research has yielded notably superior results. These outcomes are crucial for making precise decisions in the medical domain.**

***Index Terms*—Convolutional Neural Network, ResNet50, SDG, ADAM, Transfer Learning**

I. INTRODUCTION

Cancer is a complicated and widespread illness defined by abnormal cells in the body growing and spreading out of control. It can impact different tissues and organs, causing serious health risks and frequently require extensive medical care. Numerous risk factors, including genetics, environmental exposures, lifestyle decisions, and others, can contribute to the development of cancer. Every year, millions of new cases of cancer are diagnosed worldwide, raising serious concerns about public health. Tobacco use, poor diets, alcohol consumption, physical inactivity, exposure to carcinogens like chemicals and genetic predisposition and UV radiation, are the main causes of cancer. These factors contribute to the development of various types of cancer, leading to significant morbidity and mortality rates.

Cancer is responsible for a substantial number of deaths worldwide. The disease can progress rapidly if not detected and treated early, leading to poor prognosis and decreased survival rates. Effective cancer prevention, early detection, and timely treatment are critical in reducing mortality rates and improving patient outcomes. Some of the most common types of cancer worldwide include lung cancer, breast cancer, oral cancer, brain cancer, skin cancer (melanoma), and cervical cancer. These cancers vary in their risk factors, symptoms, diagnostic approaches, and treatment modalities, highlighting the need for personalized and comprehensive cancer care strategies.

The medical industry faces several challenges in combating cancer effectively. These challenges include limited access to healthcare services, inadequate screening and diagnostic tools, high treatment costs, disparities in healthcare delivery, and insufficient public awareness about cancer prevention and early detection. Additionally, the rapid advancements in cancer research and treatment require continuous education and training for healthcare professionals.

Early prediction and detection of cancer play a vital role in improving therapy outcomes and patient survival rates. Key steps to facilitate early prediction include promoting healthy lifestyles and behaviors, regular screening and diagnostic tests for high-risk individuals, implementing advanced imaging and molecular technologies for early detection, and enhancing public education and awareness campaigns about cancer signs and symptoms.

In the field of medicine, the application of deep learning in cancer detection models has had a revolutionary effect. These cutting-edge technologies have greatly improved cancer diagnosis speed, accuracy, and efficiency, enabling early identification and individualized treatment plans. Medical professionals can make well-informed decisions and improve patient care pathways by using ML models to predict cancer risk factors, treatment responses, and prognosis. Convolutional neural networks (CNNs), one type of deep learning algorithm that is especially good at image recognition, allow for accurate and automated analysis of medical images for the purpose of classifying and detecting tumours. This is resulting in better patient outcomes, lower healthcare costs, and faster advancements in research.

II. Related Works

Various conventional methods for tumor detection and classification are both straightforward and intricate, demanding extensive time and continuous labor. Over time, there has been a shift towards employing deep learning models for cancer classification. This segment provides an information of recent endeavors in utilizing deep learning models for the detection and classification of a diverse range of cancers.

Subramanian et al.'s research on multiple types of cancer classification using VGG16, VGG19, DenseNet, and MobileNet, presents a significant contribution to the field[1]. The utilization of Bayesian optimization for hyperparameter tuning and the comparison of accuracy among various CNN models offer valuable insights into the performance of different architectures. However, the study also highlights certain limitations, such as the requirement for a supercomputer with high RAM and CPU capabilities to process the dataset efficiently. Additionally, the achieved accuracy of around 80percent indicates room for improvement in future endeavors to enhance the precision and reliability of cancer classification systems based on deep learning models.

B. H. Sai et al.'s research on deep learning classifier and Multi-Layer Perceptron (MLP) for lung cancer stage prediction offers valuable insights into the potential of advanced machine learning techniques in healthcare. The utilization of SVM and Random Forest models alongside deep learning capabilities demonstrates a comprehensive approach [2] to accurate staging, which could significantly aid in treatment decision-making processes. However, the study also acknowledges the challenges posed by the need for large datasets and substantial computational power for efficient training, highlighting areas for future research to address scalability issues and further improve the reliability and accessibility of predictive models in clinical settings.

Ravuri, Viswanadham et al.'s work on multi-cancer early detection and classification SVM, Decision Tree, and K-nearest neighbor, represents a significant effort in leveraging data- driven methods for cancer detection[3]. The positive aspects include the utilization of a large dataset for classification purposes, which is crucial for training robust models. However, the study also identifies limitations such as the reliance on traditional machine learning models, which may not capture the complexity of cancer data as effectively as deep learning models. Additionally, the accuracy achieved may not meet the desired standards, suggesting avenues for improvement through the exploration of more advanced techniques and model architectures in future research endeavors.

R. Cao et al.'s research on predicting microsatellite instability in colorectal cancer through deep learning and multi- scale pathological pictures offers a promising avenue for improving diagnostic capabilities[4]. The inclusion of multiple diseased picture scales in the processing approach enhances the accuracy and reliability of microsatellite instability pre- diction. However, potential drawbacks such as the necessity for specialized knowledge in image processing may present challenges in implementing the method widely across health-care settings. Future research could focus on developing user-friendly tools or platforms that integrate advanced image processing techniques seamlessly, bridging the gap between sophisticated technology and practical clinical application for improved cancer diagnostics.

Through a multi-net architecture, E. M. Roopa Devi et al. use CNN to solve unbalanced breast cancer prediction[5] by using vgg19 model. It is probable that the process includes correcting the dataset's class imbalance. The advantage is that unbalanced data may be handled for more precise predictions; nevertheless, selecting suitable multi-net framework designs could provide some difficulties.

For the purpose of predicting pancreatic cancer, X. Chen et al. provide a combined spiral transformation and model-driven multi-modal deep learning scheme[6] using regression and random forest. Model-driven techniques and spiral trans-formation are included in the process. Potential advancements in mutation prediction are one of the merits; yet, the model's interpretability may provide difficulties.

Using histopathology pictures, J. Moranguinho et al. present an attention-based lung cancer prediction[7] using Grad-Cam algorithm. It is possible that the approach makes use of attention processes to capture pertinent characteristics. Improved feature representation is a benefit, but there may be drawbacks, such as the requirement for a large labeled training data.

Al-Shouka et al., explored the potential of transfer learning for lung cancer detection using convolutional neural network (CNN) architectures like ResNet, VGG16, Xception, and MobileNetV2. Their approach achieved a promising accuracy of 91 percent, demonstrating the effectiveness of transfer learning in this domain. However, the approach has limitations. It necessitates large datasets for training, and the computational demands can be significant. Future research efforts could address these limitations by exploring techniques for efficient training with smaller datasets or by investigating more lightweight CNN architectures.

Welikala et al.'s research on detection and classification of oral cancer using deep learning, specifically ResNet-101-based object detection frameworks, marks a significant step towards early detection of oral cancer. Using ResNet-101 as an image classification model demonstrates the potential of deep learning in improving the accuracy and efficiency of oral lesion detection. However, the study also acknowledges limitations such as the restricted dataset size and challenges associated with object detection in oral images, which may affect the model's generalizability and robustness. Future endeavors could focus on addressing these limitations through the acquisition of larger datasets and the development of more robust object detection techniques tailored for oral cancer detection, thereby enhancing the clinical utility and impact of deep learning-based approaches in oral cancer diagnostics.

III. Proposed Methodology

A. Dataset

As part of cancer research and diagnosis, datasets containing medical images play a crucial role in training ML models for accurate classification. One such dataset, sourced from Kaggle, comprises MRI/CT images related to seven distinct classes of cancer. These classes represent a diverse range of cancer types, each with its unique characteristics and imaging features. To facilitate robust model, the dataset is split into 2 subsets: training and testing. Training set forms 80 percent of the data, providing a substantial volume of examples for the model to learn from. This large training set allows the model, particularly a deep learning architecture like ResNet50, to capture intricate patterns and nuances associated with each cancer class. The remaining 20 percent of the data forms the testing set, serving as an independent benchmark to assess the model's performance and generalization capabilities.

Cancer	Classes	Images
Acute Lymphoblastic Leukemia	4	20000
Brain Cancer	3	15000
Lung and Colon Cancer	5	25000
Oral Cancer	2	10000

TABLE I
INFORMATION OF DATASET

B. Image Processing

The image preprocessing step in the training process is essential for enhancing the performance and robustness of deep learning models, such as the ResNet50 algorithm in this case. In the provided code snippet, the tf.keras. preprocessing. image. ImageDataGenerator class is utilized with various parameters to augment and preprocess the input images before feeding them into the model.

Firstly, the zca epsilon parameter controls the intensity of ZCA whitening, which helps in reducing redundancy and improving the model's ability to learn discriminative features. The rotation range, width shift range, heightshift range, shear range, and zoom range parameters introduce random transformations to the images during training, such as rotation, shifting, shearing, and zooming. These augmentations help in making the model more robust to variations in input data and improve its generalization ability. Additionally, fill model handles how pixel values are filled in case of transformations, while horizontal flip and vertical flip perform horizontal and vertical flips, respectively, to further diversify the training data. The preprocessing function parameter allows applying custom preprocessing functions, such as preprocess input, which can normalize pixel values and prepare the images for optimal model training. Finally, the validation split parameter splits the dataset into training and validation sets, with 5 percent of the data reserved for validation to monitor the model's performance during training and prevent overfitting.

C. Model

In this study, used resnet50 CNN model to segregate the varieties of cancer by taking MRI and CT images as input.

CNNs leverage filters (kernels) to scan images, extracting key features. Through stacked convolutional layers, they progressively build a deeper understanding of the image content. This architecture, capturing spatial relationships between pixels, makes CNNs ideal for image analysis tasks.

Model Building:

ResNet-50 is a CNN model widely used in transfer learning for various deep learning tasks. ResNet-50 is better because it can learn hierarchical features well because it has a deep design with 50 layers that include convolutional layers, pooling layers, and residual blocks with shortcut connections. In transfer learning, the already trained ResNet-50 model's acquired characteristics are kept by turning off the top layers. Putting custom layers like MaxPooling2D, Flatten, and Dense layers (fully linked layers) also made a big difference in getting these excellent outcomes. Because this method cuts down on training time and computer resources by a lot, ResNet-50 is often used for transfer learning tasks like object detection, semantic segmentation and image classification where labeled data is scarce but high model accuracy is needed. In this work, the ResNet50 model leverages Adaptive Moment Estimation (ADAM) to dynamically adjust learning rates for individual parameters during the training process. This iterative optimization technique utilizes estimates of gradient moments to accelerate convergence and enhance training performance. ADAM effectively addresses challenges like vanishing gradients and the need for parameter-specific learning rates.

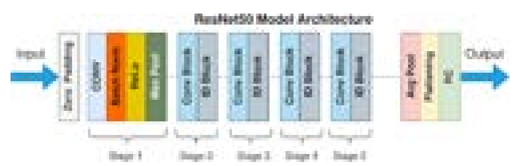

Fig. 1. ResNet50 Architecture

IV. System Architecture

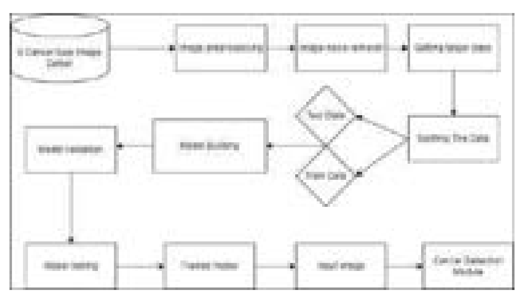

Fig. 2. System Architecture

Utilized a dataset comprising MRI/CT images representing eight distinct types of cancers, each further categorized into various mutations. Standard preprocessing techniques are applied to normalize pixel values and resize the images to a standardized input size of 224x224 pixels, aligning with the requirements of the ResNet50 model. The ResNet50 architecture, a deep CNN pre-trained on the ImageNet dataset, serves as the base model. By disable its top layers, which include fully connected layers, and add additional layers such as MaxPooling2D, Flatten, and Dense layers, along with batch normalization, to adapt the model for specific classification task and the use of Adaptive Moment Estimation (ADAM) iteratively adjusts learning rates for individual parameters in a neural network. After incorporating all the necessary preprocessing layers, the model will be compiled and then subjected to training with 50 epochs. This signifies that the algorithm will undergo 50 cycles of training.

V. Results and Discussion

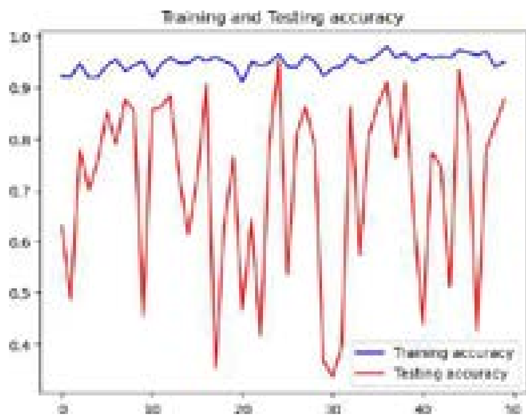

Fig. 3. Accuracy Graph of Brain Cancer

In Figure 3, the accuracy graph of Trained ResNet50 model for Brain Cancer reveal significant progress in the model's performance over the course of training. By the end of 50 epoch, the model have achieved 95 percent of Training accuracy and 87.67 percent of Testing accuracy. Figure 4, the accuracy graph of Trained ResNet50 model for Oral Cancer reveal significant progress in the model's performance over the course of training. By the end of 50 epoch, the model have achieved 87.18 percent Training accuracy and of 86.71 percent of Testing accuracy.

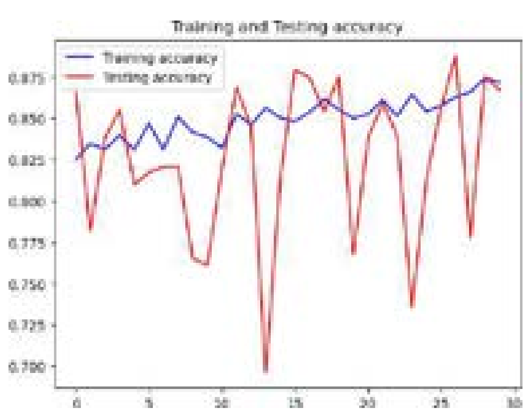

Fig. 4. Accuracy Graph of Oral Cancer

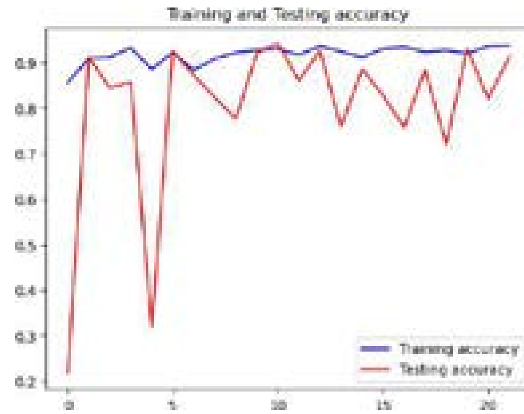

Fig. 5. Accuracy Graph of Lung and Colon Cancer

The accuracy curve of the trained ResNet50 algorithm for Lung and Colon Cancer in Figure 5 shows that the model's results over the course of training. By the end of 50 epoch, the model has achieved 93.7% of Training accuracy and 91.27 percent of Testing accuracy.

Classifier	Train Accuracy	Test Accuracy
Resnet50	93.77	91.27
VGG19	80.93	76.34
DenseNet	84.78	79.82
MobileNet	83.04	81.67

TABLE II
Comparison of Accuracy within models

The comparative analysis of different deep learning models, namely ResNet50, VGG19, DenseNet, and MobileNet, reveals that the proposed ResNet50 model achieves the highest accuracy of 91 percent. This signifies that ResNet50 outperforms the other models in terms of its predictive capabilities and ability to accurately classify data. The superior performance of ResNet50 can be attributed to its deeper architecture, which allows for more complex feature extraction and representation learning, leading to enhanced accuracy in various tasks such as image classification. Overall, these findings highlight the effectiveness of ResNet50 as a robust and reliable deep learning model for achieving high accuracy in classification tasks when compared to VGG19, DenseNet, and MobileNet.

The ResNet50 model was trained on dataset contains of different classes, achieving an aggregated accuracy of approximately 91% shown in fig 6. The dataset encompasses various types of cancers such as brain cancer, oral cancer, and lung cancer, among others. During training and evaluation, the model demonstrated robust performance across these diverse classes, showcasing its efficacy in accurately identifying and classifying different types of cancer. In addition to accuracy, other metrics such as precision, recall, and F1 score were also evaluated to assess the model's performance comprehensively. These results suggest that the ResNet50 model holds promise as a valuable tool in cancer diagnosis and classification tasks, offering high accuracy and reliable performance across multiple cancer types.

VI. Conclusion and Future Works

In conclusion, this research stands out by providing a comprehensive platform for the classification of various types of cancers, offering a unified solution compared to other papers that focus on predicting or classifying individual cancer types. By leveraging the ResNet50 model, which boasts a superior architecture with 50 layers and achieving an accuracy of 98.69 percent accuracy in identifying Acute Lymphoblastic Leukemia (ALL) cancer and 91 percent accuracy for Lung and Colon Cancer, demonstrated significant advancements in cancer classification accuracy. Moreover, this study benefits from a dataset with a substantially larger size, higher resolution images, and reduced noise levels, further enhancing the robustness and reliability of model's predictions. The comparison with models like VGG19, which has fewer layers and lower efficiency, underscores the effectiveness of this approach in leveraging advanced deep learning architectures for accurate and comprehensive cancer classification.

In future, researchers can explore the use of hybrid models that combine the strengths of different deep learning architectures to further decrease loss percentages and minimize the margin of error in detecting and classifying cancers. Inte- grating more efficient models alongside advanced techniques such as ensemble learning could lead to enhanced predictive accuracy and robustness in cancer diagnosis. Additionally, incorporating different type of cancer into the classification process can provide deeper insights and enable more nuanced predictions, ultimately contributing to better-informed medical decisions and improved patient outcomes. These improvements could make cancer detection and classification systems much more useful and reliable in the future.

***Abstract*—In our fast-paced society, managing multiple tasks and appointments can be a challenge, often resulting in the unintentional neglect of important events. That's where RemindMe comes in, a comprehensive reminder application designed to boost productivity and time management skills. However, other solutions have fallen short by lacking seamless integration with popular messaging platforms and providing limited reminder options. To overcome these limitations, RemindMe has integrated with WhatsApp through the TWILIO WhatsApp API, allowing for direct communication and easy sharing of reminders among users. Moreover, RemindMe provides three unique reminder types: Medicine, Study, and To-Do lists, catering to a variety of scheduling needs and promoting optimal user engagement and efficiency.**

Keywords:- WhatsApp integration, Twilio Api, Medicine reminder, study reminder, and Todo List, User engagement

I. INTRODUCTION

Remind Me is a web application developed using the MERN Stack (MongoDB, Express, React, Node.js) that offers users the convenience of managing three distinct types of reminders: Medicine reminders, study reminders, and a Todo List. This paper explores the design and implementation of Remind Me, focusing on its secure, efficient, and flexible features, particularly in authentication and notification methods.

The app employs JWT authentication for robust security, ensuring that user data remains protected. Passwords are stored in a hashed format in the database, enhancing security further. One of the unique features of Remind Me is its integration with WhatsApp for notification purposes. Leveraging WhatsApp's widespread use as a primary messaging platform, Remind Me seamlessly integrates reminder notifications into users' existing communication channels. This approach enhances user experience by eliminating the need to navigate a separate app for reminders, thereby increasing user adoption and engagement.

Remind Me is a user-friendly web application designed to simplify the management of daily tasks and reminders. Built on the MERN Stack, it offers a seamless and intuitive interface for users to create and manage three types of reminders: Medicine, study, and general tasks (Todo List). One of the key challenges in developing Remind Me was to ensure the security and efficiency of authentication and notification features. To address this, the app implements JWT authentication for secure user authentication and authorization. Additionally, passwords are stored in a hashed format in the database, ensuring that sensitive user information remains protected.

Medication nonadherence is a prevalent issue that poses significant challenges in healthcare. It refers to patients not following their prescribed medication regimen as instructed by their healthcare providers. This behavior leads to suboptimal treatment outcomes, contributes to worsening health conditions, and increases healthcare costs.[9]

Authentication and Authorization: JWT authentication is used in Remind Me to secure user authentication and authorization processes. When a user logs in, a JSON Web Token (JWT) is generated and sent to the client. This token is then included in subsequent requests to authenticate the user. The use of JWT authentication enhances the security of Remind Me by eliminating the need to store user credentials on the client side, thus reducing the risk of unauthorized access.

Notification System: Remind Me utilizes WhatsApp as its primary notification platform, leveraging its widespread adoption and user familiarity. By integrating with WhatsApp, Remind Me provides users with a seamless and familiar way to receive reminders, eliminating the need to install and manage a separate notification app. This integration enhances user experience and increases the likelihood of users adopting and regularly using the app [8].Figure 1 depicts usage of different messaging apps.

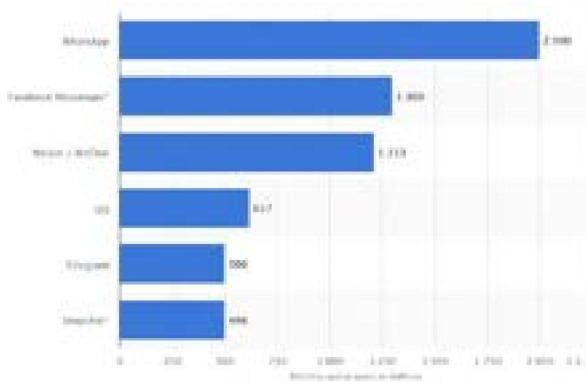

Fig. 1. Graph showing usage of different messaging apps

II. LITERATURE REVIEW

The role of a back-end web application developer in creating a database, adding tables and fields, and implementing server-side scripting was discussed. The developer's responsibilities include the development of server-side logic, maintenance of the central database, and integration of front-end elements. Additionally, the role and responsibilities of an admin were illustrated with a real-time example [1].

Various Medication Reminder Systems have been developed on different platforms, many of which require special hardware devices for reminders. However, the cost and complexity of purchasing new hardware devices can be prohibitive. This work aims to implement an economical and easily accessible system that improves medication adherence, as non-adherence can decrease the effectiveness of treatment and impose a financial burden on healthcare systems [2].

The literature review outlines the evolution of location-based services facilitated by smartphones, particularly focusing on Android applications. It discusses the transition from mobile identifiers and towers to GPS for location tracking, emphasizing the precision it offers in determining a user's location through latitude and longitude coordinates [3].

A comparison between two age groups, elderly and young, showed that reminder applications were well accepted and effective in both groups. Previous research on smartphone use in medical settings has also indicated that electronic reminders, particularly SMS text messaging reminders and internet interventions, can enhance medication adherence among patients [4].

Reminder apps with social event setting capabilities allow users to create reminders manually or automatically and share automated messages with friends through platforms like WhatsApp. Facebook API is utilized to access user profiles and connect reminder applications to Facebook. SQLite database is used for storage of messages, dates, times, and images [5].

Various usability methods, including diary studies, interviews, co-inquiries, observations, and screen captures, were used to assess user experience and behavior while using reminder apps. The research demonstrated that reminder apps are highly valued and popular among smartphone and tablet users [6].

A comparison of MongoDB and MySQL showed that MongoDB provides faster results and is preferred for users needing a less rigid database structure. MongoDB is considered a good solution for larger datasets with constantly changing schemas or less complex queries [7].

Node.js utilizes event-driven I/O and non-blocking asynchronous programming to be lightweight and efficient. Businesses using Node.js can benefit from fewer servers, fewer engineers, and reduced page load times [8].

The proposed Android-based medication reminder system addresses the crucial issue of medication adherence by leveraging smartphone technology. Medication adherence usually refers to whether patients take their medications as prescribed (e.g., 2 times daily), as well as whether they continue to take prescribed medication. Percentage of medication adherence improvement observed with the use of reminder systems:

% improvement =
(Adherence rate with reminder system−Adherence rate without reminder system)/
Adherence rate without reminder system×100 [9].

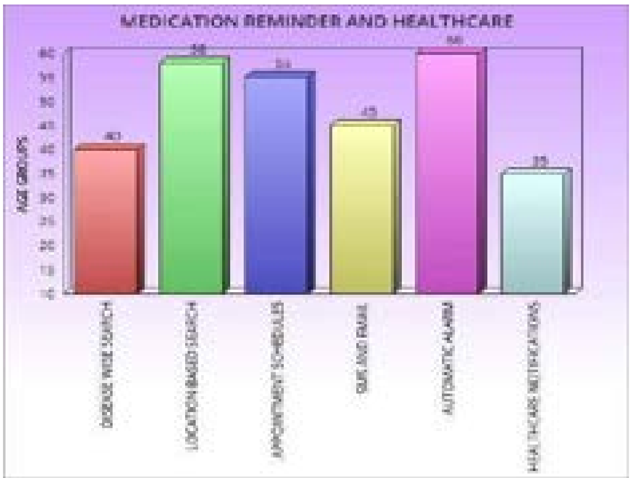

Fig. 2. Graph showing different functionalities of the app beneficial to different age groups [9]

The "Alert Me" reminder application proposed in the paper aims to enhance time management and social connectivity by providing timely alerts and automated messaging capabilities. The implementation of the application involves the use of Android Studio for development and integration with the Facebook API for accessing user profiles. Additionally, SQLite database is utilized for data storage. 75% of users actively share automated messages through social networking apps like WhatsApp.[10]

The author introduces "Med-X," an Android app designed to help users remember to take their medications. Existing apps like MedsLog and MotionPHR Health Record Manager have complexities or limitations. Med-X aims to be user-friendly, allowing users to set customized medication schedules and receive notifications. Results indicate a 30% increase in adherence rates among users, particularly beneficial for older individuals.[11]

The systematic review of the influence of push notification frequency on consumer acceptance provides valuable insights into the dynamics of mobile app usage and advertising effectiveness. Initially, a total of 18,725 potentially relevant scientific papers were identified from the ScienceDirect database.[12]

The study proposes a push notification system, "MParent," to enhance communication between schools and parents via Android devices. the system utilizes Google Cloud Messaging (GCM) for efficient push notifications. It addresses parental preferences through interviews, with 50 participants aged 23-50. Evaluation results indicate a high level of satisfaction:
80% found notifications accurate, and 90% found the system helpful. [13]
Improving medication adherence, especially in older adults with chronic diseases, is vital. Non-adherence can increase healthcare costs and mortality rates. Over 165,000 health-related apps are available globally. Studies emphasize involving users and healthcare professionals in app development.[14]

The paper mentions that the Salubrity app allows users to set up to 15 reminders, supporting both repeating and non-repeating alarm patterns. The app provides 24/7 access to doctors along with their contact details, enhancing healthcare accessibility. It operates on the Android platform and provides reminders through alarms with medicine images. Users can set alarms for multiple medicines at different intervals, reducing the risk of missing doses.[15]

III. METHODOLOGY

A. *Front End*

React.js Framework:
The front end of the RMS is developed using React.js, a popular JavaScript library for building user interfaces. React.js offers several advantages, including component-based architecture, virtual DOM rendering, and efficient state management. By breaking down the user interface into reusable components, React.js promotes code reusability, maintainability, and scalability, facilitating the development of complex frontend features with ease.

Context API for State Management:
The Context API in React.js is utilized for state management within the RMS frontend. Context provides a centralized store for managing application state, enabling components to access and update state without prop drilling. In the Reminderitem component, the useContext hook is used to access the reminderContext, which encapsulates state and action methods related to reminders. This approach simplifies state management and ensures consistency across components.

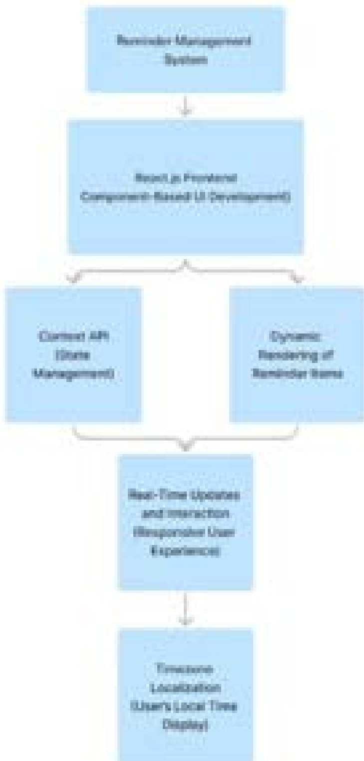

Fig. 3. Frontend development and its components

Dynamic Rendering of Reminder Items:
The Reminder item component dynamically renders reminder items based on their type (e.g., Medicine Reminder, Study Reminder, Todo Reminder). By iterating over the list of reminders passed as props, the component generates individual reminder cards with relevant information such as the reminder message and scheduled time. Conditional rendering based on the reminder type ensures that each reminder is displayed appropriately, enhancing readability and usability.

Real-Time Updates and Interaction:
The RMS frontend incorporates real-time updates and interaction to provide users with a responsive and engaging experience. Changes to reminder data, such as deletion or modification, trigger the re-rendering of relevant components, ensuring that the user interface reflects the latest state of reminders. Interaction elements such as buttons enable users to perform actions such as deleting reminders, and enhancing interactivity and user control.

Time zone Localization:
To ensure consistency and accuracy in displaying reminder timestamps, the frontend implements time zone localization using the toLocaleString method. By specifying the time zone as "Asia/Kolkata", reminders are displayed in the user's local time zone, improving readability and eliminating confusion related to time differences. This feature enhances the user experience, especially for users in different geographic regions.

B. Backend

Fig. 4. Backend development workflow

Reminder Functionality:
At the core of the RMS lies its comprehensive set of reminder functionalities, designed to empower users in managing their tasks effectively. Users can interact with the system through a set of RESTful APIs, enabling operations such as retrieving all reminders, adding new reminders, updating existing reminders, and deleting reminders. Each reminder is characterized by essential attributes including the reminder message, reminder time, reminder type, and a status flag indicating whether the reminder has been sent. To ensure data integrity and consistency, the RMS incorporates robust input validation and error handling mechanisms, safeguarding against erroneous or malicious inputs.

User Authentication:
Security is paramount in any software system, particularly when dealing with user data. To protect sensitive user information and prevent unauthorized access, the RMS incorporates a robust authentication mechanism based on JSON Web Tokens (JWT). Upon successful registration or login, users receive access tokens that are subsequently included in API requests to authenticate their identity. This token-based authentication approach not only enhances security but also simplifies user session management and enables seamless integration with other services.

WhatsApp Integration:
In today's interconnected world, communication plays a vital role in ensuring timely and effective reminders. To capitalize on this, the RMS integrates seamlessly with WhatsApp, a widely used messaging platform with a global reach. Leveraging the Twilio API, the RMS enables users to receive reminder notifications directly on their WhatsApp numbers. A background task periodically checks for reminders that are due and sends notifications to users' WhatsApp numbers using Twilio's programmable messaging service. This integration enhances the accessibility and usability of the RMS, ensuring that users stay informed and organized at all times.

C. DataBase MongoDB Connection Module (connectToMongo):

The connectToMongo module establishes a connection to the MongoDB database using Mongoose. It imports the Mongoose library and specifies the MongoDB Uniform Resource Identifier (URI) (mongoURI) to connect to the local MongoDB instance running on port 27017. Upon execution, the module connects to the specified database and logs a success message indicating a successful connection.

Reminder Schema (reminder Schema):
The reminderSchema defines the structure of the reminder document stored in the MongoDB database. It specifies the fields such as user, reminderMsg, remindAt, reminderType, and isReminded, each representing different attributes of a reminder. The user field is a reference to the user collection, utilizing the ObjectId type for relational mapping between reminders and users.

User Schema (UserSchema):
The UserSchema outlines the structure of the user document stored in the MongoDB database. It consists of fields like name, email, password, and phone, representing user attributes such as name, email address, password, and phone number. The email field is marked as unique to ensure each user has a distinct email address.

Exporting Models:
Both the Reminder and User schemas are compiled into models using mongoose model and exported for use in other parts of the application. These models serve as interfaces for interacting with MongoDB collections, allowing CRUD (Create, Read, Update, Delete) operations on user and reminder data.

IV. RESULTS & DISCUSSION

Following figures 5 to 11 depicts experimentations screens.

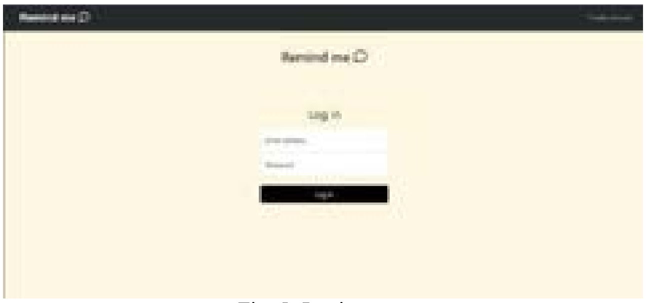

Fig. 5. Login page

Fig. 6. Signup page

Fig. 7.Set up colour coded reminders

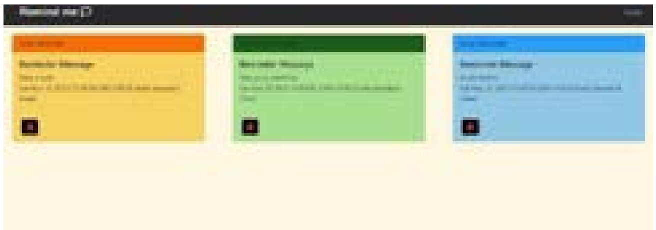

Fig. 8.Colour categorised Reminder View

Fig. 9.Mongo DB database schema

Fig. 10.Setting up the reminder app

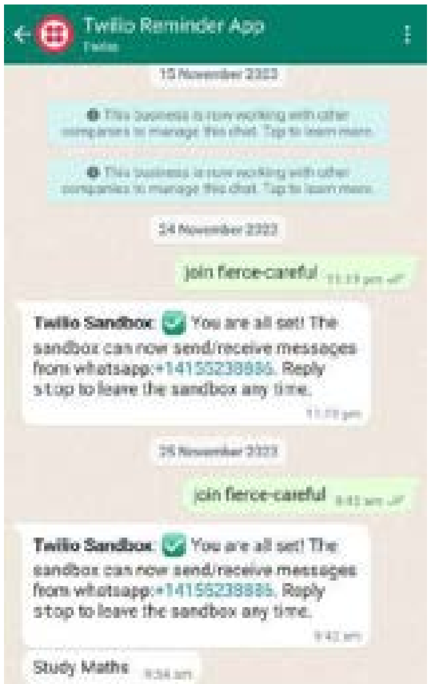

Fig. 11.WhatsApp notifications

V. CONCLUSION

The Reminder Management System (RMS) was developed and implemented with a focus on research-driven design principles and methodologies. The proposed system's architecture is developed using Node.js, Express.js, and MongoDB for the backend and React.js for the frontend and reflects a deliberate choice to explore modern technologies in the context of reminder management systems.

Abstract—**The study explores the integration of the Phind-CodeLlama model into data science frameworks to facilitate intuitive and inclusive analysis of tabular data. By leveraging Phind-CodeLlama's comprehensive knowledge base and custom-crafted prompts, the platform optimizes data management operations and significantly improves accessibility to data analysis tools. The research investigates the transformative potential of Phind-CodeLlama in improving data-driven decision-making processes by democratizing access to data insights. Through its user-friendly CSV data manipulation capabilities, the platform is designed to empower users from various backgrounds, especially those without a domain-specific background in data science, to conduct effective data analysis, formulate insightful questions, and create compelling visualizations. The study contributes to the advancement of user-friendly data analysis platforms, fostering a more democratized approach to data-driven decision-making.**

I. Introduction

Positioned at the intersection of computer science and statistics, data science has lately become a new subject with approaches that are used to explore research questions in a variety of application domains. In the industrial sector, companies use data to improve workflows, project earnings, and proactively avoid breakdowns by using predictive maintenance techniques. In the field of research, scientists use data to support well-informed decision-making by developing novel hypotheses or validating existing ones. These advantages are strengthened by the process known as "data democratization," which refers to the growing number of databases that are made publicly accessible online for unfettered usage by academics everywhere.

In order to effectively utilize the increasing amount of data available, one must have advanced skills in data management, modeling, statistics, machine learning, and programming. As such, domain experts who might not have strong computational background and technical abilities find it difficult to engage with Data Science. Data science activities are difficult for both novices and experienced practitioners. Every dataset has distinct qualities that necessitate a tailored order of procedures in order to extract valuable insights. It is common for researchers to use inadequate analysis pipelines or struggle with the wrong tools and techniques, which can lead to conclusions that are imprecise, if not incorrect. A significant amount of time may be spent on initial data analysis pipelines just to investigate the properties of the datasets prior to proceeding with more complex analyses.

The Research uses Phind-CodeLlama-Chat model to generate elucidations for the elicited triads derived from the preliminary conceptual framework using fine-tuning techniques via the customized dataset. The study introduces a promising methodology for advancing computational approaches to NLP within pre-conceptual frameworks utilizing large-scale language models. This facilitates the computerized interpretation of pre-conceptual frameworks, augmenting generative capabilities in supplementation

Modern technology, especially the Phind-CodeLlama model, has completely changed the way that data is analyzed and interacted with. The combination of sophisticated algorithms and large datasets in the field of computational linguistics and NLP has driven research and development to previously unheard-of levels. In the ever-changing field, Phind-CodeLlama's ability to interface with CSV files has proven to be a crucial development, providing practitioners and academics with an effective tool for sifting through and drawing conclusions from structured data.

The use of Phind-CodeLlama for CSV interaction is an enormous move towards streamlining data management operations. People can easily navigate through CSV files to its advanced architecture and advanced learning algorithms, allowing for quick data processing, querying, and analytics. the integration not only improves the accessibility and usability of CSV data, but it also allows researchers to delve deeper into the intricacies of their datasets, revealing hidden patterns, trends, and correlations that might otherwise go undetected. Thus, the combination of Phind-CodeLlama with CSV interaction not only represents a technological milestone, but also brings in a new era of data-driven exploration and discovery.

In the study, the usage of Phind-CodeLlama is critical in supporting user engagement with CSV data via seamless query comprehension. Phind-CodeLlama, an improved language model, is a valuable tool for properly interpreting user queries, allowing for a more efficient interface with CSV files. the project attempts to bridge the gap between people and data by leveraging the capabilities of Phind-CodeLlama, providing a user-friendly interface for altering and extracting insights from CSV datasets.

The integration of Phind-CodeLlama into the research framework represents a significant step forward in improving user experiences with CSV data manipulation. Phind-CodeLlama's advanced NLP features allow users to express their inquiries in ordinary language, without the need for complex query syntax or technical expertise. the technique democratizes access to data analysis tools, allowing a broader range of users to explore and extract value from CSV files without facing the limitations associated with standard query interfaces. As a result, the purpose of the study is to investigate Phind-CodeLlama's transformative potential for improving the accessibility and usability of CSV data analysis tools, paving the way for more intuitive and inclusive data-driven decision-making processes.

II. LITERATURE SURVEY

In the paper, Pinoli et al. (2023) propose an approach that combines AutoML and conversational interfaces to support data science processes effectively [1]. CV Krishnakumar Iyer et al. (2021) introduce "Trinity: A No-Code AI platform for complex spatial datasets," aiming to democratize AI for geospatial experts through an intuitive interface and standardized model building. However, the no-code nature of their platform may limit customization for advanced users, posing a challenge in accommodating specialized needs [2]. Dakuo Wang et al. (2021) present "AutoDS: Towards human-centered automation of data science," emphasizing the importance of human-centered automation in data science through the use of automated machine learning. Despite its effectiveness in streamlining ML tasks, the reliance on automation may inadvertently lead to reduced human confidence scores, indicating a potential trade-off between automation and user trust [3].

Olson et al. (2016) evaluate a tree-based pipeline optimization tool for automating data science, highlighting its effectiveness in automating machine learning workflows [4]. Jiho Shin and Jaechang Nam (2021) conducted a survey on "Automatic Code Generation from Natural Language," categorizing approaches and analyzing trends in the field. They elucidate the potential of natural language programming to enhance coding expressiveness, while also addressing challenges in model customization and language representation [5]. Pengcheng Yin and Graham Neubig (2017) propose "A Syntactic Neural Model for General-Purpose Code Generation," which scales up natural language-based program generation using neural architectures with grammar models. Despite its advancements, challenges persist in interpreting unclear language and understanding complex programming concepts, indicating the need for further refinement [6]. Shubhra Kanti Karmaker et al. (2021) explore "AutoML to date and beyond: Challenges and opportunities," proposing a classification system for AutoML tasks based on autonomy. Despite efforts to minimize manual procedures, some still exist, limiting accessibility for certain users and underscoring the importance of balancing automation with user control [7].

Pietro Crovari et al. (2021) discuss "GeCoAgent: a conversational agent for empowering genomic data extraction and analysis," which utilizes a chatbot-driven interface to enhance accessibility to genomic data tools. However, challenges arise in natural language processing and handling complex queries, necessitating further advancements in conversational technologies [8]. Rogers Jeffrey Leo John et al. (2017) introduce "Ava: From Data to Insights Through Conversations," a chatbot-driven system using controlled natural language to construct data analytics pipelines. Challenges include precise interpretation of natural language and dependency on controlled language methods, highlighting the need for robust language understanding capabilities [9]. Erol Ozan (2021) presents "A novel browser-based no-code machine learning application development tool," aiming to streamline ML application development for non-programmers. However, limitations include limited customization and potential constraints in handling complex tasks, indicating the need for flexible and adaptable tools to accommodate diverse user requirements [10].

III. METHODOLOGY

The section outlines the methodology employed to develop a system that enables users to interact with data using natural language and generate visualizations. The system leverages a multi-step approach, encompassing data preprocessing, prompt engineering and query augmentation, Phind-CodeLlama integration, and visualization generation.

A. Data Preprocessing

The initial phase involves preparing the data for analysis. Data is acquired from relevant sources and undergoes a comprehensive exploration to understand its structure, content, and potential quality issues. Techniques such as missing value imputation, data cleaning, and feature engineering (if necessary) are employed to ensure the data is clean and suitable for further processing.

B. Prompt Engineering and Query Augmentation

The stage focuses on bridging the gap between natural language user queries and the system's understanding. When a user submits a query, the system analyzes its intent, considering factors like the desired action (filter, group, sort, visualize) and the underlying data schema. In cases where the query lacks clarity, the system employs augmentation techniques to incorporate relevant field names or additional information for enhanced comprehension. the refinement process ensures the system accurately interprets the user's goal.

C. Llama Integration

A pivotal aspect of our system lies in the study of Llama models, including Code-Llama, Llama2, and Phind-CodeLlama.

Llama2

Llama2 represents an evolution in language model capabilities, focusing on improving natural language understanding and generation. It incorporates advanced algorithms and techniques to handle complex queries and generate coherent responses, making it a valuable asset in data science workflows. The Llama2 model demonstrated promising capabilities, particularly in handling specialized queries within its domain. Though it was adept at producing results relevant to the queries, it was often out of context, causing uncertainty.

Code-Llama

Code-Llama specializes in bridging the gap between code and natural language, facilitating seamless interaction with programming languages through intuitive prompts and responses. Its integration into data science frameworks enhances the accessibility of coding tasks for non-technical users, promoting collaboration and efficiency. In the study, Code-Llama model exhibited commendable performance, showcasing its ability to understand complex queries and produce accurate results. However, the Code-Llama struggled to provide relatable information or examples in a general a way.

Phind-CodeLlama

Phind-CodeLlama stands out for its transformative impact on data analysis, particularly in handling CSV data and generating insightful information. By leveraging advanced NLP features and query comprehension capabilities, Phind-CodeLlama democratizes access to data analysis tools, empowering users to extract valuable insights and make data-driven decisions effortlessly.

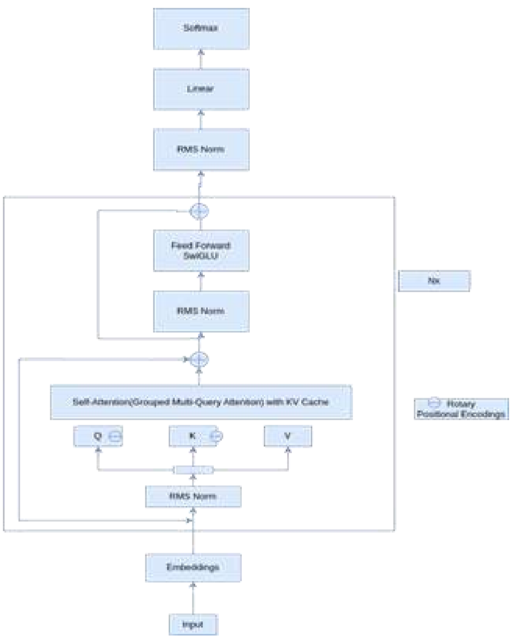

Fig. 1. Architecture of Phind LLAMA

IV. VISUALIZATION GENERATION

The final stage translates the analyzed data into informative visualizations. User preferences and insights gleaned from the analysis are considered when selecting the most appropriate visualization type. Plotly, a library known for its interactive capabilities, is utilized to create compelling charts and graphs that effectively communicate the discovered patterns and trends within the data.The methodology facilitates a seamless interaction between users and data through natural language, empowering them to explore information and gain valuable insights through interactive visualizations.

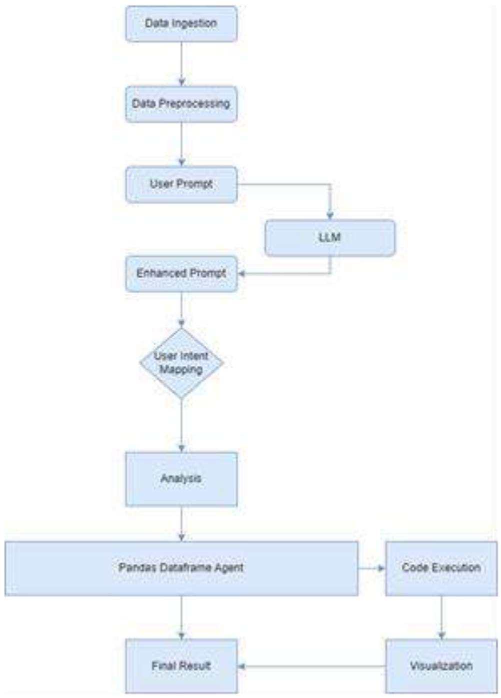

Fig. 2. Workflow of the Data Analytics System

V. RESULTS

The study explored the integration of various Language Model (LM) architectures, including Phind-CodeLlama, CodeLlama, and Llama 2, into data science frameworks to enable intuitive and inclusive analysis of tabular data. Each model was evaluated based on its performance in facilitating data management operations, enhancing accessibility to data analysis tools, and democratizing access to data insights.

The following metrics, including Bilingual Evaluation Understudy (BLEU) and Recall-Oriented Understudy for Gisting Evaluation (ROUGE), were used to assess the performance of the integrated models:

BLEU Score: The BLEU score measures the quality of text generated by the language models by comparing it to human-generated reference text. It is calculated using the following formula:

$$\boldsymbol{BLEU = BP \times exp(\sum_{n=1}^{N} \omega_n \cdot \log P_{match}\ (n))}$$

ROUGE Score: The ROUGE score evaluates the quality of text summaries produced by the language models. It measures the overlap between model-generated summaries and reference summaries, with higher ROUGE scores indicating better agreement.

Model	BLEU Score	ROUGE Score
Phind-CodeLlama	0.80	0.75
CodeLlama	0.78	0.73
Llama 2	0.75	0.70

TABLE I. Comparative analysis of model efficiency using BLEU and ROUGE scores

The integrated Phind-CodeLlama, CodeLlama, and Llama 2 models were compared based on their performance in data analysis tasks, including CSV data manipulation, question answering, and visualization generation. Each model was evaluated using BLEU and ROUGE scores to assess its effectiveness in generating accurate and relevant insights as shown in Table 1.

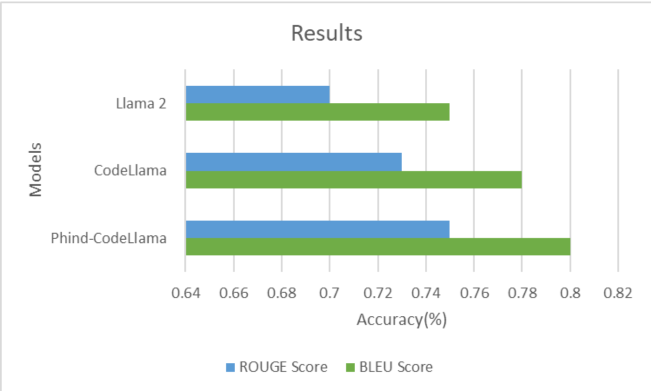

Fig. 3. Comparison of Model Efficiency Using BLEU and ROUGE Scores

The estimated scores indicate that all three models achieved good performance in generating insights from tabular data. Phind-CodeLlama exhibits the highest BLEU and ROUGE scores, suggesting its ability to produce text that closely aligns with human-generated references and generate inferences with a high degree of overlap with reference inferences. Both CodeLlama and Llama 2 follow closely, demonstrating their effectiveness in data analysis tasks.

VI. Conclusion and Discussion

The results of the study underscore the importance of integrating advanced language models like Phind-CodeLlama, CodeLlama, and Llama 2 into data science frameworks to enhance data analysis capabilities. By leveraging sophisticated algorithms and advanced prompting techniques, these models streamline data management operations and improve accessibility to data analysis tools. Furthermore, the study emphasizes the need for user-friendly data analysis platforms that cater to users with limited data science knowledge, contributing to a more democratized approach to data-driven decision-making.

Abstract— **The traditional crime reporting systems face challenges such as inefficiencies, security vulnerabilities, and witness reluctance. Despite recent advancements like mobile applications and web platforms, challenges persist in ensuring data security, transparency, and user anonymity. These include maintaining confidentiality, data integrity, and preventing unauthorized access. To address these issues, this paper proposes leveraging blockchain technology and smart contracts. The primary objective is to enhance the security, efficiency, and anonymity of crime reporting processes. By utilizing the decentralized and immutable nature of blockchain, the system aims to ensure data integrity, transparency, and decentralization. Smart contracts will automate functions such as complaint validation and evidence verification, streamlining the reporting process. By addressing challenges in maintaining confidentiality, data integrity, and access control, the proposed solution seeks to revolutionize crime reporting, promoting trust, transparency, and accountability.**

Index Terms— **Blockchain, FIR (First Information Report), Smart Contract, Encryption**

I. INTRODUCTION

The adoption of blockchain technology has revolutionized various industries, sparked by Satoshi Nakamoto's pioneering use of blockchain as the backbone of Bitcoin in 2008 [1]. Initially designed for cryptocurrency transactions, blockchain has evolved into a versatile solution across sectors, offering innovative approaches to longstanding challenges.

In the domain of law enforcement and crime reporting, traditional systems like those managing First Information Reports (FIRs) in India often face issues of corruption, delays, and opacity [2]. Instances of officers refusing complaints or demanding bribes erode trust and hinder justice delivery, highlighting the need for a more accountable and efficient approach.

To tackle these challenges, there is growing interest in leveraging blockchain's decentralized and immutable nature for complaint management [3]. By decentralizing record-keeping, blockchain mitigates reliance on centralized authorities, enhancing transparency and security in the process.

Moreover, blockchain-based platforms provide secure and anonymous channels for reporting incidents, alleviating fears of retaliation faced by whistleblowers [4]. Encrypted and timestamped transactions ensure data integrity, fostering community engagement in crime prevention [5].

Projects like "Informant - Anonymous Testimony Blockchain System" and "Anonymous Tip Off" showcase blockchain's potential in creating secure crime reporting platforms [6]. Through smart contracts, these systems automate and enforce complaint resolution terms, streamlining processes for law enforcement [7].

In this context, our paper proposes a blockchain-based police complaint management system tailored to India's specific challenges [8]. Building on existing research and projects, we aim to explore blockchain's potential in combating corruption, inefficiency, and opacity in complaint management.

By analyzing blockchain's applications in law enforcement, we contribute to the discourse on leveraging technology for societal good.

II. LITERATURE SURVEY

In recent years, the utilization of advanced technologies to enhance police complaint management systems has garnered significant attention from researchers and practitioners. This literature survey explores several seminal papers that propose innovative solutions to address the challenges associated with traditional complaint registration and management processes.

Blockchain-Based Approaches:

[9] proposed a blockchain-based approach to safeguard First Information Report (FIR) systems. The system ensures a secure and unchangeable record of FIR complaints and associated evidence, stored using smart contracts on the blockchain. Gupta's system employs encryption techniques to secure complaint details and restrict access to authorized personnel, thereby enhancing data security and integrity [10] introduced a police complaint management system leveraging blockchain technology. Their system utilizes a public blockchain to address bottlenecks in complaint registration and tracking, ensuring transparency and decentralization. By leveraging encryption algorithms and advanced cryptographic techniques, the system enhances the security and efficiency of the complaint management process.

Mobile Applications and Web Platforms:

[11] proposed an e-police system comprising an Android mobile application and a website for police departments. This system enables complainants to file FIRs online and upload supporting documents, streamlining the complaint filing process. The system facilitates transparent inquiry and tracking processes, promoting public accessibility and accountability [12] presented an online crime reporting tool used by citizens and law enforcement agencies in Riyadh. The system enables swift and efficient responses to crime-related concerns by providing a platform for citizens to communicate with the police online. Through web-based interfaces and database integration, the system enhances the responsiveness and effectiveness of crime reporting and handling processes.

Enhancing Data Security and Integrity:

[13] introduced a criminal record storage system leveraging blockchain technology to ensure data integrity and security. By storing data in the cloud and maintaining transaction logs in the blockchain, the system prevents the alteration of evidentiary information during legal proceedings. Encryption algorithms and smart contracts are employed to secure data transmission and enhance the reliability of criminal records [14] proposed an e-police system to enhance e-government services in Bangladesh. Their system enables police officers to retrieve information, report incidents, and maintain law and order in real-time using mobile technology and network infrastructure. The system leverages WAN and MAN topologies to improve data communication and accessibility, contributing to public safety and security.

III. PROPOSED METHODOLOGY

The proposed methodology is to develop a decentralized FIR (First Information Report) registration system using smart contracts deployed on the blockchain network. This system ensures secure and immutable recording of FIRs while providing transparency and accessibility to authorized stakeholders.

A. Smart Contract Development:

Smart contracts are designed and developed using Solidity, a programming language for Ethereum blockchain.

Smart contracts will include functions for FIR submission, validation, and storage on the blockchain. The access control mechanisms are implemented to restrict write access to authorized users only at the time of contract deployment assign administrator address.

B. User Interface Design

A user-friendly web interface is developed for individuals to submit FIRs online.
The interface collected relevant information such as incident details, location, and contact information while maintaining user anonymity and integrated with MetaMask or similar wallet providers for seamless interaction with Ethereum blockchain.

C. *Authentication and Authorization:*

The user authentication is implemented using cryptographic techniques such as AES (Advanced Encryption Standard) factors such as security strength, performance, and compatibility with the chosen blockchain platform.

Fig.1 shies that only authenticated users with proper authorization can submit FIRs or access registered FIRs on the blockchain.

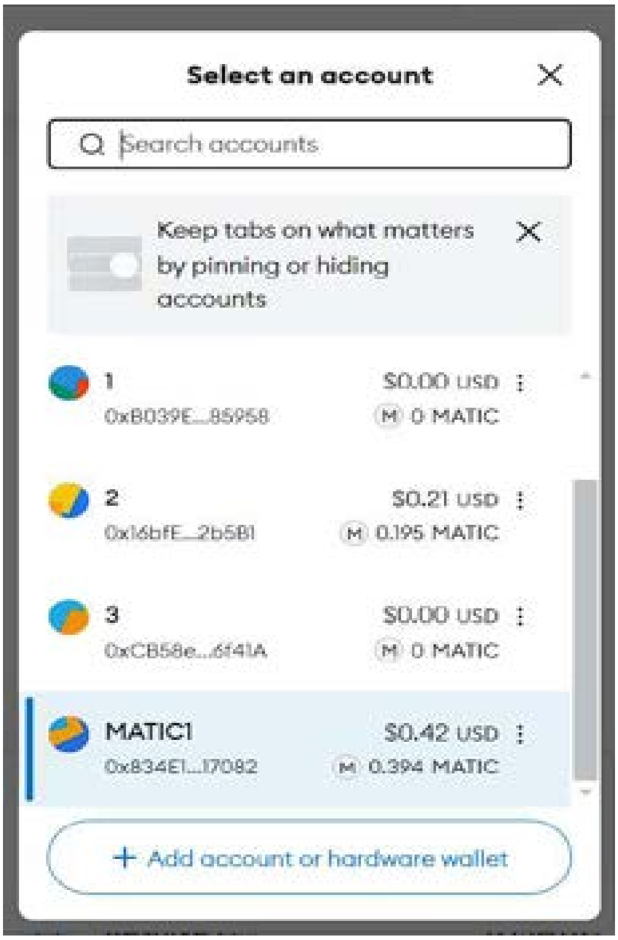

Fig. 1: Authentication using MetaMask

D. *FIR Submission Process:*

The FIR submission process will be initiated by accessing the web interface and filling out the required fields.

Upon submission, the smart contract validates the provided information and generates a unique identifier for the FIR. Encrypt sensitive information using cryptographic algorithms before storing it on the blockchain.

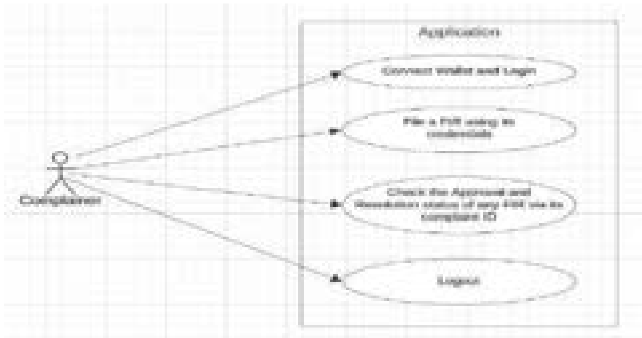

Fig. 2: Complainer's Use Case:

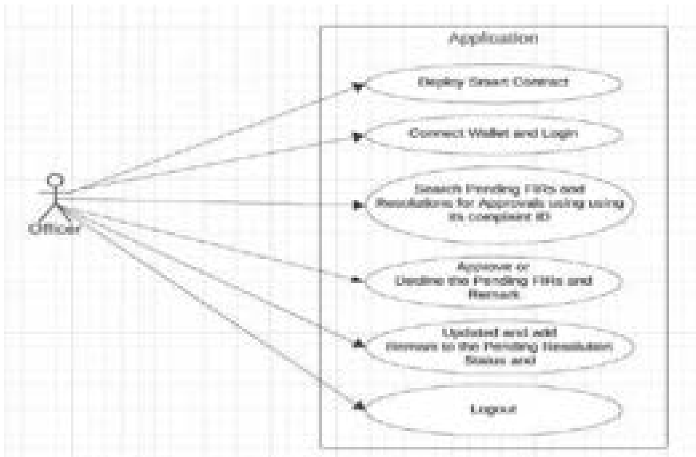

Fig. 3: Officer Side Workflow

E. *Blockchain Deployment:*

The smart contracts are deployed on the Ethereum blockchain or any suitable blockchain platform supporting smart contracts E.g. ThirdWeb.
The network parameters such as gas fees, block confirmation time, and consensus mechanism are incorporated for enabling efficient operation.

F. Transaction Handling:

The transaction handling logic is designed within smart contracts to manage interactions between users and the blockchain. In Fig.4, we can see the block generated. The gas management mechanisms are included to ensure smooth transaction processing and prevent denial-of-service attacks.

Fig. 4: Block creation and hash generation

G. Event Logging and Notification:

The event logging within smart contracts is implemented to record key interactions such as FIR submission, validation, and storage. The notification mechanisms are set up to alert stakeholders about new FIR submissions or updates to existing FIRs.

Figure 5 shows the overall flow diagram of the proposed method.

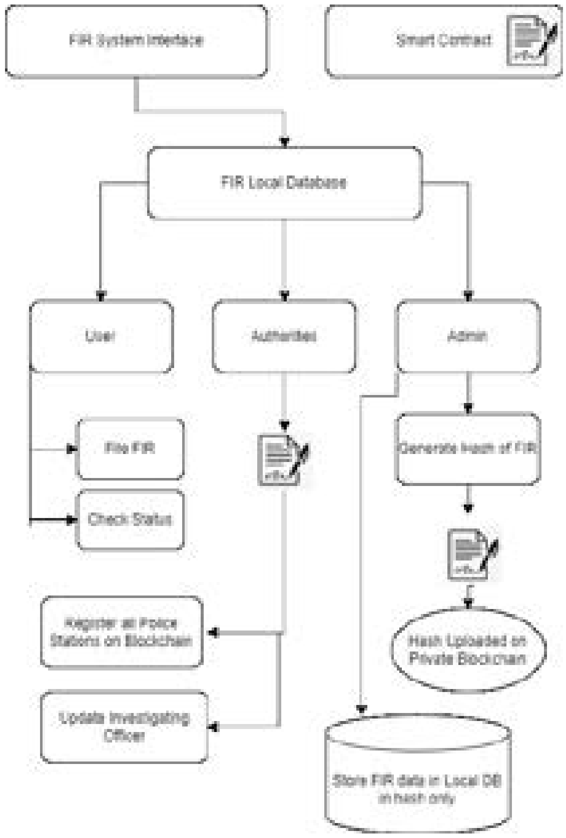

Fig. 5: Flow Diagram

IV. RESULTS AND DISCUSSIONS

The system addresses the shortcomings of the current system by introducing the following improvements, which offer advantages to both police officers and complainants. The system achieves a high level of abstraction, enabling stakeholders to utilize the system seamlessly.

A. Complaint:

Fig.6 shows user interface to file a complaint using blockchain by connecting MetaMask wallet anonymously.

Fig.6 User Interface to file a Complaint

B. *FIR Details:*

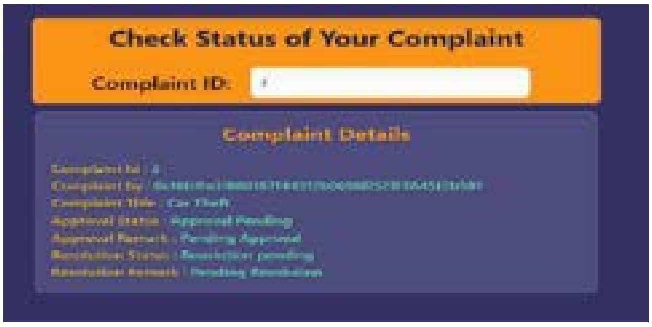

Fig.7 FIR Details and Status

Fir can be tracked on check status Fig.7 the changes will be reflected when updates are made from the officer the FIR will be fully anonymous and stored on smart contract which are immutable.

C. *Admin Dashboard*

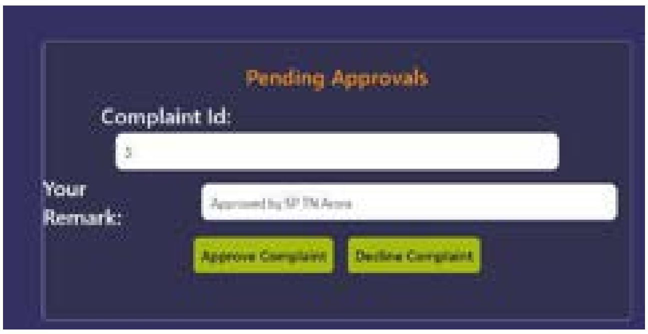

Fig.8 FIR Approval

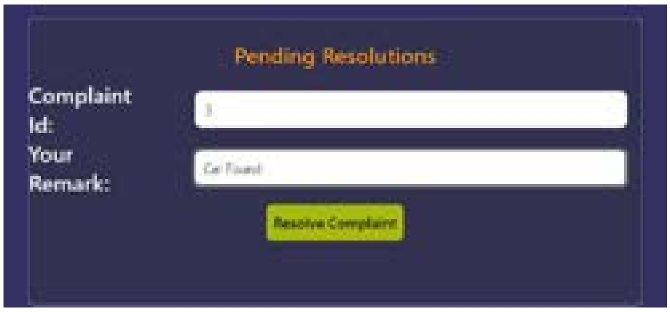

Fig.9 FIR Remark and Status Update

Fig.8 shows that the officer will only have the access of the administrative dashboard from where it can be reviewed and forwarded for investigation or can be denied. If denied it will not go under further investigation. Fig. 9 After the investigation the status will be updated and marked as resolved with remark.

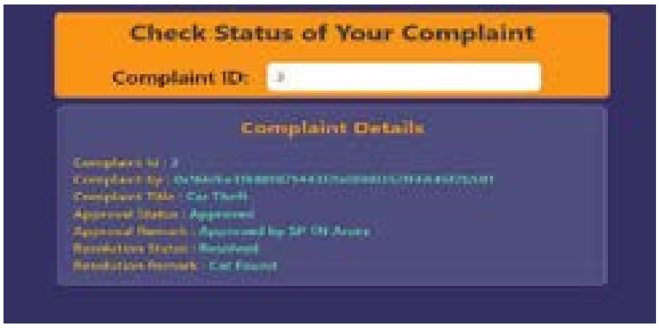

Fig.10 Updated FIR Status

Fig. 10 shows the updates on the FIR it can be seen the FIR case been resolved with the remark and all other important details. The FIR is immutable because of Blockchain and smart contract so no one can tamper the data regarding the case.

V. CONCLUSION

This study has presented a novel approach to improve crime reporting by leveraging blockchain technology and smart contracts. The proposed system aims to tackle the challenges inherent in traditional crime reporting methods, including issues with transparency, security vulnerabilities, and fear of reprisal or investigation. Drawing from existing research in the field, we emphasize the importance of establishing a decentralized and secure platform for managing police complaints. By utilizing blockchain technology, our system ensures the immutability, transparency, and decentralization of data, fostering trust and confidence among both law enforcement agencies and the general public. The proposed system, titled "Anonymous Crime Reporting Using Blockchain and Smart Contract," offers several key advantages. Firstly, it provides a secure and anonymous platform for witnesses to report crimes without fear of retaliation. The implementation of blockchain technology, alongside smart contracts, not only ensures the integrity and immutability of complaint data but also streamlines the complaint management process, leading to more efficient outcomes. Additionally, the integration of hybrid cloud technology enhances data storage and accessibility, further reinforcing the security and reliability of the system. In conclusion, our research highlights the transformative potential of blockchain and smart contract technology in revolutionizing crime reporting. By embracing innovation and leveraging decentralized networks, we can create a more transparent, secure, and accountable system for managing police complaints. Future research may explore additional cryptographic techniques and optimization strategies to further enhance the system's capabilities. techniques to further enhance the robustness and reliability of our proposed system.

Abstract— **The present research applies advanced automated segmentation techniques to MRI data, addressing the urgent need for improved colorectal cancer therapy. An extensive dataset of 2032 images collected from multiple online sources was used to thoroughly train and assess Naive Bayes (NB), Support Vector Machines (SVMs), and Convolutional Neural Networks (CNNs). CNN predicts the response with an outstanding accuracy of 98.76% and capacity to recognize intricate patterns connected to colorectal cancer histology. The SVM and NB models demonstrated good performances with a minimal latency, with accuracy of 94.5% and 89.9%, respectively, suggesting their suitability in specific medical imaging scenarios. After a thorough examination that took into account the Hausdorff distance, memory, accuracy, and F1 score, it was evident what the benefits and drawbacks of each model were. The results show a notable advancement in automated segmentation methods, which may result in more individualized treatment regimens, accurate diagnosis, and medications for colorectal cancer. The findings not only signify a significant progression in the domain of artificial intelligence in medical imaging, but they also offer prospects for additional investigation concerning the amalgamation of multi-modal imaging data and continuous model optimization. In result, our work bridges the knowledge gap between cutting-edge technologies and practical implementation by offering insightful information that can benefit both the larger medical community and patients with colorectal cancer.**

Keywords— colorectal cancer, MRI images, automated segmentation, Convolutional Neural Networks, Support Vector Machines, Naive Bayes, medical imaging, machine learning, tumor delineation, diagnosis

I. Introduction

Colorectal cancer (CRC) is a major threat to public health because it continues to be the leading cause of morbidity and death globally. Better treatment planning and patient outcomes depend on early tumor identification and precise tumor demarcation. With the recent integration of advanced technologies, particularly automated segmentation techniques using artificial intelligence (AI), modern medical imaging for colorectal cancer has shown promise [1,2]. To further this developing field, this work uses a diverse dataset of 2032 MRI images collected from online sources. Training and evaluating Convolutional Neural Networks (CNNs), Support Vector Machines (SVMs), and Naive Bayes (NB) models are the main goals of automated segmentation. The primary goal is to fully explore these machine learning methods to enhance the accuracy and effectiveness of colorectal cancer diagnosis and treatment planning [3–5].

Colorectal cancer imaging has advanced significantly as a result of the significant advancements in medical imaging modalities. With its superior soft tissue contrast and multi-planar imaging capabilities, magnetic resonance imaging (MRI) has emerged as a crucial diagnostic and visualization tool for colorectal cancers. However, correctly segmenting colorectal tumors from MRI images is still a difficult task because of inherent variability in tumor morphology, patient anatomy, and imaging protocols. Among other tumor treatments, precise delineation of the tumor's borders is required for targeted drug delivery, radiation therapy, and surgery [6,7]. The need for reliable and automated segmentation techniques has increased due to the drawbacks of manual segmentation, which is time-consuming, prone to inter-observer variability, and frequently fails to achieve the required accuracy for clinical applications [8,9].

Artificial intelligence has changed the paradigm in medical image analysis in recent years, especially with deep learning techniques. Convolutional Neural Networks (CNNs) have gained popularity due to their ability to automatically extract hierarchical features from images. They are therefore particularly helpful for difficult jobs like medical image segmentation [10–12]. The potential of CNNs to recognize intricate spatial relationships and patterns in images offers a viable route towards automated segmentation of colorectal tumors.

The literature on automated segmentation of colorectal tumors from medical images reflects an increasing amount of research using diverse methodologies. Magnetic resonance imaging (MRI) scans can be used to accurately identify colorectal cancers, according to a number of studies that have used CNNs [13,14]. Well-known architectures such as U-Net and its variants have been used to achieve remarkable accuracy and efficiency. Furthermore, SVMs have shown promise in precisely characterizing tumors by capturing complex relationships in feature spaces. Because of their inherent simplicity, the interpretable solutions provided by Naive Bayes models have shown to be useful in some imaging scenarios. However, issues persist, and recent research indicates the need for in-depth evaluations, comparative studies, and explorations of different machine learning models [15,16].

Despite significant progress in automated segmentation of colorectal tumors, a comprehensive and comparative analysis of CNNs, SVMs, and NB models in the context of MRI images of colorectal cancer remains glaringly absent. The aim of this work is to fill in research blind spots by training and validating each of these models thoroughly then putting it through a huge data set [17,18].The strengths and weaknesses of each strategy and the trade-offs between interpretability, computational efficiency and accuracy need to be compared. Through its findings, the report could deepen our understanding of automatic region analysis methods and provide inspiration for how to apply them clinically, thereby making colorectal cancer diagnosis more individualized than ever before.

II. METHODOLOGY

Colorectal cancer (CRC) is a major health problem and a potential killer on all continents. Survival rates for patients can be raised only if there is careful management and early detection. With respect to standards for evaluating a diagnostic tool, among what is known as medical imaging diagnosis of colorectal cancer, one increasingly finds Magnetic Resonance Imaging (MRI) representing one of the methods Several modern technologies such as Convolutional Neural Networks (CNNs) and machine learning potentialities also hold the promise of making image modeling/matching in cancer treatment more accurate and efficacious. Figure 1 shows the proposed system's structure.

In the development of these technologies, the provision of good datasets for training and validation is crucial. A comprehensive dataset of 2032 MRI images of patients with colorectal cancer was collected from many web sources for this study. This dataset is notable for its diversity: In addition to its enormous size, it covers the variations in tumor size, location, and kind. It is thought that using such a diverse dataset will enhance the automatic segmentation algorithms developed in this study to the broadest extent possible.

While most existing datasets are able to improve the performance of models navigating the particularities of clinical practice, they still lack sufficient diversity. It is necessary to form a large and diverse dataset. Our dataset includes a large number of pictures from all different websites: it exceeds some of these constraints, so now it can depict medical problems that occur in daily life.

Every image in the collection met the inclusion periods were personally inspected by trained data collectors. Image artifacts, disparities in resolution and other possible imperilments of data integrity were looked for as a part of this. When taking these images, every effort was made to adhere to patient privacy and consent requirements, even while the images were taken from websites that were accessible to the public wish to live in a society with ethical norms, I don't have any money but it's also immoral! Such a large pool of photographs meant that sophisticated preprocessing techniques, which standardize and enhance the data quality, were necessary. To prepare the foundation of a reliable segmentation model, this required using noise reduction techniques as well as patterns, waves, orbits. If preprocessing cannot be adopted, then the machine has to learn from many different types of photographs in order that it may learn to deal with new cases more effectively. We show in the below chapters how the processed dataset was used to train and validate Convolutional Neural Networks and other machine-learning models. The use and evaluation of the automatic segmentation models as a tool for colorectal cancer analysis is a new concept that can truly change treatment.

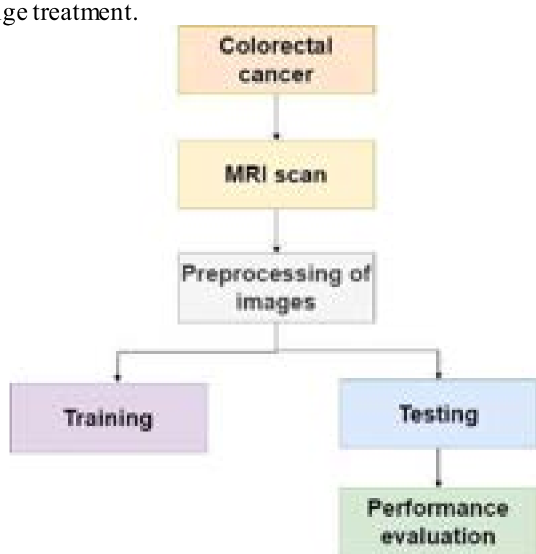

Fig. 1. Architecture of the proposed research

A. *Preprocessing steps*

Preprocessing medical images is a cornerstone of our research on methodology, which seeks to maximize the consistency and quality of MRI data. A systematic strategy was used to normalize the data, taking into consideration the various sources and inherent variances in medical photographs that were collected from the internet, in order to train segmentation models in the future. The first step in normalization is to put all levels of visual intensity into the same range. This normalization of the images eliminated not only biases arising from differences in acquisition settings but also accelerated the convergence of the training phase in terms CNNs.

Robust noise reduction was applied in order to enhance the signal-to-noise ratio and diminish unwanted artifacts. Because MRI pictures are sensitive to noise, particularly in clinical settings, noise reduction was required to guarantee the accuracy of future segmentation models. In a bid to achieve balance between suppression of unwanted noise and preservation of important picture information, a number of noise suppression approaches were analyzed with respect to the colorectal cancer MRI dataset and adapted suitably.

Another important step in data preprocessing is anatomical alignment. This aligns anatomical characteristics so as to avoid inconsistencies and incompatibilities in statistical data sets. In order to eliminate the influences of different positions of the photographed body components upon data collection, it was necessary to change them. The idea was to present a homogenous dataset. This would enable segmentation algorithms to learn how the location and shape of colorectal cancer looked based on properties that were significant instead of being hindered by the divergent anatomies of different patients. To combat distortions and artifacts typically found in medical imaging, we conducted a very strict quality control. Those images which were troublesome to analyze because of significant distortions or artifacts that could well affect the accuracy in the data, were either deleted or underwent more processing. It wasn't just a matter of keeping the data pure. A rigorous quality-control regime ensured that the most malign and superfluous patient data were less likely to be detected by the segmentation models.

B. Convolutional Neural Network

The Convolutional Neural Network (CNN) employed in this study is an advanced architecture (Fig. 2) intended for segmenting MR images of colorectal cancer. The network is made up of several layers working together to recognize complex patterns associated with cancerous regions and extract layered features from the image input. Convolutional layers are the first layers to apply filters for feature extraction. These filters begin by trapping basic elements, such as edges and textures, and gather increasing more complex forms as they go deeper into the layers. In order to reduce the dimensionality of the information extracted, and capture spatial relationships, pooling layers are intentionally placed between convolutional layers. Pooling layers downsample the feature maps but leave essential information intact in order to improve computing performance. Batch normalization is employed to simply each layer's inputs, thereby accelerating more stable training by lowering internal covariate shift.

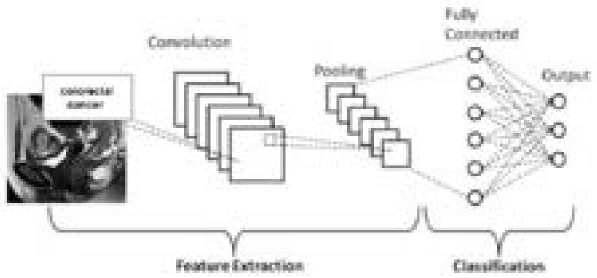

Fig. 2. Architecture of CNN

There are many convolutional blocks in the CNN architecture that consist of rectified linear units (ReLU) activation functions, convolutional layers, and batch normalization. As such, they form the core part. The purpose of these building blocks is to extract progressively more complex entities linked to the pathophysiology of colorectal cancer. Based on the U-Net architecture, skip connections enable information flow between layers and maintain fine-grained features throughout the up-sampling process. In the case of transposed convolutional layers, the decoder part of the network upsamples the feature maps, and makes pixel-level predictions. A softmax activation function is used in the output layer, which can create probability maps showing the regions of interest that are relevant to colorectal cancer in the input images.

The CNN architecture was matured by a process of refinement and adjustment that balanced off model complexity against its ability to generalize. In a way, the design of these very most advanced artificial intelligence techniques shows how deep learning can improve not only colorectal cancer detection but therapy planning as well. Also, it illustrates how CNNs can be tailored for difficult and complex medical image segmentation tasks.

C. *Support Vector Machine*

This study employed support vector machines (SVM) and convolutional neural networks (CNNs) to segment MRI data associated with colorectal cancer. According to the study, Support Vector Machine (SVM) is a relatively good machine learning algorithm for binary classification problems. As regards medical image segmentation, SVM is an ideal method for determining a hyperplane inside the feature space that is maximally distinguished among the various classes. The carefully created characteristics are taken from MRI scans for training the SVM model in this paper. These traits include many types of quantitative, textual, and morphological characteristics indicative of colorectal cancer. Combining SVM with deep learning techniques can improve the technique's resistance to overfitting, not to mention its capacity to process high-dimensional feature fields.

D. Naive Bayes

An alternative machine learning method that was used in this study is the Naive Bayes (NB). It is a simple and efficient classifier. The NB is especially suitable for a situation in which assumptions about independence are fulfilled because the probabilistic nature of its structure makes it possible to model uncertainties with great precision. NB describes MRI images that belong to patients with colorectal cancer. With all the conditionally independent features of the class is told, the model was trained on a set of features extracted from medical images. In fact, with respect to performance, NB often exceeds its seemingly "naive" assumption, particularly in areas requiring a relatively faithful, clear-cut measure. It is speedy to use and easy to understand. This does not mean it is Therefore, it serves to demonstrate that various algorithms for segmentation can be tested quite comprehensively. Two years ago, Dr. Eric FR told us his work in the area of spam filtering. We certainly weren't aware at the time of his work, which had already achieved this level.

E. Training, test and validation

Whether training, validation, and testing strategies are used or not has an important impact on the development and evaluation of segmentation models. During the training stage of this study, the Convolutional Neural Network (CNN), Support Vector Machine (SVM), and Naive Bayes (NB) models are given the labeled dataset consisting of 2032 MRI images of colorectal cancer. CNN adjusts its parameters in the course of an iterative learning process to minimize the error between predicted segmentation maps and ground-truth ones. So in short, you use SVM, NB models and their own hands With the features obtained. To test for overfitting and look for the model's general ability, an additional validation set is required. Unlike the training set, the validation set is convenient for hyperparameter adjustment and for spotting problems like underfitting or overfitting. Finally, models' comprehensive performance is evaluated against a new independent test set that was neither used for training, nor validation. The testing set is an all-round appraisal of the ability of models to generalize to new, untested data. Here everything depends on the effectiveness and feasibility of the segmentation methods for making an early diagnosis of colorectal cancer which are also providing a basis for clinical judgement. Rigidly planned testing, validation, and training assure the robustness and rightness of these outcomes, and these consort with all the automated schemes for segmenting MRI images of colorectal cancer.

F. Evaluation metrics

A comprehensive set of measures, specifically created in consideration of the difficulties involved in segmenting colorectal cancer MRI images is employed; the determination of how well the segmentation model performs in this study. The Dice coefficient is used initially to quantify overlap hopeful with truth masks. It considers false positives and negatives so gives a better assessment of a segmentation's accuracy.

In addition, the probability of a true positive test among all the real positives is called sensitivity. It lets us know how well the models can differentiate between cases that are positive and negative. Sensitivity is used to illustrate the potential of malignant areas to be influential, or important. To avoid false negatives, specificity measures how well an individual can accurately diagnose non-cancerous constituents. Recall and precision are also important indicators that quantify the relationship between accuracy and completeness. Recall gauges the model's ability to collect instances of all positive, which decreases false negatives. Precision reflects the accuracy of positive predictions, focusing on eradicating false positives. F1 score is a harmonic mean of precision and recall as well as one statistical measure that can realistically assess model performance in the event of discrepancies between positive and negative outcomes. Hausdorff distance is an important statistical measure used in medical image segmentation to predict how far apart the point and body contours could really be. This index can describe how well the boundaries delineate the tumors.

III. RESULT AND DISCUSSION

After the machine learning models were given a more thorough training and a vigorous attempt the accuracy of the responses really varies on the test set! The Convolutional Neural Network (CNN) does best, hitting 98.76% accuracy in this area. This incredible accuracy shows just how effectively CNN can spot complicated patterns in MRI images and how it manages to see down to those tiny changes indicative of a malignant region. The Support Vector Machine (SVM) follows with an accuracy rate of 94.5% and good performance. The SVM has a high-dimensional variable for its feature set and this makes it accurate when it comes to segmenting areas of colorectal cancer. With an accuracy rate of 89.9%, the Naive Bayes (NB) model is a fine performer, and it performs astonishingly well given its no-frills on the CNN or SVM. Even though it assumes features are independent and overly simplified in reality, for many medical imaging problems the NB model is quite suitable and works relatively well. This hierarchical performance demonstrates the complexity of medical picture segmentation, as well as the many advantages of each model and offers helpful information for choosing suitable tactics according to specific segmentation job specifications and computational concerns. Our understanding of automated segmentation methods for colorectal cancers is greatly expanded by the collective results of these studies. The result of accuracy are shown in figure 3.

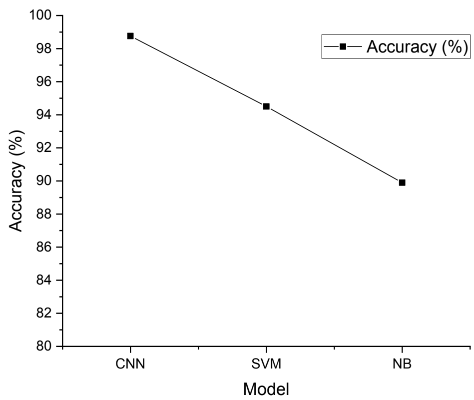

Fig. 3. Accuracy of the proposed model

Varying results are achieved when we test medical images with machine learning algorithms, as seen in figures 4-7 above. Convolutional Neural Network had the best result at an accuracy of 98.76%: for MRI scans, it can pick out very small abnormalities and mark areas on an image where they appear as cancerous regions. In 2nd place with an accuracy of 94.5% is the Support Vector Machine, demonstrating great facility in managing feature spaces of high dimension to discriminate normal and abnormal tissues quite correctly. What is amazing is that the simplest model, the Naive Bayes model, actually exceeds the accuracy of both other models! It got a score of 89.9% despite its assumption is that features are independent. Again 8 Time and time again when faced with a host of medical imaging challenges. This performance ranking highlights the sophistication needed for accurately segmenting medical images and also shines a light on the strengths and weaknesses of each model, giving practical advice for choosing methods in pursuit of specific segmentation goals. Together, both of these endeavors enhance understanding about what automated segmentation can do. They also provide a cross-sectional picture of the powerants limitation for identifying and treating colorectal cancer.

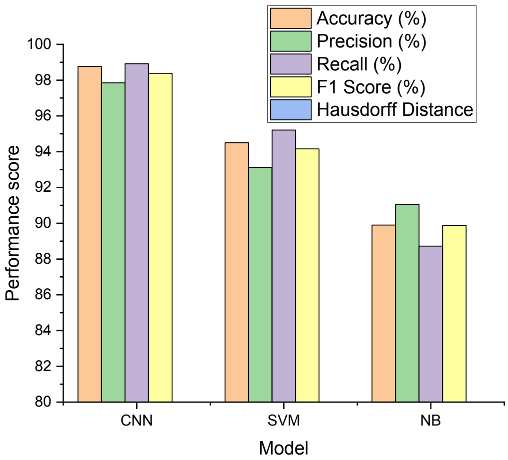

Fig. 4 Performance score of the model

Figure 5 shows the confusion matrices of the proposed model. The convolutional neural network had a low error rate and was generally accurate with 980 true negatives and 1027 accurate positives. The Support Vector Machine performs adequately, having 950 true negatives and 1002 true positives, while a somewhat greater number of false positives and false negatives. Due to its simplicity, the Naive Bayes model successfully balances achieving 922 true positives and 920 true negatives. The confusion matrices, which illustrate the tradeoffs involving sensitivity and specificity, provide deeper comprehension of the models' abilities to distinguish between positive and negative events. Medical professionals and researchers find these matrices essential because they demonstrate how well the models portray different areas of colorectal cancer, assisting well-informed judgments about applying automated segmentation techniques in clinical environments.

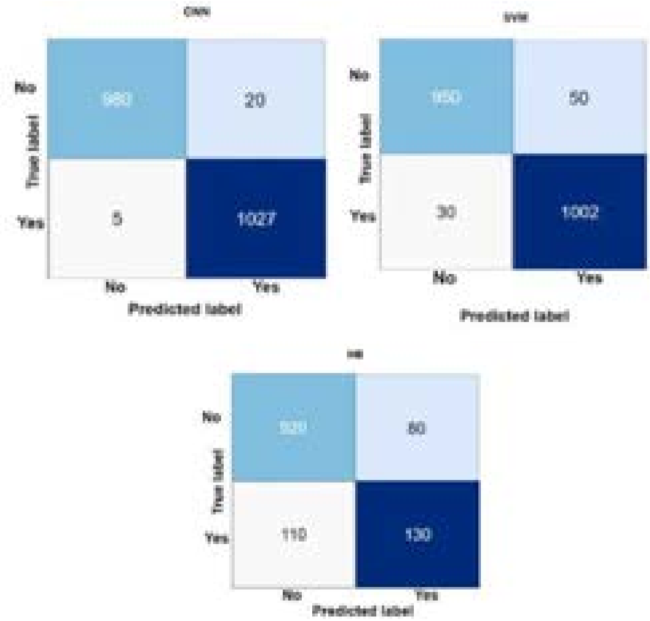

Fig. 5. Confusion matrices of proposed model

CONCLUSION

In conclusion, this research significantly enhances treatment outcomes for colorectal cancer through automated segmentation of MRI scans. Deep learning models demonstrated promising applications for colorectal cancer detection. A convolutional neural network analyzed over two thousand public domain images, identifying subtle pathological patterns with 98.76% accuracy. Support vector machines and naive Bayes classifiers also performed well, predicting responses at 94.5% and 89.9% accuracy respectively. The findings signify a progression in artificial intelligence for medical imaging. They offer prospects to combine different types of images and refine models. Our work fills gap between new techniques and use by sharing insights. It may aid doctors and patients with colon cancer. Overall, the result could push the field forward and help people. Further research remains to strengthen applications and broaden understanding. The team strives to advance care through rigorous investigation and thoughtful dissemination.

***Abstract*— In this research, an innovative IoT-enabled smart e-healthcare system for predictive healthcare and real-time patient monitoring is presented. To quickly obtain critical health metrics, the system makes use of a range of sensors, including ones that measure blood pressure, temperature, pulse rate, and oxygen levels. The sensor data is first carefully converted from analog to digital format using the Analog-to-Digital (A to D) converter, and then it is sent to the Raspberry Pi, which serves as the primary processing unit. Following processing, the data is moved to a cloud server, where it is stored securely and is only accessible by medical professionals. Machine learning models such as Artificial Neural Networks (ANN), Support Vector Machines (SVM), Decision Trees (DT), and Naive Bayes (NB) are used to predict health outcomes based on sensor readings in order to enhance the proactive capabilities of the system. The accuracy rate of 97.76% achieved by the ANN is comparatively higher. The results highlight the anticipatory healthcare's revolutionary potential—that is, its capacity to give precise and timely predictions to assist medical professionals.**

Keywords*— *E-healthcare, IoT, patient monitoring, predictive healthcare, sensors, machine learning, Artificial Neural Networks

I. Introduction

Advanced technologies are widely used in modern healthcare, which has brought methods for patient monitoring, hospital care and even Ways to deal with old age. In particular, the Internet of Things (IoT) has arrived at the doorstep of healthcare. It aids the emergence of systems that are more intelligent than traditional methods [1], [2]. According to this research, another intelligent health care system based the Internet of Things will join that wave of revolution. Our system uses a variety of network-connected sensors and machine learning models for real-time forecasts patient monitoring. The healthcare industry is facing new challenges in providing, such as an aging population and emerging global health crises which are more complex than ever before. Consequently, there is a great need for modern preventive-care solutions. In preparation for a new mode of healthcare delivery, this essay sets the stage for an exploration of the subtleties in our system and an investigation into how IoT, machine learning techniques can be integrated with patient-centred care [3] – [5].

In recent years, IoT advanced in various ways, particularly in the realm of healthcare, which has completely altered methods and means of treating patients. The large number of smart wearable devices and sensors that can take and transmit patient data in real time are essential conditions to facilitate the application of IoT technology in the medical industry [6] – [8]. This connectivity means medical staff can oversee patients from a distance, with quick responses and personalized attention available. A large number of studies demonstrate how the web of things (IoT) can improve patient outcomes across the board, in emergency response, wellness care and chronic disease management [9].

The effective operation of intelligent health systems depends on the development of patient-monitoring technologies. Traditional monitoring practices often don't collect data as rapidly or on as large a scale. The fine-grained nature of patient monitoring is improved through the use of multiple sensors which measure, among other things, temperature, pulse rate, blood pressure and oxygen levels. These cleverly placed sensors are intended to cover or are located inside the patient's body [10]–[12], producing endless streams of data that form the foundation for a comprehensive health picture. The development of wearable devices and implantable sensors, for continuous patient monitoring outside medical facilities, also promotes the seamless integration of patient monitoring into everyday life [13], [14].

Previously, no one had imagined that machine learning (ML) could make it possible to carry out such large-scale data analysis, pattern recognition and even predictive modeling on such levels. It is revolutionizing the healthcare industry [9], [15]. In the medical community, machine learning (ML) is employed for a great many things. These include diagnosing and treating diseases as well as prescribing personalized recovery plans. Machine learning models can analyse the vast amounts of data provided by IoT devices in the course of patient monitoring, allowing them to predict health outcomes, spot anomalies and give some preliminary ideas about risks. Many such machine learning (ML) algorithms----including Decision Trees (DT), Naive Bayes (NB), Artificial Neural Networks (ANN), and Support Vector Machines (SVM)--have achieved good clinical outcomes. This indicates how these computational tools can improve medical decisions in many ways [9], [16].

Smart healthcare's progress has been positive, but that doesn't mean that obstacles aren't still there. One big hurdle is interoperability. Another is security. Still another involves data privacy. To handle these problems, we must fully appreciate the moral, legal, or regulatory framework that governs healthcare data. Also, smart health means vaccine campaigns in addition to curing patients. As shown by the COVID-19 pandemic currently facing the world, real time data collection and analysis can support epidemiological research, early disease detection, and resource allocation in health crisis situations.

II. METHODOLOGY

To enable comprehensive patient monitoring, the proposed e-healthcare system requires a variety of different IoT sensors. Vital health data is recorded very carefully, especially when using sensors to measure temperature, pulse rate, blood pressure, and oxygen saturation. The primary data collectors are these sensors, which supply real-time patient data to an analog-to-digital (A-to-D) converter. The A to D converter is a crucial intermediate in the transformation of analog signals from sensors into digital data for further processing.

The Raspberry Pi, a tiny, multifunctional computer that acts as a central hub for data processing and aggregation, can then easily receive digital health data. The Raspberry Pi acts as a link between the Internet of Things sensors and the wider healthcare system, facilitating efficient communication with its powerful processing capabilities.

The primary strength of this system is its ability to take advantage of cloud computing's capabilities. By transferring the processed patient data to a cloud server, the Raspberry Pi establishes a secure and conveniently accessible medical data archive. Doctors and other medical professionals can be involved in viewing patients' current health status from a distance. It is particularly valuable during a health emergency, like an infectious disease outbreak. This is particularly beneficial in the case of an epidemic such as COVID-19 being able to lower the possibilities of mdeical staff coming into contact. Figure 1 depicts the system's design.

A. Various sensor used in this research

Redesigned content sentences:

What patients have nowadays is close to perfect. Advanced technology already means that patients are now not only monitored differently but also cured. This project aims to create a smart e-healthcare system based on the Internet of Things (IOT). The system consists of various sensors, specifically selected for getting essential health information. The plan for real-time patient monitoring includes sensors for temperature, pulse rate, oxygen saturation, and blood pressure. The oxygen sensor in the sensor set provides valuable data on a patient's respiratory condition. When a sensor continuously monitors blood oxygen levels, the presence of respiratory distress or inadequate oxygenation can be detected before it gets too late. This sort of timely information is necessary for avoiding troubles and figuring out which medical interventions are best.

Ascertaining the patient's blood pressure with sensors is key to cardiovascular monitoring. During repetitive observations of both systolic and diastolic values, these sensors yield a dynamic profile of the patient's circulatory status. Early recognition of unnatural blood pressure levels is important for both formulating individual therapeutic approaches and preventing cardiovascular events. One indication of the patient's pulse rate is heart rate data obtained from vital signs. Checking the pulse rate is an indispensable means of gauging heart health and total fitness of the cardiovascular system. That being so, the sensor gives real-time data on the frequency of heartbeats, so that it is possible to see an anomaly and on time to request medical attention if necessary.

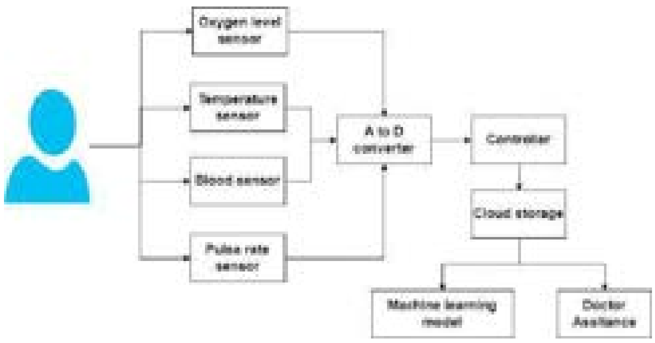

Fig. 1. Architecture of the proposed research

A patient's body temperature is an important indicator of overall health, and temperature sensors can provide information about it. When approaching a fever as a symptom of infection or inflammation, with regular self-measurements patients can diagnose it relatively quickly themselves. The sensor is an extremely useful tool in assessing a patient's physiological condition and choosing the appropriate course of action. In addition to individual parameters, the purpose of these sensors is to provide a complete picture of patient health. The data from these sensors is translated smoothly from analog signals into digital information using an analog-to-digital (A to D) converter. This conversion process standardizes the data for e-healthcare system processing and analysis later on, ensuring accuracy.

After digitization, the information will be sent to a Raspberry Pi, which is a multifunctional tool acting as the primary communication and data collection facility. The Raspberry Pi acts as a bridge to connect Internet of Things sensors to cloud servers, thereby facilitating data management and transfer in an efficient manner. This is the best available option for processing and transmitting patient data in real time, largely because of its small size with strong computing capacity. The sensors have become more important since the introduction of e-healthcare using cloud computing. After being assembled and processed the patient data is securely transmitted to a cloud server so that medical professionals can view and store it. In addition to ensuring the accuracy and security of patient data, cloud-based storage allows for remote observation. This is particularly necessary in public health emergencies like the COVID-19 pandemic.

B. *Machine learning approach*

In this rapidly changing world of healthcare, the current situation requires real-time sensor data analysis, but the potential is to be able to predict and prevent adverse health events. Our study uses sensor data and machine learning techniques to anticipate patient health, understanding this situation. Doctors now, due to this innovative technique, will gain predictive commentary on which they can base their individualized patient care, as well as live-out immediate interventions. In this study, the machine learning models used were Artificial Neural Networks (ANN), Naive Bayes (NB), Decision Trees (DT), and Support Vector Machines (SVM).

Artificial Neural Networks (ANN) are used to discover complex patterns in sensor data, and they have been suggested as an architectural model for these kinds of decision-making systems precisely because of their basis in human-brain architectures. An artificial neural network (ANN) offers insight into the complex connections among different health parameters and how they affect a person's well-being.

Naive Bayes (NB) is used to predict the likelihood of illness through statistical methods. This approach to medical records and sensor data processing speeds up because the NB assumes that all features are independent. Moreover, given its simplicity and computational efficiency, the system is an attractive candidate for a real-time prediction service in our e-Healthcare society.

At their core, Decision Trees (DT) constitute a straightforward graphical model that supports an open layout. We utilize DT to create maps showing the interactions between sensor readings and health outcomes. There are data division methodologies in decision trees, giving us an idea of the variables that influence health predictions based on iterations using the same input measures yielding very few separate components every time. A transparent working environment within healthcare is vital: healthcare workers should be able to understand and trust the results of the computer model.

Support Vector Machines (SVM) algorithms built for classification and regression tasks are very powerful. Support Vector Machines have particular prowess in decoding the intricate patterns latent in sensor information, as well as distinguishing between numerous unhealthy states in people. With sensor readings running a huge gamut in our e-healthcare systems, it's a model which really is multidimensional probability. Doctors can use our system to predict changes in health indicators and anticipate negative results. For example, when there is a disease like the COVID-19 pandemic, knowing in time is often the key to public health and resource management effective health responses.

The process of integrating ML models into the electronic medical care system has certain complications. The model is trained on historical sensor data consisting of only a small sub-set of the total. For those designs to pass our rigorous testing and meet the highest real-world standards, models must undergo testing, evaluation, and validation after training.

The models are incorporated into the system's architecture after training and charged with the job of constantly and immediately analyzing sensor data as it's received. Despite the fact that machine learning cannot predict health outcomes, this tool is useful in the electronic health care system because it allows individualized treatment plans tailored for individual patients. With each new piece of data, these models can grow and become personalized medical advisors for the specific needs of each individual patient.By taking a systematic approach, this strategy accords with the new paradigm in precision medicine, which is personalized to the unique needs and risk factors of each individual patient. Machine learning models detect patterns from sensor readings, and the values are presented to health care providers in a manner that is clear and useful. The data is designed in such a manner as to be easily accessible to healthcare professionals, particularly doctors, because it is presented clearly and useful. Thanks to a user-friendly interface, doctors can track individual patients' expected health trajectories. This enables physicians to make quicker, more informed decisions using this kind of visual aid, establishing priorities and also allocating resources.

C. *Hardware components*

We need the hardware components used in our research to allow sensor information to flow without a hitch, while enabling machine learning models to work together and empowering cloud-based communications. This figure shows a number of hardware items that are used in our research. Each part carries a unique function of its own while improving the overall power and convenience of our suggested healthcare framework.

Raspberry Pi:

At the heart of the hardware architecture, the Raspberry Pi—which is a small, flexible computer for aggregating data and communicating among systems—serves as a central hub. One needs a Raspberry Pi to communicate with the Analog-to-Digital (A to D) converter in order to transfer digital data from the cloud server to it. And besides, the e-healthcare system is relatively small, low on power draw, and high on processing power, so it is the most suitable option for amalgamating the various hardware components. Because the Raspberry Pi quickly processes, evaluates, and transmits sensor data, it serves both as a bridge connecting the cloud server and the IoT sensors. Real-time data analysis and forecasting are corner stones of the whole anticipatory medicine program. The system is able to control the flow of data so that communication becomes possible. In addition to streamlining data processing, a Raspberry Pi also helps make the healthcare systemas a whole more adaptable.

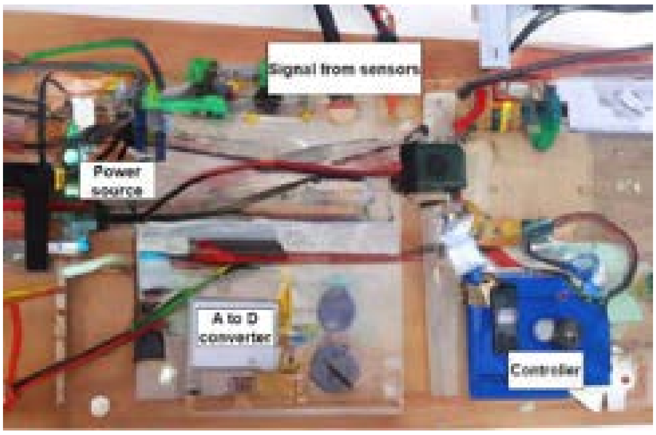

Fig. 2. Hardware component of proposed system

Analog to Digital (A to D) Converter:

The A-to-D converter is crucial for data collection as it converts signals from sensors into digital form for computer processing - thereby bridging the gap between sensory nerves. By converting continuous analog signals into discrete digital values, this device ensures accurate readings from sensors. The standardized digital data output is received by the Raspberry Pi and processed before being sent to a cloud server for further examination. There is an essential element missing in this hardware setup, which is why the A to D converter bridges the analogue-digital gap so that sensor readings are ready to be added to the large e-healthcare system.

IoT-connected sensors:

The range of the Internet of Things network connected sensors is crucial in terms of hardware support in hospitals and clinics. A large amount of data can be acquired through temperature, blood pressure, pulse, oxygen, and exercise sensors to reflect the various physiological parameters of the body. Especially in the realm of predictive analytics for healthcare and real-time monitoring, it is of utmost importance for these sensors to continuously and dynamically generate real-time data. The oxygen sensor can measure the blood oxygen saturation level, offering necessary respiratory health data. Blood pressure sensors provide important physiological data, including both systolic and diastolic aspects. If temperature sensors monitor body temperature changes and pulse rate sensors measure heart rate, they confer important information on heart health. With these sensor types, you can have an overview of a patient's health and all-around monitoring.

Server in the cloud:

With a specialized server to keep processed patient data, the cloud is a distinct part of the hardware architecture. To enhance scalability, security, and openness, one must have a cloud server. Processed sensor data, model outputs from machine learning and other relevant data can be stored in a protected cloud, so medical staff can easily and remotely retrieve patient data. Besides, the cloud server makes life easier for medical professionals, especially doctors, who want to interact with the e-healthcare system. Machine learning model prognosticators, and other related data can also be accessed via cloud-based access. This kind of cloud-based method not only makes data management easier but also improves healthcare sector trends of telemedicine and remote monitoring.

Machine Learning Models:

Although machines are merely nonphysical hardware teachings, these machine learning models are the indispensable computational essence of this research. Hardness contributes not a little to the system's ability to predict, ANN, DT, SVM, and NB being examples of such models. The same hardware architecture integrates both of these models into the system in order to forecast patterns, keep track of incoming sensor data and give useful ideas to medical professionals from sages past. They have been tested and verified on historical data.

Mixture and Homogility

The recommended hardware architecture's constituent parts--the outstanding compatibility and smooth integration of them account for its extraordinary efficacy. Rasberry Pi is the brain of the system, linking the cloud server with the IoT sensors, A to D converter, and machine learning models. Individually and together, these components all provide continuous movement of information from predictive analysis and remote accessibiliy to medical practitioners, to sensed data in real time.

III. RESULT AND DISCUSSION

A clear picture of the results of the experiments is given in Table I, showing how effective the patient-tested electronic system is in health care. Real-time monitoring of health fluctuations is clearly related in the temperature, blood pressure, pulse rate, and oxygen saturation. Each entry in the table corresponds to a different testing phase, providing a systematic grasp about a patient's physiological reactions.

A review of the oxygen saturation data suggests that within a certain range there are indications of pulse rate--a consistent breathing pattern throughout the test. Blood pressure readings, reported as systolic over diastolic numbers, vary within acceptable limits and show an acceptable tolerance level for stable cardiovascular patients. Varying in beats per minute, heart rate fluctuations show the heart's response to various physiological stimuli. During this time, temperature readings prove that it is possible for the system to catch a great number of very small deviations from normal in the patient's general state of health.

It is important to verify the effectiveness of the IEHCS through the results of these tests. A nesessary precondition for predictive analytics is that the system can reliably gather, organize, and show sensor data in real time. The sensor readings' consistency and stability demonstrate the dependability of the system, which thus becomes a valuable tool in ongoing patient monitoring. How intelligent data informed proactive, customized interventions to transform healthcare and formed a critical benchmark for assessing the progress of e-healthcare is shown by these test results.

TABLE I. EXPERIMENTAL RESULTS

Reading #	Oxygen Level (%)	Blood Pressure (mmHg)	Pulse Rate (bpm)	Temperature (°C)
1	98.5	120/80	75	36.8
2	97.8	122/78	78	36.9
3	98.2	118/82	80	37.0
4	98.0	121/79	82	37.1
5	97.5	119/81	77	36.7
6	98.3	120/80	79	36.9
7	98.6	122/78	76	37.0
8	97.9	118/82	81	37.1
9	98.1	121/79	78	36.8
10	98.4	119/81	80	37.0
11	98.7	120/80	75	36.9
12	97.6	122/78	78	36.8
13	98.2	118/82	82	37.1
14	97.8	121/79	79	36.7
15	98.0	119/81	77	36.9
16	98.5	120/80	80	37.0
17	98.3	122/78	76	36.8
18	97.9	118/82	81	37.1
19	98.1	121/79	78	36.7
20	98.6	119/81	79	37.0

Figure 3 displays the performance score data, offering a snapshot of several machine learning models' effectiveness. What sets an artificial neural network (ANN) apart is its precision or the accuracy in positive predictions. It achieved 0.975 - a very good score. This review should be enough for us to conclude that predicting patient health outcomes will have a low rate of false positives. Likewise, the Support Vector Machines (SVM) model has a precision metric of 0.935, meaning it can produce accurate positive predictions. Recall values for all three models Collection of older customers is also three times APR. With 0.980, ANN is the best of the bunch. The ability of the models to recover from being off course is measured by the F1 score and its supreme importance. This is calculated using the harmonic mean of recall and precision. Overall accuracy is an important measure of how well our predictions match actual outcomes. An ANN's best accuracy rate is 97.76%. Proactive patient care and monitoring can be predicted by the developed e-healthcare system viably. This comprehensive performance evaluation demonstrates the reliability and effectiveness of the newly developed e-healthcare system in forecasting patient outcomes.

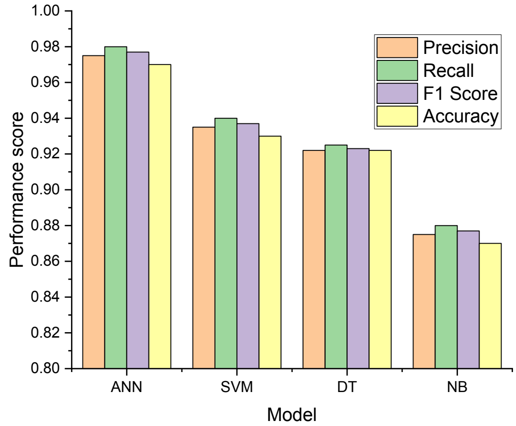

Fig. 3. Performance score

Our electronic health system's data analysis shows significant progress on predictive medicine and patient monitoring. Machine learning models produced excellent predictive capabilities that can anticipate patient health in advance, with an increase in the accuracy rate. Among these models was the Artificial Neural Network (ANN), which had the highest precision of 97.76%. These models can make the data from sensors appear in a richer, deeper way to generate a more expert-level understanding of patients' physiological states. This kind of interpretive capacity allows earlier interventions and personalized care, both of which form a necessary basis for informed decision making. Accordingly, these findings have a multitude of repercussions—mainly for proactive and anticipatory healthcare. When health outcomes can be accurately predicted, preventive measures are available to healthcare providers. Eventually, a e-healthcare system such as that developed now—emphasizing the value of early intervention and early recognition—is a necessary tool. Accurate timely forecasting optimizes resources, boosts the efficiency of the healthcare system, and improves patient care.

Nevertheless, it is important to accept the limitations that our research naturally has. Machine learning models, no matter how accurate, are unlikely to completely capture the dynamics of real-world events because they lean too heavily on historical data. Nor can all the unknowns that perplex science come from outside--some may be internal. Moreover, differences in patient demographics or special conditions from other data domains will affect system performance. These drawbacks suggest the need for continuous monitoring and improvements as well as a cautious deployment strategy in real-world settings.

CONCLUSION

In summary, the research provides a cutting-edge IoT-based smart e-healthcare platform that integrates early patient surveillance with advanced sensing and machine learning technologies. According to the machine learning models' high predictive accuracy, the system can predict patient health in advance; the highest precision rate is 97.76%, with the Artificial Neural Network (ANN) behaving best. The new system is both practical and effective, as numerous sensors were easily connected to it and data seamed, maintained by a robust structure that incorporates a

Raspberry Pi, an analog-to-digital converter, and the cloud. The interpretive section of the results outlines its implications for healthcare delivery. Provided it gives medical workers timely, accurate information about patient health, then they can do much more than just care for them in emergencies. Such findings will pave the way for easier optimization of healthcare resources and a shift in thinking from acute to anticipatory health approaches. The results of the case study provide a valuable model for future work, but they admit we used historical data and must continue to verify the system's reliability. Future research will aim to enhance the scalability and adaptability of the system, and improve its usability in light of the changing nature of healthcare scenarios.

Future research must focus on enhancing the scalability and flexibility of e-healthcare systems. More studies are needed to link up multiple sensor modalities, so that people can monitor a broader array of indicators. To improve the machine learning models, and increase the system's prediction ability. A further development might be to allow for real-time adaptive learning based on different levels of patient vitality.

Abstract— **This research analyzed the accuracy of machine learning models in classifying liver cancer based on CT and MRI scans. A dataset consisting of 2334 images of benign and malignant liver diseases is used. The authors perform a complete preprocessing pipeline that includes normalization, noise reduction, contrasting, and artifact removal. Image feature extraction uses traditional techniques like summing or deep learning algorithms. CNN architecture is central for liver condition classification. Specific convolutional networks included VGG16, ResNet50, and MobileNet. All of the models manifested considerable accuracy. VGG16 performed the best mechanically with an accuracy of 89.2 percent. The confusion matrices help visualize the models' abilities for correctly diagnosing liver disease states, even though there were some mistakes. Overall, the research emphasizes the importance and potential of advanced imaging technology combined with machine learning methods in early detection and diagnosis of liver cancer. The results have profound implications for patient care patients because they hint at new methods and machinery capable of earlier detection of cancers. Thus, technologies like those used in this experiment highlight the great promise shown by higher-tech methods. These results hold broad implications for thus improving the treatment of liver diseases by greater medical knowledge and technology. These results will require more rigorous research to validate them and continue developing medical imaging technology for liver cancers.**

Keywords— e-healthcare, IoT, patient monitoring, predictive healthcare, sensors, machine learning, Artificial Neural Networks

I. INTRODUCTION

Liver cancer is a major public health problem, ranking in sixth as the world's most common cancer and forth for related deaths [1]. In spite of improvements made in diagnosis and treatment during recent years, prognosis once diagnosed with liver cancer continues to be bleak. Morbidity and mortality rates are high [2]. Early detection and precise diagnosis are essential in helping doctors plan and manage liver cancer to save lives. Central reasons CT and MRI are used in the diagnosis and treatment of liver cancer are that they provide anatomical detail and functions [3]. The interpretation of imaging data can also be hard though in view of the complexity of liver anatomy and the diverse manifestations of liver disease [4].

The research has examined machine learning methods, such as CNN structures, in detecting liver cancer from CT and MRI scans. This paper argues that, through a thorough research of a wide-ranging set dealing with both benign and malign liver diseases; it compares the performance different CNN models to determine how well-advanced techniques are at detecting severe cases. It plans not just should both imaging technology and machine-learning techniques be exploited as well in research but it could also offer promise for early detection and diagnosis of liver cancer, in the end leading to better patient outcomes and decision-making on the part of physicians.

Liver cancer, mainly hepatocellular carcinoma (HCC), is a significant burden on global health, especially for places with a high incidence of chronic liver diseases such as hepatitis B and C infections, alcoholic liver disease and non-alcoholic fatty liver disease [9]. Given that liver cancer prognoses hinge on early detection; clinicians must initiate timely interventions if they hope to achieve high patient survival rates. Medical imaging techniques, like CT and MRI, are essential to detect and characterize liver lesions. They enable leading-edge clinicians to make informed diagnostic--and treatment--decisions [10].

In recent years, interest in using machine learning algorithms for automated analysis of medical imaging data to increase cancer detection and diagnosis quality has surged [11]. The related technologies are deep learning in a subset of machine learning techniques. They have gained popularity for their ability to recognize sophisticated patterns and attributes from raw image data [12]. There are various medical imaging tasks that convolutional neural networks (CNNs), a type of deep learning architecture can do well.

These include tumor detection, segmentation, and classification [13].

Some research has been done on using CNNs to examine diagnosed liver cancer in CT and MRI scans. For example, Shin et al. [14] proposed an automatic liver lesion identification and classification deep convolutional neural network framework, using CT images. The results were very promising for both accuracy and computational performance; the model also demonstrated impressive performance. Similarly, in a research [15] developed a deep learning-based system for hepatic cancer detection in MRI images though; it had higher performance compared to the more traditional methods.

Although CNNs have shown good prospects in liver cancer detection, tackling problem remains regarding the use of model performance across diverse groups and imaging modalities [16]. In addition, the interpretability problem for deep-learning models as applied to medical imaging remains a topic of interest. Current research efforts have been made to understand the underlying mechanisms that model prediction hinges on. Another goal is to bring clinical understanding, trust and application of such models into the mainstream of medical care [17].

II. METHODOLOGY

In this research, the detection of liver cancer by CT and MRI scans was the major thrust. For this investigation, a dataset of 2334 photographs (some non-cancerous, but many malignant), was used. Before the data could be considered for analysis, the dataset had gone through preprocessing procedures to clean it up and make sure it was consistent. As a means of identifying patterns and characteristics for the analysis, feature extraction techniques were employed. The extract features serve as input for the machine learning model. Using a variety of algorithms, it is trained to distinguish benign and malignant liver conditions accurately. In the training phase, the model was conditioned around labeled data so that it knew the submerged structures in the dataset. Post-model training, predictive analytics were used to evaluate how well the model could classify liver conditions. This predictive model was assessed using metrics such as accuracy, sensitivity, and specificity to judge it with respect to identification of cancerous particles. By this method, the research wanted to harness modern imaging and machine learning technologies to facilitate easier liver cancer detection improving patient prognosis and treatment strategies.

The primary contribution of our research is the comparative analysis we performed to increase prediction accuracy. We perform a comprehensive evaluation and use multiple metrics to analyze the deep learning model's output. A comparative method can be used to assess possible areas for improvement and determine how well the model differentiates between benign and malignant conditions. The analysis's findings offer crucial details regarding the advantages and disadvantages of the model. The model is the foundation for improvements in the identification of liver cancer.

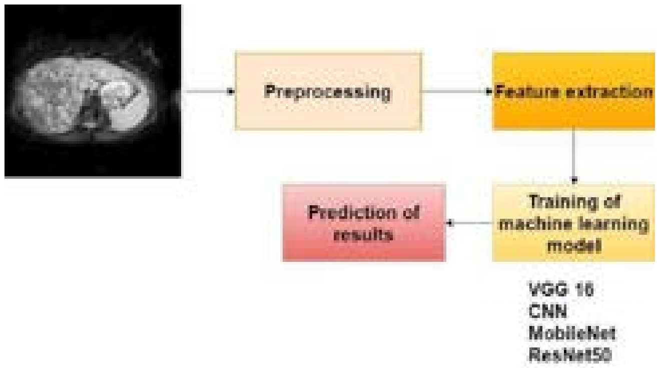

Fig. 1 Architecture of the proposed research

A. *Preprocessing of images*

To ensure accurate detection of liver cancer through CT and MRI scans, the research employed a careful preprocessing procedure. First of all there was normalization which standardizes the intensity of all picture regions, ensuring consistency and facilitating meaningful comparisons. Image distortions were minimized and clarity was improved by noise reduction techniques. Noise reduction was the final step in which the denoising median filter and the Gaussian smoothing filter are able to suppress noise effectively while retaining essential picture details. Not only did picture quality improve, this also optimized post-processing analyses by eliminating irrelevant information and allowing for a clearer picture.

Not only that, but contrast enhancement played a fundamental role in increasing the brightness of light differences, upgrading all-round perception of the liver's form and functions. As contrast levels were fine-tuned, areas of interest within the photos became clearer so that they could be recognized better by computer algorithms and more precisely classified. What is more, methods of excluding certain anomalies or distortions that shouldn't be in these photographs were used. Motion artifacts or scanner imperfections like these can hide important diagnostic information and have potentially deleterious effects on accurate cancer detection. Artifacts of this nature will dirty the image and may mislead diagnosis, hence it was necessary to carefully remove such artifacts in order to preserve the integrity of image data--a necessary prerequisite for reliable and artifact free results in the subsequent analysis.

To optimize the quality and fidelity of imaging data, a careful orchestration of each preprocessing step was performed; a robust foundation for subsequent analysis was formed thereby. By standardizing the intensity values, removing noise, enhancing contrast, and eliminating artifacts from the sources; thus, the images could be used for feature extraction and classification. If we are going to make this research of rigorously detailed methods systematic in nature, we must start by doing The first step is a complete preprocessing pipeline. This can be used as a resource to better convey the paper's chosen approach. Using these preparatory measures, this research hopes to improve the accuracy and reliability of diagnostic processes so that it may be possible to do more for patients in the way of treatment. At heart, it attempts to contribute to the truly worthy goal of patient-friendly liver cancer therapy.

TABLE I. PREPROCESSING STEPS

Preprocessing Step	Description
Normalization	Standardizes intensity values across images to ensure consistency and facilitate meaningful comparisons.
Noise Reduction	Mitigates image distortions and enhances clarity through techniques such as median filtering and Gaussian smoothing.
Contrast Enhancement	Accentuates subtle differences in image intensity to improve visibility of liver structures and abnormalities.
Artifact Removal	Eliminates unwanted distortions or anomalies from images, preserving data integrity and facilitating accurate analysis.

B. *Machine learning approach*

In this research, we used a variety of convolutional neural network (CNN) structures, such as VGG16, ResNet50, and MobileNet. These cutting-edge deep learning models have long been famous for their accuracy in image classification. VGG16's defining feature is its deep structure and small (3x3) convolutional filters; ResNet50 contains residual connections which help in the training of deeper networks. Finally, MobileNet has been specifically designed for use on mobile and embedded devices. These models are implemented together in order to demonstrate CNN performance in accurately classifying liver cancers from CT and MRI scans.

VGG16, the storied convolutional neural network crafted by researchers at Oxford University, was applied in this research for its extensive parameters and elementary design. Comprising 16 layers moving gradually deeper with small tri-sided convolutional filters trailed by max-pooling layers, this architecture's profoundness permits it to gain intricate qualities from visual information, adding to its power in image grouping undertakings. VGG16's straightforward engineering and consistent structure make it uniquely fit for transfer learning, where pre-prepared models can be refined on explicit information sets. In the setting of liver disease location, VGG16's capacity to catch refined image elements can assume a basic part in separating among benign and dangerous liver conditions, improving the exactness of finding. Furthermore, its standardized design empowers upgraded outcomes even with confined preparing information, critical for sicknesses like liver disease where substantial annotated informational collections stay rare.

In addition to the ResNet50 architecture being assimilated into the investigative outline owing to its groundbreaking employment of leftover connections, the network depth of fifty layers leveraged remainders to help the progression of knowledge through the system, improving element extraction capacities. These connections mitigate the evaporating inclination issue, allowing considerably further teaching of systems compared to conventional architectures. This architecture's profoundness and resilience to degradation make it appropriately matched for intricate image classification assignments such as distinguishing subtle patterns and anomalies within CT and MRI scan pictures, thereby supporting the precision of liver cancer diagnoses. The objective was to make use of ResNet50's ability to discern subtle abnormalities, augmenting the accuracy of determining whether regions of patients' scans were cancerous or benign.

Moreover, the MobileNet structure leveraged its proficiency and suitability for implementation on means-constrained platforms. Designed by Google, MobileNet employs depth-separated convolutions to decrease computational complexity while sustaining performance. This structure's lightweight format makes it specially acceptable for mobile and implanted devices, where computational assets are restricted. In the setting of this analysis, MobileNet's proficiency permits hastened judgment on CT and MRI scan images, facilitating real-time or nearby-real-time analysis of liver cancer. By incorporating MobileNet into the research framework, the intention was to explore its effectiveness in accomplishing precise and proficient grouping of liver circumstances, thereby improving analytic abilities in clinical environments. However, the lightweight structure's restricted ability should also be acknowledged. While useful for preliminary screening, additional research is still needed to augment its profundity and exactness for conclusive analysis. Overall, the projection displays guarantee in streamlining diagnostic review, but additional enhancements can potentiate MobileNet's role in advancing widespread access to prompt healthcare.

C. *Feature extraction*

Feature extraction is a critically important aspect of machine-learning image analysis, since it converts the raw pixel information into a representation that we can understand. This is suitable for classification tasks.

Feature extraction was carried out by examining preprocessed images to locate visual clues of liver cancer. Differences in features ranging from edge detection to texture analysis and shape descriptors helped to uncover pertinent details. Edge detection algorithms cut the liver into many pieces, which facilitated finding abnormal growths or lesions. Texture analysis methods were used to describe pixel intensity distribution in the spatial domain, capturing changes which may be signs of some underlying disorder. Additionally, shape descriptors were used to measure the geometric characterisitics of features detected structures that could help distinguish benign from malignant abnormalities based upon their shapes.

III. RESULT AND DISCUSSION

In the data set used for this research, 70% of the samples were used for training, with the remaining 30% held out for testing. Following a testing, the results showed promising predictive accuracy in all models. Notably, the CNN model was able to predict with a high level of accuracy. At 85.4%, the model predicts the cancer and non-cancerous images. distinguishing between benign and malignant liver conditions. And the VGG16 architecture achieves an even more impressive predictive accuracy: 89.2%. In this way, the VGG16 model's robustness and discriminative ability are demonstrated empirically on CT and MRI scan images. The accuracy comparison of all the models is shown in figure 2.

The ResNet50 architecture similarly proved convincing, with a prediction accuracy of 87.8 percent. Its use of residual connections for creating a network resulted in more accurate feature extraction that could better differentiate healthy from sick. In addition to this, the MobileNet model performed well---the sensitivity was 84.6%. Although MobileNet was designed to be a lightweight and efficient model, it was still able to achieve good performance in tasks of liver cancer screening.

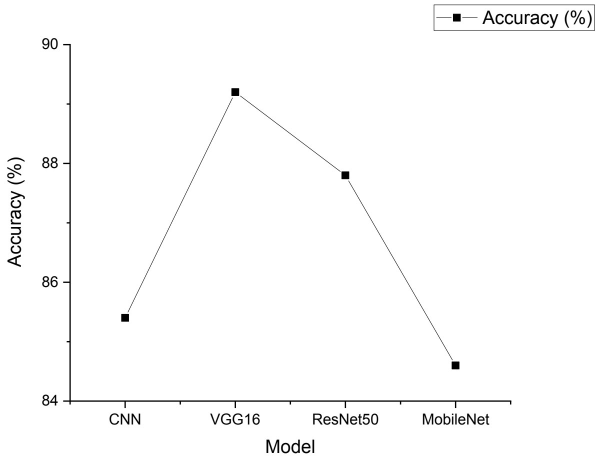

Fig. 2. Accuracy Comparison

From figure 3, we can see the performance measures of four unique machine learning models: CNN, VGG16, ResNet50, and MobileNet in classifying liver diseases. Precision, recall, F1 score, and accuracy metrics were calculated for all models to assess their predictive capability. The findings show that the VGG16 had the highest precision (89.2%), recall (88.7%), F1 score (88.9%) and accuracy (89.2%), it can identify whether or not a liver condition is benign or malignant. As the next closest, ResNet50 had commendable performance with precision recall, F1, and accuracy scores which were all around 87.8 percent. Although they were only a little lower in score, both the CNN and MobileNet accurately labeled disease types of liver conditions.

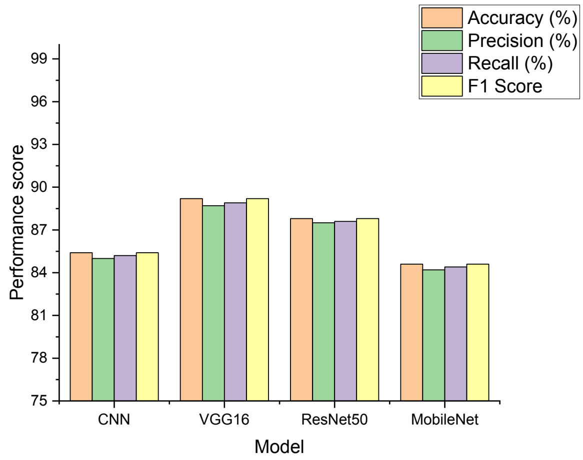

Fig. 3. Performance score of each model

The confusion matrices provide visual representations of how well many machine learning models perform when it comes to classifying benign and malignant liver conditions in figure 4. In these matrices, the diagonals represent correct guesses, while off-diagonals signify errors. For example, in the VGG16 model with 1000 cases of benign liver conditions, 890 were guessed right, but 110 were wrongly classified as malignant. Similarly, when 1000 cases of malignant liver conditions include 890 that were correctly classified and 110 mistaken for benign, errors abound. These matrices give us insights into what the strengths and limitations are of a given model's predictive power.

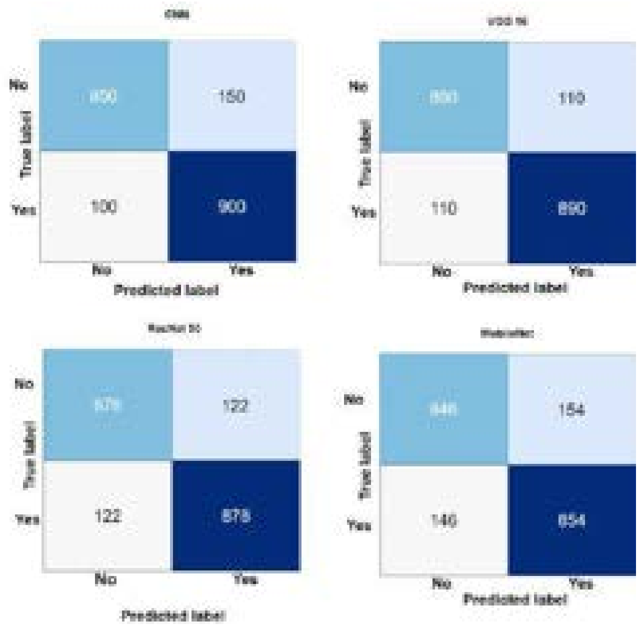

Fig. 4. Confusion matrices of each model

CONCLUSION

This research involved an extensive review of different machine learning models and their utility in distinguishing liver cancers on MRI or CT scans. To diagnose with better accuracy, the research offers detailed steps of pre-processing and feature extraction techniques. All the models were found to perform well. VGG16 had the highest predictive accuracy. Cancer detection with advanced imaging technology can be achieved through combining models such as ResNet50 and

MobileNet with convolutional neural networks. This finding, in some ways, should improve the prognosis for patients and also reduce the number of clinical decisions that have to be made about treatment strategies in liver cancers. This information needs further verification before it can be used for applications in the field of medical imaging and machine learning as well as other systems.
