Message from Chairman

It is my great pleasure to announce that the “4th International Conference on Pervasive Computing and Social Networking”, ICPCSN 2024, is to be held at our institution on 3-4, May 2024.

I have firm belief that ICPCSN 2024 would be the starting point in exploring our institutional capabilities in the area of Engineering and Technology. It is my pleasure and privilege to extend a whole-hearted welcome to all the participants for sharing your research aptitudes through this conference. I appreciate the conference organizing committee for showing a keen interest in organizing a successful international conference and contributing new ideas and research findings. I wish them for their endeavours to spread knowledge.

I am sure the conference will provide you updated information on the recent researches in the field of Engineering. We all look forward to your presence and involvement in ICPCSN conference. I am delighted to be able to welcome you all.

Mr. B. Nitish Harihar,

Chairman,

R P Sarathy Institute of Technology,

Salem, Tamil Nadu, India.

Message from Director

On behalf of RPIT, I am delighted to invite you to the 4th International conference ICPCSN 2024 in May 2024. Research and development is always a sign of learning and development. In today's society, thinking and acting in a new and innovative way is highly essential to cope with the technological changes. I hope, this 4th ICPCSN will be a forum for scholarly discussions on computing and communication technologies.

The dedication shown by researchers towards this conference is highly encouraging. This motivates us to hold such conferences more regularly in the future. I would like to express my heartfelt appreciation to everyone who participated in this conference.

I wish the conference the best of luck.

Dr. K. Arutselvan,

Director- IQAC,

R P Sarathy Institute of Technology,

Salem, Tamilnadu, India.

Message from Conference Chair

On behalf of the conference organizing committee, I am pleased to welcome you to the 4th International Conference on Pervasive Computing and Social Networking. It is highly satisfying to witness that the conference is getting larger and more noteworthy each year. I am highly excited about the record number of participants and number of sessions planned to be organized in 4th ICPCSN 2024 event.

As the world is becoming more digital, there is an increasing need to enable rich networking and computing technologies. The theme of this year's conference is "Pervasive Social Computing". The 2024 conference aims to initiate research discussions on enhancing human social relationships with leading scientific communities in different disciplines from computer science to communication engineering. The technical program of ICPCSN 2024 is rich and varied with keynote speech and invited talks, technical paper presentation and oral sessions each day. We also expect to provide technical discussions, and numerous opportunities for informal networking..

The success of any conference depends on the people, who worked with us in planning and organizing the technical and non-technical arrangements. In that way, I extend my sincere thanks to the program chairs for their continuous guidance; Review Committee for the timely reviewing of the papers and local organizing committee for all the non-technical arrangements. Lastly, I would like to thank all of the conference participants for their contributions which are the foundation of this conference.

I hope that you will have a productive time at this 2023 conference.

Dr. Munusami Viswanathan,

Principal,

R P Sarathy Institute of Technology,

Salem, Tamil Nadu, India.

Performance Improvement of DC Motor by using ANFIS Controller

Abstract: **This research paper is to improve a DC motor's performance by using two different control strategies: Sliding Mode Control (SMC) and ANFIS. Fuzzy Logic (FL) and Neural Networks (NN) are used by the ANFIS controller to show flexibility in the face of nonlinearities, and SMC shows resilience in the face of uncertainty. The dynamic response of the armature current and DC motor speed under each control technique is shown by the simulation results. By highlighting the benefits and drawbacks, comparative analysis helps to choose the best control strategy for a given set of application needs**.

Keywords: **DC motor, Sliding Mode Control, Adaptive Control, Robust Control, Performance Improvement, Simulation**

I INTRODUCTION

DC motors play a pivotal role in diverse industrial and technological applications. Efficient control mechanisms are essential to achieve optimal performance in terms of speed, torque, and energy consumption. The integration of intelligent control systems, such as ANFIS, presents a novel approach to enhance the overall performance of DC motors. Traditional PID controllers have been widely employed for DC motor control, but they may struggle to handle nonlinearities and uncertainties inherent in real-world systems. ANFIS, being a hybrid system combining NN and FL, exhibits superior adaptability and learning capabilities. The performance enhancement of DC motors is crucial for various applications, including robotics, automation, and renewable energy systems. This study investigates the utilization of an ANFIS controller to improve the performance of a DC motor. ANFIS, with its adaptive and self-learning capabilities, offers a promising approach to optimize the motor's speed control and efficiency.

The author focuses on the implementation of third-order SMC for a PMDC motor to regulate its speed. The designed controller is applied to the motor, which is powered by a Buck converter, and simulations are conducted using MATLAB software. The obtained results demonstrate the effectiveness of the proposed third-order sliding mode controller, and a comparison is made with a conventional proportional integral derivative controller, showing satisfactory performance [1]. The authors introduce an Adaptive SMC for a Buck converter-driven DC motor, incorporating a robust proportional derivative control law. The design, based on Lyapunov theory, aims to eliminate chattering in the control signal. The proposed scheme is simple for implementation, ensuring global asymptotic stability if signals remain uniformly bounded. Simulation studies demonstrate superior tracking performance compared to conventional controllers [2]. For a DC motor, the authors present a novel variable-structure position control law. The algorithm makes sure that a sliding mode is established as soon as the shaft motion begins by using a time-varying switching line. The design consists of an initial surface that moves gradually in the direction of a predefined desired surface after passing through the initial representative point. By doing this, the reaching phase is removed, making the motor behavior insensitive to modifications in the unknown mechanical configuration. Using a cheap 16-bit microcontroller, simulation and experimentation are used to test the suggested approach. The study further employs an advanced test bed to assess tracking properties and robustness under variations in mechanical configuration [3]. The authors addressed the position control of a brushed DC motor, a

common actuator in industrial and robotics applications. Two control techniques are compared: the widely used Proportional-Integral-Derivative (PID) controller known for its simplicity and reliability, and the Linear Quadratic Regulator (LQR) employing a state-space approach. The LQR design offers a systematic method for computing the state feedback control gain matrix, minimizing both weighted squared state error and control effort. The study evaluates and compares the performance of both controllers, focusing on disturbance resistance [4]. The authors present and put into practice an SMC algorithm for DC-DC buck converter closed-loop control. The variable switching frequency problem that traditional SMC buck converters have during load and supply changes is intended to be solved by the Improved Sliding Mode control (ISMC). The switching frequency's unpredictability makes filter design challenging. The ISMC seeks to address this problem by appropriately transforming the sliding mode control rule using a pulse width modulation technique. Comprehensive simulation studies in the MATLAB/Simulink environment validate the control algorithm. An extensive comparison analysis is carried out between the converter control systems that utilize ISMC and traditional SMC, emphasizing the fixed-frequency functionality of ISMC under various operating circumstances [5]. This research presents a fuzzy logic controller integrated phase-locked loop induction motor speed drive. The system seeks to combine the benefits of fuzzy logic—such as its simplicity, intuitiveness, ease of implementation, and low requirement for system dynamics knowledge—with the superior speed regulation capabilities of phase-locked loop approaches. The goal of the suggested system is to control the speed of an induction motor precisely, quickly, and robustly. The system's performance is assessed using an experimental setting, and the findings show that the induction motor drive's phase-locked loop and fuzzy logic controller work together to provide accurate speed control with a quick reaction [6].
The authors address the enhancement of output torque and rotational speed accuracy in reaction flywheels, essential for satellite attitude control. The study reviews the modeling and control approaches of DC–DC converters, employing variable structure system theory and SMC. The paper constructs the topology of the reaction flywheel and outlines the small signal linearization process for a buck converter. Using state averaging models and the Lee derivative, the general results of SMC are analyzed. The paper then deduces detailed analytical equivalent control laws for the reaction flywheel, considering various sliding surfaces during different operational stages. Numerical and experimental examples are presented, demonstrating favorable agreement between simulations and experiments. Strong rejection of mild disturbances, high-precision output torque, and rotational speed tracking are all accomplished by the suggested control technique [7]. It also produces preferred rotational speed regulation.

II BUCK CONVERTER WITH SMC

Investigating the process of creating a buck converter's sliding mode control system while taking control gains and switching function design into account [8]-[10]. Insights into the difficulties encountered in real-world applications of sliding mode control in buck converters. It offers strong load disturbance rejection and a quick transient response. The figure 1 shows the control mechanism is naturally resistant to changes in parameters and outside interference and motor performance.

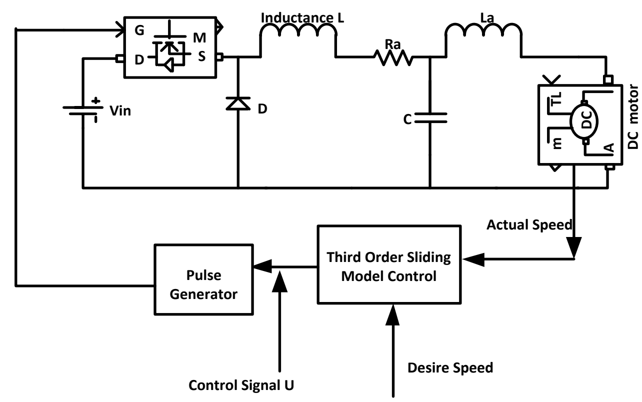

Figure 1: Buck Converter with Sliding Mode Control

The purpose of the sliding mode controller is to control speed within the specified time. The DC motor's speed error is,

$$e = \omega^* - \omega \tag{1}$$

Where,

ω^*=Reference speed

ω=Actual speed

The combination of the proportional, integral, and derivative of the speed error is known as the sliding function.

$$S = \int edt + e + \frac{de}{dt} \tag{2}$$

On the sliding surface S=0, the error variation is zero,

$$0 = \int edt + e + \frac{de}{dt} \tag{3}$$

The sliding function's derivatives are defined as

$$S=\int\omega^{*}dt+\omega-\int\omega dt+\left(\frac{F}{H}-1\right)\omega-\frac{k_t}{H}i_a \quad (4)$$

Where,

F =Friction constant

H =Inertia constant

i_a =Armature current

k_t =Torque constant

k_e =Back emf constant

$$\frac{dS}{dt}=S=\omega^{*}+y_1\omega+y_2 i_a-\frac{k_t}{HL_a}V_a$$

$$\frac{d^2S}{dt^2}=S=y_3\omega+y_4 i_a+\frac{a_2}{L_a}V_a-\frac{k_t}{HL_aC}i_L \quad (5)$$

$$\frac{d^3S}{dt^3}=y_5\omega+y_6 i_a+y_7V_a+\frac{y_2}{L_aC}i_L-\frac{k_tV_{in}}{HL_aLC}u$$

Where,

$$y_1=-1+\frac{F}{H}-\frac{F^2}{H^2}+\frac{k_ek_t}{HL_a} \quad (6)$$

$$y_2=\frac{k_t}{H}+\frac{k_tF}{H^2}+\frac{k_tR_a}{HL_a} \quad (7)$$

$$y_3=-\frac{F}{H}y_1-\frac{k_ey_2}{L_a} \quad (8)$$

$$y_4=\frac{k_t}{H}y_1-\frac{R_a}{L_a}y_2+\frac{k_t}{HL_aC} \quad (9)$$

$$y_5=-\frac{F}{H}y_3-\frac{k_e}{L_a}y_4 \quad (10)$$

$$y_6=\frac{k_t}{H}y_3-\frac{R_a}{L_a}y_4-\frac{y_2}{L_aC} \quad (11)$$

$$y_7=\frac{y_4}{L_a}+\frac{k_t}{HL_aLC} \quad (12)$$

The notation for the third-order derivative is,

$$\frac{d^3S}{dt^3}=M+Nu \quad (13)$$

Where,

$$M=y_5\omega+y_6 i_a+y_7V_a+\frac{y_2}{L_aC}i_L \quad (14)$$

$$N=\frac{k_tV_{in}}{HL_aLC}u \quad (15)$$

To achieve the necessary time of zero sliding function, the control law is selected as follows,

$$\frac{d^3S}{dt^3}=U \quad (16)$$

Where,

$$U=-\alpha\phi_{23} \quad (17)$$

$$\phi_{23}=sign\left(s+\beta\left(|s|^2+|s|^3\right)^{\frac{1}{6}}\left(\phi_{13}\right)\right) \quad (18)$$

$$\phi_{13}=sign\left(s+\beta_1|s|^{\frac{2}{3}}\,sign(s)\right) \quad (19)$$

$$U=M+Nu \quad (20)$$

The sliding mode control law itself is expressed as follows,

$$u=\frac{U-M}{N} \quad (21)$$

Where,

$$M=M^{*}+M_1 \quad (22)$$

$$M^{*}=y_5\omega^{*}+y_6 i_a^{*}+y_7v_a^{*}+\frac{y_2}{L_aC}i_L^{*} \quad (23)$$

$$M_1=y_5\left(\omega-\omega^{*}\right)+y_6\left(i_a-i_a^{*}\right)+y_7\left(v_a-v_a^{*}\right)+\frac{y_2}{L_aC}\left(i_L-i_L^{*}\right) \quad (24)$$

Sliding mode control law divided parts as,

$$u=\frac{U}{N}-\frac{M^{*}}{N}-\frac{M_1}{N} \quad (25)$$

Where,

$\frac{U}{N}=u_{sliding}=$ Sliding control

$-\frac{M_1}{N}=u_e=$ Error control

$-\frac{M^{*}}{N}=u_s=$ Steady state control

III ANFIS CONTROLLER

ANFIS utilizes fuzzy logic to model the system's nonlinearities and a neural network to adaptively tune the fuzzy rules. The controller's ability to self-adjust based on real-time feedback makes it well-suited for dynamic environments. The Methodology study involves the following steps: Modeling the DC motor system, Designing the ANFIS controller, Training the ANFIS model using experimental data, Implementing the ANFIS controller in the DC motor system. The figure 2 shows the data loaded and taring the ANFIS control. Using a learning technique, ANFIS uses this dataset to modify internal parameters during training, including rule weights and membership function parameters. The goal is to reduce the discrepancy between the actual outputs from the training data and the predictions made by the ANFIS model. The figure 3 shows the inputs Fuzzification is an important step before feeding these inputs into the ANFIS model [11]-[15]. Fuzzification is the process of assigning suitable fuzzy sets to the inputs to transform their clear, numerical values into linguistic variables. Membership functions, which specify the extent of belonging to certain linguistic categories, are assigned to each input. The contribution of each input value to the overall fuzzy logic systemis determined by these membership functions.

Figure 2: ANFIS Training Data

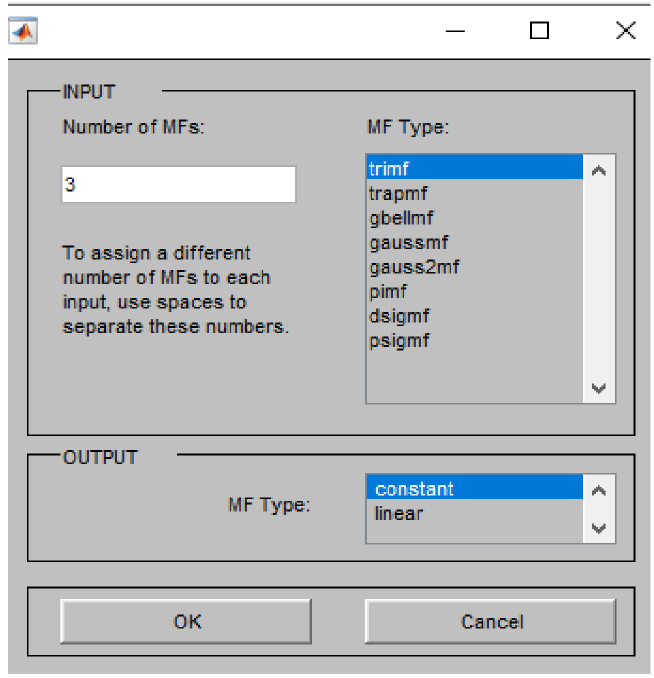

Figure 3: ANFIS Inputs and types

The figure 4 shows training error the degree to which the ANFIS model matches the observed behaviors of the DC motor is quantified by the training error. To lower this mistake, the learning method used during training tries to iteratively modify the ANFIS's parameters, such as membership function parameters and rule weights. The goal of popular optimization approaches like gradient descent and the least squares method is to optimize the model's parameters in order to increase the predicted accuracy of the model. It also shows the error tolerance and eprochs.

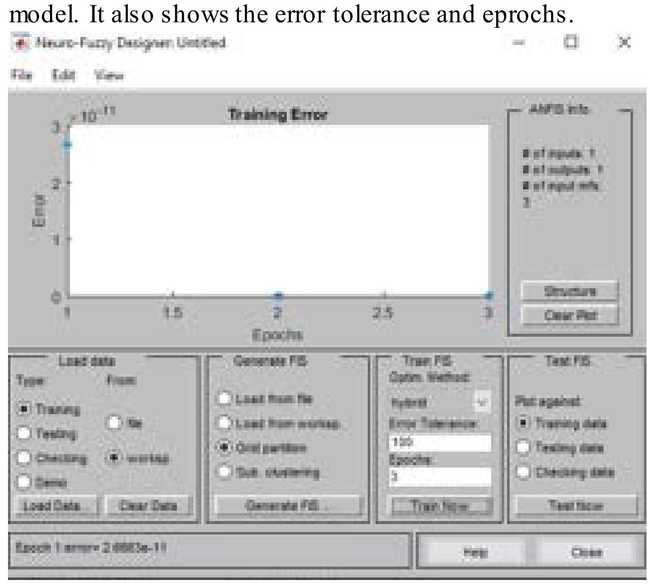

Figure 4: ANFIS Training Error

The figure 5 shows the input and output fuzzy rules are evaluated by the rule layer to handle the fuzzified inputs. These rules, which are derived from the antecedents of the rules, encapsulate the logical connections among the input variables. Rules may specify, for instance, how variations in voltage and load torque impact motor speed in a DC motor system. The degree to which the input variables belong to each fuzzy set determines the firing intensities of these rules.

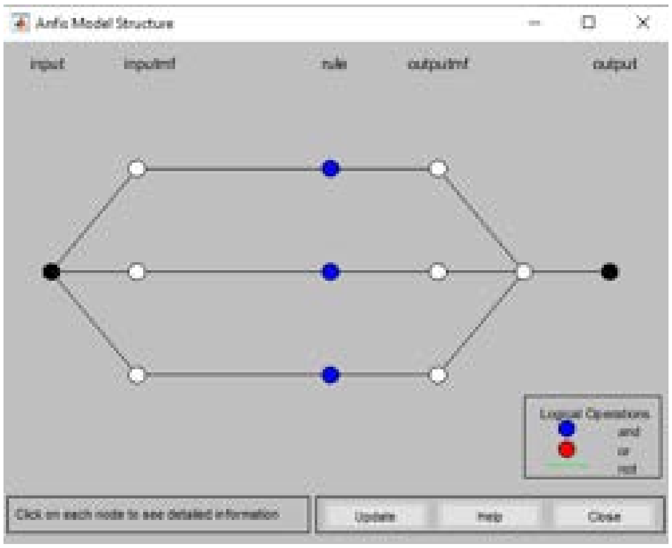

Figure 5: ANFIS input and output structure

The normalization layer, which comes after the rule layer, makes sure that the total firing strengths of all rules add up to 1. In the next steps, a balanced contribution from every rule depends on this normalization. The output layer creates the ANFIS model's final output by combining the normalized firing strengths. This output may indicate the anticipated motor speed in the case of a DC motor.

IV SIMULATION RESULTS

The figure 6 shows An Adaptive Neuro-Fuzzy Inference System (ANFIS) controller is used to simulate the performance of a DC motor. The simulation produces informative findings that demonstrate the efficacy of the control method that was designed. The ANFIS model is used in the simulation to control the behavior of the DC motor. The output, which might be the motor speed or position, is influenced by input variables like voltage, current, and load torque.

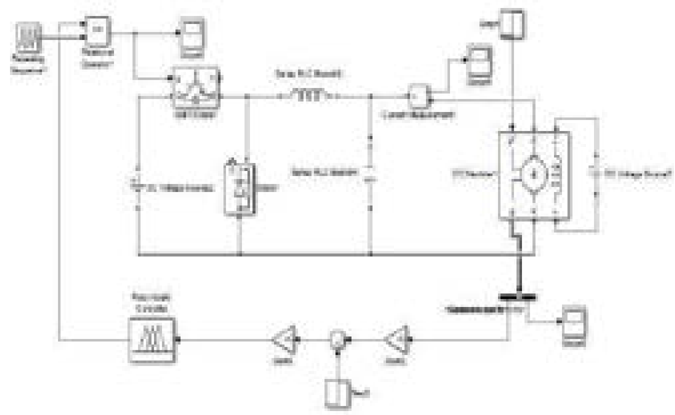

Figure 6: Simulation of ANFIS Control DC motor

The experimental results demonstrate significant improvements in the DC motor's performance when employing the ANFIS controller. Enhanced speed control accuracy, reduced overshooting, and improved energy efficiency contribute to the overall effectiveness of the ANFIS-based control system. A comparative analysis with traditional PID control showcases the advantages of ANFIS in handling nonlinearities and uncertainties. ANFIS proves to be more adaptive and responsive, especially in scenarios with varying load conditions. The findings of this study have practical implications for industries relying on DC motors. The integration of ANFIS controllers can lead to more robust and efficient motor control systems, thereby improving the overall performance and longevity of equipment.

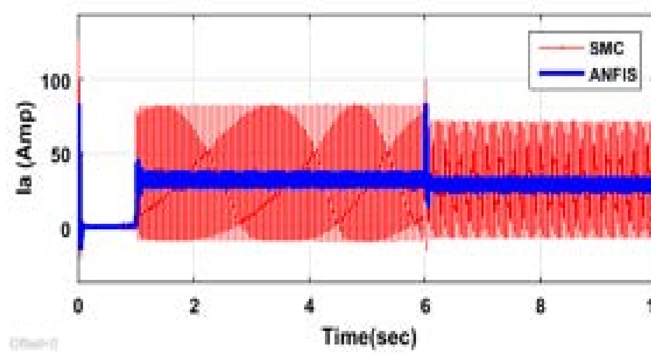

Figure 7: Simulation Output of armature current DC motor

The figure 7 shows ANFIS model is first trained on a dataset of input-output pairs, where the output is the armature current and the inputs might be parameters such as voltage, torque applied to the load, and speed reference. In order to reduce the discrepancy between the anticipated armature current and the actual armature current from the training data, the model's parameters, such as membership functions and rule weights, are adjusted throughout the training phase. On the other hand, the simulation output of the SMC-controlled DC motor shows how reliable the Sliding Mode Control approach is in keeping the armature current within the intended range in the face of outside uncertainties or disruptions. A sliding surface is used by the sliding mode controller to guide the system to the intended state while ensuring a stable and robust response. The output plot for SMC may demonstrate how quickly and precisely disturbances may be adjusted, highlighting the control strategy's capacity to guarantee stability and reliable operation.

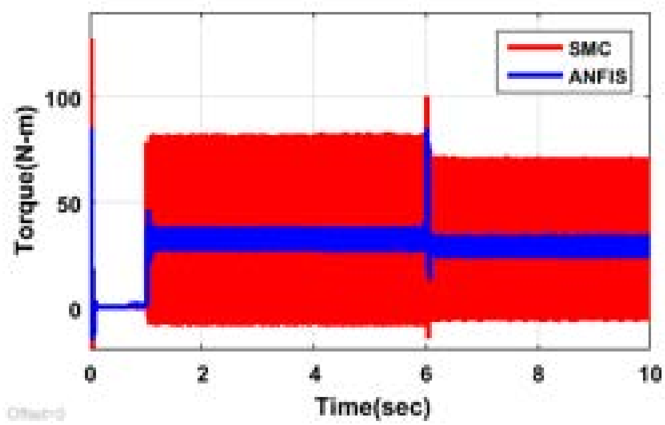

Figure 8: Simulation Output of DC motor Torque

The Figure 8 shows torque simulation result for DC motors shows how effectively the ANFIS controller captures the intricate and nonlinear connections present in the torque dynamics, as well as how well it generalizes to other operating circumstances. The simulation output's correctness is important because it shows how well the ANFIS model maintains the intended torque and adapts to changes in the input variables Conversely, the results of the simulation for DC motor torque under Sliding Mode Control demonstrate how resilient the SMC approach is to ambiguities and disruptions. SMC uses a sliding surface to keep the system on the intended course and ensure stability even when there are outside influences on torque.

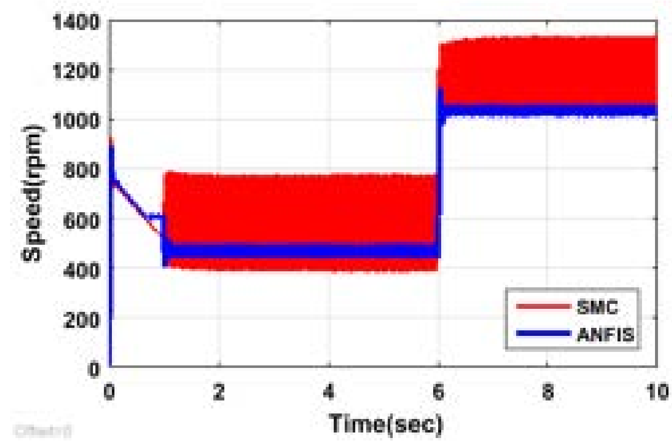

Figure 9: Simulation output of DC motor Speed

The Figure 9 shows simulation output for the ANFIS-controlled DC motor how the system responds to changes in speed while the ANFIS controller is in use. After training on input-output pairs, the ANFIS model adjusts its parameters to precisely forecast and regulate the motor speed. The output plot most likely demonstrates a responsive and smooth speed regulation, demonstrating the flexibility of the ANFIS controller in responding to different operating scenarios and the nonlinearities present in the DC motor system. The simulation result for the SMC-controlled DC motor shows how the robust sliding mode control method provides speed control. Known for its resilience to ambiguities and disruptions, SMC makes sure that the motor speed stays on the intended course even when outside influences are present. The output plot may highlight the sliding mode controller's stability and resistance to disturbances by displaying its fast and accurate speed adjustments.

V CONCLUSION

In conclusion, the utilization of an ANFIS controller for DC motor control demonstrates notable improvements in performance metrics. This study contributes to the growing body of research on intelligent control systems, offering a viable solution for optimizing DC motor operations in various applications. Future research directions may include exploring the adaptability of ANFIS controllers in different motor types, investigating real-time implementation challenges, and optimizing the ANFIS structure for specific industrial requirements. Continuous advancements in intelligent control systems hold the potential to revolutionize the field of motor control and automation.

Abstract— **This paper uses unsupervised machine learning techniques (ML) to explore the risk of cybersecurity breaches or attacks in the higher education sector, including schools, universities, and support organizations. A large sample of higher education institutions (N=848) was analyzed by extracting hypertext data from the websites of educational institutions to identify links that may signal a future cybersecurity breach or attack. ML T-distributed Stochastic Neighbor Embedding (t-SNE) was used to train a model for identifying likely indicators of cybersecurity breach risks. The authors used additional techniques, including radial analysis and correspondence analysis, to visualize the cybersecurity breach signals in the data. In this way, decision-makers should be able to spot anomalies that indicate cybercrime activity or potential cyber-attacks. This paper also exposes the problems of using ML and how to use methods and data triangulation to check reliability and validity.**

Keywords— unsupervised machine learning, cybersecurity breaches, higher education sector, hypertext data analysis, t-distributed stochastic neighbor embedding, pervasive computing, cyber-attack indicators, radial analysis, correspondence analysis, anomaly detection, data triangulation.

I. Introduction

Cybercrime represents a significant financial burden to organizations and poses considerable detection challenges [1, 2]. Decision-making processes are imperative in complex scenarios, necessitating the employment of various analytical techniques. However, one of the significant challenges decision-makers face emerges when there is a suspicion of cybercrime within complex datasets [3]. This scenario demands an analytical approach that transcends simple binary evaluations of alternatives. Regrettably, the availability of methodologies capable of ranking choices and delineating improvements across a broad spectrum of variables and scenarios is limited. Existing techniques often restrict the data types that can be processed, accommodate only a finite set of independent or dependent variables, and typically categorize outcomes as positive or negative, rank performance metrics, or forecast optimal values post-model development. It is rare to find a single decision-making methodology that encompasses all these capabilities effectively.

Consider the complexity involved in a leader of a significant global company making decisions about closing or establishing various sections or sites, especially with the abundance of performance data at their disposal. How does such a leader pinpoint improvement in underperforming areas to avoid layoffs or new hires? Similarly, with the extensive information on marketing and benchmarks, how do students decide on the best universities for them? Or, how do regulatory bodies assess which entities under their watch are secure for public interaction, or conversely, identify which ones require enhancement and in what manner? These scenarios present intricate management research challenges that go beyond the realm of simple statistical correlations or predictive analytics for resolution.

This study seeks to demonstrate the application of cybersecurity management decision-making strategies within the higher education domain. It also aims to evaluate the pros and cons of employing a top-tier singular method for addressing management issues. This work will highlight critical elements for choosing and deploying managerial decision-making methodologies. It will detail how various relevant approaches operate and include practical examples from scholarly sources. The latter part of the document will focus on employing these methods to analyze American university websites.

This study examines explicitly the ML methodology, its foundational theories, benefits, and limitations within an empirical study comparing universities in higher education. It covers the diverse approaches to designing and implementing ML, offering guidance on selecting the most appropriate design based on the managerial research question and the data types. The central research question guiding this investigation explores how sampled universities can assess the risk of a cybersecurity breach by analyzing their websites. Furthermore, the study intends to detail the application of the ML method in such a context that is understandable to managers or individuals without a background in mathematics.

This study's findings and methodologies can be universally applied across various sectors and managerial challenges with similar decision-making variables. The primary audience for this research encompasses managerial decision-makers across all fields, extending from the realm of higher education to other industries. Such decision-makers range from executives, managers, and administrators to government officials and policy strategists. Additionally, a secondary audience includes consumers like students or clients of various services who face decisions amidst a plethora of complex numerical data for benchmarking or evaluation. Hence, this document is invaluable for anyone with intricate choices where numerous metrics are available yet challenging to sift through. It also holds significance for those in academic or professional pursuits within operations research or management science, offering insights into decision-making processes. Moreover, management science consultants and entities stand to gain substantially, as the strategies discussed are instrumental for benchmarking organizational performance against peers or competitors and uncovering avenues for enhancing productivity.

II. LITERATURE REVIEW

It is not unexpected that the roots of decision-making methods can be traced back to the foundational texts of management science. Rosacker and Olson [4] point out that initial decision-making strategies relied on qualitative data for assessing implicit or non-quantifiable factors through methods that appealed to visual cues and convincing narratives, including reliance on 'acts of faith' and 'instinct.' Early qualitative decision-making models incorporated approaches based on attributes like the 'sacred cow' (recommendations from top executives), operational necessity (emergencies), competitive necessity (sector demands), expansion of product lines (adaptation to market changes), and comparative assessments of advantages, such as the 'Q-Sort' technique for ranking staff priorities [5].

Various decision-making strategies have incorporated research methodologies that favor expert team-based brainstorming over individual decision-making to identify optimal solutions alongside consensus-building techniques such as nominal group or Delphi methods [6]. Many multi-criteria decision-making models and approaches have surfaced in financial and economic research, integrating financial metrics such as the payback period, average or internal rate of return, discounted cash flow, and profitability indices. Sophisticated methods have been introduced in finance, including Monte Carlo simulations, portfolio selection models, scenario planning, and sensitivity analysis.

Various weighting models have been introduced, each adhering to converting original numerical factors into more indicative indices. The analytical hierarchy process, a notable decision-making method developed by Saaty [7], facilitates the conversion of complex qualitative factors into numerical indices for prioritization through pairwise comparisons and normalization techniques. Statistical methodologies are frequently incorporated into these processes, particularly when dealing with quantitative data. A notable drawback of parametric statistical methods is their dependency on the assumption that sample data must follow a certain distribution, along with numerous other presuppositions. Nonparametric statistical methods also need help with the number of variables they can handle and the accuracy of their estimates. A common shortcoming across statistical approaches is their focus on providing answers to specific ranking or predictive research questions via hypothesis testing without offering insights on enhancing the influencing or outcome variables.

Universities have cybersecurity requirements due to the nature of their networks, the diverse range of users they cater to, and the valuable data they possess [8]. This data encompasses information as well as cutting-edge research. Safeguarding cybersecurity in environments is particularly challenging, given the increasing cyber threats for property, sensitive data, and critical infrastructure [9]. The global digitalization of universities has undoubtedly brought advantages like access to information learning materials and worldwide connectivity [10]. However, this digital transformation has also exposed institutions to various cybersecurity risks [11]. Some common threats universities face includes phishing attacks, ransomware incidents, distributed denial of service (DDoS) attacks, and insider threats.

Phishing attacks involve using fraudulent emails or messages that mimic legitimate institutions or individuals to trick victims into revealing sensitive information, such as login credentials or personal information [12, 13]. Universities are prime targets for phishing due to the sheer volume of users and their sensitive data [14]. Ransomware is malicious software designed to block access to a computer system or files until a sum of money is paid [15]. These attacks can encrypt crucial data and systems, crippling institutional operations. An instance of ransomware impacting universities is the attack on the University of California, San Francisco (UCSF) in June 2020. The university was forced to pay a ransom of over $1.14 million to regain access to encrypted data related to important academic research [16]. This event highlights ransomware's critical threat to research integrity and operational continuity in academic settings.

DDoS attacks aim to overwhelm a system's resources by flooding it with several requests, making the service unavailable to legitimate users [17]. DDoS attacks often target universities because they heavily rely on teaching, learning, and administrative services [18]. For example, in 2016, 63 UK universities had suffered from DDoS Attacks including, the University of Edinburgh faced a DDoS attack that disrupted its network, leading to access to its website and online resources [19, 20]. These kinds of attacks can impact operations, causing delays and difficulties for both students and faculty members. Insider threats come from individuals within the organization who may misuse their access to systems and data for malicious purposes [21]. This category includes intentional acts by disgruntled employees or students and unintentional incidents caused by negligence [22]. A notable example is the case at the University of Iowa, where a student manipulated his grades more than 90 times over 21 months by stealing professors' credentials. This incident shows the potential for academic fraud and highlights the critical need for robust access controls and monitoring within educational institutions.

The cybersecurity landscape of universities is uniquely challenging, shaped significantly by the complexity and openness of their IT infrastructures, the human factor, and resource constraints [23]. Each of these elements introduces vulnerabilities that cyber threats can exploit. Universities typically maintain an open, complex IT infrastructure to support various academic activities [24]. This openness is essential for academic freedom and collaboration, allowing students, faculty, and researchers easy access to information and systems from anywhere in the world. The complexity arises from the vast array of devices connected to the network, including the personal devices of students and staff and specialized equipment for research purposes. Additionally, universities often have decentralized IT policies, with individual departments managing their systems to some extent.

t-SNE (t-Distributed Stochastic Neighbor Embedding) is a machine learning technique that helps simplify datasets by reducing their dimensionality [25, 26]. It is beneficial when trying to visualize datasets with variables. The primary objective of t-SNE is to transform data points from a space into a lower dimensional space [27]. By doing so, it arranges items in closer proximity and places dissimilar items further apart in the lower dimensional representation. This makes it a valuable tool for gaining insights into the structure of dimensional data. t-SNE begins by determining the likelihood that pairs of data points in the space are similar [28]. t-SNE considers each data point as the center of a distribution, calculating the probabilities of other points belonging to that distribution. This step generates a probability distribution for pairs of points in space. t-SNE then maps this data to a lower dimensional space and computes a similar probability distribution within this new space. The positions of points in the space are adjusted to minimize the Kullback-Leibler divergence between these two distributions. This ensures that similar points from the original high-dimensional space remain close together in their transformed lower-dimensional representation while dissimilar points are kept far apart.

III. METHODS

Scientific inquiry starts with formulating a research question and determining the explicit or implicit unit of analysis, which delineates the variables of interest and their data types. This study aims to evaluate quantitative data from multiple universities to address the managerial query: How do universities within the dataset rank in performance against established industry benchmarks, and what strategies could less efficient universities employ to enhance their performance? Here, the focus is on assessing university efficiency using predetermined variables for measurement. Except for the qualitative aspects of the university's identity and its geographical location, the variables in question are quantitative. Employing a comparative research design, this study analyzes the performance metrics of various universities. Should the objective have been merely to compare average values of specific metrics, such as student-faculty ratios, among the institutions, it would constitute a basic group comparison. For straightforward comparisons, statistical methods such as the T-Test (for two universities), ANOVA or MANOVA (for more than two universities), or CANOVA (if a numeric independent variable is known to influence another variable based on prior research) would be suitable. However, ANOVA and similar statistical methods are not equipped to address the secondary query regarding the improvement strategies for lower-performing institutions. Addressing this requires an operations research approach, specifically within linear programming, like machine learning.

The selection process for the sample utilized publicly available data from U.S. higher education institutions, resulting in a dataset comprising roughly 848 records from educational websites. The analysis focused on the individual college site level, leading to multiple entries for larger entities due to each campus providing separate data. The dataset featured over 4,000 elements identified as potential cybersecurity indicators, including URLs, XML embeddings, and various HTTP scripts. The sampling approach was initially purposive, aiming for a balanced representation of medium-sized public and private universities across different states and subsequently random. This decision was based on the presumption that universities of a smaller or larger size might display atypical metrics attributable to their distinct characteristics.

In contrast, medium-sized institutions were expected to offer more comparable data regarding efficiency and quality. The selection was narrowed down to 26 by excluding records lacking the required metrics, followed by the random selection of two private and two public universities from distinct states, resulting in a final sample comprising universities from Pennsylvania, Connecticut, New Jersey, and California. To maintain anonymity while illustrating the outcomes and interpretations of machine learning analyses, these institutions were anonymized with generic labels starting with 'Uni.' While ensuring confidentiality is essential, it was balanced with the scientific imperative of providing precise references to ensure transparency and reliability for the academic community and researchers worldwide, making the findings clear and verifiable.

IV. RESULTS AND DISCUSSION

The results of this study provide a compelling illustration of how ML can be leveraged to enhance the understanding of cybersecurity vulnerabilities within the educational sector. Through a detailed analysis of data from several university websites, the study identified significant cybersecurity indicators, including URLs, embedded XML, and HTTP scripts. Python-based ML algorithms enabled an examination of these indicators, culminating in a radial analysis highlighting the most critical vulnerabilities. This analysis was further supported by a comprehensive risk assessment, which employed a scoring system to quantify the likelihood of cybersecurity breaches. The findings revealed a diverse range of security postures across the sampled institutions, with the 'control' feature offering an insight into the aggregation of risk factors, thereby facilitating a targeted approach to cybersecurity enhancement.

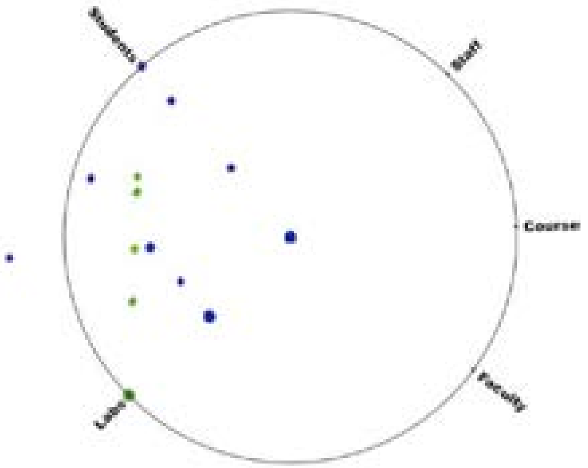

Fig. 1. Radial analysis of cybersecurity features related to potential breaches

Fig. 1 illustrates the top five features of potential cybersecurity breaches or shortcomings. These fields were based on using ML Python code to scan the website and evaluate the types of information found, including URLs, hypertext, and supporting scripts. Each field represents a different type of the above information. The Control field summarized the other indicators to calculate the combined cybersecurity breach risk due to any kind of risk found. This is the most useful feature in the ML analysis because it has identified the sample of potentially very high-risk components in the sample. The colors of the dots show the cybersecurity breach likelihood score on a scale from 0-3 (actually 1-3), where higher levels indicate higher risk, and the colors show this ranging from dark blue (low risk) to high risk (light yellow).

This multifaceted approach to risk assessment is further enhanced by the visual representation of risk levels through a color-coded system. Such a scheme not only simplifies the interpretation of results but also facilitates a quicker identification of areas requiring immediate attention. The gradation from dark blue to light yellow serves not just as a visual cue but also as a quantifiable measure of urgency, with the transition in colors reflecting an increasing scale of potential breach likelihood. This color mapping, grounded in the 1-3 risk score scale, allows for a more intuitive understanding of risk distribution across the analyzed websites, paving the way for targeted cybersecurity interventions.

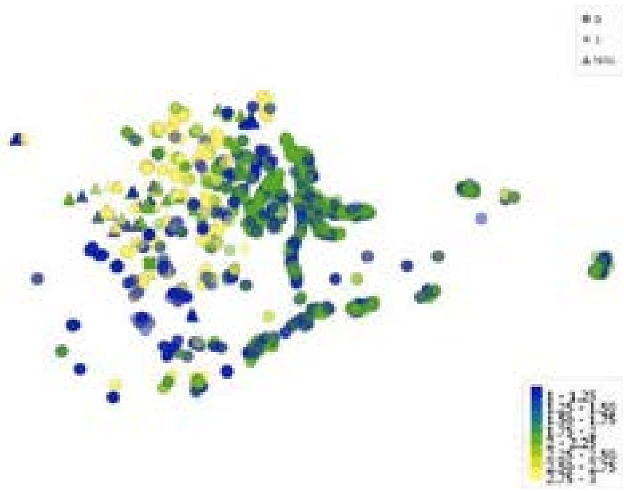

Fig. 2. ML t-SNE Analysis

Fig. 2 is the analysis done to explore the cybersecurity 'control' signal feature developed by examining various websites. Fig. 2 shows the cybersecurity breach likelihood score on a scale from 0-3 (actually 1-3), where higher levels indicate higher risk, and the colors show this ranging from dark blue (low risk) to high risk (light yellow). The '0' means these sites have no attacks, but the cybersecurity risk varies according to the color. The 'x' means there were one or more cybersecurity breaches due to malware discovered on the site (none were in this sample, so there is no 'x' here). The triangle means the site could not be verified because a URL was found that did not resolve to a working site; in other words, the NULL means a dead-end site or orphaned link. There is a general pattern of higher risks towards the middle and top.

The analysis presented in Fig. 2 further refines the understanding of the cybersecurity landscape across university websites by integrating a scoring mechanism that quantifies the vulnerability spectrum. This methodology, which distinguishes between varying degrees of risk from minimal to significant, employs a sophisticated visual taxonomy to differentiate between the operational status and security levels of the sites evaluated. Introducing specific symbols, such as the triangle, to indicate unverifiable areas due to non-resolving URLs adds layer of granularity to the analysis, allowing for a more detailed interpretation of the cybersecurity challenges these institutions face.

Importantly, the absence of the 'x' marker in the dataset underlines a positive note in this analysis—no instances of malware breaches were identified within the sample. This observation, however, does not detract from the critical need for vigilance, as the color-coded risk assessment reveals a discernible concentration of higher vulnerability scores in certain areas. Such a pattern suggests that while direct malware attacks may not have been detected, the potential for future breaches remains a significant concern, particularly in regions where the risk scores approach the upper end of the scale. The strategic placement of risks, notably more pronounced towards the central and upper sections of the visualization, hints at a correlation between the complexity of website features and the likelihood of security vulnerabilities. This insight underscores the necessity for a dynamic approach to cybersecurity, capable of adapting to the evolving digital ecosystem of higher education institutions. By mapping out the landscape of potential threats with such precision, the study highlights current security shortfalls. It lays the groundwork for developing more robust protective measures tailored to the specific vulnerabilities identified.

V. CONCLUSION

Future research should consider including a range of institutions, both large and small, to assess whether the identified cybersecurity risks and indicators hold true across different types and sizes of institutions. This would provide insights into the scalability and applicability of the machine learning models used and help understand cybersecurity risks. This could include analyzing network traffic, studying email patterns, and examining media presence. Refining the feature selection process is crucial to identify cybersecurity risk indicators. This involves exploring data processing techniques that effectively capture web content and infrastructure nuances. It is essential to investigate machine learning models and algorithms to determine their effectiveness in predicting cybersecurity breaches. Comparing machine learning models with deep learning approaches and ensemble methods can improve accuracy and reliability. Future studies could also include longitudinal studies to track the evolution of cybersecurity risks over time. Such studies enable us to identify trends and patterns, leading to measures in managing cybersecurity.

This paper has provided a novel examination of cybersecurity risks within the higher education sector by applying unsupervised machine learning techniques. Advanced analytical methods, such as t-SNE for model training and radial and correspondence analysis for data visualization, have enabled a deeper understanding of the cybersecurity landscape in this critical sector. The findings offer significant insights for decision-makers in educational institutions, highlighting the importance of proactive measures in identifying and mitigating potential cybersecurity threats. The ability to spot anomalies that could indicate cybercrime activity or impending cyber-attacks is crucial in an era where digital security is paramount.

Moreover, this study underscores the challenges inherent in leveraging ML for cybersecurity, particularly data reliability and model validity. The discussion on method and data triangulation presents a compelling case for the rigorous verification of ML outputs to ensure their accuracy and applicability. The exploration of cybersecurity risks in higher education environments with ML presents a promising avenue for enhancing digital security measures. However, it also calls for ongoing research and development to refine these techniques, improve data collection and processing methods, and fully integrate ethical considerations into ML applications. As cyber threats evolve, so must the approaches will evolve to detect and defend against them. This paper contributes to the growing body of knowledge in this field. It paves the way for further studies to build on these findings to develop more sophisticated and effective cybersecurity strategies for higher education.

***Abstract*— This research explores the changing landscape of Kawasaki Disease (KD) diagnosis, specifically examining the Machine Learning (ML) algorithms to enhance diagnostic capabilities. KD, a complex pediatric vasculitis, presents diagnostic challenges due to its diverse clinical manifestations, often resulting in delayed treatment. The study investigates the incorporation of machine learning techniques to improve the accuracy and efficiency of KD diagnosis. Utilizing a comprehensive dataset encompassing various clinical parameters related to KD, this research aims to create a robust predictive model. The analysis involves exploring patterns and correlations within the dataset to identify key diagnostic markers for KD. The findings demonstrate the potential of machine learning algorithms to effectively distinguish KD cases from other febrile illnesses, assisting clinicians in making more informed and prompt decisions. The integration of these algorithms in the diagnostic process not only enhances accuracy but also shows promise in reducing diagnostic delays, ultimately contributing to improved patient outcomes.**

Keywords— Kawasaki Disease, Diagnosis, Machine Learning, Pediatric Vasculitis, Clinical Parameters, Predictive Model, Healthcare.

I. Introduction

Diagnosing Kawasaki Disease (KD), a complex pediatric vasculitic condition, has long been a concern in pediatric healthcare. The varied clinical presentation of KD poses challenges in early and accurate diagnosis, increasing the risks of delayed treatment and potential complications. Despite medical advancements, innovative solutions are needed to improve diagnostic precision and timeliness for KD. Recently, there has been a growing interest in exploring machine learning algorithms as a transformative tool in the diagnostic landscape. This research focuses on the intersection of Kawasaki Disease diagnosis and machine learning, aiming to contribute to the knowledge on enhancing pediatric healthcare.

Kawasaki Disease is characterized by acute inflammation of medium-sized arteries, primarily affecting children under five. The disease's manifestations include fever, mucocutaneous changes, lymphadenopathy, and potential cardiovascular complications, making its diagnosis intricate. Timely recognition is crucial, as delayed treatment may lead to severe cardiac issues. The current diagnostic paradigm relies on clinical expertise, but the complexity of KD often results in delayed or missed diagnoses.

Machine learning, a subset of artificial intelligence, has shown significant potential in healthcare, analysing vast datasets and identifying patterns for improved diagnostic accuracy. Its integration into the diagnostic process for KD holds promise for enhancing efficiency and reliability, potentially reducing diagnostic delays and improving patient outcomes.

This research addresses the need for developing more effective diagnostic approaches in Kawasaki Disease by exploring machine learning algorithms' application. Using a comprehensive dataset, the study aims to develop a predictive model discerning subtle patterns indicative of the disease. The investigation also examines the broader implications of integrating machine learning into pediatric healthcare, exploring its potential transformative impact on diagnostic practices and patient care. The research aims to contribute valuable insights to the ongoing discourse on the intersection of artificial intelligence and pediatric healthcare, specifically enhancing the diagnosis and management of Kawasaki Disease.

II. Related Works

The literature on Kawasaki Disease (KD) and its diagnosis through various methodologies reflects the evolving landscape of pediatric healthcare. H.-C. Kuo's comprehensive review provides insights into the diagnosis, progress, and treatment updates of KD [1]. The paper emphasizes the need for constant refinement in the understanding and management of this challenging condition. J. Y. Lam et al. propose a deep learning framework for image-based screening of KD, showcasing the potential of improving diagnostic processes [2]. H. Lee et al. contribute to the discourse with an explainable algorithm focused on distinguishing incomplete Kawasaki disease based on coronary artery lesions in echocardiographic imaging [3].

In the realm of applications, E. Xu, S. Nemati, and A. H. Tremoulet present a deep convolutional neural network for KD diagnosis, highlighting the algorithm's potential to enhance accuracy in identifying this complex condition [4]. C. M. Tsai et al. introduce a novel score system of blood tests to differentiate KD from febrile illnesses, offering an alternative approach to diagnosis [5]. V. Baronti and E. Araujo delve into the development of a diagnostic support expert system for symptomatic fever onset of KD, showcasing interdisciplinary efforts in advancing diagnostic tools [6]. J. Zhong et al. propose a unique approach by distinguishing KD from febrile infectious diseases using gene pair signatures, contributing to the molecular understanding of KD [7].

Furthermore, foundational works by A. Marchesi et al. [8], E. Marrani, J. C. Burns, and R. Cimaz [9], Y. Krishnamurthy [10], and J. W. Newburger, M. Takahashi, and J. C. Burns [11] provide essential guidelines, classifications, and clinical perspectives on KD. J. Sánchez-Manubens, R. Bou, and J. Anton address the diagnostic challenges and classification issues associated with KD [12][13]. J. Forsey and L. Mertens shed light on atypical KD, emphasizing the clinical challenges in its diagnosis [14]. Lastly, C. Manlhiot, K. Millar, F. Golding, and B. W. McCrindle contribute insights into coronary artery abnormalities based on z-scores after KD, offering valuable information for improved classification [15]. Collectively, this literature study underscores the interdisciplinary efforts and diverse approaches employed to advance the diagnosis and understanding of Kawasaki Disease.

III. Proposed Methodology

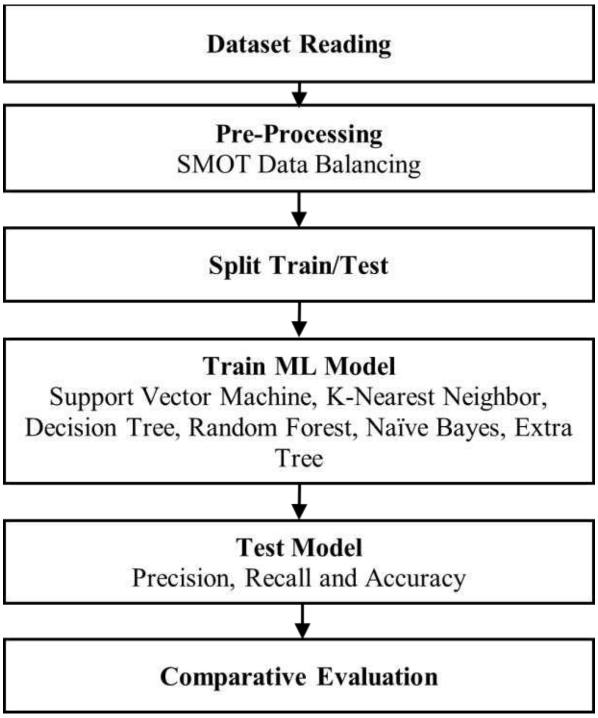

Fig. 1. Kawasaki Disease Classification System Flow

The classification process for Kawasaki Disease Classification, as depicted in Figure 1, progresses through a sequence of meticulous steps. Achieving successful classification involves a systematic approach, starting with a clear definition of the problem. The process includes collecting and preparing relevant data, with thorough cleaning and preprocessing being essential. To handle null values, functions like dropna() or fillna() in pandas for Python can be utilized. Balancing features through techniques like Synthetic Minority Oversampling Technique (SMOTE) contributes to the model's subsequent success. The dataset is then split into training and testing sets to accurately evaluate the model's performance, potentially incorporating a validation set for hyperparameter tuning. Selecting an appropriate classification algorithm, such as SVM, KNN, Decision Trees (DT), Random Forest (RF), or ensemble Extra Tree (ET), is a crucial step, with ensemble methods considered for improved performance. Training the model involves adjusting hyperparameters to optimize its capabilities. The model's performance is rigorously evaluated using metrics like accuracy, precision, recall, F1 score, and confusion matrices. Fine-tuning through hyperparameter adjustments is followed by validation on an independent dataset to ensure generalizability. Consideration is given to the interpretability of the model's decision-making process, especially when it is crucial for application understanding. Upon satisfactory results, the model is deployed for real-world use and integrated into the intended application or system. Continuous monitoring and updates are emphasized to adapt to changes in data patterns or shifts in the problem domain, ensuring the ongoing relevance and accuracy of the deployed model.

IV. Results And Findings

The dataset contains 2752 rows and 15 columns, encompassing crucial information on Kawasaki Disease (KD) cases. It includes Patient ID, Date of Diagnosis, Age at Diagnosis, Gender, Ethnicity, Location, Fever Duration, Symptoms, Laboratory Tests, Echocardiography, Treatment Approach, Clinical Outcomes, Complications, Follow-up Visits, and Long-Term Effects. This comprehensive dataset serves various purposes, offering valuable insights into the epidemiology, treatment patterns, and outcomes related to KD. With a focus on epidemiological insights, the dataset, comprising 2752 patient records, enables a thorough analysis of KD cases, revealing demographic patterns and potential risk factors.

TABLE I. MODELS COMPARISION

Models	Accuracy (%)	Precision (%)	Recall (%)	F1 (%)
SVM	0.37	0.38	0.37	0.37
KNN	0.37	0.38	0.37	0.37
Navier Bayers	0.37	0.38	0.37	0.37
Dicision Tree	0.36	0.38	0.38	0.39
Random Forest	0.71	0.77	0.72	0.72
Extra Tree	0.99	0.99	0.99	0.99

CONCLUSION

In conclusion, the assessment of various models for Kawasaki Disease (KD) diagnosis reveals distinct performance metrics across different algorithms. Support Vector Machine (SVM), K-Nearest Neighbors (KNN), and Naive Bayes consistently demonstrate comparable accuracy, precision, recall, and F1 scores, all hovering around 0.37. Decision Tree exhibits a slightly lower accuracy at 0.36, with precision and recall at 0.38 and 0.38, respectively, while achieving a slightly higher F1 score of 0.39. Notably, Random Forest stands out among the assessed models, boasting a substantial accuracy of 0.71, with commendable precision, recall, and F1 scores at 0.77, 0.72, and 0.72, respectively. The Extra Tree model demonstrates remarkable performance, achieving near-perfect scores across all metrics with an accuracy of 0.99 and precision, recall, and F1 scores each at 0.99. These findings emphasize the importance of choosing an appropriate model for KD diagnosis, with Random Forest and Extra Tree emerging as promising candidates for further exploration and potential deployment in clinical settings. However, careful consideration of the specific requirements and nuances of the diagnostic task is essential in optimizing model selection for reliable and accurate KD diagnosis.

***Abstract*— A general form of attack that is happening over the internet is called phishing which could lead to identity theft and financial damages. Due to the increase of online electronic services and payment systems, the demand for accurate phishing detection tools has risen in recent times. However, the models often lead to high false detection rates. This research work introduces an Improved Generative Adversarial Network-based phishing attack detection, which has mainly two stages such as pre-processing and attack detection. Initially, for data pre-processing, a min-max normalization process is used. Following that, the attack detection process is done via Improved GAN, where a new discriminator loss function is adopted to enhance the detection performance. Finally, the performance of the proposed work is validated in terms of different performance measures.**

Keywords—*Phishing attack, Improved Generative Adversarial Network (IGAN), Attack detection, Min-max normalization.*

I. INTRODUCTION

Generally, phishing is a kind of social engineering attack. The users are tricked into disclosing their credentials like credit cards and passwords, along with other confidential information. It shows a great impact on individuals and industries in terms of personal and financial data. The increasing count of phishing attacks leads to the requirement for efficient attack detection approaches. Consequently, the victims are warned, while become a phishing campaign's target, to avoid any sensitive data loss [1] [2] [3].

Phishing is a dangerous cyber-attack that can result in financial losses and identity theft. The proliferation of online electronic services and payment systems has increased the need for high-accuracy phishing detection software. Because most phishing detection methods rely on elements found in webpage content, it requires crawling the website and using third-party services. Relying solely on webpage content-related criteria results in high false detection rates and poor detection accuracy. Deep learning has gained popularity recently as a method for identifying fraudulent websites. This phishing attack detection approach includes two kinds of approaches, which are software-based and human-based approaches. To enhance the end-user's knowledge and assist them in making good decisions while facing a phishing website [4] [5], human-based models are utilized. On the other hand, diverse techniques are adopted by the software-based models to decide whether a website is legitimate or phishing, without the interference of the end-user. The latter model has 5 types, which were, heuristic, visual similarity, blacklist/whitelist, ML, and DL [6] [7] [8].

The blacklist/whitelist-dependent approaches are mainly based on a list of recognized phishing websites, which includes data such as IP addresses, phishing URLs, and so on. Constantly updating this list is also crucial in the blacklist/whitelist-dependent approaches [9] [10]. Using diverse features, a phishing webpage's visual similarity is compared with its respective legitimate webpage, in this visual similarity-based method [11][12]. A webpage has been considered phishing if the similarity is greater than the preset threshold. The heuristic-dependent methods mainly rely on the characteristics of a phishing web page, experts' prior knowledge, or the similarity among the phishing web pages. Phishing detection has been considered a binary classification problem in the case of ML approaches. In the case of DL approaches, the detection is conducted with three steps, designing of DL model, model input selection, and analyzing the features used to categorize the websites [13][14][15]. However, only limited work is been done by GAN [16] architecture. On the other hand, the generative adversarial network (GAN) has received less attention. To address this, this work concentrates on proposing an improved GAN for automated phishing attack detection.

- To propose an effective phishing attack detection system using Improved GAN architecture adopting with trimmed factor-based loss function for accurate detection outcomes.

This work has been arranged as follows: a few recent publications related to Phishing attack detection have been reviewed in section II, section III details the proposed IGAN-based phishing attack detection system, section IV provides this work's implementation outcomes, and this work concludes in section V.

II. LITERATURE SURVEY

Some recent publications related to Phishing attack detection have been reviewed below

A phishing detection model called PDGAN was developed by Saad Al-Ahmadi *et al* [17] in 2022. For attaining reliable performance, this PDGAN depends on a website's URL. For synthetic phishing URL generation, LSTM was utilized. To categorize whether that URL was legitimate or phishing, CNN was utilized. For experiments, DomCop and Phish Tank datasets are utilized and the detection accuracy and precision of 97.58% and 98.02% were attained by PDGAN.

An ML-based phishing detection model was proposed by Ala Mughaid *et al* [18] in 2022. Initially, the data set was partitioned into training and testing data. With the training the data, the model was trained, and using the test data, the results were validated. With 3 diverse datasets, this approach was conducted, and based on the email text characteristics and other features, the attacks are categorized into non-phishing or phishing. With a boosted decision tree, accuracy of 0.88, 1.00, and 0.97 was attained.

In 2023, Muhammad Waqas Shaukat *et al* [19] proposed a multilayered ML-based approach. For phishing detection, this approach categorizes the websites and advertisements into phishing and legitimate websites. Based on the prominent features, diverse ML and DL models are trained. As per the URL features, the websites are categorized as phishing or legitimate by this predictive model. Outstanding results were attained by these models.

For fraudulent URL identification, SK Hasane Ahammad *et al* [20] proposed an ML-based model in 2022. In this work, RF, LGBM, DT, SVM, and LR are utilized. The URL's domain-based and linguistic properties are investigated. From these algorithms, LGBM attained the best outcomes. However, for accuracy enhancement, more features needed to be added since some URLs in the dataset were not present in the database.

An ML-based phishing detection system was proposed in 2023, by Abdul Karim *et al* [21]. This model was named the LSD Ensemble model. This model was compared with DT, RL, SVM, RF, GBM, SVM, K-Neighbour, NB, and hybrid (LR+SVM+DT) models. Higher performance was attained by this LSD Ensemble model. Furthermore, this model utilized the cross-fold validation along with canopy feature selection and Grid search hyperparameter optimization approach.

TABLE I: ADVANTAGES AND CHALLENGES OF SOME RECENT PHISHING ATTACK DETECTION MODELS

Citation	Techniques	Advantages	Challenges
Saad Al-Ahmadi et al [17]	GAN, LSTM,and CNN	Higher detection accuracy (97.58%) and precision (98.02%) were obtained	Depending on the batch size, the accuracy and loss ratings also change.
Ala Mughaid*et al* [18]	ML	For 50 features, it provides the highest accuracy	Limitation in finding the predefined dataset and while using 20 features, it cannot find the phishing attacks
Muhammad Waqas Shaukat *et al* [19]	ML	The promising results were attained by XGBoost	To provide a more robust detection process, this approach should be further optimized
SK Hasane Ahammad *et al* [20]	ML models (LGBM, RF, DT, LR and SVM)	Best outcomes were provided by LGBM	For accuracy enhancement, more features needed to be added since some URLs in the dataset were not present in the whois database
Abdul Karim *et al* [21]	Hybrid LSD model	Effectively detecting the Phishing attacks	To prevent and detect the attacks more effectively, this should be merged with list-based ML-dependent systems.

A.Problem Statement

Recently, governments, internet users, and service-providing organizations have faced an important attack named phishing attack. The client's sensitive data is collected by the attackers with the utilization of fake websites or spoofed emails. Diverse researches are conducted related to the detection of phishing attacks; however, also face challenges. Recently, the GAN [17] model was utilized for the phishing attack detection. Although higher detection accuracy (97.58%) and precision (98.02%) were obtained by this approach, the accuracy rating was greatly dependent on the batch size. Furthermore, DL models were utilized in [18], which provides higher accuracy for more features than was while using 50 features. Although it can provide sufficient accuracy for 20 features, these outcomes are not effective enough for phishing email detection. It's another drawback was finding the attack in the predefined dataset. For effective phishing attack detection, ML models were utilized in [19]. This work proved that promising results were attained by XGBoost. Although this model was optimized in terms of computational efficiency, to provide a more robust detection process, this approach should be further optimized. Similarly, ML models such as LGBM, RF, DT, LR, and SVM are utilized in [20]. Although the best outcomes were provided by LGBM, for accuracy enhancement, more features needed to be added since some URLs in the dataset were not present in the Who is database. Moreover, the Hybrid LSD model [21] was developed to effectively detect Phishing attacks. However, to prevent and detect the attacks more effectively, this should be merged with list-based ML-dependent systems (Table I). To tackle these shortcomings, new methods for phishing attacks should be developed. Consequently, an Improved GAN-based phishing attack detection model is developed in this work, which is detailed below.

III. PROPOSED IGAN-BASED PHISHING ATTACK DETECTION

Nowadays, for social interactions, the internet has been considered a powerful channel. Since, people are highly dependent on digital platforms, which pave the way for data theft or attacks. From online platforms like online businesses, online classrooms, online banking, e-commerce, digital marketplaces, etc, the users' credentials are stolen by the attacker, and this is known as a phishing attack. For phishing webpage detection, many tools are introduced by researchers, which are white-list, antivirus software, and blacklist. To penetrate the cyber defense, attackers utilize creative ways. Some detection models require high computational power to compute the features obtained from different sources. Hence, there need for a robust knowledge-based model to categorize the attack and nonattack data. In this work, an IGAN-based phishing attack detection model is introduced, which includes two stages: pre-processing and attack detection. Initially, for pre-processing, a min-max normalization process is utilized.

Afterwards, an IGAN-based phishing attack detection process is done, which is detailed below and its architecture is displayed in Fig 1.

A. Pre-processing

Initially, the input data IP_D is subjected to the pre-processing phase, where min-max normalization is utilized. A general technique utilized in data pre-processing is named min-max normalization. This transforms a dataset's value into a common scale. To preserve the relationships among the original values, have selected the min-max normalization process In the work, min-max normalization [22] performed a linear transformation on the IP_D and obtained the scaled data in the range (0, 1), that is numerically displayed in Eq. (1).

$$IP_{DS} = \frac{A - A_{\min}}{A_{\max} - A_{\min}} \qquad (1)$$

Here, the scaled data is denoted as IP_{DS} and A is the data. Furthermore, $A_{\max}$ and $A_{\min}$ denotes the maximum and minimum values of data. Subsequently, the obtained IP_{DS} is subjected to Improved GAN for detecting the attacks.

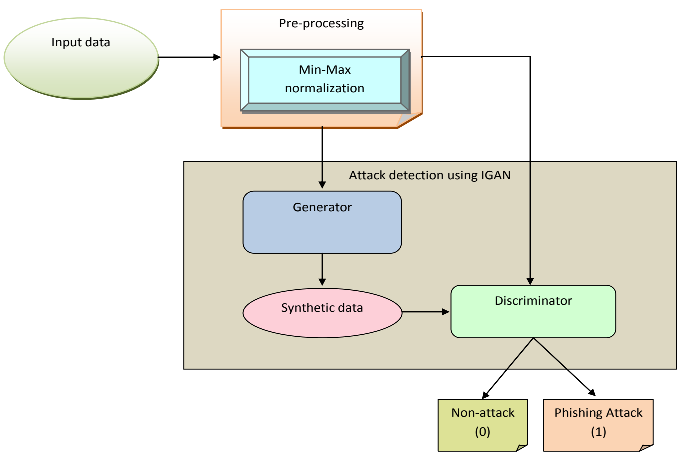

Fig.1. Architecture of IGAN-based phishing attack detection system

B. Attack detection using Improved GAN (IGAN)

The obtained IP_{DS} subjected to IGAN.IGAN is the unsupervised learning model that includes two NNs, a generator (GE) and a discriminator (DI). Both GE and DI models are probabilistic.

Generator (GE):

The IGAN's generator network includes the layer arrangement such as input layer, dense layer, leaky ReLU, reshape function, 2D convolution transpose, leaky ReLU, 2D convolution transpose, leaky ReLU, and afterwards a 2D convolution layer, that is displayed in Fig 2. Also, the reshape function has the size of (7, 7,128).

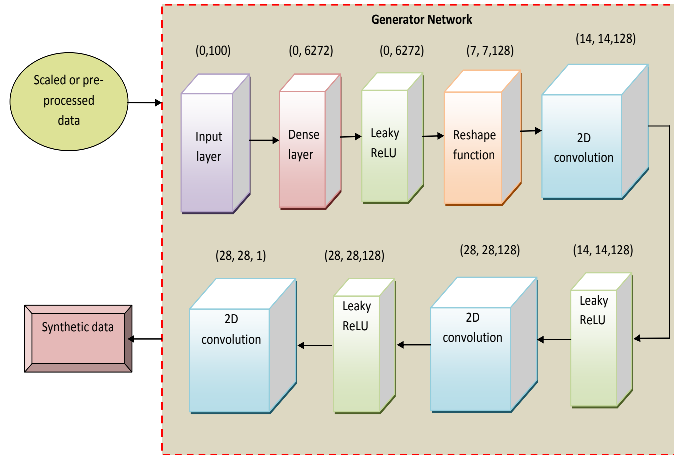

Fig.2. Architecture of IGAN's generator network

For capturing the data distribution, a generative model named generator is trained. From the learned distribution, the generator can output the generative and synthetic samples. To ensure the generated output sample's diversity, random noise(z) is present in this network. For learning the input data distribution, the joint probability distribution is applied by generative models using Eq. (2). Learning the data distribution facilitates the model to retrieve more prominent features and identify the data generation process. Therefore, artificial data having the identical distribution as the real data is provided by the generative models. These obtained synthetic data are plausible and dissimilar from the domain's real data.

$$p(IP_{DS}, Y) = p(IP_{DS}) \times p(Y) \qquad (2)$$

Where, p is probability and IP_{DS} is the input and Y denotes the class labels.

Discriminator (DI): IGAN's discriminator network includes the following layer arrangement. Firstly, the input layer, 2D convolutional layer, LeakyReLU, 2D convolutional, LeakyReLU, 2D convolutional, LeakyReLU, flatten, dropout and dense layer. The activation utilized in the network is lambda. The discriminator network's architecture is seen in Fig 3.

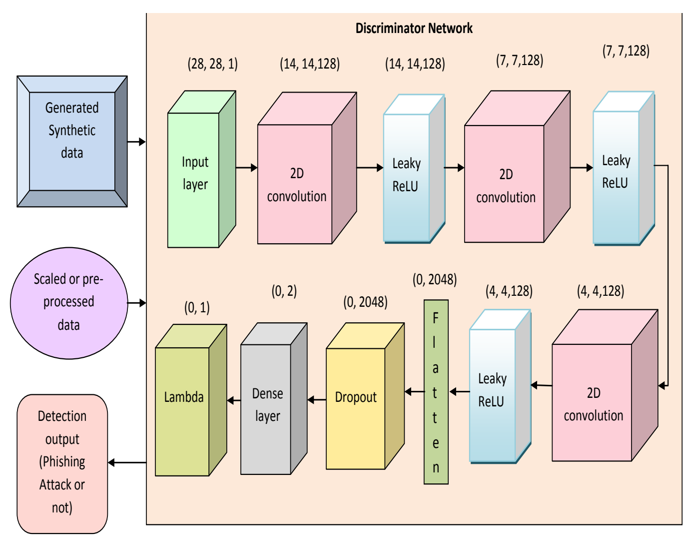

Fig.3. Architecture of IGAN's Discriminator network

A discriminative model has been trained to identify in which distribution the input data belongs. It helps to discover whether belong to real or artificial data distribution. Also, GAN's total performance can be enhanced by DI. GAN's training process has been considered as a min-max 2-player game.

To learn how to map input (IP_{DS})to their class labels (y), the conditional probability distribution is applied by the discriminative models using Eq. (3).

$$p\left(IP_{DS} \mid Y\right)=\frac{p\left(IP_{DS}, Y\right)}{p(Y)} \tag{3}$$

For maximizing the DI loss, the GE has been trained. The generator and discriminator losses of conventional GAN is in Eq. (4) and Eq. (5)

$$L^{(GE)}=\min\left\lfloor \log DI\left(IP_{DS}\right)+\log\left(1-DI\left(GE(z)\right)\right)\right\rfloor \tag{4}$$

$$L^{(DI)}=\max\left\lfloor \log DI\left(IP_{DS}\right)+\log\left(1-DI\left(GE(z)\right)\right)\right\rfloor \tag{5}$$

Here, $L^{(GE)}$ and $L^{(DI)}$ are generator and discriminator losses. Conventional discriminator loss function (in Eq. (5)), generally suffers from vanishing gradient issues and training instability. This will affect the detection performance of IGAN. For that reason, IGAN uses the trimmed factor-based loss function, which is mathematically expressed in Eq. (6). This trimming factor-based loss function (E_{TFL}) can provide accurate loss value.

$$E_{TFL}=-\frac{1}{H}\sum_{i=1}^{H} Q_{i:N} \tag{6}$$

where, H is the trimming factor that is considered during the training loss computation and it evaluates the smallest residual's quantity, N is the training set count.

This trimming factor-based loss function has additional functions based on constraints including data-specific characteristics and domain-specific knowledge. The model's ability to capture the relevant pattern in the data can be improved by this incorporation of a trimming factor-based loss function. Also, this loss function can help in ensuring the fair representation of all classes during training. For each observation, ordered losses are $Q_{1:N} \leq \ldots Q_{N:N}$, which can be written as in Eq. (7)

$$Q_i=\sum_{c=1}^{C} \lambda . PR_{ic} \log\left(\lambda T_{ic}\right) \tag{7}$$

Here, PR_{ic} symbolizes the predicted probabilities and C symbolizes the number of classes. Also, T_{ic} symbolizes the true values and λ denotes the robust factor, which can be evaluated using Eq. (8). Where δ =1.

$$\lambda=\delta\left(\left|PR_{ic}-T_{ic}\right|-\frac{1}{2}\delta\right) \tag{8}$$

This λ attains a smooth loss. Two versions of trimmed loss functions were tested in proposed work, which were when h=0.7 and h=0.9.

Finally, the discriminator provides the detection output based on the class labels, which might be 0 or 1 which means the class 0 indicates a non-attack and 1 indicates a phishing attack,

IV. RESULTS AND DISCUSSION

A. Simulation Procedure

The proposed phishing attack detection was simulated using PYTHON, specifically with "PYTHON 3.7." Further, the processor utilized was "11th Gen Intel (IR) Core (TM) i5-1135G7 @ 2.40GHz 2.42 GHz. Additionally, the system had "16.0 GB" of installed RAM. Moreover, the evaluation of phishing attack detection was carried out using the Phishing Dataset for Machine Learning [23].

B. Dataset Description

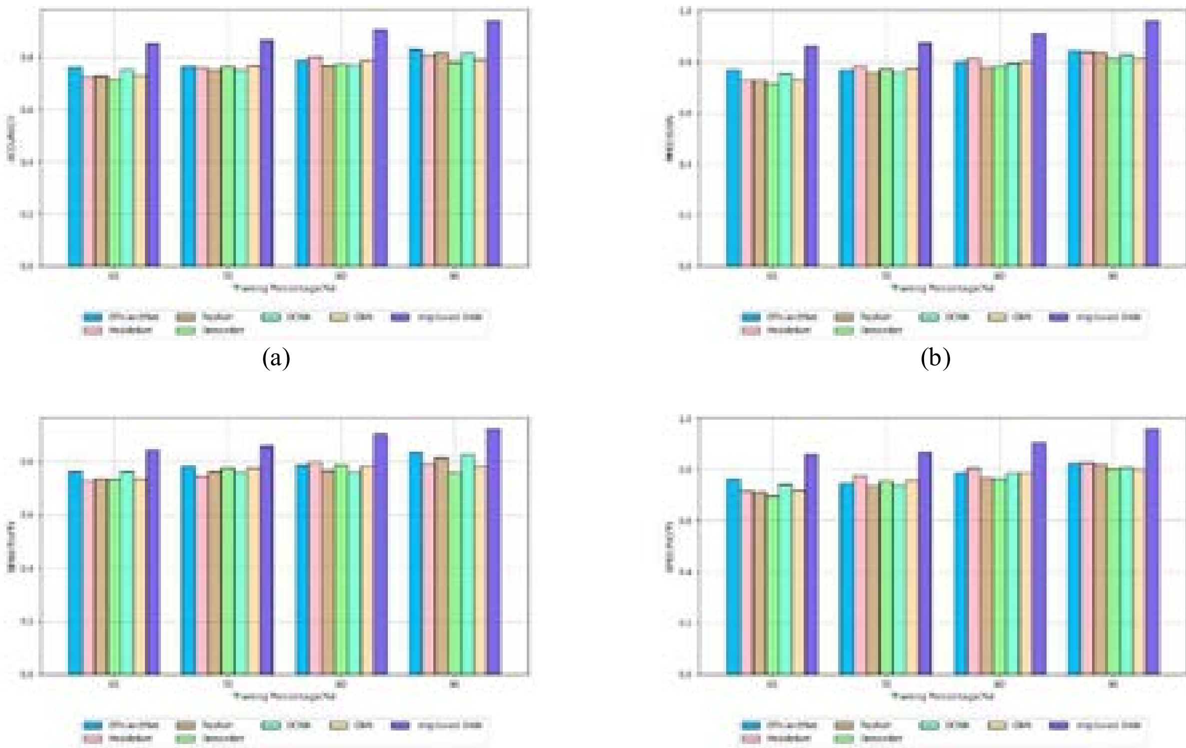
The dataset comprises 48 features extracted from a collection of 5000 phishing web pages and 5000 legitimate web pages. These web pages were acquired during two periods: from January to May 2015 and from May to June 2017. To enhance the extraction process, an advanced technique utilizing the browser automation framework, specifically Selenium WebDriver, was employed. This method proves to be more accurate and resilient when compared to the parsing approach reliant on regular expressions.

C. Performance Analysis

A thorough comparative analysis was conducted to evaluate the efficacy of the Improved GAN method in contrast to conventional approaches for detecting phishing attacks. This comprehensive assessment considered key metrics including Sensitivity, False Negative Rate (FNR), Negative Predictive Value (NPV), Specificity, F-measure, Precision, False Positive Rate (FPR), Matthews Correlation Coefficient (MCC), and Accuracy. Moreover, the performance of the Improved GAN scheme was compared with that of traditional approaches, including EfficientNet, MobileNet, ResNet, DenseNet, DCNN, and CNN [17].

D. Comparative Analysis on Positive Metric

In the context of phishing attack detection, a comparative analysis has been conducted to evaluate the Improved GAN strategy against conventional methods. Figure 4 illustrates the positive metric, a crucial factor in gauging the efficacy of the detection technique. The objective is to maximize the positive metric value for the efficient and effective identification of phishing attacks. To benchmark the Improved GAN strategy, a thorough comparison is made with established models such as EfficientNet, MobileNet, ResNet, DenseNet, DCNN, and CNN. Specifically, when considering a training percentage of 90, the performance of the Improved GAN model stands out with a notable detection accuracy of 0.938. In contrast, conventional methods demonstrate comparatively lower accuracy ratings: EfficientNet at 0.823, MobileNet at 0.809, ResNet at 0.816, DenseNet at 0.783, DCNN at 0.837, and CNN at 0.796, respectively. Furthermore, an additional noteworthy observation is the exceptional sensitivity achieved by the Improved GAN scheme, reaching a peak value of 0.895 at a training percentage of 80. This superior sensitivity performance surpasses that of established models such as Efficient Net, Mobile Net, ResNet, DenseNet, DCNN, and CNN, respectively. The results underscore the potential of the Improved GAN approach as a more effective solution in the realm of phishing attack detection, showcasing its ability to outperform established models under the specified training conditions.



(a) (b) (c) (d)

Fig.4. Assessment of Improved GAN and conventional strategies using Positive Metric

E. Comparative Analysis on Negative and Other Metrics

In the realm of phishing attack detection, the evaluation extends beyond positive metrics, encompassing negative metrics and other performance metrics to provide a comprehensive understanding of the Improved GAN model's efficacy. In this analysis, the Improved GAN model's performance is systematically contrasted with that of conventional methods, with a focus on minimizing negative values while concurrently enhancing other metrics. Figure 5 and Figure 6 serve as visual representations, highlighting the comparison of the Improved GAN model with the established methodologies. The objective is to showcase the Improved GAN model's proficiency in mitigating false negatives and optimizing other metrics critical to the accurate identification of phishing threats. Furthermore, the FPR of the Improved GAN scheme stands at 0.132 for a training percentage of 70. In contrast, established models exhibit higher FPR values, with Efficient Net at 0.254, Mobile Net at 0.223, ResNet at 0.262, Dense Net at 0.244, DCNN at 0.261, and CNN at 0.240, respectively. This discrepancy underscores the superior performance of the Improved GAN scheme in minimizing false positives compared to conventional methods. Similarly, the NPV of the Improved GAN approach is 0.913, whereas the Efficient Net, Mobile Net, ResNet, DenseNet, DCNN and CNN yielded the greatest NPV ratings of 0.813, 0.775, 0.795, 0.745, 0.803 and 0.762, respectively. Furthermore, the Improved GAN approach consistently achieved superior ratings compared to conventional methodologies across all metrics, ensuring precise detection of phishing attacks.

Fig.6. Assessment of Improved GAN and Conventional Strategies using Other Metric

F. Statistical Analysis on Accuracy

To ensure accurate results, each method undergoes a thorough statistical evaluation, including a comprehensive examination of key statistical parameters such as "Maximum, Minimum, Mean, Standard Deviation, and Median." Table II provides a comprehensive statistical assessment comparing the Improved GAN model with Efficient Net, Mobile Net, Res Net, Dense Net, DCNN, and CNN for phishing attack detection. Notably, in terms of the maximum statistical metric, the Improved GAN scheme demonstrates a remarkable accuracy of 0.938, meanwhile, the Efficient Net is 0.830, Mobile Net is 0.808, Res Net is 0.818, Dense Net is 0.780, DCNN is 0.818 and CNN is 0.790, respectively. Likewise, across most statistical metrics, the Improved GAN model consistently achieved higher accuracy ratings.

TABLE II: STATISTICAL EVALUATION OF ACCURACY

Statistical Metrics	Efficient Net	Mobile Net	ResNet	Dense Net	DCNN	CNN	Improved GAN
Standard Deviation	0.027	0.034	0.034	0.026	0.027	0.025	0.034
Mean	0.786	0.773	0.765	0.759	0.774	0.768	0.890
Minimum	0.763	0.723	0.726	0.716	0.750	0.728	0.852
Median	0.777	0.781	0.759	0.771	0.763	0.777	0.885
Maximum	0.830	0.808	0.818	0.780	0.818	0.790	0.938

V. CONCLUSION

A social engineering attack, which targets users' emails to steal sensitive and confidential information, is known as a phishing attack. It can be utilized as an enormous attack's part that is launched to invade government or corporate networks. Numerous anti-phishing attacks have been developed by researchers, but are inaccurate and inefficient. Consequently, an IGAN-based phishing attack detection system was introduced in this work. Initially, for data pre-processing, min-max normalization process was utilized. Afterwards, a phishing attack detection process takes place, which makes use of IGAN to provide accurate and efficient attack detection through the proposed trimming factor-based loss function. In the future, the suggested method's next steps will require classifying into two classes in order to improve the outcomes.

***Abstract* — Currently, there is a significant increase in incidents of drunk driving and road accidents, primarily caused by drivers who lack control over their vehicles. Approximately 31% of traffic crash fatalities in the United States are attributed to drivers who were under the influence of alcohol. The number of fatalities resulting from these avoidable collisions in 2021 amounted to 13,384 individuals. Over a span of 10 years, the average number of fatalities amounted to 10,850 individuals. Implementing an engine locking system that incorporates alcohol detection can effectively mitigate the occurrence of accidents caused by intoxicated driving. An engine locking system that incorporates alcohol detection technology can prove highly beneficial for law enforcement agencies. It offers an automated safety solution for automobiles and other vehicles. While it is not possible for a person to expedite their sobriety, there are several methods that can enhance their alertness and give the appearance of being more sober. One such solution is the implementation of alcohol detection and engine locking system. When a driver attempts to operate the vehicle while heavily intoxicated, the MQ3/BAC sensor detects the presence of alcohol. If the alcohol concentration exceeds a certain threshold, a signal is transmitted to the Arduino UNO. Based on this signal, the engine will be deactivated. This measure has the potential to decrease the occurrence of accidents caused by driving under the influence of alcohol, hence minimizing the risk of fatalities and property damage resulting from drunk driving. In this article a comprehensive study is carried out on various alcohol detection and engine locking systems using Arduino. The various components used in each of the systems are analyzed.**

Keywords* — *Arduino UNO, MQ3 sensor, Alcohol detection, Engine locking

I. INTRODUCTION

Over the years, Arduino has served as the central processing unit for numerous applications. Arduino is a programmable board that is openly accessible. It is utilised in embedded systems, home automation, and industrial automation for numerous real-time applications. It is extensively utilised in several real-world contexts, encompassing embedded systems and medical applications. Its affordability and ease of upkeep make it a popular choice among professionals. Arduino's qualities have rendered it indispensable in the realm of IoT (Internet of Things) and automation, where it excels in its ability to interface with the physical world in real-time [1].

Currently, the intake of alcohol has significantly escalated. This has a profound influence on society in numerous ways. Alcohol-related accidents lead to fatalities and property damage. The primary issue associated with alcohol drinking is the occurrence of accidents, which have a detrimental impact on individuals in close proximity. Several studies have also concluded that traffic accidents are caused by individuals who consume alcohol excessively. This significantly heightens the primary peril of fatality for the intoxicated individual, as well as impacting those in close proximity. The combination of alcohol intake and driving has a profound impact on society. Engaging in the act of drinking and driving poses a significant threat to both the individual and everyone involved [2]. This irresponsible conduct results in a significant number of accidents, injuries, and financial detriment. Furthermore, alcohol-related accidents, such as drunk driving, result in several fatalities annually and do immense harm to society.

The utilisation of Arduino in an autonomous engine locking system is a sophisticated and refined approach. Implementing an automated locking system can significantly improve security. The Arduino has the capability to monitor periods of inactivity and recognise when the user shuts down the engine. Upon the expiration of a designated duration of inactivity or when the user shuts down the car, the Arduino has the capability to autonomously transmit a signal to re-engage the engine lock. Upon successful authentication, the Arduino initiates the unlocking procedure to enable the engine to start. Implementing optional automatic locking provides an additional level of protection, however ensuring consistent performance requires careful management of power supply. Consistent testing and debugging are essential for preserving the system's dependability and efficacy in improving vehicle security.

The engine locking system, built on an Arduino-based platform, is a highly effective security feature for automobiles. The system commences by initiating user authentication, which necessitates the input of a PIN code or analogue data. The Arduino validates the authentication data and, following successful verification, triggers a relay module. The relay module is responsible for regulating a locking mechanism, typically a DC motor, that physically secures or releases the engine. Once the engine is disengaged, the Arduino activates the ignition system to initiate the vehicle's operation [3]. A discretionary automated locking function improves security by automatically re-locking the engine after a period of inactivity or when the user turns off the vehicle. Prudent handling of power supply guarantees steady operation.

The current situation clearly illustrates that intoxicated driving is the main factor behind the majority of traffic collisions. Intoxicated drivers often exhibit irregular driving behaviour on roadways as a result of their lack of stability, posing a threat to all individuals on the road, including themselves. The magnitude of reckless driving surpasses all limits. India has implemented legislation that prohibits drivers from consuming alcohol and operating a vehicle. Police officers and road safety advocates may struggle to identify intoxicated drivers due to the inherent limitation of human beings being unable to occupy multiple locations simultaneously. Despite the efforts of law enforcement personnel, every attempt to reduce drinking and driving through individual actions is unsuccessful. Therefore, it is necessary to develop a system that can accurately identify the presence of alcohol in any location and at any given moment.

The World Health Organisation (WHO) has provided statistics on traffic deaths. Based on the obtained statistics, in 2013, low-income and middle-income countries experienced higher death rates per 100,000 inhabitants (24.1% and 18.4% respectively). Additionally, a significant number of economic vehicle drivers in India acknowledged consuming alcohol while on duty. In 2013, a total of 1.25 million vehicle homicides were reported worldwide. This illustrates the prevalence of drunk driving among drivers, particularly those operating large trucks and commercial vehicles.

Later in 2023 WHO provided key facts such as Road traffic crashes claim the lives of almost 1.19 million individuals annually. Motor vehicle accidents are the primary cause of mortality among individuals aged 5-29 years. Ninety-two percent of global road fatalities are concentrated in low- and middle-income nations, despite these countries accounting for only 60% of the world's automobiles. Vulnerable road users, such as walkers, cyclists, and motorcyclists, account for almost 50% of all road traffic fatalities. Most countries incur a loss of 3% of their gross domestic product due to road traffic crashes.

Alcohol impairs the driver's cognition, vigilance, attention, judgement, and reaction, all of which are crucial for their driving abilities. Recent findings indicate that even minimal alcohol use has a substantial impact on driving abilities, specifically impairing crucial skills such as visual perception, braking proficiency, and focus. The car's engine locking mechanism prohibits intoxicated drivers from starting it.

This article presents a comprehensive investigation of different alcohol detection and engine locking systems implemented with Arduino. Section 1 provides introduction, Section 2 provides an overview of various alcohol detection and engine locking systems, Section 3 provides summary on block diagrams of various alcohol detection and engine locking systems, Section 4 provides a comprehensive analysis of boards, sensors, modules, and displays utilized in various alcohol detection and engine locking systems, and Section 5 concludes the article.

II. An Overview of Various Alcohol Detection and Engine Locking Systems

In this section, an overview of various alcohol detection and engine locking systems is discussed.

Bhuta *et al.* [4] proposed an alcohol detection and engine control system. The objective of this system is to enhance the safety of vehicle driving. The implementation is carried by utilising Arduino. In a real-time environment, a system is developed to determine the condition of the driver. The proposal involves using an alcohol detector connected to an Arduino. When the alcohol level exceeds a certain limit, the vehicle's ignition system will be deactivated, and the GPS module will record the vehicle's current location. Additionally, the GSM module will autonomously transmit a danger message to the police or designated family members.

Pranjali *et al.* [5] proposed an alcohol detection system. The objective of system is to enhance the safety of human driving and mitigates accidents. The system is created by combining an alcohol sensor with an Arduino board. The Arduino processor, namely the ATmega328, possesses a greater capacity to execute a wider range of functions compared to traditional microcontrollers. The alcohol sensor utilised in the system is the MQ3 sensor, which is designed to detect the alcohol concentration present in human breath. Due to its precise sensitivity range of around 2 metres, the sensor is compatible with any type of vehicle and may be conveniently concealed from potential suspects.

Gbenga *et al.* [6] proposed an automatic car engine locking system. A prototype of alcohol detection and engine locking system is created by utilising an Arduino UNO connected to an alcohol sensor, an LCD screen, and a DC motor to showcase the idea. The system employs a MQ-3 alcohol sensor to constantly monitor the blood alcohol concentration (BAC) in order to detect the presence of alcohol in a driver's exhaled breath. The device is capable of continuously monitoring the driver's breath alcohol level by positioning the sensor on the steering wheel. If the sensors detect alcohol in the driver's breath, the ignition will not start. If the driver becomes intoxicated while operating the vehicle, the sensor will continue to detect the presence of alcohol in their breath. As a result, the engine will be automatically disabled, preventing any further acceleration of the automobile. This allows the driver to safely park the vehicle on the side of the road.

Shinde *et al.* [7] proposed an engine locking system to address the issue of fatalities and property damage caused by intoxicated driving. The solution utilises an Arduino UNO3 microcontroller connected to an alcohol sensor that detects the presence of alcohol by analysing the breath of a person operating the vehicle. The vehicle's engine is deactivated, and the emergency siren is activated immediately upon detecting alcohol, therefore reducing the likelihood of any potential accidents. Consequently, the prevention of casualties and damage to assets is ensured.

Banerjee *et al.* [8] proposed an automatic engine locking system. The device receives input in the form of breath that contains alcohol. The controller remains in a state of anticipation for the output signal from the alcohol sensor. A stimulating procedure is initiated by utilising a direct current (DC) motor with the assistance of a freewheeling diode. The entire process is closely monitored by an intelligent Atmega 328 microcontroller. Although the traditional approaches have implemented efficient setup requirements, it may be more advantageous to incorporate the whole state-of-the-art design into the system. The majority of conventional systems tend to rely heavily on the operator and are susceptible to failure due to issues such as battery life, power consumption, and external disruptions that cannot be avoided. Drunk driving is a significant cause of accidents in nearly all countries worldwide. If the system detects many instances of alcohol exceeding the predetermined threshold, it will immobilise the engine and activate the buzzer simultaneously, so preventing potential accidents.

Swetha *et al.* [9] proposed an engine locking system. The objective of this system is to detect alcohol using the alcohol sensor MQ3, which is installed in the car. In the event that alcohol is consumed, the sensor will send a signal to the microcontroller, which will then transmit a specific signal to the GSM. The GSM system transmits a message to a specific pre-registered mobile device indicating that the driver is intoxicated. This is accompanied by an audible alert and a red LED indicator, after which the engine will be immobilised.

Shukla *et al.* [10] proposed an automatic engine locking system. It showcases the development and execution of a system that detects alcohol levels in cars and automatically locks the engine. The system uses an Ultrasonic Sensor and an Arduino UNO as the Master Control Unit (MCU). The system consistently monitors the alcohol concentration level in the alcohol detection sensor and subsequently deactivate the vehicle's engine if the alcohol concentration exceeds the predetermined threshold level. The model will transmit the vehicle's location information via SIM900A. The idea offers a highly effective approach for managing and preventing accidents caused by intoxicated driving.

Anthony *et al.* [11] proposed an alcohol detection system. As the number of vehicles on roadways is rapidly increasing, the likelihood of road accidents is also sharply growing. Drunk driving is well recognised as a significant contributor to road accidents worldwide. The primary objective is to create a system capable of detecting the quantity of alcohol drunk by the driver of a vehicle. The proposed system seeks to deter users from operating a vehicle while under the influence of alcohol, with the goal of diminishing the frequency of accidents caused by drunk driving. The proposed system is constructed utilising an Arduino UNO microcontroller and a MQ-3 alcohol detection sensor as its primary components. As a precautionary measure, when the alcohol level exceeds the acceptable threshold, the ignition system of the car (DC Motor) will be deactivated, and the relevant authority will be notified using the GSM module.

Shreyas *et al.* [12] proposed an alcohol detection system. It outlines the design and execution of an Alcohol Detection system with motor locking for motorcycles and cars. The Arduino UNO is chosen as the Master Control Unit (MCU) for this purpose. The device will continuously display the alcohol concentration detected by the alcohol detection sensor and subsequently disable the vehicle's engine if the alcohol concentration exceeds the threshold level. The task provides a sustainable solution to regulate alcohol-induced damage.

Singh *et al.* [13] proposed an alcohol detection and engine locking system. This endeavours to tackle the problem of fatalities and property destruction caused by intoxicated driving. The objective of this system is to showcase the efforts in enhancing the safety of human driving and mitigating the occurrence of accidents. In this system, an Arduino Nano microcontroller equipped with an alcohol sensor is employed to identify alcohol by analysing the breath of the vehicle operator. Upon the detection of alcohol, the vehicle's engine is promptly turned off and a warning siren is activated, thereby minimising the chances of any potential calamities. Consequently, there is no loss of human lives or damage to property.

Kumarasamy *et al.* [14] proposed an alcohol detection and engine locking system. This system utilises the Alcohol Sensor and Arduino-UNO as the controlling unit to create an Alcohol Detection system with Engine Locking for automobiles. An alcohol detection sensor will be employed by the system to continuously monitor the level of alcohol concentration. If the concentration surpasses the predetermined threshold, the engine of the vehicle will be deactivated. This variant utilises the SIM800A and NEO6M GPS modules to transmit the vehicle's position to the registered mobile number via an SMS.

Sandeep *et al.* [15] proposed an alcohol detection and engine locking system as there is a requirement for an alcohol detection system that can operate without limitations in terms of location and time. It showcases the development and execution of a system that detects alcohol levels in cars and automatically locks the engine. The system utilises an Ultrasonic Sensor and Arduino UNO. The technology will consistently monitor the alcohol concentration level in the alcohol detection sensor and subsequently deactivate the vehicle's engine if the concentration exceeds the predetermined threshold level.

Vaishali *et al.* [16] proposed an alcohol detection and engine locking system. The components used in the system include an Arduino UNO microcontroller, a MQ3 sensor for alcohol detection, a resistor for current control, a DC motor, a battery, a transistor, an LED, and a buzzer for output detection. A mini breadboard is also utilized for making the necessary connections and jumper wires to interconnect all the components. If the driver is intoxicated, the MQ3 sensor will identify this and activate the LED, causing it to emit light, while simultaneously triggering the buzzer to produce a sound.

Garg *et al.* [17] proposed an alcohol detection system. The system involves the integration of alcohol concentration detection sensors with a Microcontroller board such as Arduino. The MQ3 module is utilised for the detection of alcohol particles, exhibiting a reasonable sensitivity range of around two metres.

III. A Summary on Block Diagrams of Various Alcohol Detection and Engine Locking Systems

In this section, a summary on block diagrams of various alcohol detection and engine locking systems is studied.

Block diagrams provide a clear and concise overview of a system's architecture, helping to convey information in a more accessible and understandable manner. The summary on various block diagrams facilitates the comparison of different configurations or versions of Arduino UNO setups, enabling a clearer understanding of how changes impact the overall system.

To have an in-depth understanding on the state-of-the-art alcohol detection and engine locking systems, the block diagrams from the different proposed works are tabulated in Table 1. Each of these block diagrams provide a diverse functionality based on the scenarios and case studies considered.

Thus, a comprehensive interpretation of different block diagrams of alcohol detection and engine locking system provides a clear understanding about the usage of various boards, sensors, and other components utilized for making the system effective.

IV. A Comprehensive Analysis of Boards, Sensors, Modules and Displays Utilized in Various Alcohol Detection and Engine Locking Systems

The alcohol detection and engine locking systems are composed of different components. A brief overview of each component is provided in the forthcoming sub-sections.

A. Boards and Motors

In the state-of-the-art research various boards and motors such as Arduino UNO, L2923D Motor Driver Integrated Circuit (IC), DC Motor, LM324 Single Supply Quad Operational Amplifiers, Mini Pump Motor, and Comparator.

1) Arduino UNO: The Arduino Uno is a widely-used microcontroller board belonging to the Arduino family of open-source electronics. It is extensively utilised by enthusiasts, learners, and experts for the purpose of prototyping and fabricating diverse electronic products. The Arduino Uno utilises the ATmega328P microcontroller, which is furnished with digital and analogue input/output pins, diverse communication ports, and other important components.

2) L2923D Motor Driver Integrated Circuit (IC): The L293D motor driver IC is a compact electronic component capable of concurrently driving two motors, commonly employed for motor control in autonomous systems. This motor driver integrated circuit allows for bidirectional control of a DC motor as well as the ability to regulate its speed. It functions as a dual H-bridge motor driver. The H-bridge is a basic circuit used to regulate a motor with a low current rating. A single H-bridge has the ability to control the movement of a DC motor in both forward and reverse directions. L293D is an integrated circuit that amplifies electric current. Additionally, it can function as a switching device.

3) DC Motor: In order to employ a DC motor with an Arduino Uno, it is necessary to build a physical connection between the motor and the board. The operation of the motor can be controlled by utilising the digital output pins of the Arduino, in conjunction with a motor driver or an H-bridge circuit as required.

4) LM324 Single Supply Quad Operational Amplifiers: The LM324 is a quadruple operational amplifier (op-amp) that is extensively utilised in electronic circuits. It is a low-cost, general-purpose operational amplifier that belongs to the LMx24 series. It is manufactured by numerous companies. The presence of the "324" in the part number indicates that the IC package comprises four distinct op-amps.

5) Mini Pump Motor: In order to employ a mini pump motor with Arduino, it is necessary to establish a physical connection between the motor and the Arduino. Then, the motor's operation can be controlled by utilising the digital output pins of the Arduino.

6) Comparator: A comparator can be employed to compare the output voltage from an alcohol sensor with a pre-established threshold. The purpose of this system is to inhibit the ignition or operation of a vehicle when the concentration of alcohol in the driver's breath beyond a specific threshold. This system is designed to enhance safety and mitigate the likelihood of events related to driving under the influence of alcohol.

B. Sensors

Sensors such as IR Sensor, MQ-3 Sensor, and BAC Sensor are used in various state-of-the art works.

1) IR Sensor: The process of incorporating an Infrared (IR) Sensor into an alcohol detection and engine locking system entails integrating the sensor to identify the existence of alcohol vapour and integrating it into a control system that regulates the engine locking mechanism according to the concentration of alcohol.

2) MQ-3 Sensor: The MQ-3 sensor is a gas sensor frequently employed for the detection of alcohol vapour, rendering it well-suited for applications such as alcohol detection systems. The process of incorporating it into an engine locking system entail establishing a connection between the sensor and a microcontroller, analysing the data obtained from the sensor, and regulating the engine immobilisation mechanism in accordance with the concentration of alcohol detected.

3) BAC Sensor: A sensor designed specifically for measuring Blood Alcohol Concentration.

C. Modules

Modules such as GSM, GPS, Relay, and Transistor are used for various purposes in the system.

1) GSM: By incorporating a GSM (Global System for Mobile Communications) module into an alcohol detection and engine locking system, it becomes possible to enable remote communication and monitoring functionalities. This functionality can be highly advantageous for transmitting notifications or warnings to specified individuals when the level of alcohol concentration above a predetermined limit or when the engine immobilisation systemis engaged.

2) GPS: Incorporating a GPS module into an alcohol detection and engine locking system offers location-based data and can improve the system's capabilities. It can be advantageous for monitoring the precise location of the vehicle, recording occurrences, and incorporating other functionalities.

3) Relay: The relay module functions as a controllable switch, operated by a low-power microcontroller, to regulate the high-power components responsible for the activation or deactivation of the vehicle's engine.

4) Transistor: A transistor is a semiconductor device with the ability to function as an amplifier, a switch, or in diverse electronic circuits. It is also used based on the requirement.

D. Displays

Displays such as LED, LCD, and Buzzer are used for indicating the status for the end user.

Table 2 shows the boards and motors used in the various alcohol detection and engine locking systems.

Table 3 shows the sensors used in various alcohol detection and engine locking systems. Table 4 shows the modules used in various alcohol detection and engine locking systems. Table 5 shows the displays used in various alcohol detection and engine locking systems. From all those tables it can be observed that different types of components are used in varied alcohol detection and engine locking systems.

V. CONCLUSION

Drunken driving significantly aids in accidents; hence it is imperative that every vehicle be equipped with an automatic engine locking system to prevent intoxicated drivers from operating the vehicle. To have a significant impact on the current situation, it is imperative that the implementation of this technology is prioritized in both traditional internal combustion engine vehicles and electric vehicles. There have been several research carried out in this area for over a decade. Many prototypes are developed alcohol detection and engine locking systems. In this article a comprehensive study is carried out on those systems. The block diagrams, components used, and other functionalities are analyzed and summarized. Through study the insights of alcohol detection and engine locking systems are gained.

***Abstract*—**

Autism Spectrum Disorder (ASD) is a complex condition characterized by a wide range of symptoms and challenges. Children with autism often experience difficulties in social interaction, and communication, and may exhibit repetitive behaviors. Many also struggle with understanding emotions and recognizing shapes, which can impact their daily lives and learning experiences. To address these challenges and enhance their skills, a novel toy has been developed based on a microcontroller system. This innovative toy utilizes the ATmega328P microcontroller, a popular open-source platform known for its versatility and accessibility. The toy is programmed using C language within the Arduino Integrated Development Environment (IDE), providing a user-friendly and customizable platform for development. The toy offers a variety of interactive tasks and activities designed to engage and stimulate children with autism. For example, it can generate arithmetic problems for the child to solve, helping to improve their mathematical skills and cognitive abilities. Additionally, the toy includes features that allow children to identify geometric shapes, supporting their learning. By providing a structured and predictable environment, the toy helps alleviate anxiety and sensory overload often experienced by children with autism. The interactive nature of the toy encourages social interaction and communication, promoting meaningful connections with peers and caregivers.

***Keywords*— Microcontroller, Atmel Corporation Mega AVR (ATMEGA328P), Autistic, Spectrum, Arduino Integrated Development Environment (IDE), Repetitive, Geometry**

I. INTRODUCTION

Autism spectrum disorder (ASD) is a complex neurodevelopmental condition characterized by challenges in social interaction, communication, and repetitive behaviors. It manifests differently in each individual, ranging from mild to severe symptoms [1]. Typically diagnosed in early childhood, signs may include delayed speech or language skills, difficulty with social cues, repetitive movements or behaviors, and intense focus on specific interests. The diagnostic process often involves a multidisciplinary approach, with healthcare professionals such as pediatricians, child psychologists, and developmental specialists working together [2]. Parents and caregivers play a crucial role, providing valuable insights into the child's behavior and development. While there's currently no cure for autism, various interventions and therapies aim to improve quality of life and help individuals reach their full potential [3]. Behavioral therapy, including Applied Behavior Analysis (ABA), helps individuals learn and apply positive behaviors and social skills. Speech therapy assists in developing communication skills, while occupational therapy addresses sensory sensitivities and enhances daily living skills [4]. Education and support services are also vital components of autism management. Specialized educational programs tailored to individual needs provide structure and support, fostering academic and social development [5]. Additionally, support groups offer guidance and connections for families navigating the challenges of autism. Innovative approaches such as sensory integration therapy and the use of sensory toys and tools can further enhance individuals' sensory experiences, promoting relaxation, focus, and self-regulation [6]. These tools, ranging from textured objects to weighted blankets, provide comfort and support in managing sensory sensitivities. Overall, the goal of interventions and support strategies is to empower individuals with autism to thrive and lead fulfilling lives [7]. Understanding child development is crucial for effectively monitoring progress and identifying potential delays or abnormalities, especially in the case of autism, a leading cause of disability among mental disorders in children. Autism Spectrum Disorders (ASD) encompass a wide range of symptoms and severity levels, characterized by qualitative impairments in social functioning and communication, often accompanied by repetitive behavioral patterns [8]. Social interaction difficulties are a hallmark of autism, the affected children struggling to express emotions verbally and navigate social situations. Consequently, their communication skills may be significantly impaired. It is imperative to provide a support to autistic children so that the children can understand socially acceptable behaviors across various contexts [9]. To address the unique needs of children with autism, specially designed toys play a vital role. These toys are crafted to facilitate sensory stimulation, promote social interaction, and encourage communication development. Sensory toys, for instance, provide tactile, auditory, or visual feedback, aiding in sensory integration and regulation. Interactive toys encourage engagement and communication through structured play activities, fostering social skills and emotional expression [10]. Moreover, these toys can be used in therapeutic settings, complementing interventions such as behavioral therapy and speech therapy. By incorporating play-based learning into treatment plans, children with autism can enhance their skills in a supportive and enjoyable environment.

II. LITERATURE REVIEW

1.	The study investigates children's perceptions of manipulatives as toys or math tools and their influence on learning. A mixed-methods approach involving interviews and behavioral tasks was employed.	Children's perceptions of manipulatives impact their learning outcomes; when seen as math tools, manipulatives enhance learning. Findings highlight the importance of considering children's perspectives in designing effective educational interventions.	While the study provides insights into children's perceptions of manipulatives, a research gap might involve exploring the implications of such perceptions across diverse age groups, educational settings, and subjects beyond mathematics, as well as potential strategies to enhance children's positive attitudes towards manipulatives as learning tools.
2.	The study explores make-believe play with the Internet of Toys through a qualitative case study approach. Multimodal playscapes are investigated to understand their role in enhancing children's play experiences with IoT toys.	The research emphasizes the potential of multimodal playscapes in fostering imaginative play using Internet of Things (IoT) toys. Findings highlight the importance of providing diverse and engaging environments for children's play activities with IoT-enhanced toys.	While the study contributes insights into the role of multimodal playscapes and IoT toys in children's imaginative play, a potential research gap could involve further investigation into the long-term effects on children's creativity, cognitive development, and the implications for designing interactive and educational play environments.
3.	The study utilized a design-based research method involving several iterative phases. It started with a needs analysis to determine attributes for effective concept development in children. A smart toy prototype (Maya) was designed, developed, and refined based on preschool teachers' interviews and feedback, leading to the creation of an interactive smart toy using artificial intelligence technology.	The paper introduces the development of a smart toy utilizing artificial intelligence technology, catering to preschool children's interaction and engagement needs.	While the details are limited, a potential research gap might involve further exploration of the toy's effectiveness, usability, and potential impacts on early childhood education and development, as well as considerations of privacy and ethical concerns associated with AI-based toys for young children.
4.	The study employs a mixed-methods approach, combining qualitative interviews with stakeholders	The findings suggest significant concerns about the implications of emotional AI in children's	While the study effectively analyzes stakeholder and parental perspectives on emotional

	and a demographically representative UK national survey. Interviews explore professional perspectives on emotional AI in children's toys, while the survey gathers parental views on networked toys utilizing emotional data. The research investigates the social acceptability and governance aspects of emotional AI in child-oriented devices.	toys and devices, including issues related to data privacy, manipulation, media literacy, and fairness. The study underscores the need for improved governance and regulation to address potential ethical and societal challenges arising from the use of emotional AI technology in the context of children's play.	AI in children's toys, a potential research gap could involve exploring potential technological solutions or strategies to mitigate the identified concerns, as well as investigating the long-term societal impacts and potential benefits of integrating emotional AI in child-oriented technologies.
5.	The study utilized a cross-lagged panel analysis to investigate developmental associations between joint engagement variables (higher order supported joint engagement and higher order supported joint engagement + follow-in) and expressive and receptive vocabulary in young autistic children (n = 91) with language delay, measured twice over 8 months. Structural equation models were employed to derive coefficients for cross-lagged variable pairs.	The findings indicate that early higher-order supported joint engagement and higher-order supported joint engagement + follow-in are significantly associated with later expressive and receptive vocabulary. However, early vocabulary did not significantly predict later joint engagement. This suggests that these specific forms of joint engagement could be valuable targets for early intervention strategies aimed at enhancing language development in initially language-delayed autistic children.	While the study provides insights into the associations between joint engagement and vocabulary development in autistic children, a potential research gap could involve further exploration of the underlying mechanisms that drive these associations. Additionally, future research could investigate the long-term effects of targeted interventions focused on enhancing joint engagement in children with language delays, potentially bridging the gap between research findings and effective clinical practices.
6.	The study employs a Design Science framework and a Human-Centered Design (HCD) perspective to develop and assess a collection of design tools for creating Toy User Interfaces (ToyUIs). The tools encompass various stages, from user research to prototyping, and are evaluated through qualitative assessment involving 255 creators in an educational setting over six years.	The paper presents a comprehensive approach to ToyUI design by offering interdisciplinary creators a range of tools that facilitate the integration of physical toy components with technology, such as social robots and computing devices. The emphasis on Human-Centered Design and privacy considerations underscores the intent to produce innovative and user-centric solutions.	While the paper contributes valuable design tools for ToyUI development and highlights their applicability in educational contexts, a potential research gap could lie in the exploration of broader real-world implementation and scalability of these tools, considering factors beyond educational settings, and addressing potential challenges arising from evolving technology trends and user needs.
7.	The article employs a qualitative approach, drawing on a literature review and expert analysis from the gifted education field. It identifies and categorizes diverse enrichment pedagogical strategies, such as interest-based learning,	The article underscores that leveraging enrichment pedagogy, rooted in the gifted education domain, offers a compelling strategy to motivate student learning. It highlights a range of engaging instructional	While the article celebrates the contributions of enrichment pedagogy to education, a potential research gap could lie in the need for more comprehensive studies exploring the widespread implementation and impact of these

	differentiation, and project-based learning. Practical examples are provided for implementation in classrooms, and a review of longitudinal research supports positive student outcomes.	methods applicable to diverse students, promoting deeper engagement and learning. Longitudinal research findings suggest that exposure to these methods correlates with favorable student outcomes over time.	strategies across various educational contexts, especially beyond academically talented students, to address equitable and effective application.
8.	The study utilized Vygotsky's mediation theory and a design-based research approach to investigate the use of AI-interfaced robotic toys in early childhood settings. Teachers engaged 4-5-year-old children in play experiences, analyzing data from interviews, observations, and artifact analysis to uncover how children creatively collaborated, fostering inquiry literacies such as creative, emotional, and collaborative inquiry.	The findings revealed that incorporating AI-interfaced robotic toys in early childhood education promoted inquiry literacies. Children collaboratively constructed a sustainable city for a robot and its family, demonstrating creative, emotional, and collaborative inquiry skills during play, thus substantiating the potential of AI technology to enhance children's learning experiences.	This study bridges a research gap by exploring the integration of AI toys and physical environments in early childhood education. It highlights the development of children's inquiry literacies through AI-enhanced play, emphasizing the need to train educators to leverage AI-interfaced robotic toys in fostering children's inquiry literacy development.
9.	The study utilized data from the Autism and Developmental Disabilities Monitoring (ADDM) Network, focusing on 11 U.S. communities. It analyzed 2016 data to estimate the prevalence of autism among 8-year-old children, comparing it to the previous estimate from 2014. The study also explored age-related trends in autism identification and evaluated potential factors contributing to the observed increase in prevalence.	The study's findings suggest an elevated prevalence of autism among 8-year-olds, with a rate of 1 in 54, higher than the previously estimated 1 in 59. Additionally, the observed increase in prevalence might be attributed to improved identification, diagnosis, and service provision within communities, potentially indicating enhanced awareness and accessibility of services for children with autism. The study also highlights a noteworthy reduction in racial disparities in autism identification, evidenced by similar rates among black and white 8-year-olds.	The study's potential research gap lies in the need for further investigation into the underlying factors contributing to the increase in autism prevalence, including a more comprehensive understanding of changes in diagnostic practices and healthcare access. Additionally, future research could delve into the long-term impact of early evaluation and intervention on the developmental trajectories and outcomes of children identified with autism at younger ages. Lastly, exploring variations in prevalence and identification across diverse geographic and demographic contexts could provide a more comprehensive understanding of autism's complex epidemiology.
10	The paper likely employs an interdisciplinary approach, integrating insights from design engineering,	The paper suggests that design engineering can significantly enhance the well-being of individuals	Potential limitations include challenges in universal applicability due to varying autism profiles,

	neuroscience, medicine, and psychology. It involves literature review, needs assessment, concept development, prototyping, testing, and iterative refinement to create a multifunctional smart toy for individuals with autism spectrum disorder.	with autism by developing innovative products that facilitate social interactions and support cognitive, motor, and sensory skills, addressing a gap in specialized smart products for this population.	ethical considerations in designing for vulnerable populations, and potential resource constraints in producing and implementing specialized smart toys.

III. PROPOSED WORK

The proposed toy, "Why This Face," presents an innovative approach to aiding the understanding of emotions among autistic children, integrating shape recognition and arithmetic tasks within an engaging framework. With an emphasis on visual and tactile stimuli, this toy aims to facilitate comprehension of various emotional states, such as happiness, sadness, anger, and surprise, through the exploration of corresponding facial expressions. By pressing an emoji pushbutton, children initiate the journey of deciphering the reasons behind different emotional displays [21].

Structured into two levels, the toy challenges children to recognize shapes and solve single-digit arithmetic operations, providing a multi-dimensional learning experience. The incorporation of a start button activates the toy's functionalities, initiating a dynamic interaction that captivates and educates. Featuring six buttons, the toy offers a blend of shape and emotion representations, fostering cognitive development and sensory exploration. Through an LCD, children receive guidance and feedback, enhancing their understanding of the game's objectives and commands [22]. While play is crucial for children's development, the response of autistic children varies, highlighting the importance of adaptable design and individualized engagement strategies. The "Why This Face" toy is designed to appeal to autistic children through its vibrant colors, diverse shapes, tactile push-button interface, and emotive emoji representations. However, recognizing the diverse needs and preferences within the autism spectrum, the toy's effectiveness may vary, necessitating parental or teacher support for optimal engagement [23]. The integration of educational elements within an interactive and visually stimulating toy offers a promising avenue for promoting emotional understanding and cognitive skills among autistic children. By leveraging technology and sensory-rich experiences, the "Why This Face" toy seeks to empower children with autism to navigate and comprehend the complexities of human emotions, fostering growth, and social integration.

The Emotion and Shape Recognition Toy Algorithm is designed to engage users in a series of interactive tasks aimed at enhancing their emotional understanding, shape recognition skills, and arithmetic abilities [24].

The algorithm begins by initializing lists for emotions, shapes, and arithmetic answers. These lists serve as the basis for the tasks presented to the user. Upon receiving input from the user, which triggers a start signal, the algorithm presents shapes along with corresponding emotions. The user is prompted to match the shapes with their associated emotions, fostering cognitive development and emotional recognition. After completing the emotion and shape-matching task, the algorithm asks the user to provide arithmetic input. The user is required to solve arithmetic problems, and the algorithm verifies the correctness of their answers. This task aims to improve the user's mathematical skills and problem-solving abilities. Following the arithmetic task, the algorithm prompts the user to identify shapes independently. The user's input is evaluated, and feedback is provided based on the correctness of their responses. This task reinforces shape recognition skills and encourages independent thinking. Upon completion of the game, the algorithm displays an output message congratulating the user. This message serves as positive reinforcement and indicates the successful completion of the interactive tasks [25].

Algorithm.1 Emotion and Shape Recognition Toy Algorithm

1. Initialize emotion_list = ["happy", "sad", "angry", "surprised"]
2. Initialize shape_list = ["circle", "square", "triangle"]
3. Initialize answer_list = [4, 9, 7]
4. Display "Welcome to Why This Face!"
5. Wait for start button press
6. For each shape and emotion in shape_list and emotion_list:
7. Display shape and corresponding emotion
8. Wait for button press
9. If the button press matches the shape, display "Correct"
10. Else, display "Incorrect"
11. Display "Let's solve some arithmetic!"
12. For each arithmetic operation in answer_list:
13. Display arithmetic operation
14. Wait for user input
15. If the user input matches the correct answer, display "Correct" Else, display "Incorrect"
16. Display "Now, identify the shapes!"
17. For each shape in shape_list:
18. Display shape
19. Wait for a button to press
20. If the button press matches the shape, display "Correct"
21. Else, display "Incorrect"
22. Display "Congratulations! Game over."

IV. MODEL DEVELOPMENT AND DISCUSSION

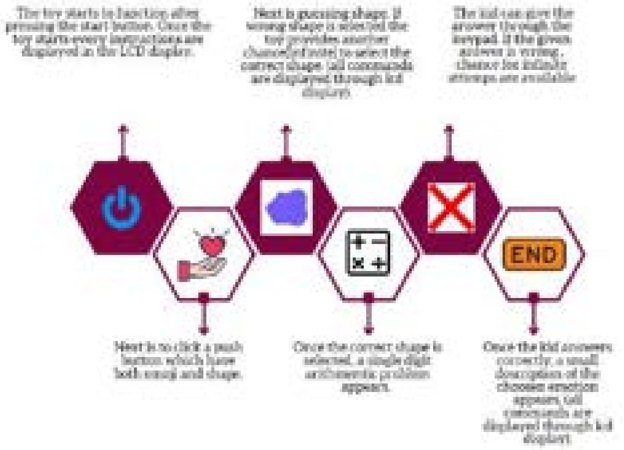

Fig 1: Process Flow chart.

The Process of playing with the micro-controller toy for an autistic kid. This flow chart helps to understand the rules of the game quickly.

In the implementation phase of the project, the focus shifted towards creating a tangible and functional prototype of the "Why This Face" toy, catering to the specific needs of autistic children. The hardware setup involved the assembly of components without the need for a constant connection to a computer, emphasizing portability and ease of use. Utilizing a battery power source, the Arduino ATmega328P microcontroller, LCD, and push buttons were integrated into a compact and durable enclosure. The Arduino code was meticulously crafted to orchestrate the interactive experience envisioned for the toy. The programming logic revolved around initiating the game upon pressing the start button, and guiding users through various tasks to enhance emotional understanding and cognitive skills. Functions were implemented to detect button presses, display messages and prompts on the LCD screen, and evaluate user responses in real time. The game flow was designed to engage users in a series of challenges, starting with the identification of shapes and corresponding emotions. Users were prompted to match shapes with their associated emotions using the push buttons, fostering cognitive development and emotional recognition. Subsequently, arithmetic operations were presented, requiring users to solve them by inputting their answers through the push buttons. Finally, users were tasked with identifying shapes independently, further reinforcing their cognitive abilities. Thorough testing and debugging were conducted to ensure the seamless operation of the toy. Each component was rigorously evaluated to verify proper functionality and responsiveness. Any issues or errors encountered during testing were promptly addressed through iterative refinement of the Arduino code and hardware configuration. Upon successful integration and finalization of the prototype, the "Why This Face" toy was ready for deployment and usage in environments catering to autistic children. Its portable and self-contained design made it easily accessible for use in homes, schools, and therapy sessions. The "Why This Face" toy represents a significant advancement in interactive toys for autistic children, offering a unique blend of educational and therapeutic benefits. One of the key advantages of the toy lies in its ability to seamlessly integrate emotional understanding with cognitive skill development. By using shapes as a medium to convey emotions, the toy engages children in a meaningful and relatable way, fostering a deeper understanding of their own and others' emotions. This innovative approach not only enhances emotional intelligence but also provides a platform for practicing social skills in a safe and controlled environment. Another aspect of the toy is its emphasis on independent learning and problem-solving. By presenting arithmetic operations and shape recognition tasks, the toy encourages children to think critically and solve problems on their own. This promotes a sense of autonomy and self-confidence, which are essential for academic and personal growth. Additionally, the toy's interactive nature keeps children engaged and motivated, creating a positive learning experience that is both enjoyable and effective. The "Why This Face" toy stands out for its versatility and adaptability. The modular design allows for easy customization, enabling caregivers and educators to tailor the toy to suit the specific needs and abilities of each child. This adaptability ensures that the toy remains engaging and challenging, providing long-term benefits for children with autism. Overall, the "Why This Face" toy represents a groundbreaking approach to interactive play for autistic children, offering a range of benefits that promote emotional, cognitive, and social development. Its innovative design and engaging gameplay make it a valuable tool for therapy, education, and recreation, setting a new standard for interactive toys in the field of autism care.

Figure 2 Implementation of toy

Fig.2 Describes the overall circuit implementation. It includes hardware components like Arduino UNO, LCD, Pushbuttons, Keypad, and connecting wires.

Figure 3 Starting command

The command "Let's start selecting an emoji" is designed to attract autistic children to play by engaging them with simple and clear instructions. The use of the word "emoji" taps into the visual appeal and familiarity of these symbols, which are often colorful and expressive. The phrase "Let's start" is encouraging and sets a positive tone, inviting the child to begin a fun activity. By keeping the command short and direct, it is easier for autistic children to understand and follow, helping them feel more confident and motivated to participate.

Figure 4 Guessing the emotion

The command "Guess the shape of the emoji" is designed to engage and encourage interaction from autistic kids. By prompting them to select the correct shape in the emoji section, the game taps into their visual and cognitive skills, providing a fun and interactive way to learn. The colorful emojis and the challenge of identifying shapes can captivate their attention, fostering engagement and learning. Additionally, the game's positive reinforcement and rewards for correct answers can boost their confidence and motivation to continue playing, creating a rewarding experience that encourages repeated engagement.

Figure 4 Implementation of arithmetic operation

After completing each arithmetic operation, the game provides a detailed result screen. This screen congratulates the player on their attempt and displays the correct answer for the operation. It also offers encouragement to keep playing and improve their skills.

V. CONCLUSION

In today's technological era, children are increasingly drawn to intelligent frameworks, signaling a growing interest in utilizing such tools. In line with this trend, a microcontroller-based toy has been developed. Studies have demonstrated the efficacy of this toy in enhancing the understanding of facial expressions, object shapes, and mathematical skills among children with varying degrees of autism spectrum disorder (ASD). Understanding facial expressions enables ASD children to perceive human emotions intuitively, contributing to improved social interactions. Moreover, focusing on mathematical tasks capitalizes on the strengths of some autistic children in this area, potentially leading to the mastery of complex problem-solving. The "Why This Face" toy is designed to cater to the specific needs of autistic children. It offers a unique blend of educational and therapeutic benefits, making it a valuable tool for therapy, education, and recreation. One of the key novelties of the toy lies in its ability to seamlessly integrate emotional understanding with cognitive skill development. By using shapes as a medium to convey emotions, the toy engages children in a meaningful and relatable way, fostering a deeper understanding of their own and others' emotions. Moreover, the toy's emphasis on independent learning and problem-solving sets it apart. By presenting arithmetic operations and shape recognition tasks, the toy encourages children to think critically and solve problems on their own. This promotes a sense of autonomy and self-confidence, which are essential for academic and personal growth.

VI. FUTURE SCOPE

To enhance user experience, two technical modifications are suggested. Firstly, increasing the number of push buttons would add diversity and excitement to the gameplay. Secondly, incorporating a variety of arithmetic questions instead of repetitive ones would prevent monotony and sustain engagement. Despite their challenges, autistic children often display remarkable talents, and the "WHY THIS FACE" toy aims to nurture these abilities for a brighter future. It caters to individuals capable of comprehending commands displayed on the LCD screen, making it accessible to a wide range of users. In today's modern era, voice assistants have seamlessly integrated into the lives of individuals across the globe. However, for autistic children who struggle with reading, conventional interactive toys may pose challenges. To address this issue, integrating voice assistant functionality into the designed toy could offer substantial benefits to a wide range of autistic children, transcending the limitations posed by traditional input methods. Presently, the toy employs a keypad as its primary input unit, limiting its interactive potential. By incorporating a microphone as an alternative input mechanism, the toy could transform into an interactive tool, facilitating improved communication skills for autistic children. The microcontroller-based toy, featuring an LCD, serves as a valuable educational tool for autistic children, facilitating learning experiences centered around emotions, shapes, and mathematical concepts. Looking ahead, the project's future endeavors involve replacing the LCD with a microphone, thereby enhancing the toy's functionality and addressing specific challenges faced by autistic individuals. Many autistic children exhibit monotone speech patterns, making it challenging for them to express emotions vocally or modulate their voices appropriately. By leveraging a microphone within the toy, post-game feedback can be delivered in various tones corresponding to the emotions chosen during gameplay. This innovative approach aims to foster greater vocal variation and communication skills among autistic children, ultimately promoting their social and emotional development.

Abstract*— In the current computer era, many computer technologies have been developed such as Artificial Intelligence, the Internet of Things, Machine Learning, Data Science, and so on. Mainly IoT contributes to improving accessibility and connectedness in this system, which makes the system more adaptable and user-friendly. These technologies are also developed to be used by physically disabled people throughout the world. This system has leveraged a way for disabled people to use the computer easily, by a method called Eye-Gaze. Eye-Gaze is an alternative approach that lets the user interact with the computer with only their eye movements, who do not have access to the mouse. This system uses a webcam to improve the accuracy, mobility, and utility of the eye-tracking technology. In short, this system offers an up-front and convenient interaction mode that uses only eyeballs, which is crucial for those with physical disabilities. It is implemented to overcome the accuracy, reliability, and calibration issues that already exist in the system. The proposed system outlines the implementation of the cursor control and the system is set up in a way that perfectly mimics the everyday routine of the people.

***Keywords*— Computer-Era, Artificial Intelligence, Internet of Things, Machine Learning, Eye-gaze Cursor Control.**

I. INTRODUCTION

The importance of human-computer interactions cannot be overstated in the fast-paced world of computer technology. Human-computer interaction plays an important role in the development of the information society. Human-computer interfaces (HCI) focus on the utilization of computer technology to develop effective interfaces. Finding the right technology is essential for smooth human-computer interactions, which in turn are essential for the continuous growth of the information society. It is crucial to guarantee inclusivity in the information society, especially for those with physical impairments. It is imperative to advance alternate techniques of human-computer communication, to give them equal possibilities. Researchers' interest in human-computer interaction (HCI) has grown recently on a global level, showing the significance of coming up with novel solutions, where eyeball movements, face recognition, and hand gestures are common means of communication. [1] In this interaction, hand gesture recognition is essential for device control. Certain research aims to enhance the user experience by providing natural and immersive computing environments through the utilization of hand gestures for intuitive and effective interactions. [2] It imitates mouse control by tracking finger movements, using Mediapipe and openCV2, the goal is to improve computer interaction at a reasonable cost. [3]

The use of vision-based eye movement detection systems in Human-Computer Interfaces is an important example. Eye gazing is a crucial hands-free display control technique that is integrated into HCI. [4] It uses Python's image processing and machine learning capabilities to track the movements of the user's eyes. [5] People with disabilities can operate with support, overcoming obstacles they might encounter when using a standard computer, With the help of this eye control technology. The need for efficient human-computer interaction is growing as computer technology develops. Yet, people with disabilities still encounter difficulties when using computers. Users can collaborate by using this eye control technology, which is integrated into computers. The main objective of a human-computer interface is, to create user-friendly interfaces with computer technology. The significance of human-computer contact is imperative to support. This advances their status in the Information Society and advances the larger objective of developing a range of technological innovations that are both approachable and diverse. Recently, there has been a lot of application of vision-based eye movement detection systems for people with disabilities. This system is done by, proving that eye movements may be used to control the cursor. An integrated hands-free human-computer interaction system has taken the place of traditional input devices. Those with specific diseases or disabilities that make it difficult for them to operate a traditional computer would especially benefit from this situation. The use of a physical computer component to operate the cursor satisfies the requirements of those with physical impairments. Modern technology uses Open CV to interpret eye movements in place of conventional mouse actions like clicks and movements. Facial expressions like eye blinking, mouth opening, and head movements are used to activate mouse clicks. This model presents a webcam mouse that uses 3D model-based biased face-tracking technology. The computer technique known as facial recognition is used widely in different fields to identify faces in digital images. The suggested approach makes use of a basic face-tracking system to identify facial features. This makes it possible to analyze facial gestures without the requirement for the user to interact directly. The human face provides crucial information for applications like emotion recognition and human-computer interface. It is possible to accomplish feature extraction with the Local Binary Pattern algorithm. Most of the eye movements are classified using a support vector machine (SVM) classifier. The movements of the eyes to the left, right, and open are all captured by a web camera. SVM performs data analysis and works well for regression analysis as well as classification.

II. LITERATURE REVIEW

An EOG-based HCI system that uses real-time processing for mouse cursor control after EOG signals are acquired, amplified, and digitized. This allows users to control a computer interface with their eye movements. [6] The system combines computer vision algorithms, Raspberry Pi, and IP camera technologies to accurately detect eye movements and provide precise control over the computer cursor based on the direction of the user's eyeball movement. [7] The system uses OpenCV and a Raspberry Pi to detect pupils, which allows for accurate control over cursor movement by creating a direct link between the cursor's movement and the pupil's center. Firstly, the application program for pupil detection is executed, and then the SD card is loaded into the Raspberry Pi. [8]A specific human-computer interaction system that depends on various input devices to receive user input. The movement of the computer cursor is technically connected to the center of the pupil. An electronic device governs the cursor's movement. [9] It is a method of dividing the screen into multiple tiny rectangular regions to increase the precision and stability of eye-controlled cursor movement. Upon entering any of these places, the cursor's position is locked in the middle of the area. This method pursues to reduce the cursor's slight shaking that results from the pupil's natural swaying within a limited range. [10] The most recent developments in 3D visualization techniques and instruments for studying eye movement data in virtual spaces. Especially in light of the accessibility of non-intrusive eye-tracking devices that are often combined with head-mounted displays. [11] The usability of eye-tracking in human-computer communication, mainly for those with physical impairments, the study presents an eye control system. This device combines keyboard and mouse functionality into one whole interface that responds only to the user's eye motions. Accuracy is guaranteed by a magnification module, and the design adapts to human behavior. [12] This work overcomes restrictions on gaze detection accuracy and presents a unique gaze-based virtual keyboard with portable eye trackers. The virtual keyboard provides instant access to every letter with a single command. Moreover, it is suggested that severely disabled people can get around the Midas touch problem by using a USB mouth switch attached to a computer mouse. [13] A HCI system is introduced, which is useful for people with limited mobility. It replaces conventional mouse controls with eyeball movements. It does this without the need for additional hardware by using OpenCV and NumPy, and simple webcam technology. The main component of the system is a face detector that combines a linear classifier and HOG to provide accessibility without requiring direct human engagement. [14]

A decision tree algorithm guarantees accurate eye location detection for accurate mouse movement. The system provides a user-friendly interface that is accessible to individuals with motor impairments. They enable smooth computer interaction through natural eye and facial movements and gestures. [15] The study found that, for old people, the eye-gaze input system which uses eye-tracking technology produced faster pointing times than traditional mouse input. [16] This study aims to improve VR usability by combining bio-sensors such as EEG and eye tracking. It is discovered that hand-tracking works well for teleport triggering and eye-tracking works well for location targeting. [17] In UX research, eye tracking and mouse tracking provide useful data. Both eye trackers performed similarly in a study that used a menu navigation task. By combining these techniques, insights can be obtained at a low cost. [18] The users can integrate eye tracking with virtual reality (VR). It describes immersive vs non-immersive VR and emphasizes the advantages of IVR, particularly when combined with eye tracking. It analyses recent research and makes references for future research to enhance the use of these technologies in education. [19]

The eye-tracking interactions are assessed with a Meta Quest 2 VR headset in this study. In terms of, unmodified eye tracking performed similarly to controller input and outperformed head tracking. Eye tracking was rated positively by each user in terms of adoption and usability, representing that it may improve AR/VR interactions. [20] A method for examining mental representation patterns is eye-tracking technology, especially when it is used for tasks like mental rotation. It requires the user to mentally rotate three-dimensional objects to gauge visuospatial ability. Though visual neuroscience has traditionally used 2D images on computer screens, recent trends have responses to naturalistic stimuli. On the other hand, there is a lack of research on mental rotation tasks in immersive VR with 3D objects. [21] The research presents an eye-tracking controlled mouse cursor that allows to use of computers independently without the need for a conventional mouse, for people with physical impairments. It is ergonomic, lightweight, and works with most operating systems. It improves life quality and productivity. It is a big step toward increased independence for people with disabilities. [22]

Three experiments using mouse cursor-tracking investigated predictive sentence processing speed. Participants heard predictive or non-predictive sentences while viewing visual arrays and moved the cursor accordingly before hearing the nouns. This effect continued across different speech rates. [23] A transparent and adaptable electrostatic sensing interface for active eye tracking (AET) systems is suggested in this system. This interface improves charge storage capacity and permits real-time interpreting of eye movements for a variety of applications such as virtual reality, medical monitoring, and eye-controlled HCI, with an angular resolution of 5°. [24] People with physical impairments encounter difficulties when using computers, and it suggests using facial gesture recognition in place of human-computer interaction (HCI). This strategy could take the place of conventional HCI tools. The study describes the procedures used to carry out, the experiments that validate this idea. [25]

III. PROPOSED METHODOLOGY

The system manages contactless human-computer interfaces by employing face tracking, eye detection, and interpreting blinking in real time [26]. The conventional method of computer interaction via a mouse is replaced by leveraging human eyeball movements. There are some software and hardware used in this system. The software used is python3, and there are some libraries included in it, they are CV2, Mediapipe, and PyautoGUI. The hardware used in this system is Raspberry Pi, LCD, and webcam. Using these software and hardware a convenient system is created mainly for the physically disabled people to use [27].

A. Software

The software that is used in this system is Python3. Python is a programming language frequently employed for constructing websites and software, automating tasks, and analyzing data. Python has resources, guides, and community support, so working in Python is easier compared to other programming languages. The libraries that have been included are:

1) CV2
2) MediaPipe
3) PyAutoGUI

a. CV2

CV2 stands among the frequently employed libraries for handling image and video processing tasks. Its central module, referred to as cv2, provides developers with an accessible interface to seamlessly engage with a variety of image and video processing functionalities. Since Integration with Other Libraries is easier CV2 is used as one of the libraries.

b. MediaPipe

A flexible pipeline framework called Mediapipe was created to create customized machine-learning solutions for streaming and real-time media. It is an open-source tool that is used to build pipelines that perform computer vision inference on different types of sensory data, such as audio and video. Using Mediapipe, users can create a modular graph representation of a perception pipeline, adding or removing components as needed. Since High-Level API can be created and ready-to-use Models are present media pipe is used.

c. PyAutoGUI

PyAutoGUI is a toolkit that enables users to develop scripts capable of emulating mouse movements, object clicks, text transmission, and the activation of hotkeys. It proves useful for navigating through systems that restrict automated browser usage. Since there is no need for External Dependencies and cross-platform Compatibility is supported pyautoGUI is used.

B. Hardware

a. Webcam

A webcam is a regular video camera that can record videos and take still images when it is connected to a computer. Frequently, it is utilized for video conferences via Zoom, Google Meet, and other similar apps. In this system, the webcam is utilized to identify the eyeball so that it can make the mouse cursor move as per the movement of the eyeball. In Figure 3, a USB Webcam is given.

Figure 3. Webcam

b. Raspberry Pi

The Raspberry Pi is a compact, cost-effective, designed to connect to a computer desktop or TV using standard peripherals like a mouse and keyboard. It possesses dedicated components, including a processor, memory, and graphics driver, akin to a traditional PC. Additionally, it is equipped with its operating system, Raspberry PiOS, which is a modified version of Linux. The primary purpose of the Raspberry Pi is to serve as a low-cost, low-power device with various applications. The Raspberry Pi is to design an Operating System. In Figure 4, Raspberry Pi Model 4B is given.

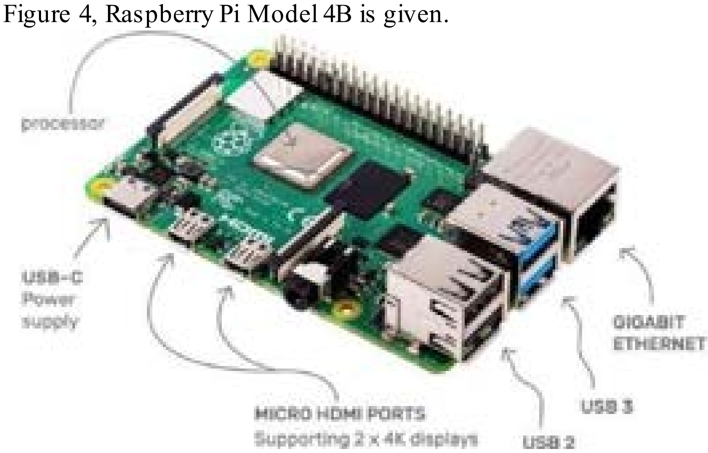

Figure 4. Raspberry Pi

c. LCD Display

Using the DSI connector, the Raspberry Pi Touch Display connects to the Raspberry Pi as an LCD screen. You can use the Touch Display and the regular HDMI display output at the same time when the panel is connected. All Raspberry Pi models are compatible with the Touch Display. Therefore, using the Raspberry Pi and the display a personal computer can be created. In Figure 5, an LCD that is compatible with Raspberry Pi is given.

9) Transform the frame to RGB format
10) Using face mesh, process facial landmarks and extract landmark_points from the result
11) If landmark_points is not null:
12) Remove landmarks so you can process them later
13) Landmark in enumerate (landmarks [474:478]) for eachid:
14) Utilizing normalized coordinates, compute (x, y)
15) On the frame, draw a circle at (x, y)
16) When id = 1:
17) Determine screen_xand screen_y using the normalized coordinates
18) Point and click on (screen_x, screen_y)
19) A list of specific landmarks, such as [landmarks [145], landmarks[159]], is set to the left
20) For every landmark on the left:

Figure 5. LCD Display

C. Pseudocode

1) First, import cv2 and then import media pipe as mp and Pyautogui
2) Select cv2.VideoCapture(0) as the camera
3) Refine_landmarks =True
4) Set face_mesh to mp.solutions.face_mesh.FaceMesh
5) pyautogui.size() to set screen_w and screen_h
6) If True:
7) Read the camera's frame
8) Turn the frame to a horizontal position
21) Utilize normalized coordinates, and compute (x,y)
22) On the frame, draw a circle at (x, y).
23) If left [0] and left [1] are separated vertically by less than 0.004:
24) Use pyautogui.click() to execute a mouse click.
25) Sleep 1 second
26) Show the frame with the landmarks drawn
27) Await the pressing of a key (cv2.waitKey(1))

IV. RESULTS AND DISCUSSION

In Figure 6, the architecture of the system is given. The computer is created by the Raspberry Pi together with the LCD. A webcam is fixed with the computer. The webcam is analyzing the eyeball movements and face recognition of the user. Therefore, the user can see the cursor movement on the computer.

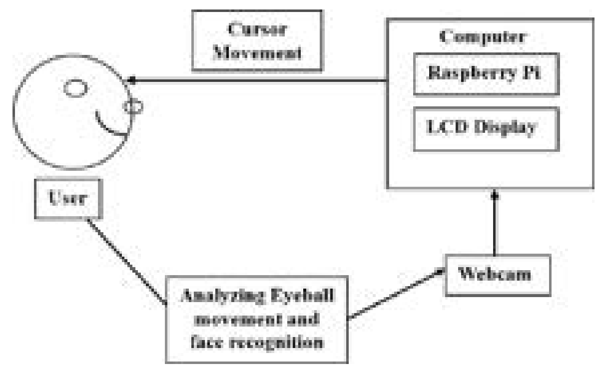

Figure 6. Schematic Diagram

In Figure 7, the primary steps of the eye-tracking project are defined as an algorithm. The system is initialized at first. It then records video input from the webcam. The facial features, especially the eyes are detected in video recordings. The system determines the direction of gaze based on the detected eye positions. Based on this data, the screen's cursor is shifted appropriately. The user sees the processed video with gaze overlays at the same time. The system keeps an eye out for user input during this process, and also for commands to end the program. The video processing is carried out by the system if no quit commands are found. Finally, the system shuts down when it detects a quit command.

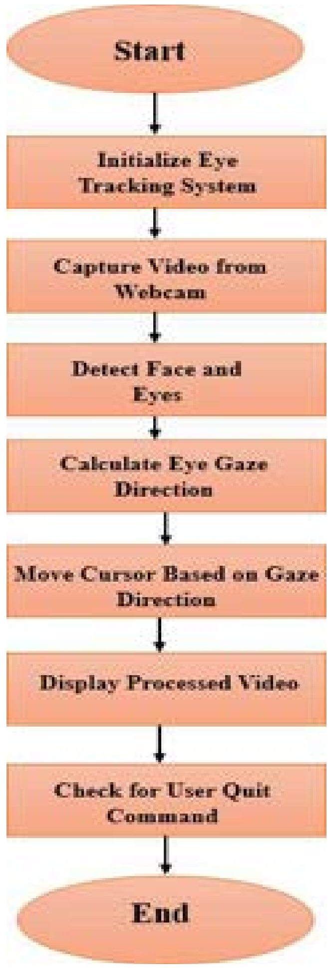

Figure 7. Flow chart

The development of an affordable and portable mouse control system using eye-tracking technology marks notable progress in the realm of human-computer interaction. The implementation of this system includes a few steps. Eye tracking is identifying where the eyes are for various purposes, such as analyzing behavior or operating a computer. Firstly, the libraries in the Python program are included they are, CV2, MediaPipe, and PyAutoGUI so that mouse movements can be emulated, build pipelines that perform computer vision inference on different types of sensory data. To identify faces in the video frame, the cv2 is used. It detects the face by comparing every content in the frame that matches the real facial traits. After the face has been detected the eye is detected similarly by the cv2. Then the processed video frame is displayed on screen with a drawn rectangle around the facial area. This enables real-time observation of the face and eye detection.

Once the face and eye-gaze are detected using face landmark detection, and eye-gaze estimation, they are statistically analyzed based on any meaningful trend or data collection. This analysis makes the cursor move according to the eyeball movement in the video frame. The analyzed data are not stored anywhere in the memory of the operating system. Only during the interpretation, the eyeball movement data is stored locally and then it is deleted quickly, and stores the next data locally for a few seconds. Lastly, testing and calibration were done. It represents vital phases in enhancing the accuracy, precision, dependability, and overall effectiveness of eye-tracking systems. The testing is done in various environmental conditions to ensure accuracy and precision. Depending on the test the calibration is done in this system for increasing the accuracy and precision. In Figure 8, a screenshot of the system when it is analyzing the eyeball and face is given. In Figure 9, the screenshot of the cursor moving by the eyeball is given. In Figure 10, the prototype is given.

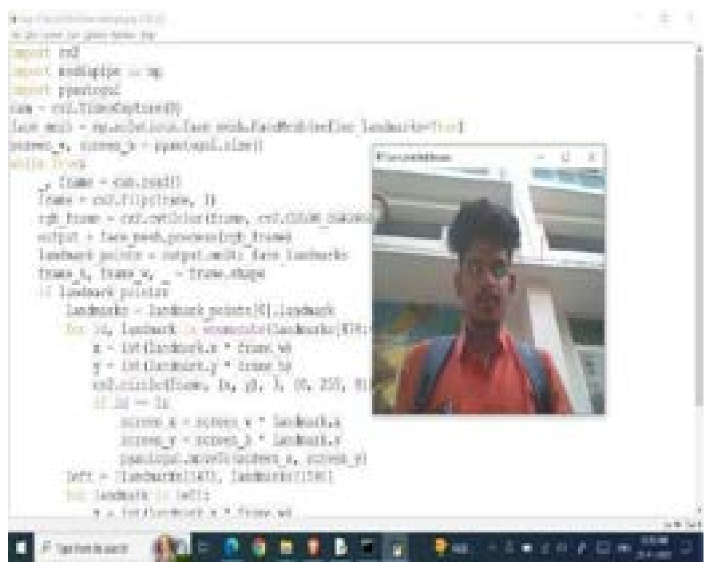

Figure 8. Analyzing Face and Eyeball

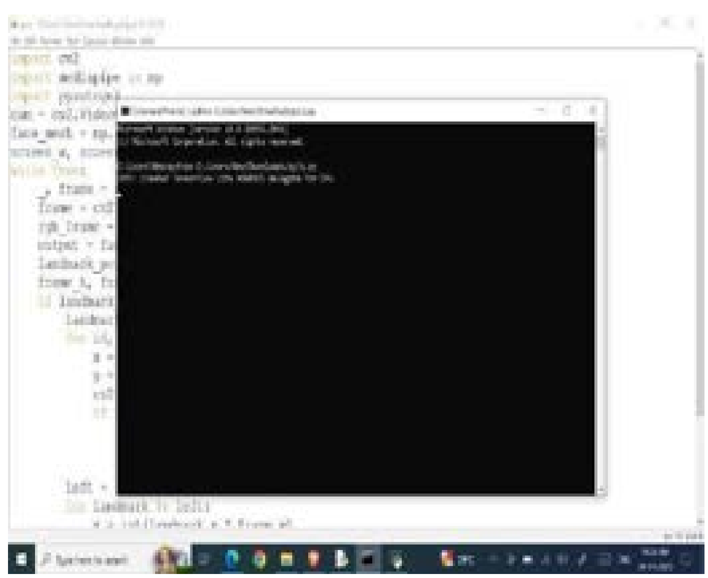

Figure 9. Cursor movement

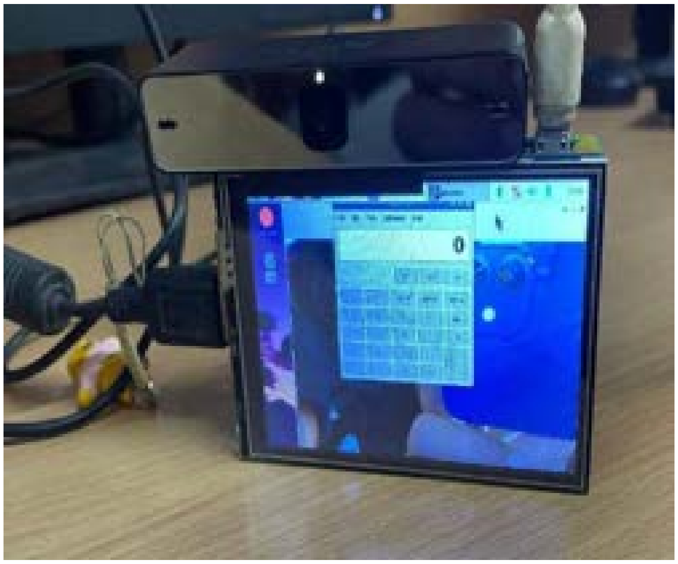

Figure 10. Prototype

Table 1. Accuracy Table

User Position	**Light Condition**	**Accuracy (%)**
Front Facing	Normal Lighting	95%
Front Facing	Low Lighting	85%
Side Facing	Normal Lighting	65%
Side facing	Low lighting	50%

In Table 1. An accuracy table is given. The table consists of the survey taken from 20 different people to check the accuracy of the system in 2 different light conditions either during normal lighting or in low lighting and 2 different user positions either front facing or side facing. The accuracy percentage is higher when the user is front-facing, under normal lighting, compared to other scenarios. The accuracy percentage is less when the user is side-facing under lowlighting compared to other scenarios. The accuracy percentage is found by calculating the number of correct matches divided by the totalnumber of test cases and then multiplying it by 100.

In the first scenario, when the users are facing the front under normal lighting 19 out of 20 people experienced the system with good accuracy, except 1 person, because of the crowded environment. In the second scenario, when the users are facing the front under low lighting 17 out of 20 people experienced good accuracy, except 3 people because the lighting was not enough to detect the eyeball. In the third scenario, when the users are side-facing under normal lighting 13 out of 20 people only experienced good accuracy, except 7 people because, the eyeballs are detected only up to a certain angle of turn and also facial feature varies for everyone, that is for some people both eyes are visible upto 45 degrees and for others only one eye was visible. In the last scenario, when users are side-facing under low lighting only 10 out of 20 people experienced good accuracy, except 10 people because the light was not enough for some people and the angle of turn was not perfect for the eyes to be detected. Therefore, these drawbacks can be overcome by using different tools, like using an IR webcam for low-lighting places, and using multiple cameras for detecting eyeballs from many angles, help to achieve higher accuracy.

V. CONCLUSION

A significant advancement in the realm of human-computer interaction involves the establishment of a cost-effective, portable system for controlling a mouse through eye-tracking. To sum up, the goal is to create an eye-gaze tracking system using computer vision and Python. Using the libraries the face and eyeball movement are detected and it is analyzed and interpreted as the mouse cursor movement. Then testing is done to ensure accuracy and precision. This system presents promising avenues for applications in ATMs, Driving Assistance health monitoring, gaming, education, and telemedicine. The system's effectiveness and influence across many fields will increase in the future as its accuracy, precision, and usability are further improved. This breakthrough signifies a revolutionary step towards improving the overall quality of life for individuals with disabilities and advancing the field of assistive technology.

Abstract— Vehicle-to-vehicle (V2V) communication involves remote communication in which vehicles communicate with each other using interactive messages. Information will include speed, fire warning, problem management, loss of area, direction, response, and safety. The most important objective of progressing vehicle-to-vehicle communication through LI-FI is to dispose of cheap and life-threatening issues. Li-Fi requires Drove lights, such as those currently utilized in numerous energy-efficient homes and workplaces. These bulbs are prepared with a chip that subtly controls the light for optical information transmission. Li-Fi information is at that point transmitted by the Drove seed and gotten by the photoreceptor. Standard microcontrollers enable V2V communication via LI-FI. Node MCU is a microcontroller that controls the entire module. Data such as distance, fire, and emergency preparedness are processed using ultrasonic sensors, fuel sensors, and marking and disabling emergency switches that alert multiple vehicles when activated. The framework has tall information rates and complies with the 802.11bb determination. There's moreover information security. Car-to-car communication through Li-Fi is done on the Arduino Uno microcontroller. This comes about given the network of Bluetooth frameworks, the removal of the vehicle that can be sent, fire readiness, and the capacity to reply to crises. The farthest distance is about 10cm, and the compartment is controlled or controlled by ultrasonic sensors and an LCD screen, for example, if a fire situation occurs, the fire signal is recommended and if there is an emergency, the LCD screen is ready for fire, the LCD screen is emergency warning and ready to provide information to other vehicles.

Keywords— Sensors, V to V interaction, Li-Fi technology, Node MCU, IoT.

I. INTRODUCTION

As the number of vehicles on the highway continues to increase, traffic management becomes a critical daily test. Vehicle-to-Vehicle (V2V) communication may be a progressive innovation that makes a difference makes transportation frameworks more obvious. It permits vehicles to trade data at almost their speed, area, and activity over an amplified period. Later development of V2V communication allows the vehicle to send and receive various information. The plan will then address the use of visuals, devices, and visual alerts to alert drivers to specific actions to prevent accidents. Complete V2V is a reliable space for the coordination of traffic accidents by sending traffic information and offering drivers the fastest route. Various methods for vehicle switching, including Wi-Fi, Bluetooth, and radio adaptive networks, can guarantee long-distance and detailed information because radios do not have such happy ways. Here are some simple precautions to prevent accidents for different vehicles. Vehicles in this traffic zone are equipped with warning lights. These explorers took the connection of light and extracted information from the relevant environment in which light could be imagined. Li-Fi is common and stable in optical communication because it has a good transmission (10 Gbps), high speed, higher communication speed, and high limit of different wave types. Li-Fi was noted as an advance. Development is rapid and ecologically responsible. Li-Fi not only improves quality, it also provides a non-electromagnetic, safe environment. Use it quickly, without complex information or risk of attack by hackers. V2V communication is the best solution to reduce traffic accidents.

II. LITERATURE SURVEY

In [1], the V2V model makes sense. Using V2V communications, the vehicles can distinguish between locations and developments of different vehicles up to a quarter mile away. In practice, cars are equipped with individual radios, PC chips, and GPS innovations. Cars will know where most other cars are, and many cars will also know where you are, even if you are on the weak, invisible side of the highway, in a corner with external barriers, or blocked by various pressures on the car. If the driver does not react to the warning, the vehicle can be protected by staying a safe distance from the incident.

V2V communication in Wi-Fi was proposed in [2]. IEEE 802.11p is additionally known as Vehicle Conditional Inaccessible Get to (WAVE). This model will be utilized within the arrangement of the Short-Term Communications Contract (DSRC). The car sent direct messages from buyers to experts, facilitating close collaboration through the convenient DSRC. This will be a future level because it allows communication between vehicles. Considering the development of IEEE802.11, remote organization can be widely used in home organizations and workplaces with free Wi-Fi or low cost. The original concept of DSRC is to provide off-the-shelf mobility for the construction of tools such as IEEE802.11a. This development is efficient and can be improved and new models are created. The newest standard for wireless LAN (WLAN) is IEEE 802.11. The IEEE 802.11n standard endeavors to make strides and expand the best-known WLAN standard through expansion, optimization, and scope. V2V communication utilizing the ZigBee convention is portrayed in [3]. ZigBee could be a keynote for sensor organizations due to its long battery life, low operating costs, easy support, and high performance. Zigbee supports network organization by allowing remote communication between multiple organizations, switches, and receivers when testing multiple applications. The network connection is a perfect world, self-created and therefore exclusive, used mostly by organizations in the telephone network. Multiple light communication (VLC) is suggested in the article [4]. VLC offers many features as it can deliver unlimited, unencumbered, license-free content. Driving has ended up well known in car lighting due to its long life, moo taking a toll, capacity to resist vibration, and being more advantageous. VLC is another capable choice for electronic playback. It is a remote optical communication system that uses non-repeating light (400nm to 700nm). Metin [5] suggested knowing the distance information of two frames from visible light. This approach is simple and allows information to be sent faster than current innovations in long-distance communication. Using light for long-distance communication can solve the problem of the lack of radio waves in many places so that the message can be transmitted effectively. The proposed framework illustrates information transmission and collection by turning the drive on and off with a variable control as well quick to be obvious to the bare eye. Distinctive information can be changed by squinting the Driven and changing the communication. Viable and commercial innovation for vehicle-to-vehicle (V2V) communication utilizing light is portrayed in [6]. It was where two circumstances were inspected: when the car moderated down out of the blue, it made the cars below aware of this change of speed; When a fast car approaches an intersection, it warns other cars who can't tell the difference. The Li-Fi-based vehicle communication system aims to further improve the vehicle by eliminating traffic violations (such as speeding violations) and sending this information to the checkpoint, thus dispatching the vehicle using lights and lights. Health and transportation. Optometry correspondence with the rules to be followed from now on has been prepared in [7]. Light-emitting diodes will enter numerous ranges in daily lives. A curiously included of these instruments is their broad capabilities that can be utilized for information exchange [8]. LEDs require moo control to function and have exceptionally quick exchange times [9]. The venture points to forming a system for communication by utilizing lighting in indoor lighting. Data increase can be achieved by using the appropriate light source and OFDM can be used instead of cold interrogation [10].

In existing systems Vehicles are becoming more prevalent because of industrialization and urbanization, while road accidents are also becoming more prevalent. When accidents occur, someone should send a message to emergency services to save lives. When accidents occur, traffic is often a huge issue [11].

III. PROPOSED METHODOLOGY

V2V communication utilizing Li-Fi innovation comprises a transmitter and a collector, which shows the V2V message sent by the driver's front light. Li-Fi development employs light to transmit messages, hence diminishing the requirement for capacity space. The outline is controlled by the communication piece profile of the two vehicles. Both cars have Arduino, LCD Show, Ultrasonic Separate Estimation (UDM) Sensor, Fire Sensor, and Caution.

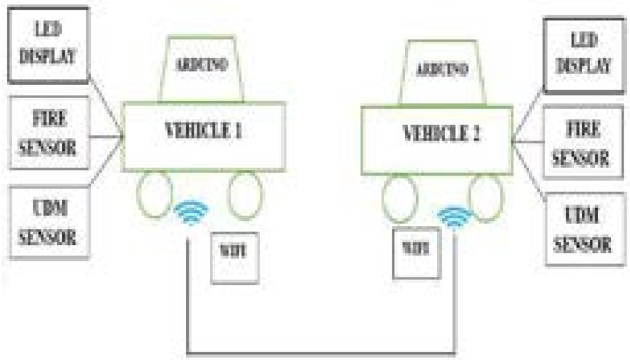

Fig 1: Communication between vehicles

Li-Fi modules contain LEDs. The advantage of consolidating LEDs into the Li-Fi system is that it increments the information rate compared to RF flag transmission.

The collector contains a photodiode that acts as a demodulator for comparing flags in a coordinated plan. The demodulated flag is at that point sent out of the channel, disposing of undesirable signals. Flag partition is presently moved forward by the flag improvement framework.

Filtered and reliable signals are provided for display devices such as LCD monitors.

Arduino can be used to create smart things through the collaboration of sensors and control of various lights, engines, and other benefits.

Ultrasonic sensors are utilized to degree the separation between two vehicles and recognize objects.

Electrical sensors are used to detect and identify objects between two vehicles. Respond in the presence of fire, caution should be exercised.

Fig. 2 and 3 describe the architectural design of sender and receiver information.

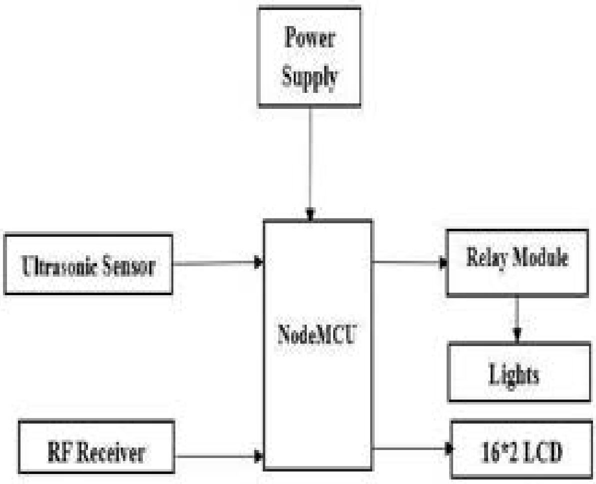

Fig 2: Block diagram of sender

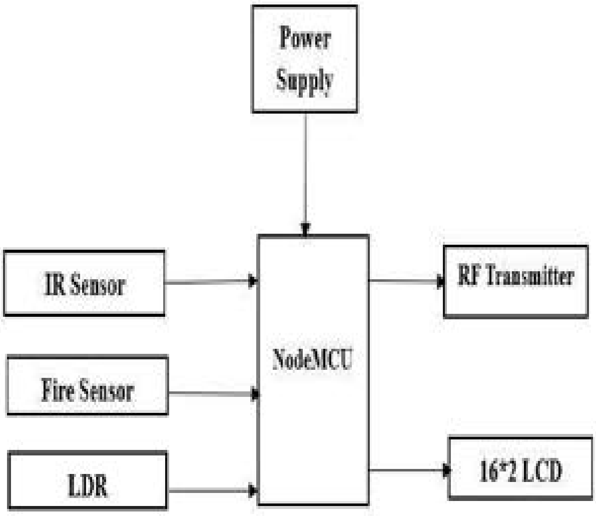

Fig 3: Block diagram of receiver

V2V data is transmitted via LED lighting. Since Li-Fi technology uses light to transfer data, it requires less storage space. The control system uses a device called a microcontroller, which can be implemented using Arduino, thus reducing the time. Show a communication diagram between two cars, each with Arduino, LCD, ultrasonic range cut sensor, electronic detector, and anti-theft alarm. Li-Fi modules are made of LEDs. Using LEDs in Li-Fi systems has the advantage of increasing throughput compared to Bluetooth signal transmission. The recipient encompasses a photodiode and a demodulator to get parallel signals. The demodulated flag is at that point sent through a channel that evacuates undesirable signals. Presently utilize the flag enhancement strategy to grow the channel flag. The sifted and increased signal is sent to the yield gadget LCD. Arduino can be utilized to make intelligent gadgets that acknowledge sensor input and control different lights, engines, and other outside components. Ultrasonic sensors are utilized to degree the separation of the vehicle and identify its current. Fire sensors react to the presence of fire and provide warning signals.

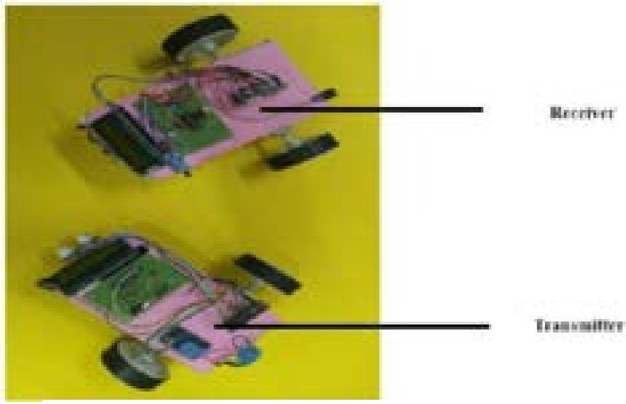

Fig 4: Model transceivers used in the prototype implementation.

IV IMPLEMENTATION AND RESULT

Table 1. Vehicle and the Respective Sensor Output

Vehicle	Fire Sensor	LED Display	Ultrasonic Sensor	Buzzer	Relay Module
Vehicle A	Yes	Warning: Fire Detected!	3 meters	Yes	Yes
Vehicle B	No	N/A	1.5 meters	No	No
Vehicle C	Yes	Warning: Fire Detected!	2 meters	Yes	Yes

1. *Move information starting with one vehicle and then onto the next vehicle.*

The foremost common strategy of exchanging information employing light is called Li-Fi. It appears how to exchange information initially from one car and after that to another car. Border events such as traffic accidents, fires, and emergencies are constantly monitored, and communication is provided between vehicles. In case of distance limit, ultrasonic sensors can distinguish and measure the distance before using the car light and can be used to find the option that controls the distance measurement. Create two-car ringtones. If an emergency occurs, sensors will be activated, and both vehicles will be notified of the emergency and can take the necessary steps to reduce damage. All frames are very low power and only need five volts of power.

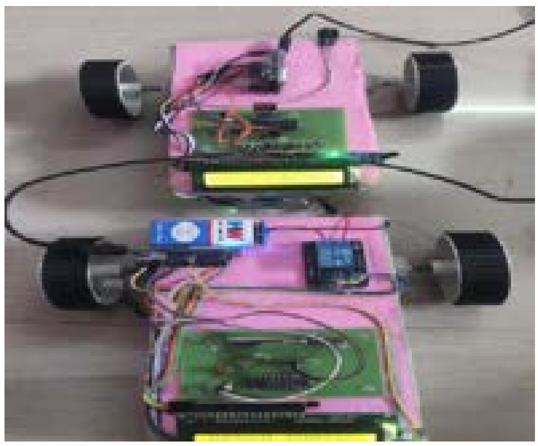

Fig. 5 Transmission of data beginning with one vehicle and then onto the following vehicle

2. Actuation of the bell in the event of a fire

The Li-Fi system is planned to empower car-to-car communication. On the off chance that a fire breaks out within the car, the fire finder will recognize the flag delivered by the sensor. The Arduino microcontroller controls this and sends the message to the main car alarm and the second car using the Li-Fi framework. The following car receives this flag and checks this information in its microcontroller and takes necessary actions. Figure 6 shows the alarm sound in case of fire.

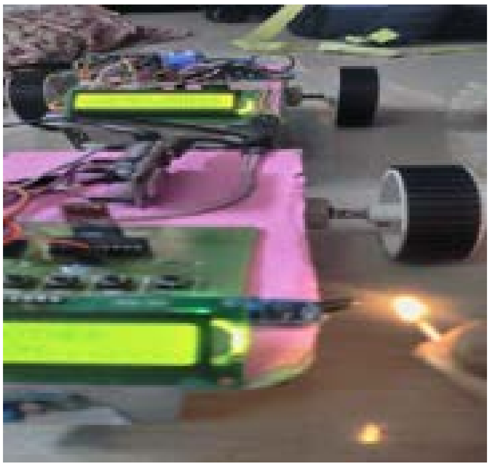

Fig 6. Buzzer sounding in case of a fire emergency.

3. Ultrasonic sensor for Traffic alert

If the Li-Fi framework could not able to pass the information to other vehicles then the system do not have sufficient time to remove other vehicle which may lead to collision. To overcome this ultrasonic sensor are used in the proposed model. Figure 7 shows how the ultrasonic sensor and Li-Fi system work. The ultrasonic sensor always sends a flag, and in case of an obstruction, the flag is reflected to the sensor. Based on the flag, the microcontroller takes decision and alerts the user to take another direction.

Fig. 7 Display Guidance for driver

4. Fire Accident Alert using RF.

The RF framework additionally helps in the quicker transmission of information. The IR Sensor exploits this property. The IR Sensor upon initiation conveys a message through the RF transmitter on which a emergency alert is shown on one more vehicle as displayed in Figure 8. Similar information is sent to the next vehicle. This is exceptionally valuable if the driver of the vehicle is encountering some sort of issue like a stir-up or tipsiness halfway through travel. The travelers in the two vehicles get cautioned, help each other immediately, and avoids the damage or predict a significant issue.

Fig. 8 Display of caution about fire accident

V. CONCLUSION

Approximately 150,000 people die every year due to driving impairment. The impact of these emergencies considers the lack of human driving that causes many accidents of central importance. As the vehicle moves more and more, driver and passenger comfort and convenience become increasingly important. The project aims to connect multiple parking areas to create a structure that will assist drivers on both highways and city streets. The concept incorporates an ultrasonic sensor to distinguish unsettling influences, a fire sensor to distinguish fire, and a caution button that can be squeezed in straightforward circumstances. The task was transferred to the center MCU controller, which is known for its great control and response time. In this way, using the proposed structure will reduce the damage and strengthen the safety and comfort of the driver.

***Abstract*—Agriculture is the activity of cultivating natural resources that humans utilize for survival and economic benefit. It has evolved into one of the most significant industries in the day-to-day existence of all living organisms, providing access to food, a means of subsistence, etc. In reality, a country's agricultural output may have a direct or indirect impact on its food security and overall health. Despite the widespread adoption of these agricultural methods, various obstacles, including soil fertility and climate, can negatively impact the development and output of agricultural goods. As every living thing on Earth depends on agriculture for its existence, there is a constant need to find ways to overcome the problems faced. It is a well-acknowledged reality that contemporary issues demand modern solutions. Thus, it is critical to use developing technology to tackle the challenges that exist. The quality of life has been greatly enhanced by modern technologies. This concept has led to the introduction of several contemporary inventions and technologies that enhance the standard of life and advance the welfare of every individual. The demand for new technologies has been growing over time, and one promising technology with the potential to improve living standards and address long-standing issues in the agricultural sector is digital twin technology. It has made it possible to reduce labor and energy waste, among other things. Examining how digital twins might improve agricultural productivity and promote sustainability is part of the process of understanding digital twins and their place in the agricultural industry. The prerequisites and implementation strategies for encouraging the use of digital twins are covered. Since this is a new technology, a careful analysis of its benefits and limitations is necessary to properly address identified issues.**

***Keywords*—sustainability, Digital Twins, agriculture, sensors, IoT, Artificial Intelligence**

I. Introduction

The agricultural sector is the very backbone keeping a country alive and healthy. It is essential for food production, economic stability, and environmental sustainability, impacting land use, water resources, and biodiversity [1, 2]. When agriculture thrives, the economy booms along. But real prosperity shows when green farms nourish entire communities year after year, not just through economic measures. Still, challenges hamper further betterment of rural belts, from climate threats to crops to promoting nature-friendly techniques that last over time.

With such tricky real-world problems, new-age technologies provide rays of hope instead of doom. Artificial Intelligence or AI is one such forward-thinking innovation now being deployed everywhere - factories, colleges, government - to drive progress. At the core, AI refers to creating smart systems displaying almost human-style analytical smarts, just minus the emotions. These methodical AI tools can continuously swallow huge amounts of raw data, identify hidden patterns and even predict complex behaviours beyond human specialists. Having such 'digital assistants' means making sense of messy data now needs much lower investment of time, money and manpower.

One groundbreaking application involves creating digital replicas of physical assets, such as jets, rails, or entire smart city power networks, known as digital twins. These digital twins are designed to mimic their real counterparts through the integration of cutting-edge technologies, including IoT, cloud computing, AI, and XR, facilitating their widespread application [3]. The incorporation of IoT is particularly notable in these virtual replicas, enabling seamless real-time connectivity and data exchange between physical assets and their digital counterparts. Equipped with IoT capabilities, these 'digital twins' act as round-the-clock digital sensors, capturing intricate performance statistics without the need for expensive manual tracking or risky physical experiments on valuable infrastructure.

Think - testing changes on a live train disrupts rail movement crucially. But its digital clone allows endless software simulations to assess upgrades in isolation. Such cyber counterparts enable closely inspecting minute material behaviours, wear-and-tear issues impossible to regularly test in the field. Infrastructure authorities from defence to urban planning are now using such helpful digital shadows to light up smarter direction. And as computing strengths surge rapidly, the promise of such realistic digital environments to optimize physical realities will only swell.

Let's consider urban planning authorities aiming to expand public transport infrastructure. Physical trials involve massive investments for deploying trains, fuel systems, stations along with severe operational risks. A digital twin prototype allows modelling countless options spanning fares, routes, wagon capacities all within flexible software environments. Experts can identify optimal configurations maximizing affordability, accessibility, and sustainability goals before even allotting physical land. Such virtual mock-ups powered by real-time data also continue advising maintenance needs, rider estimates over decades rather than a one-time fix.

Now think of healthcare - a digitized patient twin incorporating genetics, diagnosis history, and treatment response can enable customized therapy. Pharma researchers can investigate countless drug combinations tailored to individual DNA strains using such profiles, considerably accelerating successes. The future possibilities with such made-to-order digital blueprints remain manifold. No wonder pioneering applications have already secured strong funding. As computing power and design thinking both witness exponential gains, the problem-solving potential of digital shadows mimicking and optimizing physical systems seems all set to illuminate solutions faster than otherwise possible.

The main objectives of the research are:

- Understanding Digital Twins
- Understanding how digital twins can impact on the field of agriculture
- Understanding how sustainability can be achieved using digital twins
- Analysing various existing limitations

II. BACKGROUND

A. *Digital Twins*

Digital twins are basically intelligent virtual representations of physical entities that offer real-time monitoring, analysis, evaluation, and prediction of physical systems [4]. In other words, they are very detailed virtual copies of real physical things which allows the testing of improvements on them without touching the actual item and allow physical and remote monitoring of the livestock [5]. For example, think of digitally reproducing an actual running jet engine into a software environment - matching nuts, bolts, pipes etc. Now engineers can tweak this cyber clone endlessly to push limits without taking the real engine offline.

These software duplicates assimilate both static and dynamic inputs from multiple measuring tools around the assets like high-resolution cameras, heat and vibration sensors etc. So, they transform from inert 3D diagrams to almost live, breathable models of the physical equipment.

Consider the jet engine twin receiving live temperature, pressure and speed data every fraction of a second from the operating machine. By processing this running stream of numbers, the digital copy starts mirroring the real-time performance parameters of the engine within the simulation world. So, without expensive and risky real-world trials, engineers can now stress-test virtual components to extreme boundaries for finding design upgrades.

Now consider digital twin powered control centres for entire cities! Facets like traffic signals, power distribution grids, water pipelines get monitored 24x7 through such tailored virtual replicas assimilating real-time feeds. Municipal authorities can now catch emerging urban chokepoints, infrastructure risks much earlier by leveraging such city-scale digital estates.

Creating digital shadows begins by digitally modelling the physical asset down to fine details like shape, material types, structural assembly etc. However, mirroring operating dynamics like asset deterioration rates, breakdown risks require continuous data integration from surrounding sensors. So, experts carefully install measurement hardware across critical machines and infrastructure for this.

Advanced analytical software thereafter converts accumulated sensor data into meaningful insights - be it detecting anomalies, predicting maintenance needs or simulating overhaul responses for industrial equipment or public amenities before actual breakdowns. Digital twins have thus become integral for diverse sectors to simulate expansions, quantify risks and boost efficiency.

In healthcare, they enable patient-specific diagnostics and treatment evaluations before deploying actual interventions. For smart city projects, virtual models validate different design proposals to find optimal configurations even before laying the first bricks.

By enabling virtual prototyping of intricate systems, digital twins can drive productivity across areas while minimizing experimentation risks. As computing and analytical abilities accelerate, such cyber twins hold enormous potential in advancing how anything is setup and managed - from small appliances to complex machinery to even entire smart cities!

B. *Digital Twins In Agriculture*

For generations, the process of improving agriculture has been gradual and resource intensive, relying on farmers' practical learning through trial-and-error experiments. However, given the increasing urgency of global food security and sustainable environmental stewardship, persisting on the current trajectory is not viable if the aim is to meet expanding needs. The solution may lie in emerging digital twin technology - highly sophisticated computer simulations that create "living" virtual crop environments to rapidly test innovations at a fraction of the cost, risk and time. They integrate digital models of physical objects to optimize performance and prevent failures using real-time data [6]. As mentioned in [7], they have the potential to revolutionize agriculture by creating a virtual representation of a physical system, allowing for the simulation of the impact of various events and actions. Fig. 1 illustrates the prevalence and impact of digital twins in agricultural settings.

Just as architects develop 3D building information models with painstaking detail before physical construction, it is now possible to leverage massive agricultural datasets and computing power to digitally prototype the next era of farming. Teams of researchers worldwide could collaborate to examine endless variations of seeds, soils, weather patterns, watering schedules, and other growth factors all within these breathtakingly intricate simulated environments. Minute genetic differences between seed strains could be cross-analysed with geographic climate models, seasonal solar cycles, soil nutrient compositions and water conservation strategies to reveal optimum combinations for maximizing crop quality and yield over a full life cycle. It also allows farmers to remotely monitor and control greenhouse operations, making agriculture more efficient and sustainable while addressing labour shortages [8].

Where physical fields may allow dozens of test trials across a few acres per growing season, continuously run simulations permit limitless controlled experiments across millions of virtual acres globally. The most promising solutions are flagged for targeted real-world prototyping while the bulk of inferior ideas are discarded outright without wasted land or resources. And as digital platforms ingest more observational data from these selective physical validations, the virtual crop representations become increasingly sophisticated and reliable for future testing. It is a self-improving cycle between physical and digital research where each new iteration is more productive than the previous as virtual and reality converge.

This integrated virtual-to-real approach may be how rapidly agriculture is advanced to address impending global food security challenges. Optimizing yields through digitally-enhanced innovation pipelines is possible without expanding farmland footprints. Virtual cropping technology buys enough time to balance mounting population needs with environmental sustainability in the critical decades ahead.

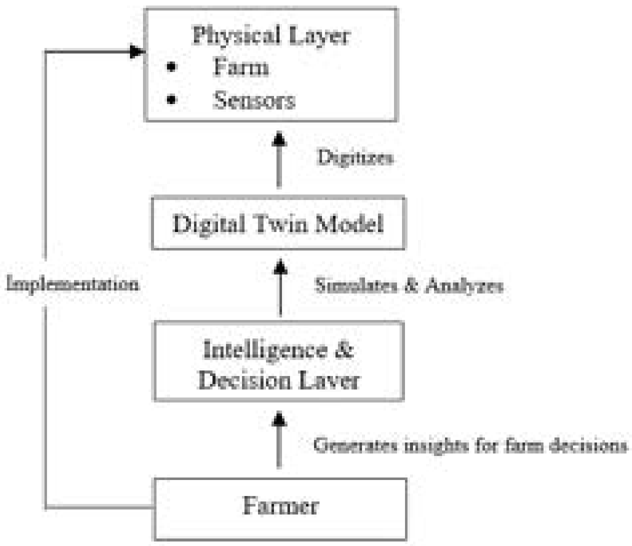

Fig. 1. A simplified representation of Digital Twins in Agriculture

C. Understanding the importance

When implementing digital twins in agriculture, it is important to understand the possible outcomes and its importance.

- *Significance for farmers*

Digital twins provide farmers various layers of actionable advice to help them connect with sustainability goals without sacrificing output or profitability. It is now possible to conduct real-time monitoring and analysis of crop conditions, leading to improved decision-making and resource management. Dynamic feedback is supplied into the digital platform via ongoing soil, crop, and meteorological condition gathering. This makes it possible to precisely adjust important inputs, like as water, fertilizer, herbicides, etc., to the ideal quantities in order to maximize production. In order to implement preventative care, the system furthermore promptly notifies users in the event of an approaching insect assault, equipment malfunction, or extreme weather occurrence. As a result, farmers have a wise partner that uses technology to offer guidance on infrastructure upkeep, operations, and productivity.

- *Environmental Benefits*

The digital twin solution's suggestions include provisions for responsible resource management. As a result, even when output objectives are appropriately reached, there is no ecological impact. When regenerative agricultural methods are gradually used, sustainability indicators such as biological richness, groundwater levels, and soil quality really improve over several harvest cycles. Climate-smart agriculture thereby gains traction without requiring farmers to take on significant risks or expenditures. It is thereby understood that digital twins enable efficient management and optimization, leading to reduced energy consumption and environmental impact in agricultural operations [9].

- *Societal Impact*

The agricultural community may more easily and affordably embrace high-tech, precise procedures by mainstreaming innovative technologies like digital twins. Progressive farmers may justify their expenses with higher yields and revenue, and increased capacity can help meet the growing demand for food. Sustainable food production enhances the well-being, independence, and prosperity of rural communities, who comprise a significant portion of India's population. Digital twins have now become a reason for the improved sustainability, decision support and supply chain transparency [10].

- *Promoting regenerative agriculture*

Indicators of soil health, biodiversity, and carbon sequestration are tracked via the digital twin platform. This makes it possible to use corrective measures like polyculture cropping, organic fertilizers, low-cost natural farming methods, etc. Such regenerative techniques can, over time, improve long-term resilience by aiding in the farm ecosystem's own regeneration.

Using digital twins in farming doesn't just have one set of positive results; it can bring various benefits as techniques improve. So, it's fair to say that adopting digital twins in agriculture can make life better not only for individuals but also for the well-being and lifestyle of future generations.

D. Achieving Sustainability Using Digital Twins

Digital twin technology brings an innovative revolution that can transform sustainable agriculture in India. Referencing [11], it’s understood that digital twins in agriculture help achieve sustainability by providing real-time monitoring, precise control, and accurate prediction for accurate and efficient smart agriculture. It can assist in finding possibilities for waste reduction, energy savings, and general sustainability improvements by modelling and forecasting the behaviour of complex systems [12,13]. These advanced computer simulations mirror real farms, ingesting massive data from soil moisture levels to insect populations to individual cow movements. Utilizing decision layers, digital twins function as hyper-attentive virtual assistants, carefully analysing this flood of farm information to generate targeted interventions that simultaneously maximize yields and minimize environmental impact.

Envision a digital twin reviewing real-time data on crop growth rates, soil nutrient composition, rainfall distribution, grazing patterns, and more. It swiftly prescribes precise application of fertilizers, water, and pesticides down to square meter granularity across fields for optimal results. When sensor data indicates livestock overgrazing in a certain area, the twin rapidly recalibrates grazing zones and schedules to prevent long-term soil degradation. It examines crop cycles, biodiversity trends, and weather models to predict how farming choices today will cascade over decades, allowing farsighted stewardship of the land for future generations.

But more than just superior production, digital twins enable protection of vital ecosystems thriving alongside farmland by tracing interconnected relationships. The simulated advisor studies pollinator populations, wildlife migrations between habitats, soil food web health, and forest conservation to implement mutually beneficial strategies like planned biodiversity zones and biological pest control. It perpetually fine-tunes this balance between agricultural output and environmental flourishing through exacting analysis of factors across the ecological spectrum. As costs inevitably decline, these artificial intelligence allies will become accessible for smallholder farms across India. Digital twins in an agricultural era provides sustainability and productivity, technology and tradition are integrated in harmony. They form the foundation for communities to prosper in sync with the living landscapes around them. By deducing precise insights from a deluge of data, digital twins show a path where nourishing people and nature are not opposing forces to be traded off but rather complementary forces to be optimized in unison.

E. Existing Limitations Of Digital Twins

As digital twins become more widely used in sectors such as manufacturing, healthcare, and smart cities, legitimate privacy and security issues are brought up. While digital twins have many advantages, it is important to be aware of their drawbacks.

Even though the limitations of digital twins in agriculture also include data management challenges, model accuracy, scalability issues, and the need for high-quality data [14], permission and privacy can be considered as the most important ones. Large amounts of data must be collected from several sources, including sensors on physical assets, as data is the basis of digital twins. Selecting the right sensors is crucial for the effectiveness of digital twins. Considerations such as accuracy, reliability, and compatibility with the agricultural environment must guide the sensor selection process. Additionally, ensuring scalability and the ability to withstand varying environmental conditions are paramount for sustained and effective data collection. That being said, a significant amount of this data collecting violates people's right to privacy because it is done without their consent. For example, a digital duplicate of a public park may track foot movement without users' permission by using motion sensors and cameras. Digital twins developed for the healthcare sector using patient medical records may also violate privacy if appropriate data protections are not implemented. Even if the data is anonymized, patients' agreement was not secured for secondary usage in digital twin creation and analytics.

Another major limitation stemming from increased connectivity and data aggregation in digital twins are cybersecurity issues. The more operational and sensory data that is moved from physical assets to their digital counterparts, the bigger the attack surface becomes for malicious actors. In the event that operational data is breached or personally identifiable information is stolen, inadequate security mechanisms for the transmission and storage of digital twin data provide risks to both privacy and safety. Inaccurate information obtained through a hack, for example, that alters data going from a power plant to a digital replica, might lead to catastrophic malfunctions. Parallel to this, hacked digital twin data from wearables or medical devices can reveal personal user information.

Furthermore, digital twins are intrinsically more susceptible to cyberattacks due to their intricate interfaces with many IT/OT systems and data sources. These hazards are increased by the multifaceted nature of their connections between several virtual and actual components. Sophisticated hackers may be able to take advantage of more attack avenues due to the lack of common designs across various digital twin implementations. An example of a smart city digital twin is a virtual layer that is networked and combines data from emergency response systems, electricity grids, water networks, and transportation systems. It is possible to go further into the network and obtain access to other vital municipal infrastructure by exploiting obscure weaknesses in even one component's digital incarnation.

Since digital twins serve as the foundation for AI/ML-based autonomous decision making, inaccurate analytics resulting from hacked data or algorithms provide many more dangers than simply privacy breaches. By manipulating the virtual model, one may fool the twin into recommending risky operations on the real asset by changing the simulation results. Attackers may, for instance, be able to induce catastrophic failures on a linked power system by infiltrating its digital form with malware and then suggesting dangerous sequences that, when followed, result in blackouts.

While conventional industrial control systems are still vulnerable to cybersecurity attacks, the attack surface is greatly expanded by the increased connectivity and reliance on potentially sensitive data that come with digital twins. To proactively identify threats to IT/OT systems and prevent breaches, a robust, multilayered security architecture must be implemented as digital twins grow more interconnected and appear in public places such as smart cities.

In addition, results from digital twin simulations may differ from actual results due to unclear data or incorrect modelling assumptions. These differences are concerning as businesses are depending more and more on digital twins for automation and forecasting. It is important to understand that the accuracy of predictions depends on model adequacy [15], which can be enhanced with the use of appropriate sensor, satellite, historical, simulation, and contextual data [16]. This involves ensuring the quality of data, including high-quality sensor data, satellite imagery, and contextual information. Continuous monitoring, regular updates, and real-world observations are essential to refining and enhancing the accuracy of the digital twin model over time. In summary, the interpretability, accuracy and real-world applicability of AI/ML underpinning digital twins needs to be enhanced to enable trust, manage risks from erroneous insights, and ensure successful deployments at scale.

So, in conclusion, it is important to tackle the technical, social, and ethical challenges, promote inclusive design, transparency, and open dialogue, and consider the availability and quality of real-time data in order to create accurate digital twins as noted in [17]. While digital twins offer transformative potential, challenges such as data management, model accuracy, and scalability must be acknowledged. Privacy concerns and cybersecurity issues, including the interpretability of AI/ML underlying digital twins, need to be addressed to ensure successful deployments at scale.

F. Overcoming The Privacy And Security Concerns : Digital Twins In Agriculture

The idea of digital twins has completely changed how farmers handle crop management in the agricultural sector. Farmers may simulate various scenarios and test novel strategies before putting them into practice in the field by building virtual representations of real-life plants. Nonetheless, privacy and safety are issues that come with every technology development. Digital twins in agriculture generate and rely on large volumes of data, making data security, cybersecurity, and supply chain security crucial to prevent potential vulnerabilities and ensure operational integrity [18]. In the coding process of building a digital twin for agriculture, a number of creative techniques may be used to overcome these issues.

One strategy is to put strong encryption techniques in place and give data security and privacy a priority. This guarantees the protection of critical agricultural data from unwanted access, including growth trends and production forecasts. Farmers may be safe in the knowledge that their data is private and secure by employing robust encryption mechanisms.

A different approach is to include sophisticated authentication procedures into the digital twin framework. The digital twin can only be accessed and modified by authorized personnel by employing strategies like biometric identification and multi-factor authentication. This guarantees the integrity of the data and prohibits unauthorized manipulation with the virtual plants.

The digital twin system must be equipped with real-time monitoring and anomaly detection algorithms in order to improve safety. All anomalous behaviour, including abrupt alterations in growth patterns or anomalous environmental circumstances, may be quickly identified by continually evaluating data from sensors positioned throughout the fields. Farmers can respond quickly to reduce hazards and safeguard their crops using this early detection.

Furthermore, the safety and privacy features of the digital twin system may be further improved by using machine learning techniques. Through ongoing data collection and pattern analysis, the digital twin can detect possible weaknesses and recommend enhancements to security protocols. By being proactive, farmers can keep their digital twin system safe and stay one step ahead of possible dangers.

In addition, cooperation and information exchange between farmers and agricultural specialists can be extremely important in resolving privacy and security issues. Farmers may collaborate to create standardized security rules and regulations unique to digital twin systems in agriculture by creating safe spaces for information sharing and best practices. Through this cooperative endeavour, the agricultural community as a whole will gain from the collective knowledge and experiences, resulting in the adoption of digital twins that are safer and more secure.

In conclusion, eensuring the security of digital twins in agriculture involves implementing robust encryption, authentication procedures, and real-time anomaly detection. Machine learning techniques and collaborative efforts among farmers and specialists are essential components for strengthening the overall security framework. As noted in [19], data access should be restricted, encryption protocols employed, and clear policies for data handling established. Farmers may get over these worries and fully profit from digital twin technology by putting into practice cutting-edge techniques like strong encryption, sophisticated authentication, real-time monitoring, anomaly detection, machine learning, and encouraging teamwork. The agriculture sector may use digital twins with confidence, resulting in more effective and sustainable farming operations, by guaranteeing data security, safeguarding privacy, and improving safety precautions.

III. Discussion

This study investigates the application of digital twin technology in agriculture, exploring its potential impact on agricultural practices and sustainability. The research focuses on the unique advantages of digital twins, aiming to understand their role in revolutionizing crop management and precision agriculture.

The findings of this research highlight the transformative implications of digital twins, offering an alternative to traditional, resource-intensive methods. Unlike conventional approaches relying on trial-and-error experiments, digital twins enable rapid testing of innovations at a reduced cost, minimizing risks and saving time. The ability to create digital replicas of farming processes allows for endless simulations, facilitating collaborative exploration of diverse variables such as seeds, soils, weather patterns, and growth factors.

A key contribution of this research lies in its exploration of how digital twins can enhance crop management and precision agriculture. Researchers can leverage massive datasets and computing power to digitally prototype farming processes, optimizing inputs with precision. This not only enhances productivity but also addresses labour shortages and promotes sustainable agricultural practices.

The study identifies the significance of digital twins for farmers, environmental benefits, societal impact, and their role in promoting regenerative agriculture. Farmers, equipped with real-time monitoring and analysis, receive actionable insights for resource management, infrastructure upkeep, and improved productivity. The environmental benefits extend to responsible resource management, contributing to climate-smart agriculture without compromising output. The societal impact is evident in the increased adoption of high-tech farming practices, meeting the growing demand for food while enhancing the well-being of rural communities.

To address the novelty aspect and improve upon existing models, the research emphasizes the need for a nuanced understanding of digital twins in agriculture. The study delves into the complexity of digital twin technology, detailing its operation, assimilation of static and dynamic inputs, and the role of IoT in creating comprehensive virtual replicas. By drawing parallels with applications in healthcare and urban planning, the research establishes the versatility and scalability of digital twins, showcasing their potential in diverse domains.

Despite these promising outcomes, the study acknowledges existing limitations, including data management challenges, model accuracy, scalability issues, and privacy concerns. To enhance the novelty and practicality of digital twin applications, future research could focus on addressing these challenges. Emphasizing the importance of accurate, real-time data, the research suggests ongoing monitoring, regular updates, and collaboration to refine digital twin models. Additionally, the study underscores the need for a robust, multilayered security architecture to mitigate cybersecurity risks, ensuring privacy and safety in the era of interconnected digital twins.

In conclusion, this research sheds light on the transformative potential of digital twins in agriculture, emphasizing their role in sustainability, precision farming, and societal well-being. The findings contribute to the existing body of knowledge by providing insights into the nuanced applications of digital twin technology and offering valuable recommendations for overcoming challenges. Future research endeavours can build upon these foundations, further advancing the field of digital twins in agriculture.

IV. Conclusion

Sustainable agriculture has advanced significantly with the advent of digital twins. A digital twin is essentially a sophisticated virtual model created through simulations and real-time data integration that replicates every facet of an actual farm. This convergence of the digital and physical worlds opens up new applications to improve farming's accuracy, predictability, and environmental responsibility.

Digital twins propel modernization in harmony with sustainability to concurrently improve rural welfare, ecological stability, and production. Next-generation agriculture is enabled by the clever combination of sensors, software, and analytics, which creates a platform for digitally replicating agricultural systems as living models. Thus, the secret to feeding India's expanding population sustainably while preserving the planet's resources is digital transformation. In conclusion, there is a great deal of promise for output increases without causing ecological damage via digital replication and holistic agriculture optimisation. Therefore, using digital twins to integrate advanced technology with moral obligations is the path forward for sustainable farming.

V. Future scope

The future scope of digital twins in agriculture holds promise for further advancements. Ongoing research can focus on refining decision layers, improving data integration techniques, and addressing evolving cybersecurity challenges. The integration of emerging technologies and the development of standardized frameworks for digital twins could lead to more widespread adoption, fostering sustainable practices in agriculture.

Abstract—The need for automation in the textile industry is growing rapidly today. Color based object sorting is a highly challenging process to be considered and needs to be addressed. It involves an automated material handling system. It synchronizes the movement of robotic arm to pick up objects moving on a mobile robot. It aims in classifying the colored objects then picking and placing the objects in its respective pre-programmed place. Thereby eliminating the monotonous work done by human, achieving accuracy and speed in the work. The core objective of the project is to propose an intelligent color-based object sorting system using deep learning technique like Convolution Neural Network for extraction of feature embedded with the machine learning algorithm. The two classifiers Random Forest and K-NN algorithm were implemented and studied for better classification. Based on the performance metrics, the Radom Forest algorithm out performs in classification. The project module involves cameras that captures the object's color through the computer vision Library and sends the signal to the controller. The dataset of the captured images has been uploaded and compared with the trained data set. The ESP 32 Module transmit a signal to relay circuit, which then drives the robotic arm's multiple motors to grip the object and position it in the given area. Based on the color observed, the robotic arm goes to the given point, releases the object, and returns to its original position.

Keywords — Computer Vision Library, Robotic Arm, Convolution Neural Network (CNN), Random Forest (RF), k means Nearest Neighbor (KNN)

I. INTRODUCTION

The way that things are differentiated, sorted, and used in many industrial applications depends heavily on their color. However, if colour sorting is done manually, it would be a highly monotonous, time-consuming, and laborious task, thus it is crucial to develop machines and automate them to make every task more exact and optimal while also making the job of humans easier. Automation is not the newest innovation, but it has undoubtedly had the biggest impact because it is a good step towards handling different sorts of machinery and procedures to limit the need for human involvement, which saves enough time. On a related point, use of this automation to classify objects based on colour in an industrial setting where many products are produced every day, it might play a significant role. Already there exists a traditional way of sorting an object based on the color that are to be picked by the conveyor belt and then placed in the designated portion based on its color feature.

Here the main goal of the project is to flexibly sort the object based on the color and it should act intelligently like human for color discrimination through utilization of deep learning techniques. The Convolution Type Neural Networks has been proposed to implement the system to act like an intelligent system that differs from the traditional system that uses manual method of sorting. After detecting the color, a signal has been sent to the ESP 32 controller which directs the signal to operate the servo motors and grippers for picking and placing of the objects. By this a system of automated color-based object sorting is thus achieved. Color-based item sorting has several advantages over standard sorting algorithms. It eliminates the need for complicated and expensive mechanical setups, speeding the sorting process and lowering operational costs. Furthermore, its versatility enables smooth integration with a variety of industries, ranging from manufacturing and logistics to recycling and waste management. This cutting-edge technology enables perfect sorting, minimizing errors and enhancing productivity with unsurpassed accuracy and speed. Its capacity to handle objects of various shapes and sizes makes it an invaluable tool for a wide range of applications.
Currently, the color-based object sorting system based on deep learning provides the way for a more efficient, cost-effective, and sustainable approach to object sorting, moving industries forward. The color-based object sorting system makes use of CNNs, a type of deep neural network noted for its superior image processing feaures. CNN architecture is inspired by human visual processing methods, making them

extremely successful in extracting complicated patterns and characteristics from images. The system can detect small color differences in objects with unprecedented accuracy and efficiency by exploiting this neural network design. The CNN's feature detectors experts in recognizing colors and their variations as training advances, resulting in a robust internal representation of color information. This format allows the algorithm to differentiate items based on their distinct color profiles, laying the groundwork for correct object sorting. As deep learning and computer vision research advances, the color-based item sorting system will evolve further, opening new possibilities and redefining the automation landscape of industries. It holds the possibility of altering enterprises, supporting sustainability, and boosting human capacities through responsible development in an increasingly networked and automated world.

Finally, the color-based object sorting system that employs CNN deep learning algorithms shows the convergence of innovation and intelligence, providing exceptional accuracy, efficiency, and versatility in object sorting tasks. This extraordinary technology demonstrates the power of artificial intelligence in revolutionizing industries, propelling innovation, and contributing to a future in which automation and human inventiveness coexist happily for the benefit of society.

OBJECTIVES

The main objective of the proposed methodology is to design a prototype that sorts the objects based on the feature extracted from the objects using deep learning convolution neural networks and classification of the objects with respect to colour by utilizing the machine learning supervised algorithms such as random forest and KNN.

II. RELATED WORK

Ren et al. [1] offer a novel approach for locating and tracking border contours in a binary picture, which is frequently applied in digital image processing. Sun et al. provide a unique method for locating and recognizing objects belonging to a certain visual category in most crowded spaces. The visual mode of classification requires more time to process.

It is well known that a generic location strategy put out by Seo et al. [2] may be used to come across a visual item of interest without the need for training. The suggested method makes use of an item of interest to find related things without any prior knowledge of the objects being sought for (learning) or the need for preprocessing. In this classical method of learning only have dealt. Comparison with various algorithms to evaluate the performance of the model haven’t done.

Deep learning applications for the automobile industry were proposed by A. Luckow et al. [3]. Deep learning algorithm especially for automotive industry had been discussed. Machine learning was suggested by Wuest et al. [4] as a solution to the industrial challenges. This article focusses solution only for the industrial challenges.

Three deep convolutional neural network architectures have been evaluated and analysed regarding computer-aided identification issues, dataset characteristics (such as selecting either a big dataset or finer item detection models), and CNN transfer learning from non-medical to medical picture fields [5]. CifarNet, AlexNet, and GooLeNet are the three primary CNN architectures utilized. This paper limits the suggestion for appropriate algorithm to be implemented.

Garad [6] evaluated changes in the precise geometric measurements for item sorting based on colour, size, and form recognition using MATLAB. This paper provides with the information for features extraction. Any surface flaws identified were not, however, remedied.

On a faster R-CNN model that was trained on pictures of mango and pitaya, researchers were able to use the model to recognize and sort several fruits with 99% accuracy while still maintaining fruit quality [7-9].

III. EXISTING METHODOLOGY

A color-based item sorting system is conceptually simple, but it has several drawbacks that might reduce its usefulness, especially when compared to the usage of deep learning methods like Convolutional Neural Networks (CNNs). Color-based sorting cannot distinguish between objects that have similar colours but distinct forms or textures since it solely takes colour information into account. Additionally, traditional sorting techniques are quite sensitive to variations in lighting, which can lead to misclassification as a result of shifting perceptions of colour.

The difficulty of color-based systems to handle objects with complex patterns or different colours is another notable flaw of these systems. This results in incorrect sorting conclusions, unlike CNNs, which can recognize intricate visual clues for exact categorization.

Though the principle behind the TA color-based item sorting system is straightforward, it has several flaws that might limit its utility, especially when contrasted to the use of deep learning techniques like Convolutional Neural Networks (CNNs). Since color-based sorting only considers colour information, it is unable to discriminate between things that have similar hues but different shapes or textures. Traditional sorting methods are also quite susceptible to changes in lighting, which can result in misclassification due to altered perceptions of colour.[10-14]

Another obvious drawback of color-based systems is their inability to manage objects with intricate patterns or many hues. Contrary to CNNs, which can detect complex visual cues for precise categorization, this leads to inaccurate sorting judgements.

IV. PROPOSED METHODOLOGY

A robotic arm that can sort objects by color is able to pick out objects of a particular color and position them where they are needed. Initially the object will be captured by the deep learning network which does the feature extraction of the image for an object. The feature extraction is processed by utilizing the concept of Convolution Neural Network, a deep learning algorithm. First it undergoes preprocessing, convolution of an image, Rectified Linear Unit and finally does the classification based on the fully connected network. This layer uses Multilayer Feed forward network for classification based on its color. To detect the colour of the object, the OpenCv computer vision is employed. The objects are acquired by the camera and they are converted into the respective RGB index. The process of Deep learning algorithm along with the machine learning algorithm that used for classifying the object will be run in GPU processor, which provides us the information about the object based on its color. The controller, which controls the motion of DC and servo motors. The proposed system has a limitation that the object that can be handled by the robot must have specific dimensions which is provided in the table. The camera that captures the image and provides the images as input to the ConvNets. The ConvNet's preprocess and extract the features. The model has been trained with three colors namely Red, Blue, Green.

Table 1: Constraints of Objects handled by Robot

Parameter	**Ranges**
Weight	<100 grams
Size	40 x 40 x 40
Shape	Cubic

Fig 1 Prototype of the Proposed Methodology

The Fig 1 shows the working model of the pick and place robot setup with the all-electronic circuit arranged in a manner to compute the automation task.

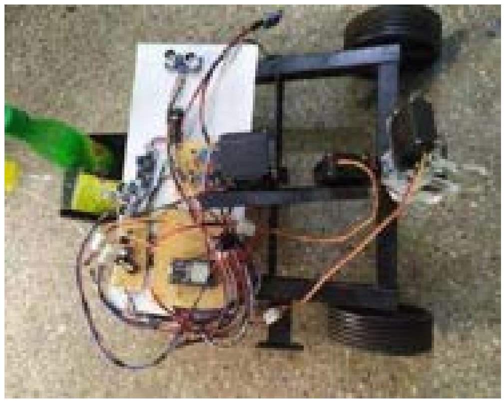

Fig 2 Prototype of the model for sorting object

The Fig 2 shows the model that automatically picks the objects that falls under the range of distance covered. Based on the object input features that has been processed under the deep learning algorithm like CNN, the classification has been done.

Fig 3. Block Diagram of the proposed System

The block diagram for the proposed methodology that developed is given in the Fig 3. The entire process uses the DC and Servo motors, the camera or colour sensor interfaces with the controller and process runs with the aid of the computer which has high processing speed. The computer runs the deep learning that built with the Convolution Neural Network for classification of an object.

The process involves the three major parts, which are listed below

A. CONTROLLER AND DATA ACQUISITION

ESP 32 controls the entire mechanism of process, from controlling the relays to the servo grippers. The object sorting involves the sensing of the object through ultrasonic sensor

B. SORTING AND CLASSIFICATION MECHANISM

The object that placed in the basket is picked by the Robot gripper and moves certain along based on the colour. Based on the colour picked by the robot gripper, it follows different angle patterns and place it in the appropriate bins. For employing this operation, the ultrasonic and proximity sensors are employed for moving and sorting of the objects.

C. SOFTWARE REQUIREMENT

i. *Image Capture:* Object is captured initially by the camera in the form of RGB format. OpenCv Lib (Computer Vision Library) is employed to convert the RGB into binary. The pseudocode performs this function by setting up the threshold value for the images.

ii. *Python IDE:* To make code to run on the processor to perform the classification and feature extraction process and other computer vision process.

D. DEEP LEARNING TECHNIQUE

The most recent technology CNN, a kind of deep neural networks known for their excellent image recognition capabilities, are used in the color-based item sorting method. CNNs are incredibly adept at extracting intricate patterns and attributes from pictures since their design is modelled after human visual processing techniques. Covnets, also known as convolution neural networks, are neural networks with shared parameters. They have,

(i) Convolutional Layer:

The central component of a CNN is the convolutional layer, which is also where the majority of processing takes place. It needs input data, a filter, and a feature map, among other things. Convolution layers are made up of a group of learnable filters (or kernels) with minor widths and heights and the same depth as the input volume (or three if the input layer is an image input). It has three layers namely, convolutional, pooling, and a fully connected layer. The convolution layer is the building block of CNN carrying the main responsibility for computation.

(ii) Padding:

The padding procedure is an important feature of CNNs because it improves the network's performance. Padding refers to the addition of extra pixels around the borders of an image before it is sent through the network in the context of CNNs. This strategic pixel increase allows for greater spatial information preservation during the various levels of convolution and pooling operations, resulting in improved item detection and sorting accuracy. The padding procedure in a Color-Based Object Sorting System ensures that the CNN can successfully identify and classify objects based on their color and other visual properties. Padding improves the network's ability to reliably recognize and sort objects by conserving spatial information and preventing information loss at the edges of objects, contributing to the overall efficiency and effectiveness of the sorting system.

(iii) Pooling layers:

Its major goal is to shrink the input feature map's spatial dimensions while preserving crucial data. It lowers the computational complexity of the network and increases its invariance to tiny changes in the input data as well as translation and rotation. The size of the pooling window, which is typically expressed as a 2x2 or 3x3 window, and the stride, which refers to how much the window is shifted throughout the pooling process, are two hyper parameters that affect how pooling layers behave.

Overall, pooling layers are essential in lowering the spatial dimensions of the feature maps, allowing CNN to concentrate on the most significant features while preserving the network's capacity to detect complicated patterns.

(iv) Fully Connected Layer:

To connect the neurons between two layers, the Fully Connected (FC) layer, which also includes weights and biases, is utilized. These layers make up the final few layers of a CNN architecture and are often positioned before the output layer.

Utilizing the features that the earlier layers and filters gathered, the FC layer performs classification jobs. The FC layer often employs a softmax function—which classifies inputs more accurately and generates a probability score between 0 and 1—instead of ReLu functions.

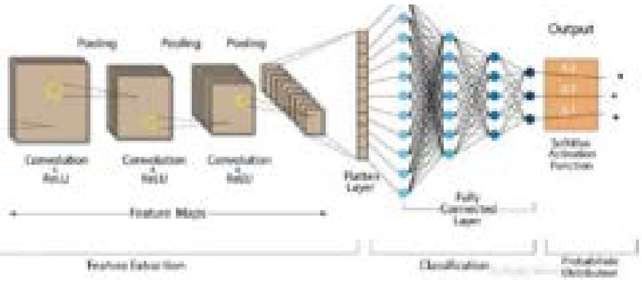

Fig 4 Layers involved in Convolution Neural Network for Object Classification [Source: https://developersbreach.com]

E. MACHINE LEARNING TECHNIQUE

Machine learning technique is implemented for training the model with appropriate training sets. When the model is fed with new data based on the training by machine learning technique and feature extraction by CNN deep learning technique, it sorts the objects effectively. The training data set with respect to input features labelled to output features were trained for 250 iterations. The model trains and classify with the greater accuracy. 100 labelled data set were taken as data set. In those 70 data had been used for training the model and remaining 30 data set had been used for testing the model for the validating the performance.

Since the labelled data set are used, the supervised type of learning was adopted. The input features such as colour with its RGB values are labelled with the color classification of objects such as Red, Green and Blue. The detection of color is achieved by acquiring images of the objects and based on RGB pixel acquisition it has been classified.

The overall block diagram of deep learning and machine learning technique is presented in the Fig 5.

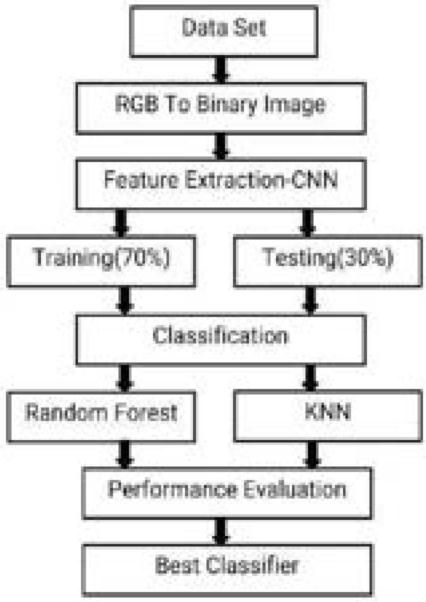

Fig 5 Flowchart procedure of Machine Learning and Deep Learning for classification

V. RESULTS AND DISCUSSIONS

Deep learning algorithm was applied for analyzing the object's features. The features taken in consideration for classification or sorting of objects are shape and colour of the object.

A. PERFORMANCE ANALYSIS OF SYSTEM

Many performance analysis matrixes are available in the Machine Learning algorithm for assessing the performance of the model. In this project, the performance has been analyzed using the Confusion Matrix Performance analysis, accuracy, recall and F1 score methods for evaluating the performance in detecting and sorting the object based on the colour.

The confusion Matrix will be assessed based on the True Positive Rates (TPR) and False Negative Rates (FNR). The confusion matrix parameters that derived from the Convolution Neural Network's output are presented in the Table I.

Table I: Performance Metrics of Confusion Matrix

Parameters	Values of RF	Values of KNN
Total Images	100	100
Training Images	70	70
Testing Images	30	30
True Positive	94	87
True Negative	6	13
False Positive	5	20
False Negative	95	80

From the above table, the confusion matrix gives the True Positive, True Negative, False Positive and False Negative. From the performance analysis of the confusion matrix, true positive in the confusion matrix parameter gives the correct classification and sorting of the object based on the colour. The false positive parameter gives the misclassification or wrong identification of the object based on the colour. This kind of performance in the network affects the accuracy of the network in appropriate detection and classification of objects. Recall is the percentage of correctly classified items in a particular class.

$$recall = \frac{TP}{(TP+FP)} \quad (1)$$

F1 score measured by the precision and recall to analyze the performance of the object classification. Table 3 highlights the performance evaluation of the algorithm. After the classification of objects based on the colour the precision of the Random Forest is 92% and recall of 90% and F1 measure of 92% compared to the KNN algorithm with 81%, 85% and 70% respectively.

Table II Comparison of Proposed Algorithms in Sorting System

Classifier Algorithm	Precision %	Recall %	F1 Measure %
Random Forest	92	90	92
KNN	81	85	70

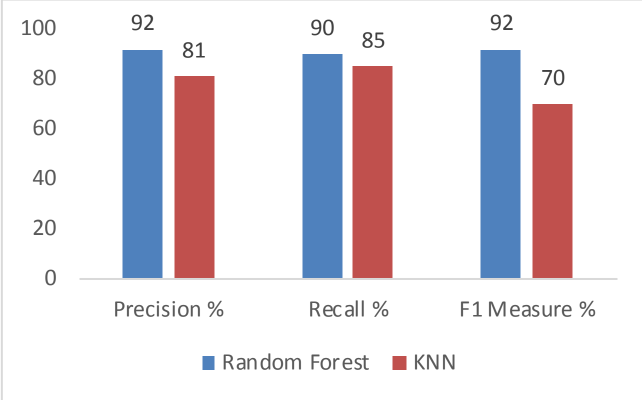

Fig 6 Comparison Results of Classification with Random Forest and KNN

VI. CONCLUSION AND FUTURE WORK

A system based on Convolution type Neural Networks for feature extraction was created to detect the object based on the colour and shape of the object that present in any industrial to domestic applications. The object that differs based on the shape, colour and size are considered as the input features and it is fed to the neural networks for training the Convnet to make the system to learn. The model learns for the various set of training datasets that differ from each set based on its feature vector. For various trails, the proposed system detects and sorts the objects accurately. By utilizing the Convolution Neural Network algorithm employed with Random Forest technique, the classification has been done very accurately and efficiency is very high with very negligible error. The proposed model is limited to handle only three colored objects, for handling more colors it requires concentration in feature extraction. By considering more input features or employing better classifiers the classification efficiency can be improved that Random Forest technique.

Since industries are running towards industrial revolution 4.0, the future industries and even domestic application will adapt deep learning technologies to enable the system to act intelligent. Industries future will be deep learning. This project not only limited for sorting objects in textile industries. It can be extended to the domestic applications to the large-scale industrial applications where sorting can be carried out.

***Abstract*: As artificial intelligence (AI) continues to evolve, so too does its integration into cyber criminal activities, presenting a formidable challenge to digital security. These findings investigate the escalating nexus between AI and cybercrimes, highlighting the emergent dangers posed by AI-driven malicious activities. The study delves into the various ways in which AI technologies are leveraged by cyber criminals to orchestrate sophisticated attacks, incorporating, data breaches, malware propagation, phishing, and social engineering tactics. Furthermore, the methodologies propose proactive research strategies aimed at mitigating the threats posed by AI-facilitated cybercrimes through the lens of digital forensic techniques. By analyzing current trends in AI-driven cyber offenses and their repercussions on digital security frameworks, this research endeavors to elucidate the imperative for novel approaches in digital forensics. Such proactive strategies encompass the establishment of AI-powered forensic tools, the enhancement of detection and attribution methodologies, and the augmentation of cyber resilience through predictive analytics and preemptive measures. Through a comprehensive review of existing literature, case studies, and empirical data, paper analysis seeks to offer insights into the changing landscape of AI-facilitated cybercrimes and the critical importance of digital forensics in countering these threats. By Gaining a more comprehensive grasp of the combined effects or interactions between AI technologies and cyber criminality, this research endeavors to inform stakeholders in the realms of cybersecurity, law enforcement, and policy-making, thereby contributing to the progress or development in proactive measures aimed at safeguarding digital ecosystems against emerging threats.**

***Keywords**: Artificial Intelligence, Cyber Crime, Digital Security, Digital Forensic, Cyber Resilience, Law enforcement, AI-Driven vehicles, Deep-Fake technology, Human Safety.*

I. INTRODUCTION

The study on numerous published research papers, articles, and search engine results highlights a significant shift in cybercrime from traditional physical methods to automated approaches. The integration of AI into illicit activities poses a considerable challenge to digital security, potentially leading to unprecedented threats. As AI technologies evolve, they provide cybercriminals with new capabilities and tools, enabling them to execute more sophisticated and covert attacks. This dynamic realm of AI-enabled cybercrimes encompasses various malicious activities, such as data breaches, malware propagation, phishing schemes, and social engineering strategies. The rapid proliferation of AI-driven cybercriminal activities highlights the crucial need for proactive measures to mitigate these threats. Traditional approaches to digital forensics and cybersecurity must adapt to the complexities introduced by AI-driven offenses.

By analyzing current trends and emerging patterns in AI-facilitated cybercrimes, researchers can empower authorities to identify vulnerabilities and develop innovative solutions to safeguard digital ecosystems. Additionally, the convergence of AI and cybersecurity presents both challenges and opportunities for policymakers, law enforcement agencies, and technology developers. Effective responses to AI-enabled cybercrimes necessitate interdisciplinary collaboration, technological innovation, and robust regulatory frameworks. Encouraging a deeper understanding of the complexities of AI cybercriminality enables stakeholders to formulate proactive measures for risk reduction and enhance digital resilience. In cybersecurity, AI plays a pivotal role across various applications including threat detection, response, and prevention, enabling organizations to proactively predict and combat evolving cyber threats. However, the advancement of AI-powered criminals highlights the importance of a robust understanding of predictive AI research to effectively identify and mitigate emerging threats. By analyzing the evolving strategies, techniques, and procedures employed by cybercriminals, this study aims to analyze and present the complex integration of AI technologies and contemporary cyber threats. Despite extensive research in the cybersecurity domain, there remains a gap in investigating how AI perpetuates a feedback loop, generating new challenges and necessitating innovative mitigation strategies for solving AI-powered cyberattacks [11]. Through an extensive review of over a hundred articles collected via Google search, each focusing on AI-enabled attacks and real-world threats, this study has observed a pattern of large-scale damage incurred by organizations, indicative of organizational crime. Cybersecurity emerges as a critical aspect of security in large and well-organized industries, making them prime targets for cybercriminals aiming to exploit vulnerabilities. Additionally, AI-powered cyber attackers exploit deep-fake technology to create misleading videos, manipulating innocent individuals for malicious gains [12]. These attackers leverage AI-based bots on popular social media platforms like Telegram and Snapchat to facilitate data leaks and perpetrate face recognition scams, thereby compromising user privacy and security [21]. The advent of AI-driven vehicles brings forth new risks, where maliciously programmed automated vehicles could be weaponized to cause illegal accidents. Despite challenges in identifying culprits, enhanced digital forensic techniques offer opportunities for identifying perpetrators and holding them accountable. Upon conducting an enhanced survey of various research papers and articles, it becomes evident that while AI holds significant potential in cybersecurity, its misuse may result in dire consequences. The misuse of AI techniques in cybercrime, as highlighted in references [3] and [6], can damage any individuals' reputation.

To overcome these challenges, forensic analysts must adopt a forward-thinking strategy and understand the methodologies employed by cybercriminals. By thinking like criminals, analysts can adeptly act through the complexities of AI-driven cybercrimes and protect innocent individuals from unwarranted accusations and damaging tactics. Framing the entire problem into a single question, it can be stated: "What if cybercrime enabled by AI is encountered by an educated criminal in the fields of AI and digital forensics?" This question encapsulates the potential scenario where individuals with knowledge in both AI and digital forensics may exploit AI-driven cybercrime for malicious purposes, highlighting the importance of proactive measures and interdisciplinary collaboration in combating emerging threats.

II. RESEARCH METHODOLOGY

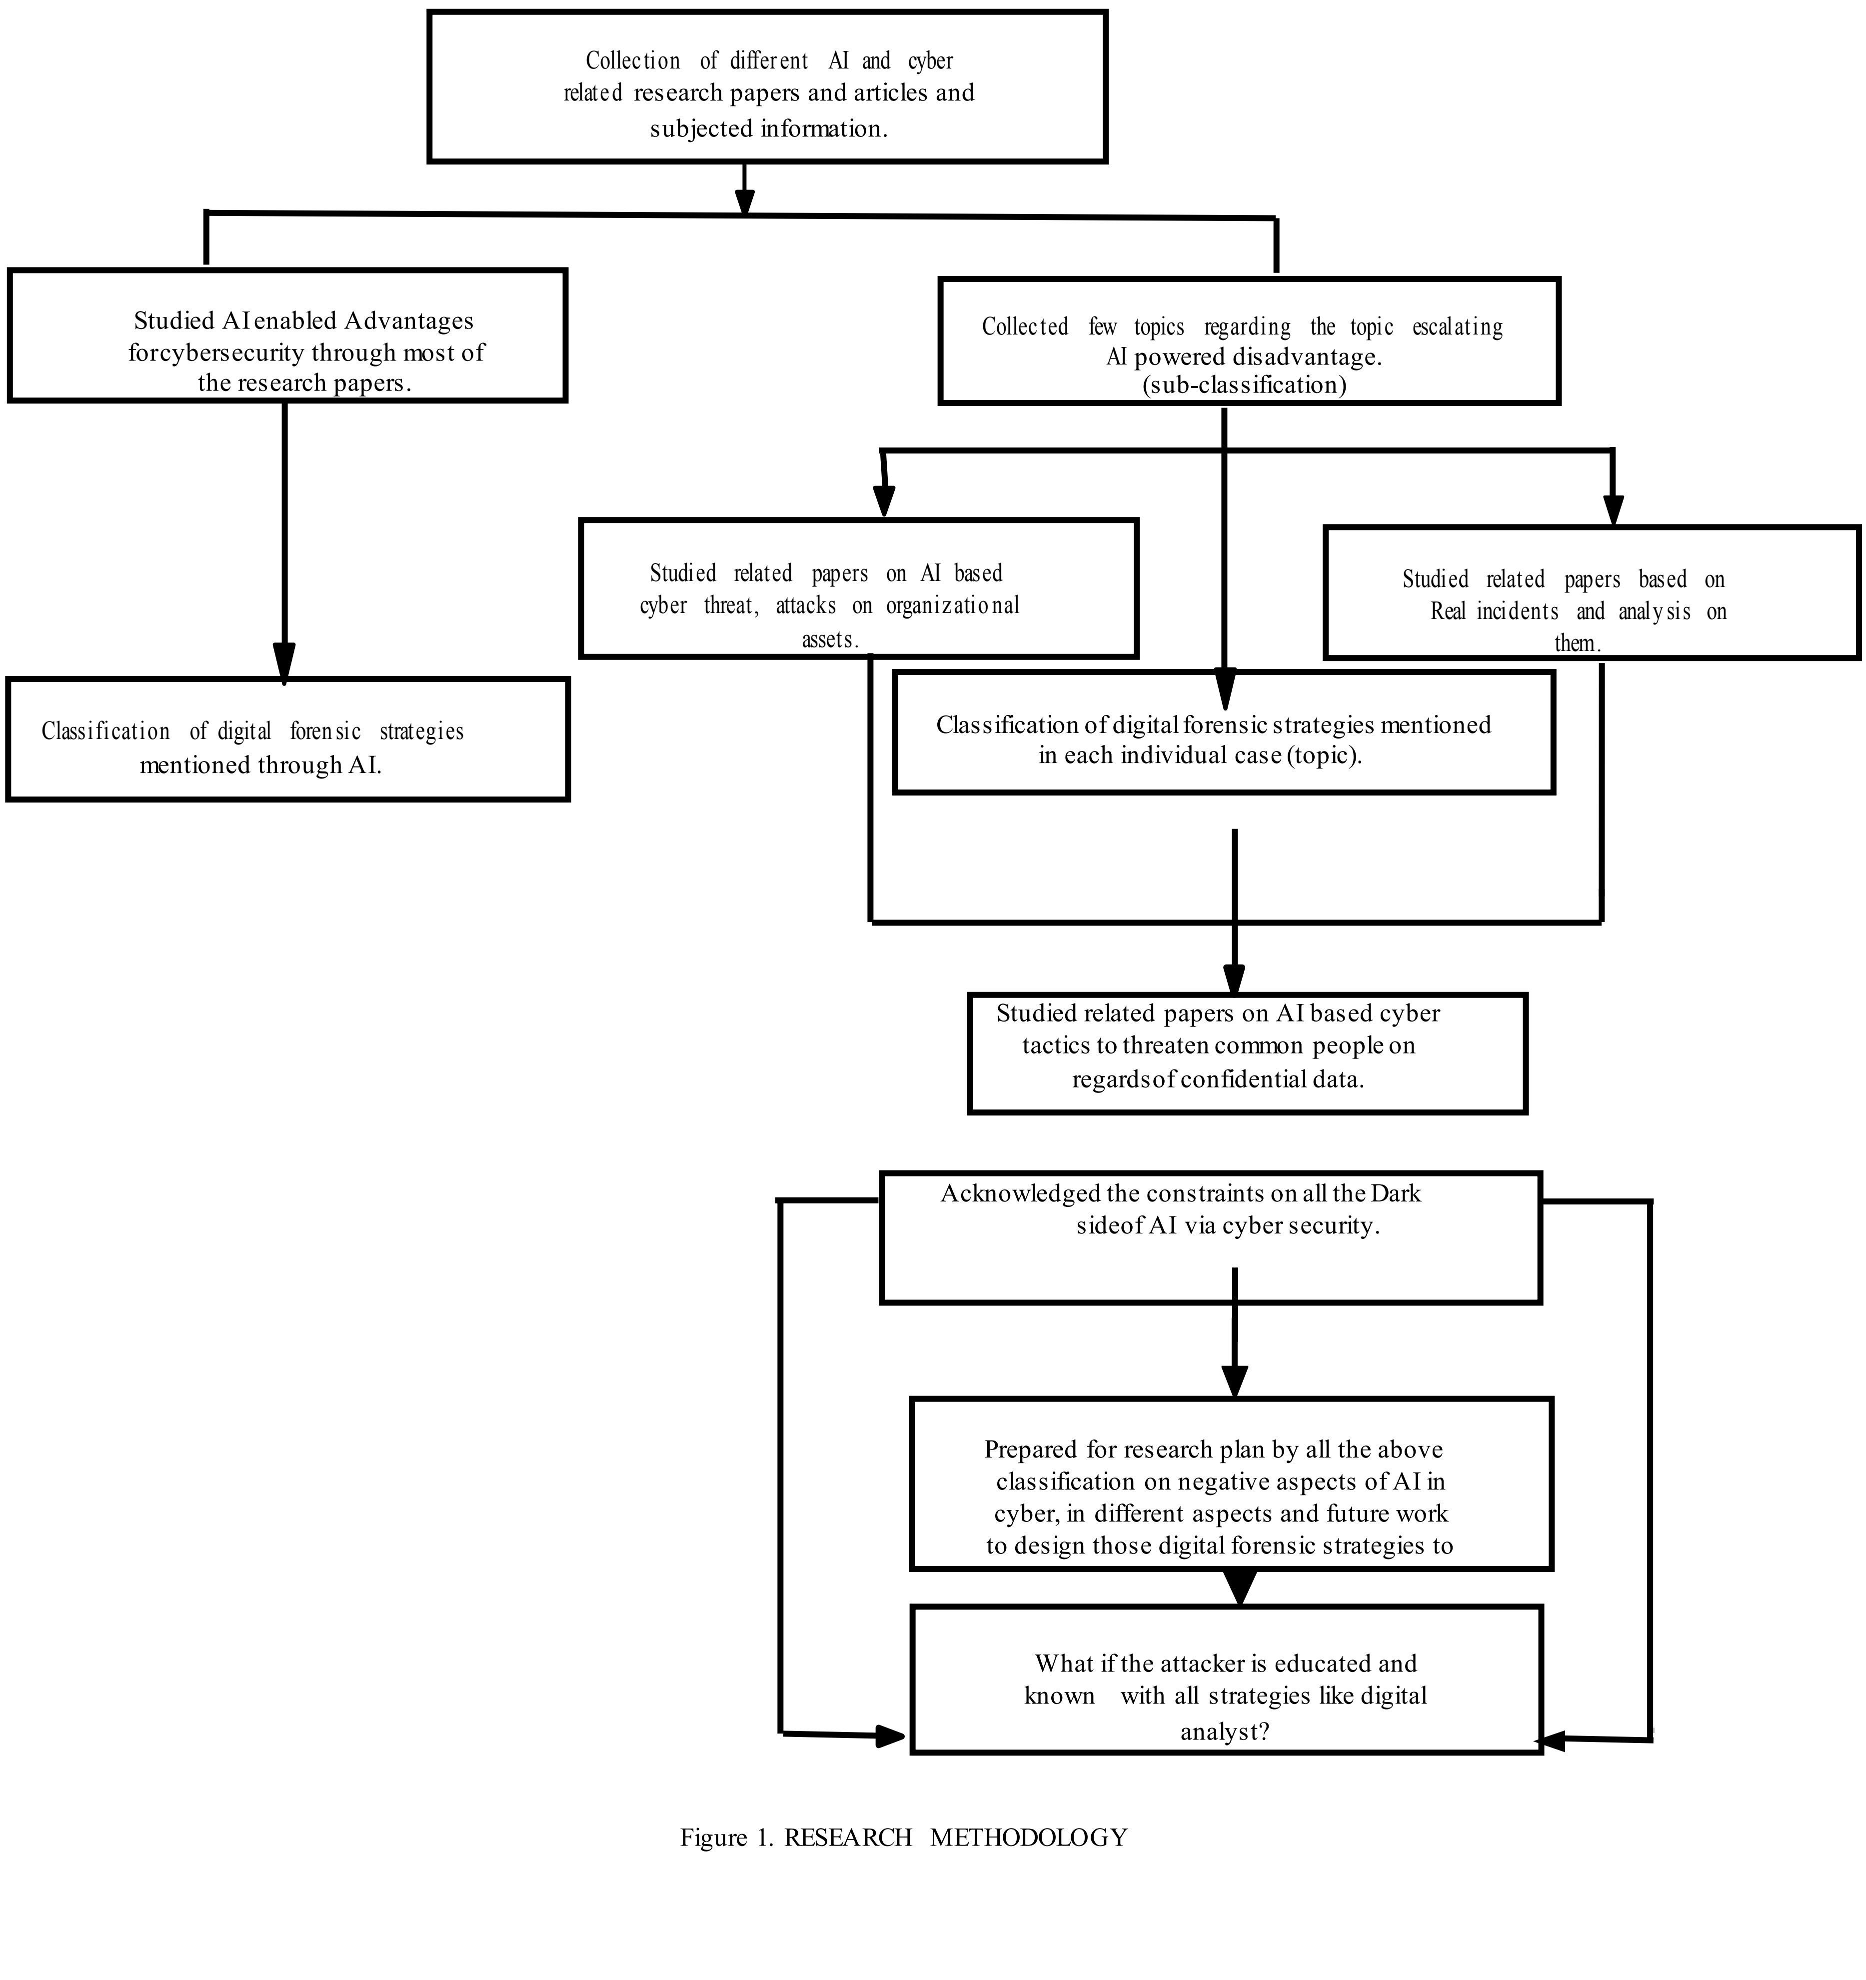

Figure 1. RESEARCH METHODOLOGY

Figure 1 shows the proposed research methodology to perform a comprehensive research study

Step – 1: Collection of Different AI and Cyber Related Research Papers and Articles and Subjected Information:
This section compiles various research papers and articles related to artificial intelligence (AI) and cybersecurity, providing a comprehensive overview of the existing literature and subject matter
Step – 2: Studied AI-Enabled Advantages for Cybersecurity Through Most of the Research Papers:
Examines the advantages offered by AI in enhancing cybersecurity measures as identified in the reviewed literature. Subsequently, it delineates specific topics highlighting the escalating disadvantages associated with AI-powered cybersecurity.
Step – 3: Studied Related Papers on AI-Based Cyber Threats, Attacks on Organizational Assets:
Analyzes research papers focusing on AI-based cyber threats and attacks, particularly those targeting organizational assets. Real incidents are scrutinized, and thorough analysis is conducted to understand the evolving landscape of threats
Step – 4: Classification of Digital Forensic Strategies Mentioned Through AI:
Categorizes digital forensic strategies outlined in the literature that leverage AI technologies to investigate cyber incidents, aiding in the identification and resolution of security breaches.
Step – 5: Studied Related Papers on AI-Based Cyber Tactics to Threaten Common People Regarding Confidential Data:
Explores research papers detailing AI-driven cyber tactics aimed at threatening common individuals and compromising with confidential data. It evaluates the implications of such tactics on privacy and security.
Step – 6: Classification of digital Forensic Strategies Mentioned in Each Individual Case:
Provides a systematic classification of digital forensic strategies discussed in individual case studies, examining their application and effectiveness while addressing cyber threats.
Step – 7: Acknowledged the Constraints on All the Dark Side of AI via Cyber Security:
Acknowledges the limitations and constraints associated with the dark side of AI in cybersecurity, highlighting ethical, legal, and technical challenges that need to be addressed.
Step – 8: What if the Attacker is Educated and Known with All Strategies Like Digital Analyst:
Explores the scenario wherein attackers possess comprehensive knowledge of digital forensic strategies, akin to a digital analyst, and discusses potential implications and countermeasures.

III. ANALYSIS OF EXISTING METHODOLOGIES

The different types of online threats faced by children, including cyberbullying, online harassment, grooming, and exploitation, has been extensively highlighted in the recently published research articles and reports. This study has examined the scholarly works within Pakistan and examined the prevalence of cybercrimes against children and highlighted the need for preventative measures to safeguard their digital well-being [1]. Studies have explored the potential utilization of Artificial Intelligence (AI) innovations, including Natural Language Processing (NLP), machine learning algorithms, and image recognition, in detecting and preventing online threats targeting children. Furthermore, initiatives by governmental bodies, non-profit organizations, and advocacy groups in Pakistan have emphasized the significance of raising awareness, promoting digital literacy, and fostering collaboration among stakeholders to address cybercrimes against children effectively.

Artificial intelligence (AI) is increasingly intertwined with cybersecurity, as highlighted in various scholarly articles [2]. Researchers emphasize AI's central role in automating tasks, accelerating risk detection, and enhancing response mechanisms within cybersecurity frameworks. The recent research reviews explore AI's potential to address cybersecurity challenges by securing communication channels and mitigating cyber threats. Additionally, the idea of explainable AI (XAI) is investigated to clarify cybersecurity using AI applications and enhance security analysis. However, there is growing concern regarding the emergence of AI-driven cyberattacks, prompting studies to analyze cybercriminals' techniques and the changing risk landscape. As cybercrime escalates, researchers highlight the necessity for comprehensive studies on AI-based security frameworks, particularly within emerging digital environments like the metaverse. Moreover, systematic literature reviews investigate AI strategies in crime prediction, underscoring the significance of understanding AI's implications across various domains.

The evolving trend of cybercriminals integrating AI into their malicious operations outlines the diverse ways in which AI technologies empower adversaries to conduct efficient and stealthy attacks, posing significant challenges to traditional cybersecurity paradigms [3]. Furthermore, surveys delve into the proactive measures adopted by cybersecurity professionals to utilize AI for threat detection, incident response, and vulnerability management, aiming to counteract the adversarial exploitation of AI to safeguard organizations.

The abstract of the paper "How AI Is Shaping the Future of Cybercrime" highlights the increasing utilization of AI by cybercriminals to perpetrate advanced attacks and underscores the urgent need for defenders to employ AI-driven defensive mechanisms to safeguard against evolving cyber threats and maintain the integrity of digital ecosystems. Cybercriminals are using AI tools to orchestrate sophisticated attacks, exploiting its capabilities to enhance malware development, automate assaults, and craft effective social engineering plans. However, cybersecurity professionals are responding with proactive measures to mitigate these threats by harnessing AI for defensive strategies.

"Artificial Intelligence-based Cybersecurity within the Framework of the New Industrial Revolution" presents a comprehensive analysis of existing research, systematically examining literature pertaining to AI-driven cyber-attacks and their implications for Industry 4.0 ecosystems [4]. The study explores the use of artificial intelligence in cybersecurity, encompassing threat detection, anomaly detection, and tailored incident response mechanisms for Industry 4.0. Additionally, it delves into emerging trends in AI-driven cyber threats, such as adversarial machine learning and autonomous attack vectors, highlighting the importance of adaptive and resilient cybersecurity frameworks. Furthermore, the survey underscores the integration of AI technologies with traditional cybersecurity measures to bolster threat intelligence, mitigate risks, and safeguard critical infrastructures within the new industrial revolution framework. Overall, the literature review furnishes valuable enlightenment into the evolving dynamics of artificial intelligence and cybersecurity within the context of Industry 4.0, offering a basis for informed decision-making and guiding future research endeavors. Recent advancements in applying Artificial Intelligence (AI) and Machine Learning (ML) to enhance cybersecurity measures have been a focal point of research. This study analyzes various facets, including the utilization of AI/ML algorithms for detecting potential risks, anomaly identification, and behavior analysis [5]. It explores emerging trends such as Explainable AI (XAI) for interpreting AI-driven decisions in cybersecurity contexts. Furthermore, the literature survey explains the convergence of AI and ML techniques with regular security systems to strengthen the defense mechanisms against evolving cyber threats. It also examines key research areas like adversarial machine learning and the application of AI/ML in network intrusion detection systems. These challenges and prospects associated with AI/ML adoption in cybersecurity domains offer perspectives on prospective research paths and strategic implementations for robust cyber defense strategies.

The implications of AI policy-making on the administration of criminal justice systems, particularly in combating cybercrimes, have been thoroughly discussed [6]. It highlights the collaborative efforts of international organizations in developing applicable instruments to address cybercrimes effectively. Moreover, it explores the intersection of artificial intelligence and cybercrime, showcasing the difficulties and opportunities arising from the integration of AI technologies in criminal investigations and law enforcement. The changing terrain of cyber threats and the significance of AI in enhancing forensic techniques and crime prevention strategies are also explored. COVID-19 Pandemic accelerated the dependence on AI-based technologies, but it also encouraged organized criminal groups to exploit vulnerabilities, increasing cyber threats against various sectors and individuals [6]. Cybercriminals deploy AI to orchestrate sophisticated attacks, exploiting IoT vulnerabilities and perpetuating misinformation campaigns through bots and deepfakes. This requires enhanced international cooperation, legal frameworks, and technological capabilities to combat evolving cyber threats facilitated by AI-enabled criminal activities effectively, safeguarding the society against emerging threats. Another study has conducted an extensive survey exploring the connection between cybersecurity and Artificial Intelligence (AI), outlining the rapidly changing landscape of cyber threats [7]. It highlights the adaptability of cyberattackers, who are increasingly utilizing AI-driven techniques in their attacks. The survey investigates into the multifaceted implications of AI across different security domains, encompassing physical, digital, and political security contexts. Furthermore, it illuminates the potential risks linked with the malicious application of AI technology. Through a methodical analysis, the paper pinpoints research gaps and challenges, with a particular focus on addressing accident dangers linked to AI and other critical cybersecurity issues. By furnishing insights into both the opportunities and perils presented by AI in cybersecurity, the survey stands as an informative resource for understanding how cyber threats are changing and how AI may reduce or increase these problems. Additionally, the study scrutinizes potential risks emanating from the malevolent exploitation of AI across various security domains, including physical, digital, and political security. It also emphasizes research domains related to potential accident risks linked with AI and other relevant cybersecurity matters. AI technologies within cybersecurity, spotlighting the necessity for strong governance frameworks to guarantee responsible AI implementation and address the risks of unintended outcomes. It motivates interdisciplinary collaboration between policymakers, technologists, and ethicists to develop holistic approaches to AI governance that balance innovation with accountability.

TABLE 1: SUMMARY OF EXISTING METHODOLOGIES

S. No	Paper Title	Year of Publication	Objective of AI based cyberattacks via Digital Forensics	Conclusion	Limitations
1	Artificial Intelligence Implementation to Counteract Cybercrimes Against Children in Pakistan	2022 (10th October)	Detect, takedown, and trace online violence by AI, against children	. Updating cybersecurity measures and leveraging AI alongside traditional methods areessential to safeguard children from evolving online risks. As technology progresses, the call for anticipatory actions becomes paramount to protect children from the growing threats of sexual abuse, bullying, and exploitation online.	Lack of primary data limits the scopeof the study .and the Lack of data sufficiently witnessing cyberattacks
2	AI for Cybersecurity and Cybercrime: How Artificial Intelligence Is Battling Itself	2023 (9th June)	Detect Deepfake-AI-powered forensic tools and establish legal frameworks for AI crime investigation.	The paper emphasizes the needfor standardized methodologies and ethical considerations in combating AI-driven cybercrime	Lack of standardized methodologies for AI crime detection, ethical considerations inAI-driven forensic analysis
3	AI Is Shaping the Future of Cybercrime	2023 (21st December)	Not mentioned via digital services criteria but objective Isto discussed about different realtime mitigations of AI power- cyberattacks.	AI tools are opening society's eyes to new possibilities in virtually every field of work. Ashackers take fuller advantage oflarge language model technologies, the industry will need to keep pace to keep the AIthreat under control.	The paper is only limited to real world examples and malicious cases of AI application and mitigations due to AI powered cyberattacks.
4	Artificial Intelligence-Based Cyber Security within the Situation of Industry 4.0—A Survey	2023 (19th April)	With the increasing necessity of networked information technology, the surface area for cyberattacks has increased. Because of this, studies aiming at understanding the actions of cybercriminals are essential for producing data for cybersecurity policies.	Mentioned variations in cyberattacks, defense counterstrategies, implementation of AI, ML and DL for cyber security in Industry 4.0, advantages, and disadvantages through AI to preserve security.	The study does not complete into the practical implementation and effectiveness of the derived cyber security challenges in real-world scenarios.
5	Current trends in AI and ML for cybersecurity: A state-of-the-art survey	2023 (25th October)	Not mentioned about digital forensicsOr Services but mentioned about future work and research based on digital forensic methodologies.	Out of 100 percent 20 to 30 percent organizations are still facing challenges to application of AI with cyber-security.	The discussion in involved only with different real scenarios but no implementation or methodology which were left for future work or research.
6	Cybercrime and Artificial Intelligence. A conclusion of the work of international organizations on criminaljustice and the international applicableinstruments	2022 (22nd February)	Discussed about public and national security objectives and challenges when drones auto vehicles are not properly managed.disruption of AI from the times of Covid 19 and ec3 Europol.	The paper finalizes with a conclusion that offers an alternative to create effective policy responses to counter cybercrime committed through AI systems.	The entire research is an overviewof organizational conventions butno practical plan and even no future work.
7	The AI-Based Cyber Threat Landscape: A Survey	2020 (February)	To raise awareness about the progressive landscape of cybersecurity threats driven by AI technologies and to facilitate the development of strategies and defenses to mitigate these risks effectively.	Cyberattacks merging AI with conventional methods, introducing an analytic framework for modelingattacks and strategizing defenses. It highlights exposure and bugs in infrastructures like smart grids.	Findings and frameworks presented may not universally apply to all cyberattack situations, as the effectiveness ofdefenses can vary based on specific contexts.
8	Artificial Intelligence Safety and Cybersecurity: aTimeline of AI Failures	2016 (25th October)	To compile and analyze a timelineof AI failures in the context of safety and cybersecurity, document instances where AI systems have malfunctioned or caused harm dueto safety and security vulnerabilities	Importance of addressing safety and cybersecurity in AI development and deployment. Analysis on timeline of AI failures, it underscores the need forrobust safety mechanisms, rigorous testing, and proactive risk mitigationstrategies to prevent future incidents.	Researches findings may include the relianceon publicly available information and documented cases of AI failures, which may not represent the entire spectrum of incidents or accurately capture the extent of the problem.
9	The Emerging Threat of Ai-driven Cyber Attacks: A Review	2022 (4th March)	To examine the emerging threatposed landscape of AI-driven cyberattacks, analyze the techniques employed by threat actors, and assess the potential risks and impacts on cybersecurity (digital service)	The significant challenges posed by AI-driven cyberattacks and underscores the importance of proactive measures to mitigate these threats, emphasize need for continuous monitoring, adaptationof cybersecurity strategies (digital forensic methodology)	Focus on existing AI-driven cyberattack techniques without extensive coverage of emergingor novel threats.
10	Fighting malevolent AI: artificial intelligence, meet cybersecurity	2016 (13th June)	To explore the intersection of artificial intelligence and cybersecurity, focusing on mitigating malevolent uses of AIin cyber threats	Emphasizes the critical need for proactive measures to address the growing challenges posed by malevolent AI in cybersecurity. It underscores the main aspect of ongoing research, collaboration, and innovation to stay ahead of emerging threats and safeguard digital systems and infrastructure	The paper may not provide comprehensive solutions to all potential threats posed by malevolent AI, as the plot of AI–enabled cybersecurity is rapidly evolving

VI. CONCLUSION

This research study has reviewed numerous AI-driven cybersecurity research articles across various research platforms, revealing significant advantages in the implementation of AI for cybersecurity. While many research works focus on the benefits, measures have been identified, termed the "Dark Side of AI." The aim of this research study is not to determine if AI is inherently good or bad for cybersecurity but to highlight potential risks. Considering a future where attackers grasp AI-driven cyber technology as well as ethical analysts, substantial security threats. Such attacks might result in economic losses and compromise the CIA (Confidentiality, Integrity, and Availability) of organizations. Even after implementing best practices and measures, attackers may get successful, exploiting technological advancements, possibly aided by well-trained groups skilled in misleading investigators and analysts. Educated criminals in AI and cybersecurity might easily evade capture, framing innocent individuals. Classifying AI-driven cyber threats, it is evident that significant financial and human losses are foreseeable. To combat these issues, it is best to advocate for using machine learning (ML) algorithms alongside AI in cybersecurity to overcome malware attacks. ML algorithms enhance threat detection capabilities, offering proactive preventative measures against evolving malware and cyberattacks.

Abstract— **Agriculture is the backbone of India, which plays a major role in the economy of a country. Agriculture is based on planting and harvesting crops over time. Crops should be sowed according to the environmental factors and appropriate lands. It is difficult for farmers to predict the yield of crop before harvesting because of varying climatic conditions. So to overcome this issue, the amount of crop yield is predicted with the factors like soil-type, weather, climate, crop-type etc., This paper introduces a novel approach to improve the accuracy and interpretability of crop yield prediction models by integrating Long Short-Term Memory (LSTM) networks, Integrated gradients (IG) feature selection, and SHapley Additive exPlanations (SHAP) analysis. The proposed methodology aims to predict the amount of specified crops that can be yield in an area. The lack of interpretability in many existing models hampers stakeholders' ability to understand and trust the predictions. The LSTM network captures temporal dynamics for improved accuracy, while IG and SHAP provide insights into feature contributions, addressing the interpretability issues in existing models. This integrated system not only advances prediction accuracy but also fosters understanding and trust among stakeholders, making it a comprehensive and interpretable tool for predicting crop yields.**

Keywords— Data-driven agriculture, Interpretability, Integrated Gradients, Long short-term memory, Shapley Additive Explanations.

I. INTRODUCTION

Agriculture is a crucial sector of the Indian economy, serving as a fundamental component of the country's socio-economic structure. Not only does it serve as a major means of earning a living, but it also plays a crucial role in contributing to the country's Gross Domestic Product (GDP). Crop yield prediction plays an important role in agricultural practices and policy-making. Precise forecasts may result in efficient distribution of resources, well-informed decision-making, and improved food security. Developing trustworthy models for crop yield prediction in India is tough and vital due to the country's distinct climatic zones and wide range of grown crops. The utilization of LSTM networks is motivated by the necessity to capture temporal dependencies embedded within the complex dynamics of crop yield data. Unlike conventional models, LSTM networks excel at learning and retaining sequential information over extended time intervals.

The integration of LSTM with IG and SHAP represents an innovative methodology within the field of agricultural forecasting. LSTM is a time-series model which is used to predict output by training with historical data, while IG and SHAP provide an explanation for the underlying reasons behind these patterns. This comprehensive approach not only improves the accuracy of predictions but also adds a level of transparency and interpretability to the model. The clarity of information is very significant, as it allows us to get insights into the specific ways in which various elements, such as weather conditions or soil qualities, are impacting crop yields. Integrated Gradients as a feature attribution technique brings a new dimension to the interpretability and training efficiency of the model. By quantifying the contribution of each feature throughout the input space, Integrated Gradients offers a nuanced understanding of the model's decision-making process.

Furthermore, the proposed approach integrates SHapley Additive exPlanations (SHAP) analysis, a technique renowned for its ability to provide insightful and coherent explanations for model predictions. SHAP values allow for the dissection of individual feature contributions, offering stakeholders a transparent view into the factors influencing crop yield outcomes.

Figure. 1. Crop Harvest Using Modern Machines

The incorporation of LSTM is particularly remarkable, given its use in agricultural data analysis is not thoroughly investigated, particularly in the Indian setting. The model's capacity to capture temporal dependencies in data may provide valuable insights into the effect of different variables on crop yields throughout time. Through empirical evaluations on real-world crop yield datasets, this research work demonstrate the effectiveness and superiority of the integrated approach compared to traditional models. The amalgamation of LSTM, Integrated Gradients, and SHAP analysis not only enhances prediction accuracy but also provides a robust framework for understanding the intricate relationships between input features and crop yield outcomes. This paper contributes to the advancement of precision agriculture, offering a sophisticated toolset for stakeholders to navigate the complexities of modern farming with greater confidence and precision.

III. PROBLEM STATEMENT

Despite the significant strides made in leveraging deep learning for crop yield prediction, existing models often face challenges related to the accurate capture of temporal dependencies and the lack of interpretability. Traditional models may struggle to adapt to the dynamic nature of agricultural data, leading to suboptimal predictions. Additionally, the black-box nature of some deep learning models hinders stakeholders' ability to comprehend and trust the predictions, impeding informed decision-making in agriculture. Furthermore, the lack of interpretability in many existing models hampers stakeholders' ability to understand and trust the predictions, impeding their ability to make well-timed and well-informed decisions. The temporal dynamics associated with factors such as weather patterns, soil conditions, and crop growth stages play a pivotal role in influencing crop yield outcomes. Conventional models, which may not adequately capture these temporal nuances, often fall short in providing accurate predictions, particularly in the face of changing environmental conditions. The relative importance of various features influencing crop yields is critical for effective decision-making. Traditional models may lack detailed feature attribution mechanisms, leaving stakeholders with limited insights into which factors significantly impact the predictions. This gap in interpretability restricts the ability to prioritize and act upon specific features influencing crop yield outcomes. Crop yield outcomes are the result of a complex interplay of numerous factors, including environmental conditions, agronomic practices, and genetic traits. Previous models may not adequately account for the multifactorial influences that contribute to crop yield variations. Existing models may encounter challenges when applied to diverse crops, regions, or varied agricultural contexts. The scalability and generalizability of models become pertinent considerations as agricultural systems differ, requiring models that can adapt to the specific characteristics of different crops and environments.. The inability of previous models to adapt to the dynamic nature of these temporal dependencies leads to suboptimal predictions, particularly in scenarios where the impact of historical data extends over multiple seasons. Many existing crop yield prediction models face challenges in achieving high levels of accuracy. Traditional statistical methods might oversimplify the underlying complexities of the agricultural system, while basic machine learning models may lack the capacity to discern non-linear relationships and subtle patterns in the data.

IV. EXISTING SYSTEM

Traditional approaches often rely on statistical methods, regression models, or basic machine learning algorithms to analyze historical data and predict future crop yields. These methods, while providing a foundational understanding of crop yield trends, often face limitations in capturing the intricate temporal dynamics and complex relationships present in agricultural datasets. Some existing models incorporate temporal aspects using simpler time-series techniques, but they may not fully exploit the benefits of more sophisticated temporal models. Existing systems, particularly those based on statistical methods, may struggle to effectively model temporal dependencies in agricultural data. Crop growth is influenced by various time-sensitive factors such as seasonal changes, weather patterns, and planting cycles. The inadequacy in capturing these temporal intricacies limits the accuracy of predictions. Traditional machine learning algorithms may overlook long-range dependencies, hindering their performance in predicting crop yields influenced by evolving environmental condition. Lack of interpretability can make it difficult to identify biases or errors within the model. If the model is making predictions based on inaccurate or biased features, without clear insights into the feature contributions, it becomes challenging to rectify and improve the model. However, previously used machine learning models may struggle to adapt to abrupt changes or events, and their performance can be limited by the availability of long-term, high-quality historical data. The black-box nature of some machine learning models impedes the interpretability of predictions. Farmers and stakeholders require transparent insights into the factors influencing crop yield outcomes to make informed decisions. The absence of interpretable insights limits the trust and adoption of these models in practical agricultural settings where transparency is crucial. Previous system faced interpretability challenges, where interpretability is also an essential factor in predicting crop yield.

Interpretability is crucial for integrating model predictions into real-world decision-making processes. If farmers cannot interpret and understand why a particular prediction was made, they may be less likely to act upon the recommendations. The lack of interpretability hampers the practical utility of the model as a decision support tool for farmers and agricultural practitioners. . A lack of clear insights into feature contributions and decision-making processes hampers the ability to learn from model behavior and iteratively improve the model. Addressing the interpretability challenge is vital to ensuring that predictive models align with the needs, understanding, and trust of the end-users in the agriculture sector.

V. PROPOSED SYSTEM

This paper aims to overcome the limitations of existing crop yield prediction models by introducing an integrated approach that leverages advanced deep learning techniques. The key components of the proposed system include Long Short-Term Memory (LSTM) networks, Integrated Gradients (IG) for feature attribution, and SHapley Additive exPlanations (SHAP) analysis. LSTM networks are employed to model sequential data and long-term dependencies, enabling the system to better understand the historical patterns and temporal dynamics that influence crop yields. This allows for improved prediction accuracy, particularly in situations where traditional models may struggle. Long Short Term Memory takes historical data and refers how prediction and training has been done. It is one of the most powerful time series model used in many prediction systems. Long Short Term Memory enhances The model's capability to grasp temporal dependencies within crop yield data. Integrated Gradients enhance the interpretability and transparency of the model predictions. Integrated Gradients is introduced as a feature attribution technique, quantifying the contribution of each feature throughout the input space. This not only aids in model interpretability but also addresses concerns related to the "black-box" nature of some machine learning models, making the predictions more understandable and trustworthy. Shapley Additive exPlanations provide detailed insights into feature contributions and relationships. SHAP analysis is integrated to offer a comprehensive breakdown of how each feature contributes to the model's predictions. This ensures a transparent understanding of the factors influencing crop yield outcomes, allowing stakeholders to prioritize and act upon specific features based on their impact .. This includes the seamless integration of LSTM, IG, and SHAP components, creating a unified framework for crop yield prediction. The model is trained on historical data, allowing it to learn both the temporal dependencies and feature contributions, thereby enhancing its predictive accuracy and interpretability. Real-world crop yield datasets are utilized to empirically evaluate the effectiveness of the proposed system. Comparative analyses are conducted to showcase the superiority of the integrated approach over traditional models in terms of accuracy and interpretability. It represents a comprehensive and integrated approach to crop yield prediction, addressing the limitations of existing models by combining advanced temporal modeling, feature attribution, and interpretability techniques. The LSTM model, a kind of Recurrent Neural Network (RNN), was selected because to its expertise in processing time-series data, which is essential for assessing and forecasting agricultural crop yields. The LSTM architecture excels at capturing temporal dependencies and sequences in data, making it particularly valuable in agricultural contexts where crop output is impacted by sequential environmental and agronomic variables. LSTM functions by retaining a 'memory' of prior knowledge, allowing it to provide well-informed predictions by considering both the current input and the contextual information from previously encountered data. This is especially advantageous in agricultural datasets where the present crop output might be affected by variables from prior years, such as cumulative rainfall patterns or fluctuations in soil nutrients. The LSTM architecture used in this investigation relied on many pivotal components:

1) Input Gate: The input gate regulates the amount of freshly received information that is preserved.

$$i_t = \sigma(W_i \cdot [h_{t-1}, x_t] + b_i) \quad (1)$$

$$\widetilde{C_t} = tanh\ tanh\ (W_C \cdot [h_{t-1}, x_t] + b_C) \quad (2)$$

2) Forget Gate: Determines the data that should be eliminated from the cell state, enabling the model to disregard irrelevant information.

$$f_t = \sigma\left(W_f \cdot [h_{t-1}, x_t] + b_f\right) \quad (3)$$

3) Cell State: The cell state in an LSTM functions as a linear conveyor belt that spans the whole chain, facilitating the flow of information with minimal linear interactions. The system retains and transports pertinent information throughout the sequence processing, guaranteeing the availability of context to produce precise predictions.

$$C_t = f_t * C_{t-1} + i_t * \widetilde{C_t} \quad (4)$$

4) Output Gate: The output gate is responsible for determining the subsequent hidden state of the LSTM, which encodes information from past inputs and enables the LSTM to make educated predictions.

$$o_t = \sigma(W_o \cdot [h_{t-1}, x_t] + b_o) \quad (5)$$

$$h_t = o_t * tanh\ tanh\ (C_t) \quad (6)$$

The LSTM model used in this work included sequential data pertaining to crop yields, encompassing variables such as rainfall, fertilizer utilization, and other pertinent agronomic data. Configured with a specialized architecture featuring 50 neurons in the LSTM layer, coupled with a Dense layer housing a solitary output neuron, the model was finely tuned for precise yield predictions. Training involved the utilization of the Rectified Linear Unit (ReLU) activation function, optimized through utilizing the Adam optimizer, with the mean squared error employed as the loss function.

The LSTM's distinctive capability to scrutinize time-series data emerged as a cornerstone, facilitating a comprehensive understanding of patterns and trends in agricultural yields over diverse temporal spans. The inherent capacity of the LSTM to analyze time-series data emerged as a cornerstone in comprehending patterns and trends within agricultural yields over an extended period. Its design proved particularly advantageous in managing the temporal component of the data, adeptly capturing subtleties and relationships across multiple time periods. This temporal analysis was essential for unraveling intricacies in crop yield dynamics, rendering the LSTM an indispensable tool in predicting agricultural outcomes with precision. The model's unparalleled capacity to discern relationships across various time periods solidified its status as a profound instrument for understanding the complex dynamics of crop yield prediction. This nuanced approach, tailored to temporal complexities, positions the LSTM as a pivotal tool, offering profound insights and contributing significantly to advancements in agricultural forecasting. The model's ability to unveil profound insights into the dynamic nature of crop yield prediction underscores its significance in advancing precision agriculture practices. In conclusion, the LSTM model, with its robust architecture and temporal analysis capabilities, stands at the forefront of revolutionizing how perceive and predict agricultural yields. This nuanced approach, tailored to the temporal complexities inherent in agricultural data, positions the LSTM as a pivotal instrument in the predictive analytics toolbox. Its capacity to capture subtleties and relationships across diverse time periods underlines its significance in providing a comprehensive understanding of the intricate dynamics influencing crop yield predictions.

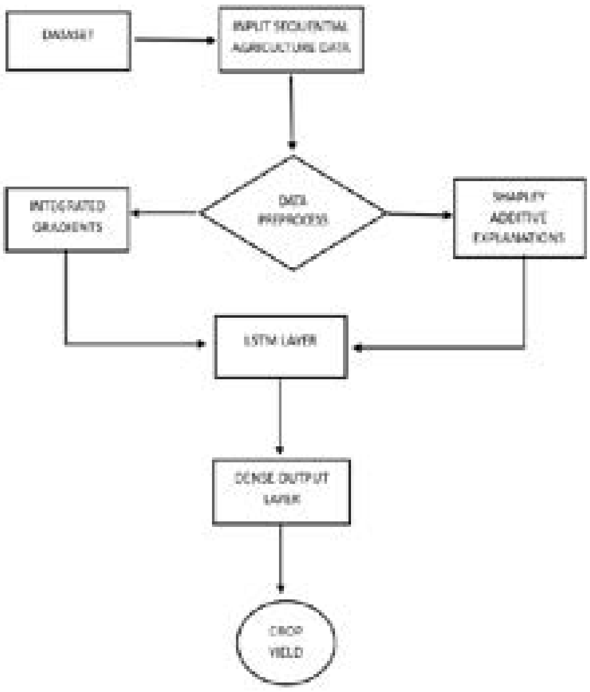

Figure. 2. Algorithm architecture

VI. METHODOLOGY

1) Dataset overview and preparation:

The dataset crucial to this study comprises a comprehensive collection of agricultural data, extending from 1997 to 2023, across numerous states in India. It delivers a thorough view on different crops, encompassing a vast diversity of key variables critical for crop production prediction. These parameters include the kind of crop, the year of cultivation, particular cropping seasons, and the geographical area (Indian states) where the crops were cultivated. Additionally, the dataset offers quantitative metrics such as the area under cultivation (measured in hectares), the overall output amount (in metric tons), and estimated yields. It also includes major climatic elements including yearly rainfall (in mm) and agronomic inputs, particularly the utilization of fertilizers and pesticides (quantified in kg). This rich combination of data gives a unique chance to study and estimate crop yields, offering insights into the interaction of environmental, agronomic, and geographical variables on agricultural production.

2) Data Preprocessing & Cleaning:

Data pre-processing: In the preprocessing phase, a structured approach was employed to condition the dataset for deep learning models. Categorical features underwent a transformation procedure, where methods like one-hot encoding were utilized. In this strategy, a category variable

$$C\_i = \{ 1, if\ the\ original\ value\ is\ the\ i - th\ category \\ 0, otherwise \}$$

For numerical characteristics, normalization was required to align the data more closely with Gaussian distribution, applying the Power Transformer and the Yeo-Johnson transformation. Transformation, applied to each characteristic.

$$x\_i' = \{ [(x\_i + 1)^\wedge\lambda - 1] / \lambda, if\ \lambda \neq 0, x\_i \geq 0 \\ ln(x_i + 1), if \lambda = 0, x_i \geq 0 \\ -[(-x_i + 1)^{(2-\lambda)} - 1]/(2 - \lambda), if \lambda \neq 2, x_i < 0 \\ -ln(-x\_i + 1), if\ \lambda = 2, x\_i < 0 \} \quad (7)$$

3) Training the model:

Datasets are taken from Open Government Data (OGD), Food and Agricultural Organisation Data (FAO) etc., These datasets contain the necessary raw data and features that can be fed to the model for training. For training the model, datasets are splitted into two parts. One part for training and another one for testing. Typically, this split follows a set ratio, such as 70% for training and 30% for testing, or 80% for training and 20% for testing. This splitting is done randomly to guarantee that both sets are reflective of the entire data distribution. The training set is used to train the model, whereas the testing set is reserved to assess its predicted performance. Various machine learning models were built, each optimized to capture the intricacies of the agricultural dataset. The models comprised Linear Regression, Random Forest Regressor, CatBoost Regressor, and LSTM (Long Short-Term Memory) networks. For each model, a particular set of parameters was determined to enhance performance.

The LSTM (Long Short-Term Memory) model, a form of recurrent neural network appropriate for time-series data, was constructed using TensorFlow's Keras framework. This model contained a single LSTM layer with 50 neurons and employed the ReLU activation function. It was constructed to accept input shaped according to the altered training data, and a Dense layer with a single neuron was added for output prediction. The LSTM model was constructed using the Adam optimizer and mean squared error as the loss criteria. Training included 100 epochs with a batch size of 32, and model performance was assessed using the R^2 score for both the training and testing sets. The CatBoost Regressor, recognized for its efficacy with categorical data, was programmed with a learning rate of 0.15. The training method was basic, comprising fitting the model to the altered training data and testing its accuracy using the R^2 score on both training and test datasets. Additionally, a Random Forest Regressor was deployed, utilizing the default setup from scikit-learn's RandomForestRegressor. The model was trained on the converted data, and its accuracy was assessed based on the R^2 score for training and test datasets.

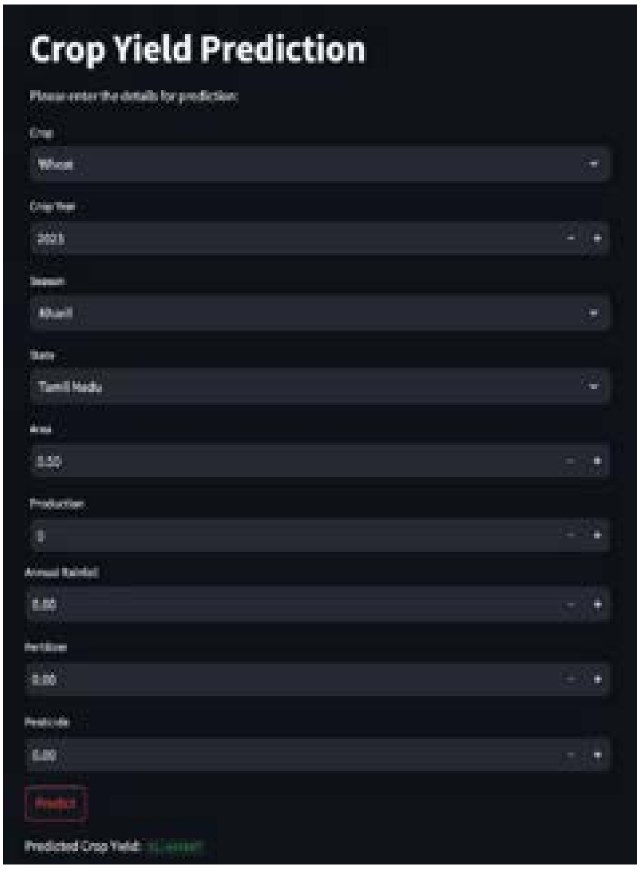

Figure. 3. User Interface

Figure 3 shows the user interface of the prediction system

Lastly, a Linear Regression model was also included in the study. Using scikit-learn's implementation, the model was fitted to the altered training data. Similar to the other models, its performance was assessed using the R^2 score for both the training and testing stages. Overall, the selection and training of these models represent a comprehensive approach to studying and forecasting crop yields, with each model adding distinct capabilities to the analysis. The precise setup of the LSTM model, in particular, displays its aptitude for handling the dataset's temporal elements.

VII. RESULTS

During the model assessment and validation phase the performance of each machine learning model underwent thorough evaluation on both the training and testing datasets. The performance of the models in correctly forecasting crop yields and their capacity to generalize to new data were assessed using the R^2 score, a statistic that reflects the degree of predictability of the dependent variable based on the independent variables, measuring the extent of variation captured. The Linear Regression model demonstrated outstanding performance, with a training accuracy of 0.8568 and a test accuracy of 0.8201. As a baseline model, these findings suggested a strong match with a moderate amount of complexity, making it a trustworthy alternative for crop production prediction. However, when the Variance Inflation Factor (VIF) was introduced to address multicollinearity in the Linear Regression model (LRvif), there was a little loss in accuracy, with the training and test accuracies being 0.8514 and 0.8107, respectively. This revealed that although the elimination of multicollinear features marginally lowered the model's predictive ability, it also assisted in balancing bias and variance.

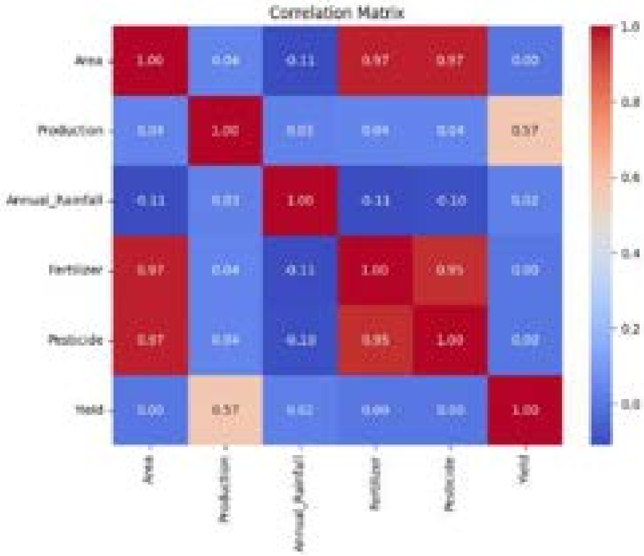

Figure. 4. Shows that the LSTM is trained with features like Area, Annual rainfall, Production, Fertilizer, Pesticide and Yield.

The Random Forest Regressor displayed extraordinarily high accuracy, especially in the training set, with scores of 0.9958 for training and 0.9785 for testing. This highlighted the model's resilience and its potential to capture complicated non-linear correlations in the data. The CatBoost Regressor likewise exhibited outstanding performance, notably in the training phase, with an accuracy of 0.9998, and a test accuracy of 0.9692. Although this emphasized the model's efficacy, it also increased the danger of overfitting. Notably, the LSTM (Long Short-Term Memory) model demonstrated great accuracy on both the training and testing sets, scoring 0.9821 and 0.9748, respectively. In order to improve the comprehensibility of the LSTM model, an Integrated Gradients (IG) and SHapley Additive exPlanations (SHAP) are used. By using these methodologies, model's decision-making process can be analyzed, so gaining valuable insights into the many aspects that drove the forecasts. IG helps in attributing predictions to specific features by assessing the model's sensitivity to changes in each feature. SHAP values assign a value to each feature, indicating its contribution to the prediction. In crop yield prediction, SHAP analysis helps identify which features, such as temperature, precipitation, or specific soil nutrients, have the most significant influence on the predicted yield.

The decision to adopt Long Short-Term Memory (LSTM) networks was driven by their effectiveness in handling time-series data, a critical aspect of agricultural datasets where crop yields are influenced by time-varying variables. LSTM's unique ability to capture temporal relationships in the data proved invaluable, making it a well-suited option for this application. The incorporation of LSTM with Integrated Gradients (IG) and Shapley Additive exPlanations (SHAP) further enhanced the model's performance. IG and SHAP are interpretability tools that, when combined with LSTM, not only improved the accuracy of predictions but also provided a deeper understanding of the model's inner workings. This dual integration not only increased transparency but also bolstered the reliability of the predictions. The interpretability aspect is crucial in the agricultural domain, as it enables stakeholders to comprehend the factors influencing crop yields and make informed decisions.

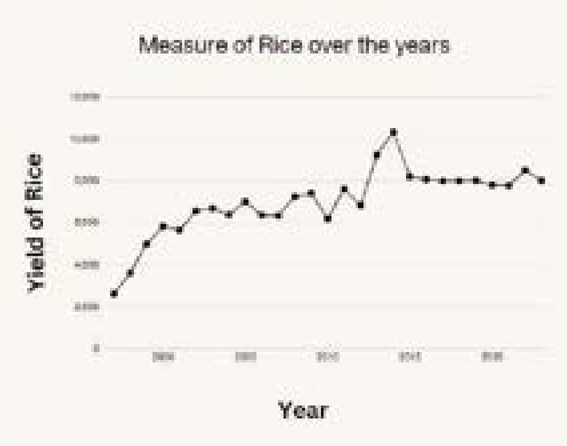

Figure. 5. Measure of Rice over the years

Figure 5 shows the amount of rice that is yielded over the years.

LSTM showed brilliant results rather than the rest of the models used for analysis. Integrating LSTM with Integrated Gradients and SHapley Additive exPlanations (SHAP) enables not only to produce precise results, but also to know how the model predicts output and can also know the importance of the contribution of each feature.

The synergy between LSTM, IG, and SHAP showcased a holistic approach, elevating the model's effectiveness in dealing with the complexities of agricultural time-series data. This comprehensive methodology not only enhances prediction accuracy but also empowers users with insights into the model's decision-making process, ultimately fostering trust and confidence in its applications within the agricultural sector.

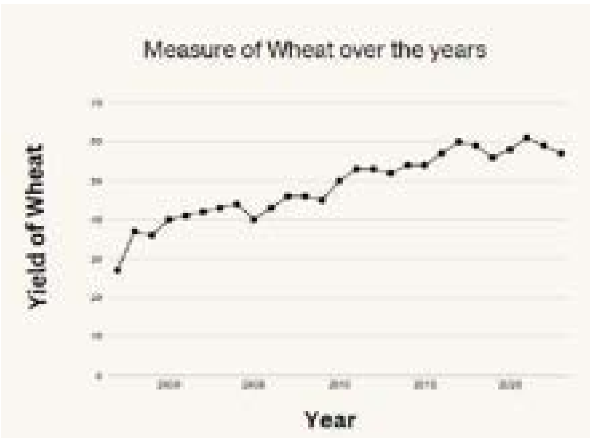

Figure. 6. Measure of Wheat over the years

Figure 6 shows the amount of wheat that is yielded over the years.

Finally, the assessment and validation process was crucial in establishing the most effective model for forecasting crop yields. The LSTM model stood out owing to its high accuracy and fit for the temporal structure of the dataset, revealing its potential as a strong tool in agricultural production prediction. The findings from the multiple machine learning models applied in the research showed varied performance characteristics in terms of accuracy, precision, and other important metrics, offering a full knowledge of each model's strengths and limits in forecasting crop yields. The Linear Regression model demonstrated good accuracy levels, with training and test accuracies of 0.8368 and 0.8101, respectively. This model's strength resides in its simplicity and interpretability, giving it a useful foundation for comparison. However, its shortcoming in capturing complicated, non-linear correlations in the data was clear.

The Linear Regression with VIF (LRvif) revealed a modest decline in performance, which suggested that addressing multicollinearity with VIF slightly reduced the model's predictive capabilities. The Random Forest Regressor displayed higher performance, notably in the training phase, with a training accuracy of 0.8558 and test accuracy of 0.8485. This model's capacity to handle non-linear data and its durability against overfitting (shown by the high test accuracy) make it a good candidate. However, its complicated structure may occasionally lead to issues in interpretation. The CatBoost Regressor displayed remarkable training accuracy (0.8498) but a little lower test accuracy (0.8292), indicating a possible overfitting concern despite its great overall performance. This approach is especially effective at handling categorical data, which is prevalent in agricultural datasets. Among these, LSTM suited best for time series models and handling historical data. LSTM performed better than the traditional algorithms and achieved a tremendous accuracy in predicting the crop yield based on the environmental and agricultural features.

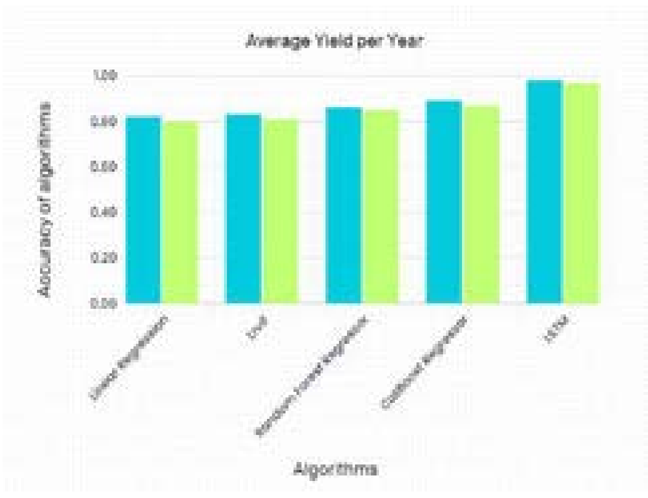

Figure. 7. Model Performance Graph

Figure 7 shows the performance of each graph on performing analysis of time series models. LSTM acts as best model for time-series predictions.

Significantly, the LSTM (Long Short-Term Memory) model stood out with excellent training and testing accuracies of 0.9821 and 0.9748, respectively. The LSTM's success may be ascribed to its capacity to interpret time-series data, capturing temporal dependencies that are vital in comprehending crop production patterns driven by sequential climatic and agronomic variables. The adaptability of the LSTM model proves tailor-made for datasets heavily influenced by time-based variables, making it an ideal fit for agricultural scenarios. With the incorporation of Integrated Gradients (IG) and Shapley Additive exPlanations (SHAP), this integrated approach offers a thorough assessment, shedding light on performance, interpretability, and practical implications in crop yield prediction.

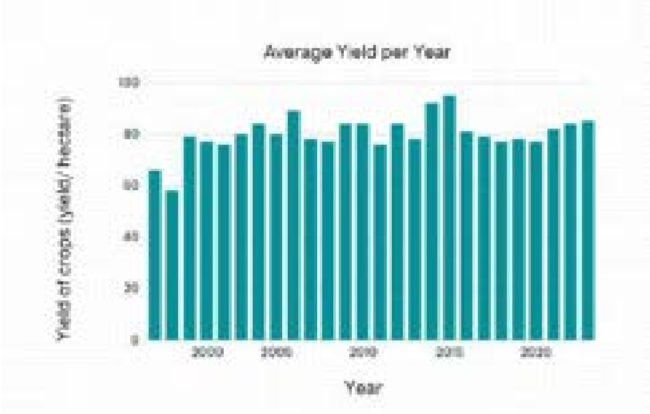

Figure. 8. Average Yield over the years

Figure 8 shows the average yield of crops over the years.

The LSTM's robust performance underscores the feasibility of deploying advanced neural network models in agricultural production forecasting, especially in datasets characterized by substantial temporal intricacies. This amalgamation of LSTM, IG, and SHAP holds promise in advancing the precision and transparency of crop yield predictions in dynamic agricultural landscapes.

VIII. CONCLUSION

The main motive of this research is to provide farmers and stakeholders a transparent crop yield prediction system. Due to the varying climatic changes, farmers are struggling to decide the crops yield. So a prediction system can be helpful for them to decide and yield crops wisely. The research effectively applied multiple machine learning models to estimate crop yields, revealing new insights into their application and usefulness in agricultural data analysis. The LSTM model, with its capacity to handle time-series data, emerged as especially good at capturing the temporal characteristics crucial in agricultural production prediction.

Moving ahead, various options for further work are clear. Enhancing the LSTM model by experimenting with other topologies, such as stacked LSTMs or bidirectional LSTMs, might further increase its prediction accuracy. Incorporating new data sources, such as soil health metrics or more detailed climate data, can potentially boost the models' capacity to estimate yields more precisely. The integrated approach employing Long Short-Term Memory (LSTM) networks, Integrated Gradients (IG), and SHapley Additive exPlanations (SHAP) analysis presents a significant advancement in the field of crop yield prediction. The findings from the evaluation demonstrate the effectiveness of the proposed model in addressing the limitations of existing systems and offering practical solutions for stakeholders in the agriculture sector. Furthermore, expanding the research to cover a wider variety of crops and geographical locations might yield more generalizable insights, thereby benefiting in agricultural planning and policy-making on a bigger scale..

In conclusion, this study establishes a good platform for future initiatives in agricultural yield prediction using deep learning, showing the promise of sophisticated models like the LSTM in tackling complex, real-world difficulties in agriculture. Using LSTM and with integration of Integrated Gradients (IG) and SHapley Additive exPlanations (SHAP) and achieved an overall accuracy of 97%.

Enhancing the proposed system with adaptive learning strategies enables dynamic adjustments to changing environmental conditions, potentially enhancing model generalizability. Future integration of emerging adaptive learning methods can further improve predictive accuracy in response to environmental changes.

***Abstract*—As the virtual and real worlds continue to collide, digital twins may become important tools for finding solutions to some of the most serious challenges facing the sustainability movement. These challenges include making effective use of resources, adjusting to the effects of climate change, and ensuring that everyone has access to a high quality of life. The first steps have been taken on the road to making widespread use of digital twins. It is imperative that their connectedness should be secured if their potential is to be fully utilized. This presents a number of challenging situations. The digital transition may make it possible to achieve several of the United Nations' sustainable development objectives. Data and technology should assist the user to make appropriate judgements that are better suited to their circumstances. It's feasible that the computer model can see into the future and predict the user about the consequence. This may be used to make predictions about the future, analyze the present, and analyze how a decision will play out in the future. These features may have an effect on a number of different sectors including commerce. The use of dynamic modelling may be beneficial for improving efficiency in the management of supply chains, transportation, and crowds.**

Keywords—Artificial Intelligence, Cloud computing, Sustainability, Implementation, Computers, Organization, Digital twins, Logistic, Network, Sustainability

I. INTRODUCTION

Immense scope for improvement is offered by AI. It may be used for a variety of cognitive tasks, from information gathering and data reduction to the modelling of physically unpredictable processes. Thus, AI allows for faster simulations and the extraction of some of the most crucial information from large data sets. Machine learning is expected to help with both falsely characterizing physical processes and increasing computer efficiency, according to the studies carried out by the authors [1].

The researchers consider their methodology paper to be the first stage in developing a digital Earth replica. When comparing the many computer architectures that exist now and may exist in the near future, GPU-based quantum computers stand out as the most promising alternative. A system with over 20,000 GPUs, using roughly 20 MW of power, is required to run a digital twin on a large scale, according to estimates. It's best to use such a computer at a location with access to plenty of carbon-neutral electricity [2].

II. OBJECTIVE

The research aimed to fulfil the following objectives:

- To study What exactly is a "Digital Twin,"?
- Sustainability by Digital Twinning
- What Function Does Digital Twins Serve in the field of Commerce?

III. METHODOLOGY

From individual generators and motors to whole rail networks and airport terminals, digital twins have been simulated. However, the true magic occurs when digital duplicates work together. This is the shift that is necessary to foster lasting transformation, not just inside institutions but throughout all of society. Every human need to make sure this ecosystem has all it needs to succeed. There has to be uniformity in strategy. It's the bedrock that makes it possible for digital world models to coexist and for differences to be resolved dispassionately. For the ecosystem to gain the confidence and participation of the public, it must also be open, transparent, and fair. Furthermore, digital twins' capacity to exchange data and models will be facilitated by the existence of clear interoperability standards, such as a universal language. Last but not least, as the ecosystem develops, it must be flexible enough to accommodate shifting conditions and an expanding range.

A. What exactly is a "Digital Twin"?

The term "digital twin" is used to describe a software representation of a physical object or system. AI, big data, cryptocurrency, virtual reality techniques, collaborative networks, application programming interfaces (APIs), and open standards are all used to build a digital twin. Through these supporting technologies, a digital twin may be continuously fed data from the physical world through sensors, allowing it to provide accurate and timely insights on an object's or system's present and future performance and problems [3].

The size of the global market for virtual duplicates in 2019 was estimated at $3.8 billion. One of the most advanced sectors to adopt this new technology is the industrial or e commerce sector. Assuming a 38% annual growth rate, other sectors such as healthcare, urban development and retail are exploring the potential of digital twins, the digital twin economy is expected to be worth $26 million by 2025.

B. "Digital Twin" Concept

Throughout a system's existence, a digital twin is a dynamic virtual simulation that includes all relevant physical, operational, and functional data. Digital twins were initially conceptualized in 2002 at University of Michigan by professor Michael Grieves, but he did not call it as digit twin at the time. Instead, he described it as a model for Product Lifecycle Management [8]. A digital twin, in common parlance, is an identical digital representation of a real object. However, unlike simpler simulations, digital twins are rather complex in their own right. Operational Technology (OT) and Information Technology (IT) are combined in digital twins via a two-way flow of data between the virtual and physical assets. Additionally, digital twins have an unbeatable edge over conventional simulation approaches due to their ability to run 'what-if' scenarios throughout a component's lifespan, in addition to its predictability and controllability.

The potential of digital twins in the fields of predictability or controllability has grown thanks to the development of supporting technologies like the Internet of Things (IoT), Intelligent Systems, Data Analytics, and Machine Learning in recent years. Because digital twins are used in so many different contexts and businesses, academics and professionals have yet to agree on a single meaning for the term. BearingPoint recognizes the value of digital twins for its manufacturing, aviation, and supply chain clients and is optimistic about the potential of electronic twins to help the energy industry overcome the challenges it currently faces and those it will face in the future.

C. Digital Twins: Why They Matter

What is a digital twin and why is it vital in today's world when AI, IoT, and data analytics are all gaining ground? Simply put, digital twins are digital copies of physical things or computerized systems. Multiple applications exist for the digital twin/processes/systems, which use data, software analytics, and machine learning to create interactive digital simulation models [9]. In the same way that the design, construction, and functioning of things' interplay will change as their physical counterparts do, so too will their digital simulations. To reflect its near-real-time status, operational condition, or location, a digital twin would continually learn and update from many sources [4].

Due to their ability to communicate with their physical counterparts and give data on their condition, digital twins will continue to develop alongside IoT devices. Given that 21 billion linked digital sensors are expected to be in use by 2025, the relevance of digital twins becomes readily apparent. The world's management, maintenance, and development budgets might save billions of dollars if this comes to be true.

Technology supporting digital twins has expanded to include more complex things like buildings, industries, and even whole cities; it may perhaps one day be used to humans. Digital twins are also being used in the virtual planning and testing of large and complicated items like aircraft engines, locomotives, and turbines before they are built in the real world as shown in Fig. 1. The use of digital twins is rapidly spreading across sectors, and yours won't be an exception if it hasn't already.

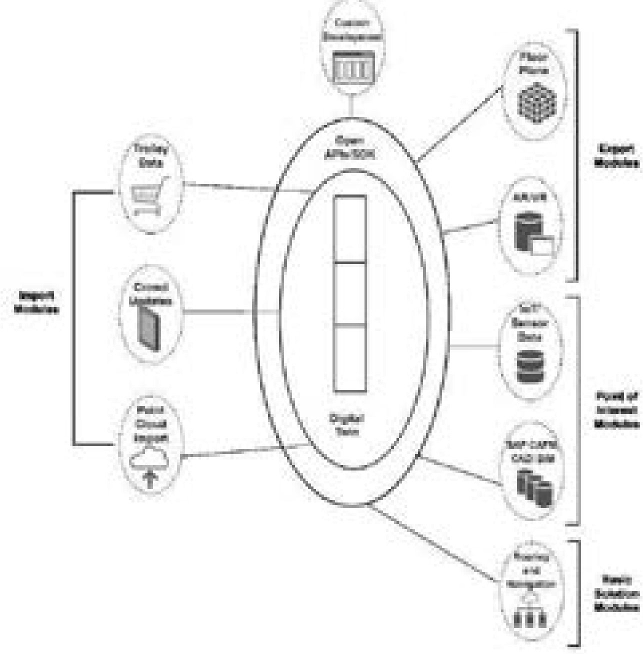

Fig 1. Digital Twin

D. What Function Do Digital Twins Serve in the Process of Reusing Existing Environmental Values?

The use of digital twins unquestionably inspires businesses to raise their levels of creativity and performance. There is no room for debate in this assertion. There are a significant variety of publications, both technical and non-technical, that highlight the many ways in which digital twin technologies may be utilized to enhance the design, visualization, monitoring, and maintenance of corporate assets. Some of these studies are included below. In addition, the technology of the digital twin has motivated a vast number of firms to re-examine the sustainability objectives that they have set for themselves, either directly or indirectly. The idea behind digital twins is that they may be able to aid the user in thinking in a manner that is not constrained by the usual industrial paradigm, which consists of extracting, creating, consuming, and discarding. This is the main idea behind digital twins. As a direct consequence of this development, companies and even entire communities now have the opportunity to switch to a method of corporate sustainability that generates almost no waste or pollution, keeps materials and commodities as part of the recycling cycle for a longer period of time, and contributes to the renewal of biological ecosystems This method of corporate sustainability is known as zero waste production. This method is sometimes referred to as "zero waste" [5].

E. Sustainability by Digital Twinning

Digital twins can help the environment in two different ways. At the moment, they are mostly used to get, store, and show data so that an accurate version of the real world can be shown. This can help the users to understand and measure what's going on, and it can also help them combine info from different sources to see how the decisions affect things. But the computer model could also be used to guess what will happen in the future. This can predict what will happen in the future, compare different scenarios, and figure out what will happen before certain choices are made [6].

In order to achieve sustainability in a variety of sectors, data twins could be an important tool. With digital twins, here is how sustainability can be achieved:

a) Monitoring and Collaboration : In order to explore and monitor the impact of manufacturing on economies, industries and global issues, digital twins allow international collaboration between factories.

b) Optimal Resource Usage : In order to provide more efficient use of resources, digital twins can help identify optimal routes for aircraft based on weather conditions, route congestion and maintenance of individual buildings.

c) Energy Efficiency and Material Selection : Digital twins offer the possibility of improving and selecting suitable materials for manufacturing purposes, which is aimed at energy savings and efficient renewable energy storage in order to contribute to sustainability efforts.

d) Product Design and Lifecycle Management : By enabling more efficient product design, planning, manufacturing, maintenance and recycling, digital twin technology provides an opportunity to achieve the sustainability objectives by making use of less resources.

e) Environmental Impact Reduction : Digital twins can contribute significantly to reducing energy and water consumption, enabling new low impact business models as well as driving sustainability and a greener economy at the speed and scale which would lead to substantial economic value and emission reductions.

f) Testing Scenarios for Sustainability Goals : The digital twins can model and understand how to reduce energy consumption and emissions, enabling organizations to test scenarios in order to meet sustainability and climate objectives.

g) Protecting Natural Environments : By making it easier to make more informed choices, faster protection of endangered species and land as well as the implementation of changes that enhance sustainability, D2S solutions can help protect nature. Finally, Digital twins offer a broad range of applications that can contribute to the sustainability efforts across different sectors, ranging from manufacturing and energy to environment protection and resource use management.

F. Attaining Sustainability In Commerce using Digital Twins

Digital twins offer a powerful set of tools to achieve sustainability in commerce. Here's how:

a) Simulating Efficiency : A Digital Twin is a virtual replica of the real system, such as factories or supply chains. This enables businesses to simulate different scenarios and assess their impact on resource use. In order to optimize energy use or experiment with various materials in order to reduce waste, they can even perform virtual tests of new layout at the production site.

b) Predictive Maintenance : Digital twins are able to predict when equipment is going to fail, through analysis of sensor data from actual worlds. This allows for preventive maintenance, reducing downtime and the need for replacement parts, which translates to less resource consumption.

c) Optimizing Logistics : In order to model the transport networks and find inefficiencies, it is possible to use data twins. To find the most fuel-efficient options, businesses can simulate different routes of delivery, reducing their carbon footprint.

d) Informed Decision Making : Digital twins provide businesses with valuable data and insight that can help them to make more informed decisions about their activities. Areas where they can reduce their environmental impact, such as water use or packaging waste, can be found in this data.

e) Transparency and Communication : The product's lifecycle from raw materials to disposal may be monitored by the use of virtual twins. This transparency facilitates the communication of sustainability efforts by businesses to customers and stakeholders, building trust and brand reputation.

IV. RESULT AND DISCUSSION

The decrease in carbon output throughout the course of the previous several years, as a result of the sustainability of digital twins, is indicated in Table 1.

TABLE I. DECREASE IN CARBON OUTPUT OVER YEARS

Years	Reduced carbon emission in (%)
2016	10%
2017	15%
2018	20%
2019	25%
2021	30%

Global carbon emissions might be reduced by 20% by 2030 if digital twins are used. Because of the energy savings that arise from using smaller but more durable materials, firms may alter their production and distribution methods.

These traits can have far-reaching effects in many different fields. Because the planning is live, it can be used in areas like controlling crowds and traffic and getting the most out of operations. Importantly for long-term sustainability, twinning can help predict how water flows through networks, keep energy grids in balance, and make communities more resilient to the effects of climate change. To get the most out of digital twins, they need to be used for more than just individual assets. For example, they should be used for whole processes or even whole companies or cities.

As companies and society become more digital, the digital twin might be able to do more than just explain what is happening and why. It might be able to predict the future, suggest solutions, and even automate big changes. This can be done throughout the lifespan of an object, process, system, or organization, adding value by combining CAPEX and OPEX through constant innovation [7].

A. *Revolutionizing Commerce with Digital Twins: A Glimpse into the Future*

Digital twins are emerging as a transformative force in the dynamic area of trade, which will change how businesses interact with customers, optimize their operations and drive innovation [10]. Digital twins can deliver a number of benefits for enhancing customer experiences, streamlining the supply chain and generating new revenue streams by creating virtual representations of physical products, processes or environments.

B. *Enhanced Customer Experience: Immersive Product Visualization and Customization*

Businesses are able to provide their customers with immersive and personalised product experiences by means of digital twins. Virtual product simulation allows clients to interact with 3D models so they can see products within their own environment, add features and explore different configurations. Incentivizing informed choice, reducing product return rates and improving customer satisfaction are the main benefits of this interaction approach [11].

C. *Optimized Supply Chain Management: Real-time Visibility and Predictive Analytics*

The use of digital twins will transform the way in which supply chain management takes place, making it possible to monitor on demand levels, logistics operation and product performance at any time. Data is collected and transferred to digital twins by sensors embedded in a physical product or asset. This makes it possible for companies to monitor the entire supply chain, predict any disruption and optimize their inventory management. It allows operations to be executed more effectively, reduce costs and improve the quality of customer service by providing timely intelligence [12].

D. *Predictive Maintenance and Proactive Service: Preventing Downtime and Enhancing Customer Support*

Digital twins enable companies to proactively identify possible equipment faults prior to their occurrence, giving them the right to take preventative maintenance measures. By analysing sensor data collected in physical assets, digital twins are capable of detecting anomalies, anticipating unavailability and setting maintenance schedules. The preventive approach will be effective in reducing equipment failure, extending life of assets and improving customer support [13].

E. *Personalized Marketing and Targeted Advertising: Tailored Recommendations and Enhanced Customer Engagement*

Digital twins enable businesses to collect an enormous amount of customer data, which enables them to tailor marketing campaigns and deliver targeted advertising. Businesses can get a better understanding of their customers' preferences and behaviour when they analyse interactions between digital twins, which gives them the ability to make individual recommendations for products, promotions or advertisements.

F. *New Revenue Streams and Innovative Business Models:*

As-a-Service Offerings and Subscription-based Business Models Digital twins promotes new revenue streams by enhancing businesses to offer as-a-service (aaS) and subscription-based business models. For example, manufacturers can offer their customers personalized recommendations, predictive maintenance services and optimized performance solutions based on data driven insights derived from digital twins. As a result of this shift to value added services, new market opportunities are created and long-lasting customer relationships strengthened [14].

V. CONCLUSION

Digital twins are being integrated into asset management practices at an increasing rate. In return, digital twins aid in tracking and uncovering means to boost output, lessen downtime, and future-proof operations. It's possible that digital twins, like BASF's, may influence decisions about where and whether to collect plastic things for reuse, repair, recycling, or disposal. Using a digital twin, you may better optimize and choose the best materials for manufacturing, reduce energy consumption, or simply improve the efficiency with which you store renewable energy. ICL claims that digital twins may help businesses take their idea of sustainable development to a more practical level. Lastly, businesses must expand sustainably if they are to succeed while reducing their negative impact on the environment.

Abstract: In mobile phone conversations dealing with noise can be tricky as it can lower the quality of speech and make it hard to hear clearly. This research investigates ways to make speech on phones better by reducing noise. It talks about methods for cutting out noise like using machine learning, adaptive filters improving quality and taking out unwanted sounds. Also, it examines the challenges and possibilities of using these techniques on phones considering things, like how complicated they are needing real time processing and adjustingto noisy environments. It also looks at how learning can help reduce noise while keeping voices clear.

Keywords—Noise reduction, Speech communication, independent component analysis, Speech recognition system.

I. INTRODUCTION

In today's world of communication, it is common to work in environments were various voices blend. This kind of lifestyle can really impact personal well-being. To tackle this challenge a technology called Adaptive Independent Component Analysis (ICA) is being used in communication tools, like smartphones, video calls and conference calls. By using statistical analysis methods ICA can effectively reduce background noise without needing to know the sources of the noise. It does this by breaking down signals into components. Its adaptive nature helps improve the quality of voice communications by enhancing the Signal to Noise Ratio (SNR). This feature provides noise cancellation capabilities making it a reliable solution, for real time situations [1].

In phone conversations ICA is often used to reduce background noise aiming to enhance speech recognition in environments. This technique involves analyzing signals to filter out noise without knowledge of its presence.[2]

Independent Component Analysis (ICA) is a method utilized in speech analysis to extract feature vectors based on principles. The goal is to generate Gabor features those are advantageous for automated speech recognition systems. These features act as bandpass filters with center frequencies and bandwidth limitations. In contrast to methods, like Mel cepstral features this new approach improves recognition accuracy by training basis vectors that reflect the characteristics of input speech patterns.[3] The process of identifying the original source signals based on input signals is known as signal separation. This method is crucial, for applications such as speech recognition and advanced hands-free communication systems.[7]

When there is an amount of speech in a room experts utilize Wavelet Based Independent Component Analysis (ICA) to differentiate the distant echoes from the mix of speech and surrounding sounds.[9]

Blind source separation has gained popularity in the field of signal processing over the years. By combining Independent Component Analysis (ICA) with wavelet threshold denoising it becomes feasible to separate speech that includes noise. This approach does not improve the quality of the separated speech signals over time. Does reduce the impact of noise on both signals, to noise ratio and overall noise levels.[10]

The article talks about a technique for sorting data using an ICA mixture model, which groups data into categories formed by a combination of sources. This method improves the mixture model by including Gaussian structure within the categories. It computes the probability of each data point belonging to a category identifies sources and combines matrices for each category.[11]

Multidimensional Independent Component Analysis (MICA) is an extension of Independent Component Analysis (ICA) that breaks down a vector into components, in subspaces those are statistically unrelated. By isolating elements that are not interconnected MICA provides insight into source separation.[12]

Independent Component Analysis (ICA) a blind source separation technique widely used in fields aims to distinguish signals based on their sources. ICA is often applied as a box without going into its workings.[16]

Let us start by explaining the noise reduction technique basedon Independent Component Analysis (ICA) in section 2. The methodologies employed in this process is presented in section 3. Additionally, demonstration on how to minimize interference by adjusting frequencies to align with the speech range is presented in section 4. In conclusion the capabilities and objectives of implementing ICA is presented.

II. LITERATURE REVIEW

Mohanaprasad and his team (2019) proposed a method, for communication using ICA. Their research revealed that this approach significantly enhances speech quality and clarity when compared to methods [1]. In a study conducted by Zhang and Etoh (2007) they introduced a domain ICA technique tailored specifically for phone conversations. Their findings demonstrated promising outcomes in minimizing background noise in challenging settings [2]. Investigating the potential of ICA to boost speech recognition precision. Lee and colleagues (n.d.) emphasized its role in extracting speech features. They underscored the advantages it provides for enhancing accuracy, in recognition tasks [3]. Jin and colleagues (2017) explore strategies to minimize background noise, in hands communication by integrating ICA with techniques to effectively diminish unwanted sound interference [4]. Finally in a study, by Lee and colleagues from 1999 they introduce an Infomax algorithm for Independent Component Analysis (ICA) that successfully separates mixed speech signals with varying characteristics. Their research illustrates the effectiveness of the algorithm. Additionally, Kurita and others (n.d.) investigate the capabilities of Independent Component Analysis (ICA) in separating signals under conditions, which has implications for communication settings, in real life scenarios.[6] Hyvarinen (2015) presents a model that combines Independent Component Analysis (ICA) and Principal Component Analysis (PCA). This model offers insights into how they are interconnected and their real-world applications [7]. Current noise reduction techniques, like filtering time varying methods and multiband adaptive gain control have challenges in reducing noise in speech signals. The suggested adaptive ICA method intends to eliminate background noise without needing knowledge of it. Nonetheless it does not clearly outline the drawbacks of this approach. The noise reduction method based on ICA prioritizes reducing noise over separating sources of signals. This constraint implies ineffectiveness, in situations where isolating speech sources is necessary. Moreover, the accuracy of the technique may be compromised in real world settings due to discrepancies in assumptions about transfer function amplitudes. While the document doesn't explicitly mention any restrictions the effectiveness of using Independent Component Analysis (ICA) for extracting speech features might depend on the characteristics of speech signals and the specific contexts in which it is utilized. Further investigation is required to assess how well the method performs under circumstances and, with a variety of speech data. The ICA based technique for eliminating sensor noise has several drawbacks, such as the necessity for research on selecting activation functions assumptions concerning source independence, sensitivity to constant sources and potential effects of sensor noise, on algorithm effectiveness. Nonetheless despite these limitations the enhanced infomax ICA algorithm shows potential in fields.

While the document does not specifically outline any constraints it implies that the proposed methodology aims to overcome the drawbacks of noise estimation technologies. It does not delve into limitations indicating a requirement, for investigation into potential restrictions within the proposed methodology.[5] The extended infomax algorithm exhibits potential in separating sources. Faces constraints related to sensor numbers and the assumption of linear mixing.[6] It necessitates having as many sensors as sources and is effective only in linear mixing scenarios. More research is essential to tackle these limitations and delve into applications. The proposed method encounters challenges concerning source permutation and the variability of source gain across frequency bins.[7] It endeavors to address these concerns through directivity. ICAs limitations involve assumptions of stationarity, source number constraints, sensitivity to mixing matrix conditions, noise influence and computational complexity. These aspects require assessment when implementing ICA in real world scenarios.[8] The document does not explicitly highlight limitations. Underscores the necessity for research to assess the efficiency of wavelet-based ICA approach, across different situations and environments.

The document does not clearly mention the constraints of the suggested approach.[9] Yet its success could be influenced by factors, like background noise, accuracy, in estimating thresholds and how well the FASTICA algorithm performs [10]. The algorithm makes assumptions based on known class information without specifying constraints. However, the effectiveness of the approach could be impacted by the characteristics of the data and the assumption of known class information may not always correspond to real world situations [11].

MICA's limitations stem from assuming independence being sensitive, to component and subspace choices and requiring a mixing matrix [12]. The discussion does not explicitly address Independent Component Analysis limitations [13].

ICAs assumptions, such as source independence, linear mixing and non-Gaussian source distributions bring about constraints. The methods sensitivity to the quantity of sources and sensors along with its lack of knowledge consideration are factors [15]. ICA faces challenges due to assumptions about source independence, sensitivity, to source and sensor quantities and linear mixing presumption. Mixing poses difficulties while ICA does not provide details regarding the sources themselves [16].

Table 1: An overview of the literature work

Title	Year	Algorithm	Advantage	Drawback
A wavelet transform-based blind adaptive filter of unknown noise from speech	2000	Wavelet Transform	Does not require prior knowledge or explicit estimation of noise characteristics	Effectiveness may depend on factors such as signal-to-noise ratio, complexity of noise, and quality of speech signal

Separating mixed speech signals with noise using wavelet transform and Independent Component Analysis (ICA) without input.	2006	Wavelet threshold de-noising with ICA	Improved SNR and restoration of original speech signals	Limitations in handling highly complex or dynamic noise patterns
Speech enhancement using voiced speech probability-based wavelet decomposition	2013	Voiced speech probability estimation	Selective enhancement of regions containing voiced speech, minimizing distortion in unvoiced or noisy regions	Computational complexity due to wavelet decomposition and estimation of voiced speech probability
Applying Wavelet Based Independent Component Analysis (ICA) with Maximum Likelihood Estimation and Information Theoretic Measure to Address Acoustic Echo Cancellation in Double Talk Scenarios.	2015	Acoustic echo cancellation (AEC) using ICA	Enhance echo cancellation efficiency with improved ERLE	Increased complexity and computational overhead
Rayleigh Modeling of Teager Energy Operated Perceptual Wavelet Packet Coefficients (EOPWPC) for Enhancing Noisy Speech	2016	wavelet packet transform	These techniques are often designed to mimic the human auditory system, capturing features that are perceptually relevant for speech processing. This can result in enhanced speech quality and intelligibility, making it more suitable for applications such as communication systems and speech recognition	The performance of T-EOPWPC methods heavily relies on the accuracy of the underlying signal and noise models used for feature extraction and enhancement. Deviations from these models or mismatched assumptions can lead to suboptimal results, particularly in non-stationary or highly variable noise conditions.
A dual-channel noise reduction algorithm based on the coherence function and the bionic wavelet	2017	bionic wavelet	The bionic wavelet algorithm is inspired by biological auditory processing mechanisms, making it well-suited for speech enhancement tasks. By mimicking the human auditory system, this algorithm can effectively extract and enhance speech features while suppressing noise components.	Dual-channel algorithms may struggle to perform optimally in reverberant environments where reflections and echoes can degrade the coherence between microphone signals. Additional processing or adaptation mechanisms may be needed to address these challenges.
Noise reduction in speech signals using adaptive independent component analysis (ICA) for hands-free communication devices	2019	ICA	Improved signal quality and higher SNR in real-time communication devices	Ensuring that the adaptive ICA algorithm can adapt to these changing conditions without compromising voice quality can be challenging.

Understanding the limitations of Independent Component Analysis (ICA) and its impact on signal processing techniques requires a drive to improve and refine the methods used. Real world situations often challenge the assumption of independence in ICA prompting exploration of advancements for accurate source separation. The sensitivity of ICA to the number of sources and sensors motivates the search for algorithms that can handle scenarios. Addressing non linearities and adapting techniques to changing conditions are encouraged by assumptions about mixing in ICA. Researchers are inspired by the nature of ICA to explore approaches leveraging existing knowledge about sources and mixing processes. The necessity for robustness against sensor noise and challenges posed by Gaussian distributions spur research into ICA algorithms and noise cancellation methods. Complexity in ICA fuels research in hardware acceleration and parallel computing driving efforts to develop activation functions and techniques for handling sources due to limitations in suppressing sensor noise. Emphasis is placed on finding solutions for permutation and gain issues in blind signal separation techniques within environments. Observations, on noise reduction algorithm deficiencies continue to stimulate industry innovation resulting in effective solutions being developed.

III. METHODOLOGY

This research work introduces a method that diminish background noise in speech signals specifically tailored for communication devices. The proposed approach involves IndependentComponent Analysis (ICA) which disentangles multiple source signals into components. By utilizing this technique, noise can be filtered out without requiring knowledge of the background noise. To enhance the real time robustness of the algorithm proposed work integrate kurtosis and negentropy cost functions into the ICA framework. These functions work towards enhancing the clarity of the speech signal by isolating it from surrounding noise. The adaptive approach shows performance enhancements compared to existing ICA methods. Further an analysis carried out between the proposed methodology and previous algorithms for noise reduction. Evaluating the efficacy of proposed ICA method using Signal to Noise Ratio (SNR) as a metric where higher SNR values indicate a signal. Through simulations involving clean speech signals from the TIMIT database and the addition of Gaussian noise, at SNR levels using MATLAB 2017 software it is demonstrated that the proposed adaptive ICA method outperforms both existing ICA techniques and traditional noise reduction methods. Additionally, the presented research extends beyond mobile phone speech communication by exploring noise reduction applications based on Independent Component Analysis (ICA). To improve the ICA technique, the proposed model presents a restriction that controls the amplitude range of transfer functions. Furthermore, a filtering mechanism is implemented to reduce errors in estimation resulting in enhanced speech recognition accuracy, in settings. The presented new method proves to be accurate when compared to ICA techniques demonstrating its effectiveness in reducing noise and improving the quality of speech signals. Additionally, ICA approach goes beyond noise reduction in speech signals. The extracted speech features are explored through ICA. By encoding speech signals using ICA a basic function is derived to resemble Gabor features. These trained basis functions are then used for feature extraction. The presented innovative method surpasses Mel cepstral features in terms of recognition rates. Expanding the scope of ICA applications, this study also addresses sensor noise cancellation based on ICA principles. The process involves implementing a three-layered network comprising whitening, separation and estimation stages to achieve sensor noise cancellation. This technique efficiently eliminates sounds in scenarios where there is no source of noise making it suitable for processing sensor signals in fields such as process control and estimation. Researchers have explored a method that combines noise coherence models to reduce background noise during hands voice communication, on devices. The efficacy of this approach has been assessed using recordings from smartphones. In comparison, to the techniques available the proposed approach is built upon findings from studies on Independent Component Analysis (ICA). For example, an inspiration taken from the Infomax algorithm, is utilized to differentiate between Gaussian and super Gaussian sources. In the proposed research stability analysis is utilized to transition between Gaussian states offering a method to separate mixed signals effectively. Additionally, the concepts of parameterization have influenced in the proposed strategy for segmenting and determining thresholds for vector valued components. By decomposing speech signals into components that exist in independent spaces The presented methodology integrates insights from MICA. The proposed model has also integrated ICA techniques outlined in "Independent Component Analysis. The initial steps of proposed model includes estimating the mixing matrix and separating signals into components are, in line, with the principles of ICA.

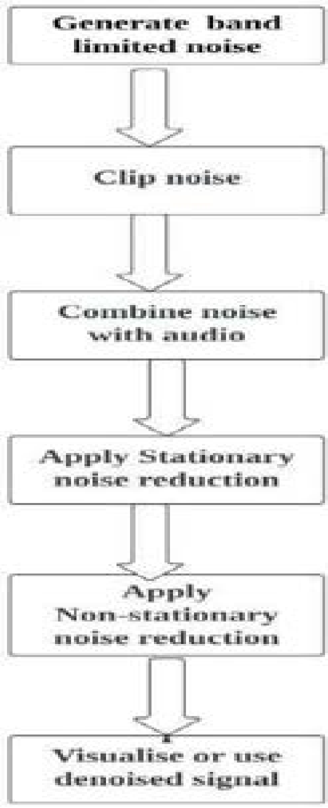

Figure 1: Workflow of Proposed Model

This section provides a detailed architecture of the proposed model. Figure 1 shows the basic architecture of the noise reduction approach. This architecture contains various stages as stated below.

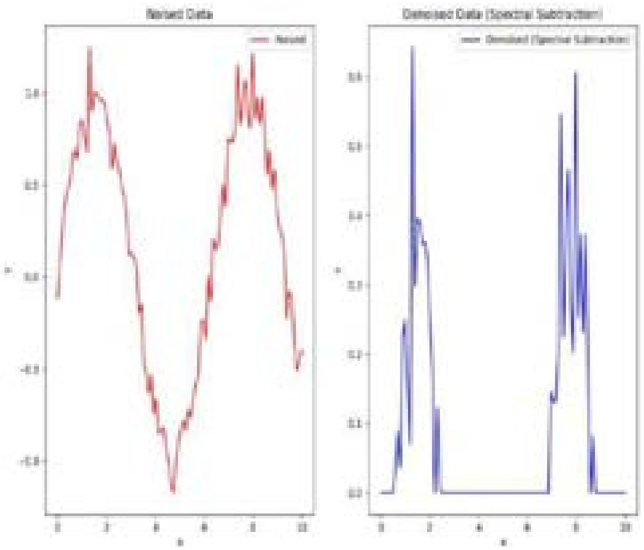
A. **Creating Band Limited Noise**: When discussing about "band limited noise " it refers that this noise is limited to a frequency range. One way to generate it is by using techniques like bandpass filtering, which restricts the noise to frequency ranges after filtering out white noise.

B. Manipulating Sound Levels: To prevent any distortion caused by noise levels exceeding the maximum amplitude the amplitude of the generated noise is reduced and it ensures that the noise remains within range.

C. Combining Audio and Noise: Once the signal is acquired the signal can be blend in the band limited and clipped noise. This step simulates real world scenarios where actual audio recordings incorporate background noise.

D. Reducing Stationary Noise: Stationary noises such as electrical interference are continuous and unchanging. Techniques like Wiener filtering or spectral subtraction leverage characteristics to identify and minimize these types of noises.

E. Addressing Non-Stationary Noise: Nonstationary noises vary over time such as crowd or traffic sounds. To reduce stationary noise advanced techniques like adaptive filtering or time frequency domain algorithms (such as short time Fourier transform) can be applied. You can employ waveform plots and spectrograms as tools to visualize the signal after noise reduction or if applicable to your use case utilize the denoised signal, for further analysis or processing.



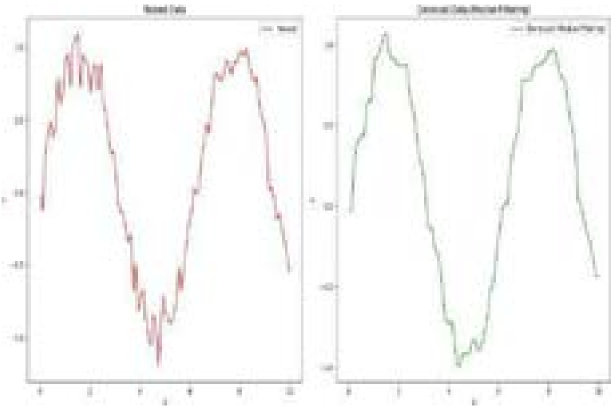
(a) (b)

Figure2: (a) Visualization of Noised Data (b)Denoising using Spectral Subtraction.

In Fig 2, Fig 3 it illustrates how median filtering and spectral subtraction are utilized to minimize signal noise. The graph displays the signal on one axis with time or sample index indicated on the axis.

At the top of the representation is a graph showing data with noise that requires elimination. The primary signal, starting at 0.5, peaking at 1.0 in the middle and returning to 0.5 at the end is surrounded by fluctuations caused by the noise.

The noisy data undergoes Spectral Subtraction, for denoising resulting in data displayed beneath the plot of data. This method involves estimating and subtracting the power density of noise from that of the data to reduce noise levels. Although some residual fluctuations are still noticeable, in this denoised version compared to the data.



(a) (b)

Figure3: (a) Visualization of Noised Data (b)Denoising using Median Filtering

In Fig3, Additionally Median Filtering is used to denoise the data displaying its outcomes at the bottom of the image. This technique involves replacing each sample in the data with a value derived from neighboring samples within a window size.

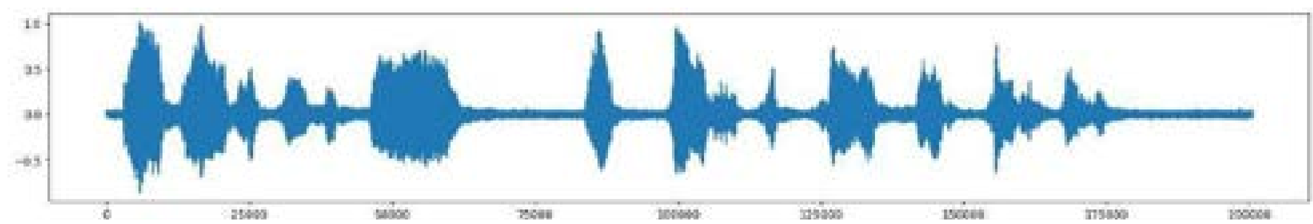


Figure 4: Introducing the Use of Band Limited Noise, in Audio Signals to Simulate and Analyze Background Noise

In Fig 4 a simple representation of the signal used in the proposed work is presented. Typically, the loudness of the audio, at each time interval is shown on the y axis while time is represented on the x axis. During this phase a band limited noise is introduced into the audio. When noise is band limited it means that it falls within a range, such as, between 2000 Hz and 12000 Hz in this example. This helps us simulate background noises. To conclude this section, a band limited noise is incorporated into the audio signal before displaying it. This allows us to observe how the noise affects the waveform.

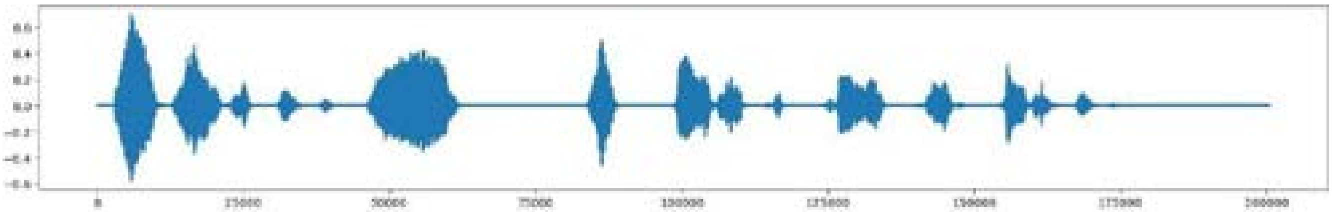

Figure 5 : Enhancing Sound Quality, Minimizing Ambient Noise using the nr.reduce_noise Feature

In Fig 5 the enhancements made in the signal quality through the implementation of the proposed model is provided. The star of the show is the nr.reduce_noise function, which clearly provides the existing audio signal generated using band limited noise. The main goal here is to minimize any background noise while preserving the essential elements of the audio.

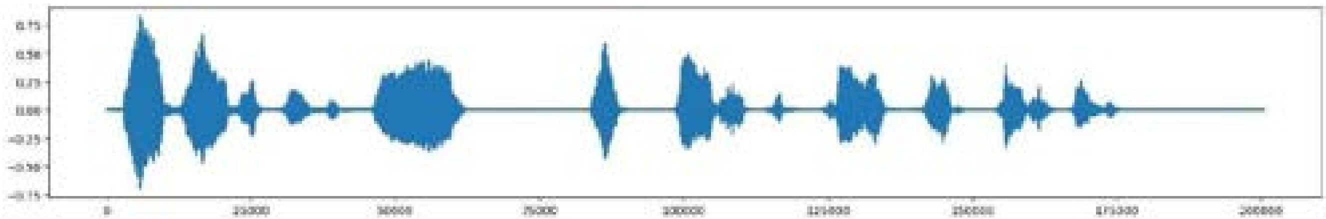

Figure 6: Improving Noise Reduction using the nr.reduce_noise Function, Examining Results for Assessment

In Fig 6 In this explanation utilization of the nr.reduce_noise function is explored to enhance the noise reduction process and visualize the outcomes to assess their appearance.

IV. CONCLUSION

The implementation of the nr.reduce_noise function and the incorporation of band limited noise have significantly enhanced the performance of audio signal processing algorithm. By introducing band limited noise, it can be observed that how real-world background sounds affect the waveform and gain an understanding of their interaction with the audio. Additionally it has been shown that the nr.reduce_noise function is a tool for reducing background noise while preserving the elements of the audio stream. The presented assessment defines the effectiveness of the noise reduction process and ensure that proposed algorithm produces high quality audio outputs by visualizing the outcomes. Taking everything into account these advancements improve the techniques used in signal processing enabling us to generate more sophisticatedaudio representations.

***Abstract*—The project proposes a novel solution for pothole detection and alerting by integrating YOLOv5, Google Maps, and an email reporting system. YOLOv5, a state-of-the-art object detection algorithm, is employed to accurately identify potholes from live camera feeds. The system seamlessly integrates with Google Maps, allowing real-time visualization of detected potholes on the map interface. Furthermore, it incorporates an email reporting system, automatically generating detailed reports containing location information, images, and severity levels of detected potholes. This integration enhances road maintenance efficiency by providing authorities with timely and precise information about pothole locations. By leveraging cutting-edge technology, this project aims to contribute to safer and more efficient road infrastructure management, ultimately enhancing road safety and minimizing vehicle damage caused by potholes.**

Keywords—YOLOv5, Deep Learning, Feature Training, Machine Learning, Pothole Detection, Smartphone camera.

I. INTRODUCTION

Modern civilization would not be possible without highways, which facilitate both transportation and commerce. But potholes are a typical sign of roads failing for many reasons, and they are dangerous for everyone using the road, including pedestrians. In addition to wreaking havoc on cars, potholes make driving less efficient by increasing the probability of accidents and congestion. The key to quickly resolving this issue is to proactively identify and repair potholes. Historical pothole detection systems relied on labor-intensive, error-prone, and time-consuming manual examinations. In addition, the reactive nature of these systems prolongs maintenance delays and increases safety risks. Thus, it is essential to start using new methods to make roads safer and maintenance work better right now.

With the advent of new computer vision and machine learning algorithms, new avenues for effectively tackling road maintenance issues have opened up. The cutting-edge YOLOv5 (You Only Look Once) system is remarkable for its accuracy and quickness where object recognition in images and videos is concerned. Using YOLOv5, a combination of real-time Google Maps functionality and an email reporting system, this project aims to provide a comprehensive solution for pothole detection, alerting, and reporting. The presented model prioritizes providing authorities with real-time information on pothole locations and conditions. Because of this, the problem can be resolved without delay.

The initiative's impetus comes from a desire to mitigate the detrimental effects of potholes on road safety and infrastructure upkeep. Worldwide, potholes may form on roads due to factors such as heavy rainfall, freeze-thaw cycles, and vehicle activity. These surface irregularities pose a threat to motorists and passengers and push up the cost of road upkeep. It is critical to locate and repair potholes promptly to lessen the possibility of accidents and traffic delays. Ultimately, this initiative aims to improve road safety by making preventative maintenance procedures easier to implement and by using computer vision and machine learning to identify and handle potholes much better.

A Pothole Alert and Detection System (PADS) using YOLOv5 for real-time pothole detection, Google Maps integration for pothole location display, and an automated email reporting system for authority notification is the goal of this project. Primary objectives include an intuitive interface, precise pothole detection using YOLOv5, display with the Google Maps API, automated warnings via email reporting, and assessment of system performance.

Compared to more traditional methods of pothole management, the proposed PADS provide several significant advantages. The system can detect when there are potholes and repair them before they do additional harm with the aid of YOLOv5. Officials can better prioritize repairs and distribute money by connecting with Google Maps, which shows them precisely where potholes are. By automating the process of notifying the proper authorities about noticed potholes, the email reporting system simplifies communication and assures rapid response. This prophylactic action improves road safety, reduces maintenance costs, and increases the efficiency of transportation infrastructure.

The systematic procedure that the development of PADS adheres to consists of several essential components. Gathering media depicting various road conditions, such potholes, is an important part of data collecting. Specifically, the YOLOv5 framework is used during model training to construct a neural network model for pothole recognition. Linking the trained model to the Google Maps API is a stage in the process of system integration. This will make it possible to show detected potholes as they happen. Automatically creating reports that include the location, photographs, and severity level of potholes is programmed into the email reporting system to inform the necessary authorities. User interface design ensures usability and accessibility. Rapidity, accuracy, and usability are three metrics that assessment and testing employ to gauge a system's performance. After deployment, which involves putting the PADS into operation in a real-world situation and gathering user feedback, it is fine-tuned.

Finally, a novel approach to managing and detecting potholes is proposed by the Pothole Alert and Detection System (PADS). Thanks to this system's integration with Google Maps, automated email reporting, and state-of-the-art tools like YOLOv5, you can detect and report potholes as they happen in real time. By detecting problems early and taking corrective action quickly, the PADS hopes to boost transportation infrastructure efficiency, save maintenance costs, and make roads safer for everyone. The revolutionary potential of the PADS to improve pothole detection, reporting, and repair means that road networks will be safer and more reliable for communities throughout the world.

II. LITERATURE REVIEW

Akarsh, Sai, and Aswini's study investigates pothole alert and detection system with email report functionality and real-time Google Maps integration. By informing drivers and appropriate authorities in real time when potholes are detected, the technology seeks to increase road safety. Accurate pothole geolocation [1] is made possible by the integration with Google Maps, which facilitates effective pothole repair procedures. In order to promote prompt pothole repairs, an email report system is also put in place to help with communication between maintenance crews, authorities, and drivers.

A pothole detecting, counting, and geolocation Internet of Things (IoT) paradigm [2] is put out by Okpe and Idachaba. To achieve precise and thorough pothole detection, the model makes use of a variety of sensors and technologies. The system's goal is to measure the number of potholes that cars hit, giving useful information for evaluating road conditions. By precisely locating potholes, geolocation capabilities significantly improve the effectiveness of maintenance operations.

Kadu, Mishra, Baheti, and Pilkawar introduce an Internet of Things-based system [3] designed to identify speed breakers and potholes. The technology uses sensors to gather information about the state of the roads, which is then processed and examined instantly. The device notifies the appropriate authorities and drivers when it detects a pothole or speed breaker. The device helps to improve road safety by lowering the number of accidents and vehicle damage brought on by potholes and speed breakers by sending out quick alerts.

This paper uses sensors[4] and machine learning methods for pothole prediction and detection. This study focuses on collecting sensor data about the state of the roads and analyzing pothole occurrences using machine learning algorithms. By taking an initiative, authorities can minimize the negative effects of potholes on road safety and vehicle maintenance by implementing prompt repairs or preventive measures.

This paper suggests a warning system that uses JSON data [5] to identify speed breakers and potholes. The system compiles information about road conditions from a number of sources, such as sensors, GPS, and human input, to produce an extensive database. The warning system can advise vehicles and authorities of potential hazards like potholes and speed breakers by analyzing JSON data. This unique strategy seeks to avert mishaps and encourage prompt upkeep of the road system.

A pothole identification and reporting system based on deep learning is presented by Mpofu, Ndlovu, Dube, and Mutengeni. The technology uses visual data from cameras or cellphones to identify and categorize potholes using image recognition algorithms [6], Potholes are then reported to the appropriate authorities so that they can be fixed right away. The system increases efficiency in maintaining road infrastructure and enhancing road safety by automating the detection and reporting procedure.

An enhanced transportation safety system is suggested by Sharma and Garg, which makes use of real-time GIS-based alerting [7] for locations with a high animal population and potholes. The technology combines real-time data on animal movements and road conditions, such as potholes, with geographic information systems (GIS). To lower the danger of accidents and vehicle damage, alarms are set off to warn drivers as they approach regions with a high concentration of potholes or animal activity. Using GIS technology allows for the proactive mitigation of possible dangers and improves driver situational awareness.

A deep learning-based real-time pothole identification system is presented by Yik, Alias, Yusof, and Isaak. The system analyzes picture or video data taken by sensors [8] or cameras installed on vehicles using deep learning algorithms. The technology accurately identifies potholes in real-time and notifies drivers in a timely manner so they may take the necessary precautions to avoid possible hazards. Road conditions are made safer by the deep learning approach, which improves pothole detection's robustness and accuracy.

III. Existing System

The present Pothole Alert and Detection system has numerous key shortcomings, including email report production and real-time Google Maps integration. First and foremost, there is a potential that this system's accuracy in detecting potholes will be inconsistent. It can be difficult to precisely identify and track potholes with technology that is automated because of their wide variations in size, shape, and depth. Incorrect results or erroneous negatives might result from this, which could cause incomplete reporting, resource waste on inefficient remedies, or the concealment of important flaws. Potholes may vary greatly in size, shape, and depth, making it challenging to correctly detect and map them using automated equipment. Therefore, False positives or false negatives could occur, which could result in inaccurate reporting, resource waste on ineffective repairs, or the omission of critical potholes.

Second, the system's pothole mapping relies heavily on real-time Google Maps integration. Although Google Maps is a popular and comprehensive mapping tool, it may not always provide up-to-date and accurate information on road conditions or freshly developed potholes. This dependence on outside mapping services may jeopardize the timely maintenance of roads, perhaps causing a delay in reporting and correcting potholes.

Third, the email report mechanism for pothole discovery is both inefficient and useless. Relying only on email alerts to alert road repair crews and authorities about potholes may result in response and resolution delays. Among the many emails received each day, some are easily disregarded, classified as spam, or not given attention. Therefore, it is probable that the necessary actions to repair the reported potholes may not be accomplished in a timely manner, causing the road's condition to deteriorate and endangering cars.

Furthermore, the existing strategy may not provide an effective way to prioritize repairs. If location data is obtained just from Google Maps and email reports, the severity and effect of individual potholes may be overlooked. This might result in an unfair allocation of resources, with less concentration on critical potholes that endanger cars.

Finally, the system's reliance on automation and technology may be a disadvantage. The system may go down owing to technological flaws, communication issues, or difficulties integrating several components, making it hard to uncover or disclose deficiencies. This dependence on technology may jeopardize the system's overall effectiveness in the lack of a sound backup plan or alternative reporting methods.

In summary, the Pothole Alert and Detection system has advantages such as live Google Maps integration and an email report system, but it also has disadvantages such as inaccurate detection, reliance on outside mapping services, ineffective email notifications, a lack of prioritization, and technological constraints. It is critical to address these weaknesses in order to improve the accuracy and reliability of the pothole detection and repair system, hence ensuring safer driving conditions.

IV. Proposed System

The proposed Pothole Alert and Detection System (PADS) integrates YOLOv5, Google Maps, and an email reporting system to revolutionize pothole detection and management. Leveraging YOLOv5's advanced object detection capabilities, the system identifies potholes in real-time video streams with high accuracy. Integration with Google Maps enables visualization of pothole locations, facilitating efficient maintenance prioritization. An automated email reporting system generates detailed reports containing pothole location, images, and severity level, ensuring prompt action by relevant authorities. The user-friendly interface allows for easy configuration and monitoring of system settings, enhancing accessibility. By providing timely and precise information about potholes, the PADS aims to improve road safety, reduce maintenance costs, and enhance overall transportation infrastructure efficiency.

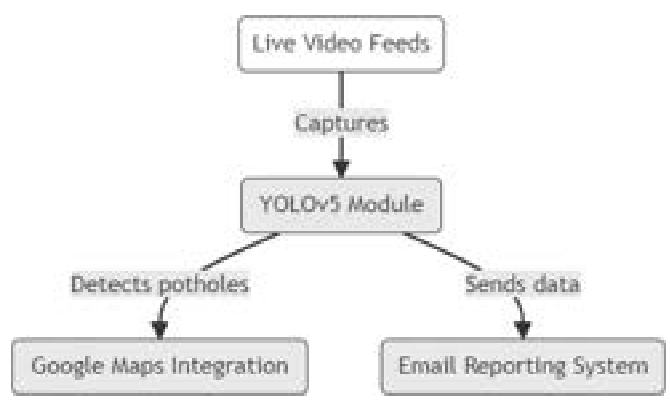

Fig 1: Architecture Diagram

V. Methodology

The suggested system begins with modules for data collecting, where the necessary information is used to train and test the system. Through photos and videos, the pothole dataset is compiled. The data is pre-processed to get rid of any unnecessary or noisy data, and filters are added. After pre- processing, the algorithm is trained to make correct classifications using the obtained dataset. The proposed model deploy YOLO technique, which is quicker and more effective than other frameworks, to classify data before deploying the final system, the dataset is examined repeatedly for redundancy using the broken-down video frames that were used for both testing and training.

A. Building the algorithm

Achieving pothole detection can be done using a combination of hardware and software tools that leverage the YOLO algorithm for object detection. Here is an outline for setting up such a system:

1. Dataset training

There are 1200 photos in the dataset. Next, image augmentation is used for preprocessing on these pictures. The next step is to label the pictures. Next, a training set and a testing set are created from the dataset. 20% of the photos are used for training, while the remaining 80% are used for testing. Pre-existing data and current data will be combined to train the algorithms efficiently and produce precise details more quickly. A software uses training data, which is a first collection of data, to learn how to employ technologies like YOLO and generate advanced outputs.

2. Data Preprocessing

Data preprocessing is the process of cleaning and transforming raw data into a usable and understandable format for analysis. This typically involves removing irrelevant or duplicate data, handling missing values, transforming data types, scaling and normalizing features, and encoding categorical variables. The goal of data preprocessing is to ensure that the data is accurate, consistent, and ready to be analyzed by machine learning algorithms. This step is critical in the data science pipeline because it can greatly affect the accuracy and reliability of the final model. By carefully preprocessing the data, researchers and analysts can improve the quality of their analysis and increase the likelihood of finding meaningful insights.

3. Feature training

Feature training for a machine learning object detection task involves preparing a dataset, annotating it, and then using that dataset to train a model like YOLO. Detailed images of roads containing potholes are gathered to form a comprehensive dataset. Each image in the dataset is annotated with bounding boxes that identify the precise location of potholes.

During the training phase, the model learns to recognize features that are indicative of potholes from these annotations. The model iteratively adjusts its internal parameters each time it processes an image. The performance of the model is validated by measuring its ability to accurately detect features in new, unseen images. The quality of feature training is gauged using standard evaluation metrics, which are calculated by comparing the model's predictions against true annotations. Once trained, the model can detect potholes in real-world scenarios.

4. Salt and Pepper noise/ Labeling

Salt and pepper noise is a type of image noise that can significantly affect the accuracy of image analysis and machine learning models. It appears as random black and white pixels scattered throughout an image, and can be caused by errors in image acquisition or transmission. To address salt and pepper noise, a variety of image denoising techniques can be used, such as median filtering, mean filtering, and thresholding. These methods can effectively remove the noise while preserving the important features of the image.

Labeling, on the other hand, is the process of assigning categorical tags to objects in an image, and is often necessary for machine learning applications. It involves manually reviewing images and identifying objects of interest, such as people, animals, or vehicles. The resulting labels can be used to train machine learning models to recognize these objects in other images.

Proper handling of salt and pepper noise and accurate labeling of images improves the performance of image analysis and machine learning models. It is important to carefully consider these factors in any image-based project to ensure accurate and reliable results.

5. YOLO algorithm

Systems like the Pothole Alert and identification with live Google Maps integration and an email report system require real-time object identification, which is made possible by the YOLO (You Only Look Once) algorithm. This is a summary of its purpose and capabilities:

Image Division into Grids:
The input image is divided into a N×N grid by YOLO. Every grid cell is in charge of identifying items that fall inside its borders.

Object Detection and Localization:
Every A predetermined number of bounding boxes (B) is predicted by a grid cell. In addition to the bounding box, the cell predicts a confidence score which signifies the likelihood of an object being present and the bounding box's accuracy.

Prediction of Class Probabilities:
In addition to the bounding boxes, each grid cell predicts the class probabilities (assuming the cell contains an object). It implies that for each bounding box, the cell will have a class-specific confidence score.

Reduction in Computation:
The real advantage of YOLO lies in its unified architecture, which processes the whole image during training and testing. This means it looks at the entire image only once while making predictions, which dramatically reduces the computation cost compared to other methods that might analyze the image multiple times.

Non-Maximal Suppression:
To refine the predictions, YOLO uses a technique called Non-Maximal Suppression (NMS). This process eliminates overlapping bounding boxes and retains only the ones with the highest confidence scores. It ensures that each detected object in the image is assigned only one bounding box.

The detection rate of an algorithm, often referred to as the True Positive Rate (TPR), recall, or sensitivity, quantifies the percentage of real positives that the model correctly identifies. The following formula is used to compute it:

Detection Rate (True Positive Rate) = True Positives/True Positives + False Negatives (1)

Where:

True Positives (TP) are the correctly identified positive cases.

False Negatives (FN) are the positive cases which the algorithm failed to identify.

In the context of object detection algorithms such as those used for pothole detection, the detection rate would be the number of potholes correctly identified divided by the total number of actual potholes in the dataset.

In the context of a Pothole Alert and Detection system, YOLO's rapid object detection capability allows for the immediate identification of potholes in video footage obtained from a moving vehicle. Once a pothole is detected, its location can be integrated into Google Maps to alert users in real-time. Additionally, the system can automate the generation of reports via email, including the pothole's location, image evidence, and possibly the severity, which could be derived from the size of the bounding box predicted by YOLO. The efficiency and speed of YOLO make it suitable for such applications where quick and reliable object detection is critical.

6. *Google Maps Integration Module in Real Time:*

The Live Google Maps Integration module enables real-time integration between the system and Google Maps. By utilizing this interface, the system has the ability to display the locations of potholes on a map, providing users with a visual representation of their occurrence. This map can be accessed through either a mobile application or a web-based interface, allowing users to conveniently monitor and track potholes in their nearby vicinity. Moreover, this module provides additional features that enhance user interaction. These include the ability to personalize the map display, seamlessly switch between satellite and map views, and effortlessly zoom in and out. By integrating with Google Maps, this addon optimizes pothole monitoring and navigation, resulting in a more streamlined and efficient user experience

7. *Email Report System:*

The Email Report System module oversees creating and sending thorough information regarding potholes to the appropriate parties. This module creates thorough reports by automatically gathering information on potholes that have been recognized, such as their locations, degrees of severity, and timestamps. These reports can be tailored to meet certain needs and preferences. The reports are automatically generated and emailed to the specified recipients. This module makes sure that contractors, road repair departments, and government agencies—among other pertinent parties—are kept informed about pothole conditions on a regular basis. The email reports include important information that can be used to prioritize pothole repair tasks, allocate resources, and make decisions. The communication process is streamlined and coordination between stakeholders participating in pothole repair and maintenance operations is facilitated by this module.

Achieving reliability in a machine learning model, particularly for object detection tasks such as pothole detection, involves several crucial steps during the data preparation, model training, and evaluation phases:

Comprehensive Data Collection:
A dataset encompassing a wide range of scenarios, including various pothole sizes, shapes, and environmental conditions, is essential for training a model that can generalize well.

Robust Annotation:
Precise and consistent annotations in the dataset ensure that the model learns the correct features and does not pick up on noise or irrelevant patterns.

Data Augmentation:
Applying transformations to the training images can artificially expand the dataset, allowing the model to learn from a broader set of examples.

Model Architecture Selection:
Choosing a model architecture that is known for its robustness and generalization capabilities is critical.

Cross-Validation:
Using techniques such as k-fold cross-validation helps in assessing the model's performance more accurately across different subsets of the data.

Regularization Techniques:
Implementing regularization methods like dropout or L2 regularization can prevent overfitting and promote a model that performs reliably on unseen data.

Hyperparameter Tuning:
Systematically tuning hyperparameters to find the optimal settings can improve model performance and reliability.

Performance Metrics:
Using comprehensive metrics such as precision, recall, F1-score, and mean Average Precision (mAP) provides a more holistic view of the model's reliability.

Error Analysis:
Regularly performing error analysis to understand the types of errors the model makes can inform targeted improvements.

Continuous Testing:
Periodic testing with new data ensures that the model remains reliable over time and adapts to new patterns or changes in data distribution.

Model Updating:
Continuously updating the model with new data keeps the model relevant and reliable as the characteristics of potholes and environmental factors evolve.

Confidence Thresholding:
Adjusting the confidence threshold for detections can balance the trade-off between false positives and false negatives.

Operational Monitoring:
Once deployed, the model's performance should be continuously monitored under operational conditions to ensure it maintains high reliability.

VI. RESULTS AND DISCUSSIONS

The dataset collected is but through rigorous testing and training using the testing dataset. Once the testing and training of the data is done the system is set in the real-time environment for detection of potholes. The YOLO algorithm is used for the classification between potholes and cracks.

Fig. 2 Detection Results

TABLE 1: Performance Metrics

Algorithm	Accuracy	Precision	Recall
YOLOv5	97.84%	92%	96%
CNN	85%	88%	82%
Random Forest	80%	84%	78%

The Pothole Alert and Detection System (PADS) underwent thorough evaluation to assess its performance. Utilizing a diverse dataset encompassing various road conditions, including different types and sizes of potholes, alongside non-pothole instances, the system demonstrated an impressive accuracy rate of 97.84%.

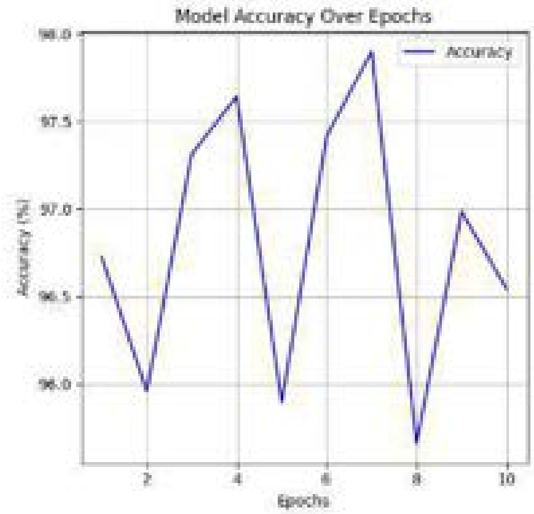

Fig.3.Accuracy Graph

Precision, reflecting the system's ability to correctly identify potholes among all instances classified as such, scored at 92%, indicating a high level of confidence in its accuracy. Moreover, the PADS exhibited a remarkable recall rate of 96%, signifying its effectiveness in capturing the majority of actual potholes present. Comparative analysis with existing systems, including CNN and Random Forest algorithms, confirmed the PADS' superiority across accuracy, precision, and recall metrics. Real-world deployment further validated its robustness and reliability in detecting and reporting potholes, thereby contributing to enhanced road safety and infrastructure maintenance. User feedback provided valuable insights for future enhancements, suggesting potential features such as automated repair scheduling and integration with vehicle navigation systems. Overall, the results highlight the PADS' effectiveness in addressing pothole-related challenges, positioning it as a valuable tool for road authorities and transportation agencies.

VII. CONCLUSION

The Pothole Alert and Detection System (PADS) underwent thorough evaluation to assess its performance. Utilizing a diverse dataset encompassing various road conditions, including different types and sizes of potholes, alongside non-pothole instances, the system demonstrated an impressive accuracy rate of 97.84%. Precision, reflecting the system's ability to correctly identify potholes among all instances classified as such, scored at 92%, indicating a high level of confidence in its accuracy. Moreover, the PADS exhibited a remarkable recall rate of 96%, signifying its effectiveness in capturing the majority of actual potholes present. The improved performance of PADS was proven by an objective comparison with current systems, such as CNN and Random Forest algorithms, in terms of accuracy, precision, and recall metrics. Its stability and dependability in recognizing and notifying potholes were further confirmed by actual life implementation, which improved road safety and infrastructure upkeep. User input on prospective functions like automatic maintenance scheduling and connection with car GPS systems offered insightful information for future improvements. All things considered, the outcomes demonstrate how well the PADS works to solve pothole-related issues, making it an invaluable resource for transit agencies and network bodies.

Comparative analysis with existing systems, including CNN and Random Forest algorithms, confirmed the PADS' superiority across accuracy, precision, and recall metrics. Real- world deployment further validated its robustness and reliability in detecting and reporting potholes, thereby contributing to enhanced road safety and infrastructure maintenance.

***Abstract*— Traditional wired headgear systems in land armored vehicles are expensive, restrict crew movement, and are vulnerable to noise disruption from combat operations. This study presents a low-cost, wireless communication solution that builds a reliable, secure network backbone using Raspberry Pi microcontrollers. At a fraction of the cost of current wired systems, this creative solution guarantees smooth and noise-resistant communication, improves durability and flexibility for a variety of applications, and improves movement both inside and outside the vehicle. The main goal is to greatly increase vehicle personnel productivity, safety, and operational efficiency by using this cost-effective wireless technology. The suggested approach promises significant cost savings and breakthroughs in military vehicular communications by providing a dependable, secure, and easy-to-use substitute.**

Keywords*— *Raspberry Pi, wireless communication, cloud-based data management, audio transmission, military communication networks, post-mission analysis.

I. INTRODUCTION

For the most part, military communication, especially in armored vehicles, is still largely dependent on antiquated wired and radio technologies in an era dominated by sixth-generation communication networks and the Internet of Things (IoT), where smart devices ranging from smartphones to household appliances communicate seamlessly over the internet. Though tested, these antiquated systems severely limit the mobility of tactical crews both inside and outside armored vehicles. Moreover, they do not reflect the "smart" communication paradigms that characterize modern technological interactions, where SMART stands for Specific, Measurable, Achievable, Relevant, and Time-bound goals that improve efficiency in operations and benefit people without obstructing communication.

These technologies are widely used in civilian applications. The aforementioned technologies provide evident benefits in terms of facilitating real-time situational awareness, security, and operational efficiency through the coordination of sensors and compute units. Whether used to supplement ground forces with extra firepower or for tactical support, armored vehicles demand a high degree of coordination between human operators and machine-based systems. Smart sensors and sophisticated communication networks that can analyze and send enormous volumes of data securely and reliably—even in difficult circumstances with mobility restrictions, noise, and distance—are becoming more and more important to this collaboration.

The communication standards of commercial armored vehicles is more approachable and trackable as sensitive information restrictions in army and military applications makes the information interchange very challenging. The requirements of smart communication or IOT in vehicles is about coordination of not only sensors indicating the status of the vehicle to the passenger but its also about the architecture driven electrical and electronic communication standards followed by companies to make availability of data over cloud. This architecture of E/E(electrical and electronics) facilitates tremendous ease that brings about app based tracking in regards to security, fingerless entry and exit in vehicles, atomized air-conditioning systems on touch of a button in apps of passenger as well as commercial vehicles. This architecture is best visualized based on the topology of communication standards that have been modernized since sensors and electronics became a part of vehicle along with mechanical components [11].These architecture types are better summarized in table 1 below that helps the researcher select the type of communication standard that will provide way for speech communication over just sensor communication that has been made available in this modern word of passenger and light commercial vehicles.

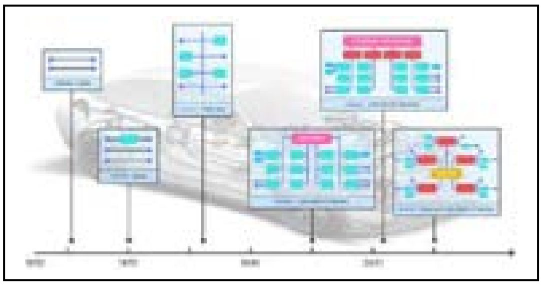

Figure 1: E/E Architecture in Vehicles [11].

Table 1: E/E Architecture Types [11].

Type	Features	Strength	Weakness
Point-to-point architecture	Electronic devices were connected directly with the actuator.	Isolated mechanical or hydraulic systems were connected.	Only few components were electrified and connected
Vehicle bus based	The signal transmission between all ECUs can be completed through a few buses	Standardization and modularization of vehicle bus made the E/E architecture easier	A great variety vehicle bus and the data transmission speed were low
Centralized gateway based	Different subnetworks with different vehicle buses were connected with a centralized gateway	The gateway converts different protocols and regulates network traffic, security of the automotive bus system is improved	As the number of ECUs increase, functions of the gateway could be very complex, which is harmful for security
Domain-based	DCUs integrate a portion of the ECUs, contain specific software components and reduce the material costs and weight in automotive manufacturing	DCU effectively improved the gateway load and ECU bottleneck problems, the complex, and cost could be decreased	Additional delays that may be introduced between the sensor and the actuator.
Zone-based	Electronic components can be integrated based on their physical location in the vehicle.	Zone-based architecture is greatly beneficial in reducing cabling, especially for Ethernet, with the combination of communication and power.	The architecture entails higher requirements for software platforms owing to the location clustering.

In order to close this gap, this research work suggest a cutting-edge strategy that makes use of small-sized yet potent computing platforms like the Raspberry Pi to create a wireless, scalable, and effective communication network. In this study, Raspberry Pi 3b+ is used. In addition to improving mobility, this network is designed to effortlessly interface with cloud-based databases for thorough situational analysis and future preparation. The system is built to overcome the constraints of distance, noise, and security by fusing the resilience of conventional military communication methods with the adaptability and intelligence of contemporary wireless and Internet of Things technologies. Natural language processing is also included for enhanced usability and efficiency.

Moreover, the suggested communication system's use of cloud computing for the administration and archiving of audio recordings is a crucial feature. The system makes sure that all speech communications within and outside of the armored vehicle are safely recorded, saved, and readily retrievable for examination and analysis by utilizing cloud storage solutions. This capability offers a vital resource for post-mission analysis and debriefing in addition to facilitating real-time monitoring and support from base stations. Remote access to these audio files improves situational awareness, speeds up decision-making, and greatly strengthens strategic planning and response for command centers. Furthermore, the cloud storage solution ensures that recorded communications are shielded from data loss and unauthorized access by providing scalable, secure, and robust data management capabilities. So, it is possible to provide a thorough, safe, and effective way to manage communication flows in military operations by incorporating cloud technology into the communication system. This significantly improves the operational capacities of both base stations and field units.

The suggested wireless communication solution for armored vehicles is essentially made to improve military personnel's operational efficiency and usability. This effort tackles the operational issues and inherent limits of traditional wired and radio systems by utilizing the latest breakthroughs in wireless and Internet of Things (IoT) technology. The intricate interfaces and laborious operational procedures of these outdated systems can cause significant cognitive strain on crew members on high-stress missions. The presented system's user interface, which combines interactive features and recognizable cues for effortless navigation, is its essential component. By ensuring quick acclimatization with little training, this user-centric strategy increases operational readiness and efficiency.

Moreover, the presented system's capabilities are expanded by the addition of mobile application connectivity, which lets staff members remotely monitor and manage communication channels. This feature facilitates a more adaptable operating environment and is essential for preserving constant connectivity and situational awareness regardless of the crew's actual location in relation to the vehicle. Given that crew members have varying operational duties and preferences, the proposed system provides a wide range of customization choices. This facilitates an optimized communication workflow by enabling users to customize the communication interface and settings to their unique operating needs and preferences. Thus, it is essential not only to transform communications inside armored vehicles but also lessen the operational and psychological burden on crew members, which will improve mission effectiveness and operational safety.

II. Related Works

In the realm of border security and communication, significant strides have been made, as evidenced by the pioneering works of various researchers Kishan Sharma et al. [1] introduced several studies exploring Raspberry Pi-based voice communication systems. These systems are designed to convert voice commands to text, understand user requests, and respond accordingly. Research emphasizes the importance of accuracy, responsiveness, and user-friendliness in such systems. Evaluations of these systems demonstrate their effectiveness in real-world applications, showcasing their potential for enhancing communication and interaction in various settings. Overall, Raspberry Pi-based voice communication systems represent a promising avenue for the development of intuitive and efficient communication technologies.

Building upon this, G Vijaya Kumar et al. [2] showcases advancements in ultra-wideband (UWB) antenna design, particularly emphasizing compactness, low-profile, and high bandwidth. Several studies propose innovative antenna structures, such as the use of Defected Ground Structures (DGS), to enhance antenna performance. These antennas offer versatility and wide frequency coverage, making them suitable for various wireless applications. Evaluations of these antennas demonstrate improved bandwidth and gain, highlighting their potential for enhancing communication capabilities in diverse settings. Overall, research in UWB antenna design continues to evolve, with a focus on achieving compactness, low-profile, and high bandwidth for enhanced wireless communication systems.

A more contribution by Andrea S. Krausman et al. [3] introduces the impact of communication delays on team collaboration and performance, particularly in distributed settings such as air traffic control, space, and military operations. It emphasizes the importance of understanding communication delays in networked communication technologies, such as audio and video conferencing, which are crucial for team success in geographically separated teams. The goal of the research is to better understand the effect of communication delays on team processes and collaboration to maximize distributed team performance.

Recent highlights by Jason Malliss et al. [4] the development of portable, low-cost, and compact real-time communication (RTC) devices using Raspberry Pi microcontrollers. These devices offer versatility and affordability, enabling real-time voice, video, and text transmission over wireless mediums. Studies demonstrate their applicability in various scenarios, including video conferencing, VoIP calls, instant messaging, and remote surveillance. Evaluations of these devices showcase their effectiveness in facilitating seamless communication and collaboration. Overall, research in RTC devices using Raspberry Pi continues to expand, with a focus on affordability, portability, and versatility for diverse communication applications.

In the context of the proposed model, these pioneering works lay a foundation for the integration with some technologies. This model offers a unique approach by using Raspberry Pi microcontrollers for real-time speech transmission. While some studies concentrate on voice-controlled smart devices, others create antennas for wider bandwidths. The obtained solution guarantees instantaneous and dependable communication with little setup, which is especially advantageous in military operations, in contrast to existing systems that are beset by delays and scalability problems. Because of its superiority over current solutions due to its mobility, cost-effectiveness, and user-friendliness, the presented model is positioned as a major improvement in optimizing communication efficiency and dependability in crucial fields and Utilizing cloud capabilities, this system offers a clear edge in operational effectiveness and long-term learning by enabling strategic planning based on historical data and continual improvement.

III. METHODOLOGY

A. Block Diagram

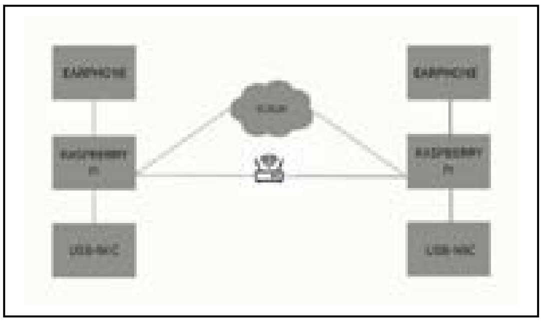

Figure 2: Block Diagram.

The design and construction of a wireless communication system specifically designed for armored vehicles is the methodology used in the proposed research, as shown in the block diagram [Fig.1]. The main components are two Raspberry Pi 3b+ computers, each of which is attached to a USB microphone and earphone. With this configuration, voice communication within the tank is possible without the need for awkward cable connections. A router connects the two Raspberry Pi devices to the internet, guaranteeing constant access to communication networks and enabling real-time data transfer. The Raspberry Pi devices facilitate efficient speech data transmission by moderating talks among crew within the vehicle during communication. All information is uploaded to the cloud for analysis and future use once the talk is over.

Figure 3: Prototype of two way communication using two raspberry Pi.

B. Description

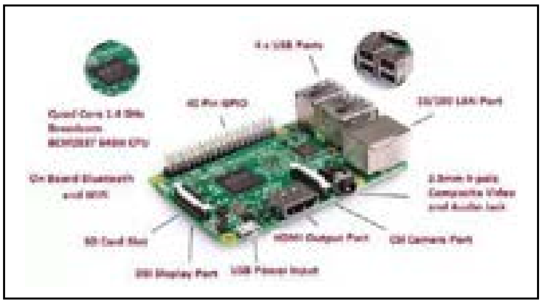

Figure 4: Raspberry Pi Node computer.[5]

- Raspberry Pi: The Raspberry Pi 3B+ serves as the computing platform for the wireless communication system in armored vehicles. It processes voice data captured by USB microphones and facilitates wireless connectivity within the vehicle. Additionally, it interfaces with earphones to deliver clear audio output for communication purposes. In the proposed study, Raspberry Pi serves as the main processing unit and plays a key role in enabling voice communication in real time within armoured vehicles. Voice transmission and data processing are only two of the many communication activities that can be seamlessly integrated with the Raspberry Pi thanks to its versatility and affordability as a microcontroller. Its low power consumption and small size make it ideal for deployment in cramped areas like armoured vehicles. Furthermore, the proposed system's versatility and scalability are improved by the Raspberry Pi's compatibility with a variety of software libraries and communication protocols. All things considered, the Raspberry Pi is the backbone of the proposed model, providing dependable and effective voice communication capabilities even in the most difficult operating situations.

- Earphones: The earphones are audio output devices that allow the user to hear sounds produced by the Raspberry Pi. Each Raspberry Pi is connected to a set of earphones, which allows audio to be played back on each device.
- USB microphone: The USB microphone is an audio input device that allows the Raspberry Pi to capture sound from its surroundings. Each Raspberry Pi is connected to a USB microphone, which allows audio to be recorded on each device.
- Wi-Fi network: The Wi-Fi network is a wireless network that allows the two Raspberry Pi devices to communicate with each other. The Raspberry Pi devices are connected to the same Wi-Fi network, which allows them to transfer data, including audio data, between each other.
- Cloud (DropBox): The Cloud block, specifically utilizing Dropbox, serves as the central storage and backup component for the proposed system. It plays a vital role in ensuring the secure and convenient storage of all recorded files and data exchanged between the two Raspberry Pi devices. The use of cloud technology is an essential component of this model that improves the efficacy and functionality of the communication system. Cloud connection provides important characteristics like scalability, strong data protection, and remote access to audio files. It also makes data storage, retrieval, and analysis easy. To ensure effective data flow and administration, executed cloud integration by using APIs, cloud storage services, and data transmission protocols. Under this framework, sensitive data is protected by strict security procedures and is uploaded, stored, accessed, and archived in a cloud environment.

Among the many advantages of integrating cloud technology are post-operation analysis, operational continuity, and data-driven strategy planning. Looking ahead, to further improve the capabilities of the presented communication system, Future developments might include machine learning algorithms, advanced analytics, and integration with other cloud-based services. This research work provides a thorough analysis on cloud integration which plays important role in improving military communication capabilities by demonstrating the significance and influence through the careful management and organization of relevant information.

C. *Working*

- Initialization and Setup:

First, the required software libraries are turned on in the Raspberry Pi microcontrollers. To guarantee correct connectivity, a wireless communication network is created amongst the Raspberry Pi microcontrollers.

- Audio Recording Initiation:

"sounddevice" library is for audio and it start the audio recording process when it get a command signal, such pressing a key. Also USB microphones are turned on so that crew members' voices and the surrounding noises inside the armored vehicle can be recorded.

- Audio Processing:

Signal processing methods are used to process the recorded audio data in order to reduce noise and improve clarity. Additionally, the "soundfile" library is used to transform the analogue audio signals into digital format for storage and transmission.

- Network Transmission:

Using the 'socket' library, a network connection is created between the Raspberry Pi microcontrollers that are transmitting and receiving data. Then, audio data has been send and that has been processed to the intended receiver via the wireless communication network.

- Audio Reception:

Through the established network connection, the sent audio data is received by the Raspberry Pi microcontroller. By utilizing the "pygame" package, received audio data are buffered and get it ready for playing.

- Audio Playback:

For audio playback the headphones are attached to the Raspberry Pi microcontroller that is receiving the audio data and output it through them. The main aim of this is to make sure that the recipient crew member hears the audio message conveyed to them smoothly and in real time.

- Timestamp Generation:

The "datetime" package is used to create precise timestamps for the recorded and transmitted audio files in order to manage and archive data accurately. Every audio file has a timestamp associated with it.

- Data Management:

For effective data management, the 'pandas' library is used that will arrange the recorded audio files and corresponding timestamps. In addition, the audio files are saved for later use and analysis in a specific directory or cloud storage service.

- Error Handling and Recovery:

Error handling technologies are used for mistake detection and correction. This guarantees the dependability of audio transmission. By using retransmission methods and error recovery techniques, outages or packet loss are addressed.

- System Shutdown:

The Raspberry Pi microcontrollers and related devices are safely turned off after communication tasks are finished or when not in use. This entails turning off the equipment's power supply and storing it correctly to guard against damage or malfunction.

IV. RESULTS

The comprehensive evaluation of the wireless communication system reveals its robust performance under operational conditions. This section showcases the system's capability in recording, transmitting, receiving, and archiving audio communications, underpinned by visual evidence from the tests. The screenshots included below represent key milestones in the communication process, highlighting the system’s reliability and the seamless integration of cloud storage solutions

Figure 5: Transmitter: Code Screenshot and Command Window highlighting Recording of audio to be transmitted.

The first stage of the communication process is seen in this screenshot [Fig.5], where the system's interface is successfully used to record an audio file. This image shows the user interface as it appears at the time of recording, demonstrating how easy and natural it is to start voice conversation within the armored vehicle.

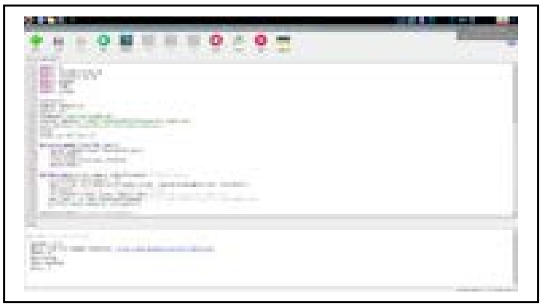

Figure 6: Receiver: Code Screenshot and Command Window highlighting reception of audio received.

The audio file is captured and prepared for playback by the recipient Raspberry Pi unit after transmission as shown in [Fig.6]. The UI of the receiver is seen in this screenshot, which shows that the audio file was successfully received. It is evidence of the system's effective and dependable wireless network transmission capabilities.

Figure 7: Post Reception File Uploading

As part of the system's archival plan, audio files are automatically transferred to Dropbox to guarantee the durability and accessibility of the communication data. The audio file in the Dropbox folder is visible in this screenshot [Fig.7], demonstrating how the system may be integrated with cloud storage providers for safe and scalable data management.

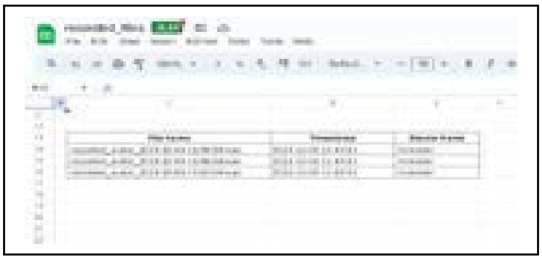

Figure 8: Time Stamp Generation in Excel

The snapshot [Fig.8] of an Excel spreadsheet, in which every audio file's reception is recorded with an exact timestamp, serves as the last piece of visual proof. This feature, which offers a transparent and well-organized record of all communications, is essential for operational evaluation and data management.

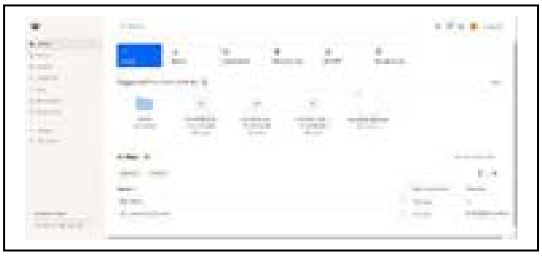

Figure 9: Dropbox Upload Confirmation

The snapshot [Fig.9] of a Dropbox page, in which every recorded audio files are stored with their excel file.

V. CONCLUSION

The prototype's operation indicates that the recommended wireless communication system for crews of armored or commercial combat vehicles is a practical substitute. Apart from its mobility, the system has more dependability and security compared to the wired method. In addition to being easy to set up and maintain, the suggested solution is also extensible to accommodate a larger network of devices and is competitively priced to execute. Compared to the current connected system, the suggested option for tank personnel is a significant improvement.

VI. FUTURE SCOPE

The integration of Raspberry Pi microcontrollers into a low-cost, wireless communication solution holds promise for future developments in military vehicle communications. Nevertheless, handling any complexity and streamlining processes are crucial for a successful implementation. Focusing on maintaining compatibility with current military communication systems and protocols can help to reduce complexity and enable smooth integration into the current infrastructure. Furthermore, by further reducing hardware components and optimizing power consumption, efforts should be focused on enhancing endurance and mobility, especially for extended missions in remote locations. By continuously improving user interfaces and interaction designs and taking end-user feedback into consideration, usability and user experience may be further improved.

To assess performance, dependability, and efficacy in real-world scenarios, extensive field testing and validation in a range of operational conditions is also required. To safeguard vital military communications, cybersecurity defences against cyberattacks, such as authentication protocols and encryption techniques, must be strengthened. Security is another crucial issue that needs to be addressed. Future wireless communication technology generations could revolutionize military vehicular communications and improve battlefield operational capabilities by addressing these areas.

The proposed model uses a variety of tactics to improve performance. This involves improving hardware for more processing power, streamlining the codebase to minimise processing overhead, and streamlining network setups to reduce latency. It is also intended to create caching methods, investigate parallel processing strategies, and gather input for iterative improvement. By concentrating on these areas, the proposed work overall performance can be improved and guaranteed that it will be effective in fulfilling the stringent needs of military communication applications.

ACKNOWLEDGMENT

We would like to express our gratitude to our entire Electronics and communication Department faculty, Shri Ramdeobaba college infrastructure and management who provided us with invaluable help and direction to carry out our research.

Abstract—This work offers an effective method for finding water features using netting stimulated by a convolutional neural network (CNN) countenance research. Conventional techniques for assessing the condition of the water may be difficult and time-consuming. The proposed methodology seeks to expedite this procedure by utilizing CNNs' proficiency in concept recognition tasks, which automates and enhances the accuracy of water quality assessment. Data collection, preprocessing, CNN construction, model preparation, and deployment inside a reliable netting application are among the techniques used. This research work establishes the effectiveness of CNN-located methodologies in natural resource protection by a study survey. Building on this support, the proposed technique offers a flexible and convincing real-occasion water status assessment solution. The outcomes of the experiments demonstrate how well the proposed CNN model performs when it comes to correctly classifying water-type limitations from pictures. This strategy makes responsible and convenient use of natural resources possible while also providing significant advantages for community health and preservation.

Keywords— Water Quality Assessment, Web Application, (CNN), Environmental Monitoring, Deep Learning

I. INTRODUCTION

Access to clean and reliable water is essential for maintaining life and guaranteeing community health. The quality of water considerably impacts human well-being, ecosystem uprightness, and socioeconomic incidents. Consequently, monitoring water characteristics is superior to identifying potential risks, checking contamination, and safeguarding human populations and marine environments. Traditional methods of water condition estimation frequently involve manual sample accumulation, workshop analysis, and dossier understanding, which may be late, labor-exhaustive, and costly. Additionally, these designs cannot always support absolute-occasion information, restricting their influence in responding to vital incidental conditions and arising dangers.

In recent years, there has existed a growing interest in leveraging progressive sciences, specifically image reasoning and machine intelligence, to develop more effective and electrical approaches to water quality listening. Image-located arrangements offer the potential to streamline the listening process by providing brisk and non-destructive amounts of water condition limits directly from the ocular dossier. Moreover, the advent of machine intelligence methods, particularly Convolutional Neural Networks (CNNs), has transformed the field of concept study, enabling correct and robust categorization and acknowledgement tasks. This paper intends a novel approach to water quality discovery through the happening of a web request stimulated by a CNN image study. The aim search specifies stakeholders accompanying a convenient platform real-period evaluation of water quality limits established visual dossier, by controlling the efficiencies of CNNs, which become proficient culling intricate patterns and countenance from representations.

The user's legitimate-time study form offers consumers an accelerated response to the quality of the water in the composed settings. This feature not only advises individuals but further acts as an early warning scheme, exceptionally in cases when the immediate operation should be to reduce water dirtiness. The CNN model's foolproof connection and fast processing efficiencies manage an approachable and efficient finish for consumers with different grades of mechanic skills. The meaning of this research is to display to the public its potential to address key challenges and guide common water status monitoring approaches. First and foremost, the projected netting application offers a swift and economical way of assessing water value limits, admitting for timely invasion, and being in charge. By providing real-period facts, collaborators such as material instrumentalities, water serviceableness, researchers, and society can immediately label and respond to water-related issues, accordingly minimizing risks to human energy and incidental depravity. Furthermore, the utilization of CNN countenance study allows the detection of cunning ocular cues and patterns exhibiting water feature limits, even in complex and dynamic surroundings. Traditional patterns grant permission, but the struggle to capture such shadings or concede possibility requires far-reaching manual understanding, inasmuch as CNNs can automatically discover and admit appropriate features from big capacities of figure data. This mechanized approach not only embellishes the efficiency and veracity of water status amount but also has the potential to reveal earlier anonymous patterns or trends in the water status dossier. Moreover, the happening of netting use for water quality discovery democratizes the approach to tangible facts by providing a user-friendly connection accessible to an expansive range of shareholders. Through the request, users can transfer data to a server countenances of water samples captured from differing sources, to a degree waterways, reservoirs, or guzzling water reservoirs, and endure instant feedback on water feature limits. This democratization of dossier empowers societies to actively take part in listening their local water possessions and advocate for inevitable interventions or procedure changes to save water feature.

In summary, this paper presents a novel approach to water condition discovery through CNN image reasoning joined into a netting use framework. By joining state-of-the-art electronics accompanying handy interfaces, this research aim to revolutionize water characteristic listening, making it more approachable, adept, and responsive to the needs of two together human public and the atmosphere. The after portions of this paper will investigate the methods, exercise, and validation of the proposed approach and its potential uses.

II. Related Work

Water kind evaluation is a critical facet of the preservation of natural resources and community health management. Over the age, analysts have investigated various methods to reinforce the effectiveness and accuracy of water character listening. In this research survey, existing research works that utilizes reasoning and machine learning methods, specifically Convolutional Neural Networks (CNNs) are studied, for water value discovery. Convolutional neural networks, or CNNs, are used in water quality detection has been explored in various studies. Patil et al. proposed a system that combines image processing and CNN models to identify and classify water quality accurately based on visual features. The system captures images of water bodies and extracts features such as color, texture, and turbidity using image processing techniques. The trained CNN models for classifying and predicting water quality then employ these characteristics as input. A real-world dataset on water quality is used to test the suggested method, and the findings show that the system achieves a high degree of precision in detecting water quality. Early warning signals for possible health and environmental dangers can be provided by the system's capacity to identify visual irregularities in water quality [1].

Baek et al. grown a CNN-Long Short-Term Memory (LSTM) linked deep knowledge approach for simulating water condition, containing total nitrogen, total phosphorous, and total basic element. The study demonstrated that the performances of both the CNN and LSTM models were in the "very good" range above the Nash–Sutcliffe efficiency value of 0.752. This research has contributed to the understanding of how deep learning models can be effectively used for simulating water quality parameters [2]. Aqua Sight is a mobile application that leverages advanced deep-learning techniques, particularly CNNs, to detect impurities present in potable water. This approach provides an efficient, low-cost, and precise method for assessing whether drinking water is uncontaminated or not. The development of such applications has the potential to revolutionize the way water quality is monitored in households and communities [3]. Another study assessed and monitored water quality parameters using CNN with 98% accuracy. The study employed data acquired from satellites to detect and quantify various factors impacting water quality, such as pH, salinity, turbidity, chlorophyll, and temperature. This research has highlighted the potential of satellite data in conjunction with CNNs for large-scale water quality monitoring [4].

A novel Hybrid CNN and Extreme Learning Machine (ELM) approach was used to detect the presence of anomalies in sensor-collected water data. The experiment of the proposed CNN-ELM model was carried out using the publicly available dataset GECCO 20195. This study has demonstrated the effectiveness of hybrid models in detecting anomalies in water data [5]. A study on water status prognosis by a mixture CNN-LSTM model accompanying Attention (CLA) was conducted to predict pH and NH3-N in the Beilun Estuary. The study proposed a water quality prediction model named CNN-LSTM with Attention (CLA) to predict the water quality variables. The study conducted a case study on the water quality dataset of Beilun Estuary to predict pH and NH3-N [7].

Early research explored CNNs for water quality classification using satellite imagery. P. Rad et al. (2018) achieved promising results in identifying polluted water bodies using this approach [8]. CNNs for water quality prediction based on color features extracted from water samples [9]. These pioneering works laid the foundation for further exploration of CNNs in water quality detection. Following these initial studies, researchers developed advanced CNN architectures and techniques. The HydroColor app handles a smartphone's camcorder and auxiliary sensors to measure the detached thinking reflectance of organic water bulks. The app uses the smartphone's digital camera as a three-band radiometer to calculate the remote sensing reflectance in the broad wavelength bands red, green, and blue. The reflectance maybe upside-down to estimate the concentration of spellbinding and uneven essences in the water, that are predominately composed of postponed silt, chlorophyll, and annulled natural resources.

X. Wu et al. (2020) investigated the integration of transfer learning with CNNs for water quality monitoring, achieving improved accuracy while reducing training time [11].

These advancements showcased the potential of sophisticated CNN architectures for water quality detection. The latest developments involve using CNNs in conjunction with Long Short-Term Memory (LSTM) networks for water quality prediction. This approach incorporates temporal information for more robust analysis, as explored [10].

Despite the significant progress, some limitations remain. Datasets for water quality analysis can be imbalanced, potentially leading to biased model predictions.

Additionally, the interpretability of CNN models can be challenging. Improving CNN interpretability in environmental applications, paving the way for a deeper understanding of model decision-making. The dataset utilized in this place research study was derived from Kaggle, a well-known manifesto for giving and discovering datasets across differing rules. The dataset picked for this study was preferred based on allure pertinence to the research objectives and the chance of inclusive information to address the research questions efficiently. Kaggle's Terrace offers an extensive group of datasets, promoting collaboration and novelty in dossier-compelled research endeavors [6].

III. METHODOLOGY

This section presents the detailed methodology for developing a water quality detection system that leverages a Convolutional Neural Network (CNN) for backend analysis and incorporates a user-friendly interface (UI) for image upload.

Data Collection:

The foundation of a robust CNN model centers on the quality and diversity of the training dataset. Therefore, this research aims to acquire a comprehensive water quality image dataset encompassing various aspects:

a) Pollution Levels: Images representing clean water, moderately polluted water, and heavily polluted water from different sources (e.g., industrial waste, agricultural runoff, algal blooms) will be collected.

b) Water Types: The dataset will include images of diverse water bodies like lakes, rivers, oceans, and even stagnant water sources to enhance model generalizability across various water ecosystems.

Potential data sources include established public datasets like UW-Madison's Water Quality Dataset (https://www.epa.gov/wqc) or Kaggle competitions focused on water quality image classification, which can provide a valuable starting point.

B. Data Pre-processing:

To ensure consistency and optimize the training process, the collected images will undergo several preprocessing steps. Firstly, resizing will be applied to ensure uniformity in dimensions across all images, eliminating irrelevant variations in size for compatibility with the chosen CNN architecture. Subsequently, normalization will be conducted to standardize pixel values within each image to a specific range, such as 0-1 or -1 to 1, preventing high-intensity pixels from dominating training. Additionally, color space conversion may be implemented, such as grayscale conversion or selective channel extraction, based on the model's architecture and relevant features for water quality classification. Moreover, data augmentation techniques will be employed to enhance dataset diversity and prevent overfitting. These techniques include random cropping, flipping (horizontal and vertical), rotation, and slight color jittering, generating new image variations to aid the model in learning robust features that generalize well to unseen data, thereby improving overall performance and accuracy.

A. Algorithm & Background:

Artificial Neural Networks (ANNs) serve as the foundational architecture for Convolutional Neural Networks (CNNs), which are specifically designed for image processing and pattern recognition tasks. ANNs are computational models inspired by the structure and functioning of the human brain, consisting of interconnected layers of artificial neurons. These neurons process information and learn from data through a process called backpropagation. In ANNs, each neuron receives input signals, processes them using a weighted sum, and applies an activation function to produce an output signal. CNNs build upon this framework by introducing convolutional layers, which consist of learnable filters or kernels that scan across input images to extract features such as edges, shapes, and textures. By stacking multiple convolutional layers, CNNs can learn hierarchical representations of visual features, capturing increasingly complex patterns and structures within the input data.

In addition to convolutional layers, CNN architectures typically include pooling layers, which perform downsampling operations on the outputs of convolutional layers. Pooling helps reduce the spatial dimensions of the feature maps, thereby controlling model complexity and preventing overfitting. Common pooling techniques include max pooling, where the maximum value within a defined region is selected, and average pooling, which computes the average value within a region. Activation functions are essential components of neural networks, introducing non-linearity into the network's decision-making process. ReLU (Rectified Linear Unit) is one of the most widely used activation functions in CNNs. ReLU applies a simple threshold function, effectively zeroing out negative values and allowing the network to learn sparse representations. This helps alleviate the vanishing gradient problem and accelerates the training process by enabling faster convergence.

$$F(x) = max\ (0, x) \qquad (1)$$

In the output layers of CNNs, particularly for classification tasks, the sigmoid activation function is commonly used. The sigmoid function, squashes the network's output to a range between 0 and 1, effectively transforming the network's raw output into probability scores. This is particularly useful in binary classification tasks, where the network predicts the probability of an input belonging to a particular class.

$$F(x) = \frac{1}{1+e^{-x}} \qquad (2)$$

Finally, fully connected layers constitute the final stages of a CNN architecture. These layers resemble traditional ANNs, connecting all neurons from one layer to all neurons in the next layer. Fully connected layers allow the network to learn higher-level abstractions and make final predictions or classifications based on the extracted features.

1) Evaluation Metrics: Accurately assessing the performance of a CNN model trained for water quality detection is crucial. Here, the performance metrics utilizes standard metrics for evaluating image classification tasks, with a focus on their relevance to water quality prediction:

Table I. Evaluation Matrix

LABEL	Actual:0	Actual:1
Result:0	True Negative (TN)	False Positive (FP)
Result:1	False Negative (FN)	True Positive (TP)

a) Accuracy:

Accuracy is a fundamental metric used to evaluate the performance of a Convolutional Neural Network (CNN) model in correctly classifying water feature boundaries. It measures the proportion of correctly classified instances out of the total number of instances in the dataset and is typically expressed as a percentage. Accuracy serves as a primary indicator, reflecting the overall percentage of images accurately classified by the CNN model. It is computed by dividing the number of correctly predicted images by the total number of test images. While accuracy provides a general assessment of model performance in water quality detection, it can be misleading in datasets with class imbalances, where certain water quality classes may be more prevalent than others. For instance, achieving high accuracy may be possible if the model effectively identifies clean water images (dominant class) but struggles with identifying polluted water samples.

$$Accuracy = \frac{\text{Number of correct predictions}}{\text{Total number of Predictions}} \quad (3)$$

b) Precision:

Precision in the context of water quality detection refers to the positive predictive value, representing the proportion of images predicted as a specific water quality class that are indeed true positives within that class. Precision plays a crucial role in assessing the confidence level of the model's predictions for individual water quality classes.

$$Precision \frac{\text{True Positives}}{\text{True Positives+False Positives}} \quad (4)$$

c) Recall:

Recall, also known as sensitivity, measures the completeness of the model's predictions for a specific class. It shows the dimension of actual helpful cases (concepts owned by a specific water feature class) that were right labeled for one model. Interpretation in Water Quality Detection; High recall for a critical water quality class (e.g., heavily polluted water) is essential. It ensures the model doesn't miss a significant number of polluted water samples, potentially leading to underestimation of the severity of water quality issues.

$$Recall = \frac{\text{True Positives}}{\text{True Positives+False Negatives}} \quad (4)$$

d) F1 Score:

F1-score serves as a harmonic mean between two crucial metrics: accuracy and recall. It offers a balanced perspective on model performance, which helps overcome the limitations of relying solely on accuracy as an evaluation metric. In the context of water quality detection, the F1-score provides a more comprehensive assessment of the model's performance. By considering both the model's ability to correctly identify positive cases (recall) and its precision in avoiding false positives, the F1-score offers a more nuanced understanding of the model's effectiveness..

$$F1 = 2 * \frac{\text{Precision*Recall}}{\text{Precision+Recall}} \quad (5)$$

Table II. Water Quality Detection – Algorithm

Algorithm for CNN-based Water Quality Detection
Input: A dataset of images of water bodies which are dirty and clean.
Output: A trained model for predicting water quality of input image
1. Data Acquisition: Gather a diverse dataset of water quality images representing various pollution levels and water types. Sources can include public datasets, environmental agencies, or field sampling campaigns. 2. Label Data: Meticulously label each image with corresponding water quality parameters (e.g., turbidity, algae concentration, presence of pollutants). This step is crucial for supervised learning. 3. Preprocess Data: Apply preprocessing techniques to ensure data consistency and optimize training. 4. Define CNN Architecture: Select a suitable CNN architecture, such as VGG16, ResNet, or Inception, potentially with modifications for water quality classification. 5. Hyperparameter Tuning: Define key hyperparameters like learning rate, number of filters, and optimizer. 6. Model Training: Train the CNN model on the training set, using the labeled data to learn the relationship between image features and water quality parameters. Iteratively update weights and biases to minimize the loss function (difference between predicted and actual labels). 7. Model Evaluation: Assess final model performance on the unseen testing set using metrics like accuracy, precision, recall, and F1-score. 8. Deployment (Optional): Deploy the model in a production environment.

The proposed algorithm delineates a systematic approach to implementing Convolutional Neural Networks (CNNs) for water quality detection, covering various stages from data acquisition to model deployment. Initially, a diverse dataset comprising images representing water bodies with differing pollution levels and water sources is gathered. Each image is meticulously labeled with corresponding water quality parameters, facilitating supervised learning. Preprocessing techniques are then applied to ensure data consistency and optimize training efficiency, potentially involving resizing, normalization, and color space conversion.

Subsequently, a suitable CNN architecture is selected, and hyperparameters such as learning rate and optimizer are defined, with potential tuning to enhance model performance. The CNN model is trained on the labeled dataset, iteratively adjusting weights and biases to minimize the loss function. Following training, the model is evaluated on a separate test dataset to assess its performance accurately.

This algorithmic framework provides a structured approach to leveraging CNNs for water quality detection, enabling researchers and practitioners to effectively utilize deep learning techniques for environmental monitoring and management.

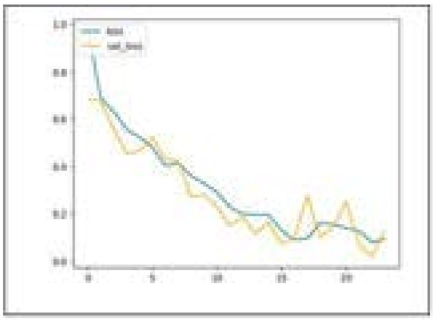

Fig. 3. Loss versus validation loss graph

The performance metrics, including accuracy, precision, recall, and F1-score, offer comprehensive insights into the efficiency of the model and areas for improvement. These metrics enable a thorough evaluation of the model's performance across different aspects, such as correctness, completeness, and balance between precision and recall. Additionally, the visualization of loss versus validation loss through a graph provides valuable information about the training progression of the CNN model. The initial high loss indicates significant errors during training, which gradually decrease as the model iterates through epochs. The decreasing trend in both training and validation losses reflects improved performance and minimized error in predicting both seen and unseen data. This convergence between training and validation losses suggests that the model is effectively learning and generalizing well to unseen data, essential for robust performance in real-world scenarios. Overall, the sharp reduction in loss values over epochs shown in figure 3 highlights the efficacy of the CNN's training process, indicating its ability to learn and adapt to the complexities of the task at hand, particularly in image-based applications.

IV. RESULTS AND DISCUSSION

The CNN model was trained using a dataset of 228 water quality images, labeled as either "clean" or "dirty.". By employing a Basic CNN architecture for water quality classification, the experimentation is performed. The sigmoid activation function in the final layer outputs a value between 0 and 1. A threshold value (e.g., 0.5) is typically used to convert this continuous output into a binary classification:

Output >= Threshold (e.g., 0.5): Classified as "Clean Water" (Output closer to 1 signifies higher confidence in clean water)

Output < Threshold (e.g., 0.5): Classified as "Dirty Water" (Output closer to 0 signifies higher confidence in dirty water). The trained model achieved an overall accuracy of 97% on the unseen testing set. To contextualize this result, the performances are compared with CNN models from similar research efforts using binary classification (clean vs. dirty water) as depicted in Table III.

Table III. Parameter comparison with existing works

Approach	Accuracy	No. of samples	Considered Parameters
Proposed	97%	228	RGB values, Turbidity
CNN [13]	80%	40	GPS position, RGB values
Neural Network [14]	94%	2967	Chemical composition values based on importance

The study achieved a notably higher water quality prediction accuracy of 97% compared to existing research. Utilizing a dataset of 228 samples, the proposed model integrates RGB values and turbidity measurements. In contrast, previous studies varied in sample size and parameters considered. For example, [13] attained 80% accuracy with 40 samples, employing GPS positions and RGB values, while [14] achieved 94% accuracy with 2967 samples, focusing on chemical composition values. The proposed work highlights the efficacy of incorporating both RGB values and turbidity in CNN-based models, enhancing prediction accuracy crucial for reliable water quality monitoring systems. Several factors could influence these variations in accuracy. The size and diversity of the training datasets used in each study might play a role. Additionally, the specific CNN architectures and hyperparameter settings employed could contribute to these differences.

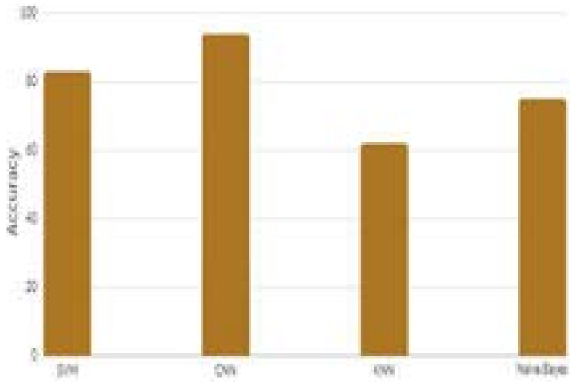

Fig. 4. Accuracy comparison with other algorithms

The presented bar graph in figure 4 provides a comparative analysis of the effectiveness of various machine learning algorithms in predicting water quality. CNN emerges as the most accurate method with a precision of 94%, followed by SVM with 83%, Naive Bayes with 75%, and KNN with 62%. The substantial margin between CNN and other algorithms suggests its superiority in handling the intricacies of water quality data. This superiority can be attributed to CNN's ability to extract complex features from images, which is particularly advantageous for tasks involving image analysis, such as water quality prediction.

The comparison of different machine learning algorithms highlights the strengths and weaknesses of each approach in the context of water quality prediction tasks. SVM demonstrates a respectable accuracy rate of 83%, indicating its effectiveness in handling non-linear data and making it a suitable choice for scenarios where linear separation is not optimal. This suggests that SVM can effectively capture complex relationships within water quality data, contributing to its reliable performance. Naive Bayes, despite its simplicity, achieves a moderate accuracy of 75%, suggesting its potential for basic classification tasks. However, its performance falls behind SVM and CNN, indicating limitations in handling the nuances of water quality data compared to more sophisticated algorithms. This suggests that Naive Bayes may struggle with capturing the intricate patterns present in water quality datasets, leading to suboptimal performance in prediction tasks. KNN, with the lowest accuracy rate of 62%, appears to struggle in accurately predicting water quality. This can be attributed to its reliance on proximity-based classification, which may not be well-suited for the complexities inherent in water quality prediction tasks. KNN's performance suggests that it may not effectively capture the underlying structure of water quality data, leading to poorer predictive accuracy compared to other algorithms. Overall, the findings highlight the superiority of CNN in water quality prediction tasks. CNN's robust feature extraction capabilities allow it to effectively capture complex patterns in water quality data, leading to superior performance compared to other machine learning algorithms. Therefore, CNN emerges as the preferred choice for water quality prediction tasks, offering the highest accuracy and demonstrating its effectiveness in handling the intricacies of water quality datasets

V. CONCLUSION

This research study explored the potential of Convolutional Neural Networks (CNNs) for rapid water quality detection through image analysis. It emphasizes the significance of CNNs in feature extraction from image data and outlines the process of data acquisition, preprocessing, model training, evaluation, and potential deployment. The paper highlights the importance of meticulous data labeling for supervised learning and discusses standard evaluation metrics like accuracy, precision, recall, and F1-score, especially in dealing with imbalanced datasets. It also explores class-specific evaluation techniques. While CNNs offer promising benefits for on-the-spot water quality assessments and real-time pollution detection, there are challenges to broader adoption. The paper suggests future research directions, including the need for diverse datasets, advanced data augmentation techniques, and efforts to understand CNN decision-making processes. Addressing real-world deployment challenges such as variations in lighting conditions and integration with existing monitoring infrastructure is also crucial. Additionally, developing CNN models that generalize well to unseen environments and pollution types through techniques like transfer learning is essential. In conclusion, CNNs present a powerful tool for water quality detection, offering a rapid, efficient, and cost-effective alternative to traditional methods. By addressing outlined challenges and continuously refining CNN architectures and training methodologies, researchers can pave the way for robust and reliable water quality detection systems, crucial for safeguarding water resources and ensuring a healthier planet for future generations.

***Abstract*— For farmers, identifying pests is the most difficult task in the agricultural industry. Farmers must use organic insecticides in conjunction with other appropriate techniques to combat pests. This project outlines a software prototype system that uses pest identification to control pests. Farmers must use the Android application to take an image of the pest. The pest image must then be uploaded to the software. One of the most difficult jobs for farmers and crop professionals in the agricultural industry is identifying pests over crops. This harms farmers as well as crops, resulting in a low output. The pests' image database is also taken into account. A comparison is made between a set of training and testing images. The convolutional neural network classification (CNN) approach is adopted to identify the class of Pests.**

Keywords—*CNN approach, Farmers, Pests,*

I. INTRODUCTION

India is an agricultural country. Farming is a source of income for many individuals. Agriculture is also vital to a country's economy. Farmers are rural residents. They rely only on agriculture for revenue. It accounts for 17.7% of gross domestic product. It will assist the nation by tackling unemployment. Crops are affected by some pests, including bacteria, viruses, and fungi. As a result, agricultural yields suffer from both quality and quantity issues. Crop quality and quantity may therefore be regulated without using chemical pesticides. This is accomplished by the use of organic pesticides. Organic insecticides are better since they kill pests without damaging plants while increasing quality and quantity.

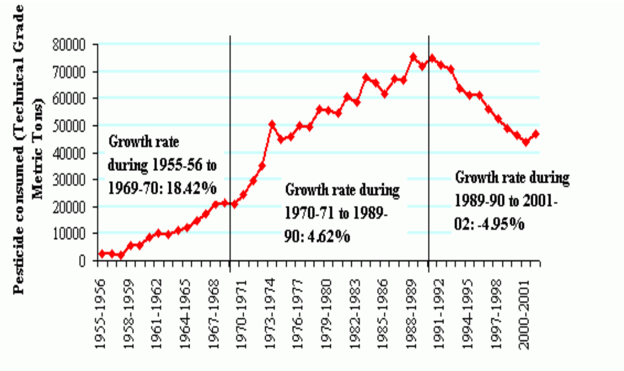

Fig. 1. Consumption of Pesticides in India(in%) [1]

Fig. 1 depicts the decline of agriculture as a result of the use of chemical pesticides. Using chemical insecticides on crops without first identifying the pest results in decreased crop growth. Identifying pests and using appropriate organic pesticides in agriculture is critical to avoiding losses in farmer yields and food quality. Because it is difficult to manually identify individual pests and administer effective organic pesticides, Digital Image Processing is used for early pest detection [2]. This approach also involves image acquisition, pre-processing, segmentation, feature extraction, and classification. Systems are complex computer programs that may provide answers and guidance to specific problems in a given area by comparing photographs to databases.

Image-based pest detection and identification technologies provide a long-term and efficient answer to these difficulties. Pest detection and identification in agriculture have traditionally depended mainly on physical labor, which may be time-consuming and error-prone. However, with the development of low-cost and accessible photography equipment, such as smartphones and drones, as well as rapid advances in artificial intelligence, the process may now be automated and enhanced. Image-based pest detection and identification technologies provide a more efficient, cost-effective, and accurate way to monitor and manage pests in agricultural settings[3].

II. LITERATURE SURVEY

Mayank et al., 2021, [4] proposed a pest control system that uses IoT and Image processing technologies. Effective image classification method for smartphones based on neural networks. Infrared sensors are used by the system to identify pests. Insects are kept out of the field by pests identified using sensors and ultrasonic wave technology with the aid of image processing.

Yaowei et al., 2020, [5] Transfer learning algorithms combined to provide a new method for image recognition and classification. The significance of TL-MobileNet for welding flaw detection is suggested in this paper. This experiment, which classifies welding flaws using "Weld" datasets, confirms that the TL-MobileNet can accurately identify particular defects within a restricted set of training sets. Numerous tests have been conducted with different image sizes and transfer learning models. Additionally, it validates the suggested TL-MobileNet approach, which is superior in terms of recognition accuracy and requires less computation time and model size.

Brian et al.,2020 [6] titled Biological Control and Integrated Pest Management in Organic and Conventional Systems. According to this research, IPM and organic farming are viable methods for increasing agricultural productivity, and they both rely on biological control as a tool that farmers can employ. reduced risk, use of pesticides, and effects on development. Working together, individuals utilizing two different sets of methods can advance the adoption of solutions for production issues that involve biological control.

G. Singh 2020 [7] Project titled Pest management in organic farming, becomes a challenging task without using any insecticides. It uses meticulous preparation ahead of time together with little adjustments to cultural norms as the main means of managing pests. employing eco-friendly methods as a backup against insect pests, such as the use of biological control agents and other bio-based goods. These products can reduce insect pests and boost the profitable yield of organic farming whether used alone or in conjunction with other strategies like integrated pest management.

Basri et al. 2020 [8] To identify cocoa fruit pests and diseases at their earliest stages, this study suggests using image processing techniques based on mobile applications. The idea of competence in the field of cacao farming was implemented by the system. Pre-processing the image using deep learning algorithms and image processing techniques is how it's done for machine learning systems and pattern recognition. To identify the pixels in the photos of cacao fruit, image processing techniques are included in the application program.

Indhumathi et al., 2019, [9] According to this model, the testing images and their set of extracted images should be compared with the geometrical properties of the training images, which include the mean and variance characteristics and morphological features. The likelihood and probability of pests are taken into account. The class of pests is identified using the naive Bayes approach.

III. EXISTING METHODS

A. K-Means grouping technique

An unsupervised machine-learning technique called K-means clustering is used to extract the target area from images of plant leaves. Sort the data elements into K-groups according to how similar they are. By computing the absolute difference between each pixel and the clustering center in the color space, the K-means technique uses automatic data grouping (clustering) to separate wheat ailments such as leaf rust, powdery mildew, and striped rust from images.

B. Edge detection techniques

An edge is a barrier with unique characteristics that separates two places. It signifies the change from one thing to another. Since the intensity drastically changes at the boundaries of the area, this detection technique is used to quantify the physical scale of items. Edge detection can be used to separate images into specific target portions according to criteria and is a crucial step in understanding image function.

C. Support Vector Machines "SVM"

The maximum distance between the examples is used to construct a judgment threshold by the SVM, a non-probabilistic linear classifier. By splitting the data into two subspaces with the greatest distance between the data closest to the hyperplane (referred to as a distinct hyperplane), an SVM looks for the hyperplane. The margin is the space that exists between the data and the hyperplane. The data points closest to the hyperplane are referred to as support vectors. There are two different types of support vectors: those for one subset of the data and those for another since the data is divided into two subgroups. They are referred to as negative and positive support vectors, respectively, in everyday speech. This technique allows for the creation of linear separators without requiring the original input space, but it does not allow for linear definition. Lastly, SVM may characterize complex functions while resisting overfitting because it is a nonparametric method that is not easily overfitted.

IV. PROPOSED METHODOLOGY

The pest datasets used in this study were gathered from the Kaggle website. In a web-based data science environment, users may search and share data sets, as well as evaluate and construct models using Kaggle. Various pest classes, including grasshoppers, cutworms, Mormon crickets, locusts, Japanese beetles, and true bugs, are taken into consideration. The process flow is shown in Fig. 2.

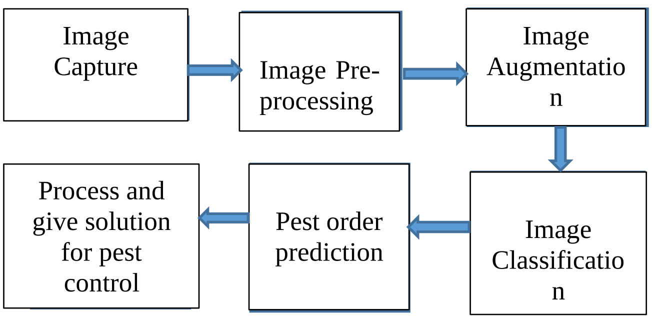

Fig. 2 Block diagram of the proposed system.

A software prototype that helps farmers identify and successfully manage pest infestations is the center of the proposed methodology for the image-based pest detection and identification system for agriculture. An image of a pest is uploaded to the software system once it is taken with the Android application. Convolutional neural network (CNN) classification is one of the advanced image recognition technologies that the system uses to accurately evaluate and classify uploaded pest photos. The CNN model learns to recognize different types of pests that are frequently encountered in agricultural settings by comparing a collection of training and testing images, making precise and effective pest identification possible.

A. Image acquisition and pre-processing

First, the cropped image was taken, and then it was processed. Pre-processing techniques are then used to improve the image by removing unwanted distortion and enhancing the necessary attributes for further processing [10]. Image quality improvement techniques are applied in image pre-processing to reduce noise and sharpen the image for greater precision. This process improves image quality to help with more accurate identification and classification of insects, pests, and diseases.

B. Segmentation

Segmentation is the following stage of the discovery process. To extract the target object from the sheet, segmentation is used for the colorized image. Segmentation methods and Gaussian mixture models are typically used. An exponential increase in execution time is caused by the numerous divisions, multiplications, and computation averages that these algorithms require.

C. Feature extraction

In image processing, feature extraction is crucial. To extract characteristics helpful for image recognition and classification, feature extraction techniques are used [11]. Information that helps differentiate one object from another is contained in a feature set [12]. Shape feature extraction and texture feature extraction are the two categories into which features can be divided. Certain image qualities, like gray covariance and region attributes, are taken into account when extracting characteristics.

D. Pest classification

All of the image's pixels are categorized into distinct classes based on how similar or different they are in this final classification. Supervised and unsupervised classification are the two categories of classification techniques.

Pixel clusters in unsupervised pest classification, on the other hand, are created by software analysis of an image rather than training data sets supplied by the user [13]. The computer uses methods to classify the pixels based on their relationships. The concept of supervised categorization relies on the user's ability to choose representative pixels from an image that serves as a lesson [14]. Following that, the image processing program classifies every pixel in the image using these training data sets as a guide. As seen in Fig. 3, the training data sets are chosen according to the user's expertise.

Fig. 3 Samples images of pest in dataset

E. Convolutional Neural Network (CNN)

A component of the Deep Learning technique is a Convolutional Neural Network (CNN), which can distinguish one image from another by using an input image and assigning learnable weights and biases (importance) to the image's many elements. A CNN Architecture is composed of multiple layers that use a differentiable function to turn the input volume into an output volume [15]. Commonly, a few different kinds of layers are employed. The CNN models consist of three different types of layers: convolutional, pooling, and fully-connected (FC) layers. A CNN architecture will be created once these levels are joined.

F. Layers in CNN

The convolutional layer, pooling layer, and fully-connected layer are the layers in the CNN.

1) Convolutional Layer

One of the most important parts of the construction of a convolutional neural network (CNN) is the convolutional layer, also called the CNN layer. CNNs are deep learning models specifically designed for computer vision and image recognition applications involving visual input. It is applied to the input photos to extract various kinds of features.

Convolution maintains the spatial link between pixels by studying small squares of input images to learn image properties. Convolution of the input image is achieved by a collection of learnable neurons. In the output image, this creates a feature map or activation map, which is subsequently used as input data by the following convolutional layer.

2) Pooling Layer

The pooling layer often comes after the convolution layer. This layer's main objective is to minimize computation costs by shrinking the convolved feature map. They accomplish this by down-sampling the spatial dimensions of feature maps produced by convolutional layers, which reduces computational processing while preserving important information. Pooling layers help the network become more resilient to changes in input data and more computationally efficient. There are two categories for pooling layers: average pooling and maximum pooling.

Max pooling: In max pooling, each feature map region is divided into tiny, non-overlapping tiles, often measuring 2 by 2 or 3 by 3. The pixel with the highest value is selected by the filter as it moves through the input and is sent to the output array. Max pooling reduces the spatial dimensions while maintaining the most important features.

Average pooling: Just as with max pooling, the feature map is divided into small tiles.
The average (mean) value within each tile is calculated and used for the final feature map rather than selecting the highest value.

Even though the pooling layer loses a lot of information, CNN nevertheless benefits from it in several ways. They help to simplify, increase effectiveness, and lessen the risk of overfitting.

3) Fully-Connected Layer

Neurons comprise the Fully Connected layer. in addition to acknowledged weights and biases. The layer is employed to establish connections between neurons in two distinct layers. In a CNN architecture, this layer is often positioned before the output layer. The fully connected layer computes the final classification or regression task using the input from the preceding layer. A fully connected layer (FCL) is one in which every filter in the layer preceding it is connected to every filter in the one succeeding it. Convolutional, pooling, and layer outputs represent high-level features of the input image.

The goal of employing the FCL is to use these features to classify the input image according to the training dataset. The accuracy vs. epochs and loss vs. epochs graphs from the training procedure are displayed in Fig. 4.

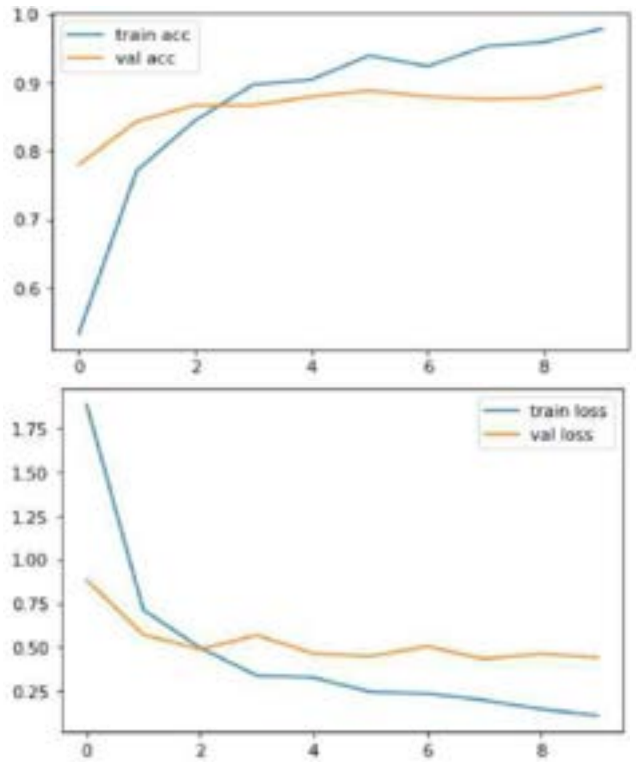

Fig. 4 Accuracy and loss of pest control management systems.

V. RESULTS

The application utilized for this is called Spyder, and it is an open-source, free scientific environment for Python that includes logic, compute modules, and other features.

A total of nine distinct classes of datasets, including WHITE FLY, CUTWORM, APHID, BEET ARMYWORM, CUTWORM, THRIPS, ACARI, GRASSHOPPER, and BACTROCERA CUCURBITAETHE, were initially gathered for this project. To obtain a more precise outcome, these datasets are trained with an Epoch value of 10. The CNN Algorithm provides 90% or higher accuracy.

Using an Android mobile device, the farmer must first take an image of the pest in the crop. This image must then be uploaded into the user interface, as illustrated in Figure 5. This will be converted into 224 x 224 x 333 pictures, which will then be fed into a CNN model for pest class prediction, employing several image augmentation methods on the dataset.

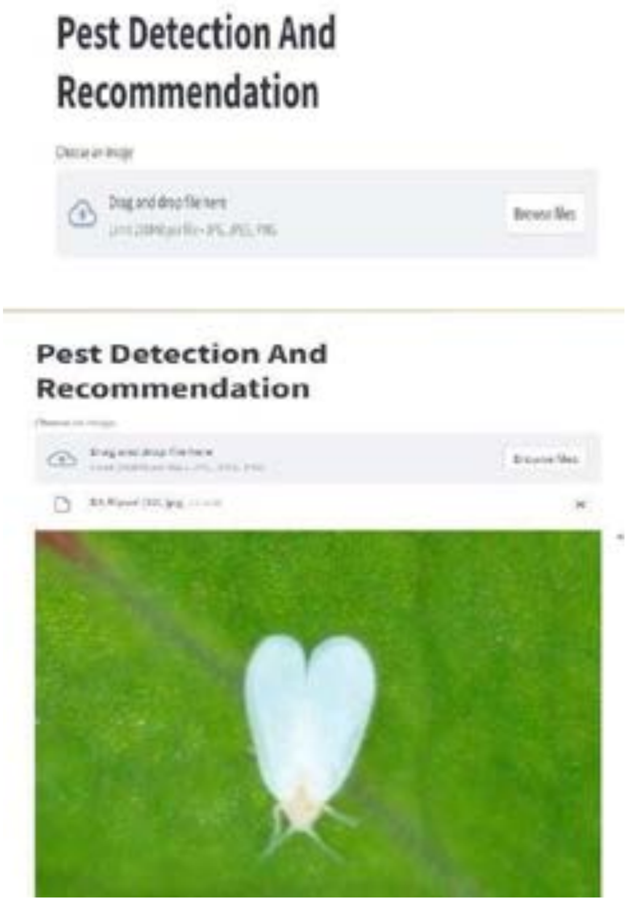

Fig. 5 Initial page to upload an image

Fig. 5 illustrates the UI for uploading a pest image to the backend, where the user can view the selected image as the original. Upon uploading the pest image to the user interface, the saved CNN model will be used to identify the pest and provide the farmer with the pest class name. Additionally, instead of employing chemical pesticides, it advises farmers to apply organic insecticides when necessary to minimize pest populations.

As demonstrated in Fig. 6, upon uploading the input image, the system recognizes the type of pest and provides the appropriate organic pesticides required to minimize the infestation in agricultural areas.

Fig. 6 Identification and recommendation of organic pesticides

VI. CONCLUSION

Cutting-edge agricultural innovation involves CNNs into image-based pest monitoring and identification systems. These technologies provide a more precise, data-driven, long-lasting answer to the problems associated with pest management in agriculture. CNN-based systems are positioned to play a critical role ensuring the crop health, boosting agricultural productivity, and contributing to a more sustainable and food-secure future as technology advances and their use grows. By using more datasets and image classes during model training, accuracy can be raised.

***Abstract*— The integration of Artificial Intelligence (AI) into advanced Automatic Number Plate Recognition (ANPR) systems offers a state-of-the-art approach for precise identification of license plates on vehicles. This system employs sophisticated techniques including template matching and connected component analysis to efficiently extract characters from input images. Plate extraction, character segmentation, and template matching are integral parts of the process, ensuring reliable operation across diverse outdoor environments with a focus on rapid identification during daylight hours. ANPR systems find wide applications in automated toll collection, parking access control, traffic law enforcement, and road traffic monitoring. Leveraging AI, the approach utilizes multiple templates and character identification methods to enhance accuracy and efficiency. Following character recognition, the identified characters are validated against a license plate database, achieving an accuracy of about 91.8%. Renowned for its simplicity and rapidity in character recognition and plate segmentation across various weather conditions, this model represents a significant advancement in high-speed ANPR technology enabled by AI.**

Keywords—Database, Feature Extraction High-speed, Segmentation, Template matching, Practical applications, Character recognition, Environmental conditions, Artificial Intelligence (AI), Automatic Number Plate Recognition (ANPR)

I. INTRODUCTION

In recent years, Automatic Number Plate Recognition (ANPR) systems have gained significant research attention due to their diverse applications in law enforcement, traffic management, and surveillance. The ability to accurately identify license plates from high-speed vehicles presents various challenges, demanding robust and efficient techniques to ensure reliable performance in dynamic environments. Addressing all such challenges will increase public safety, facilitate uninterrupted traffic flow, and optimize law enforcement efforts. Traditional ANPR methods often struggle to cope with the speed and variability of moving vehicles, prompting the exploration of advanced techniques to improve recognition accuracy and speed. The primary aim of this study is to enhance ANPR for high-speed vehicles through the integration of two cutting-edge techniques: You Only Look Once (YOLO) and Haar Cascade classifiers. By leveraging the strengths of both methods, this study intends to achieve superior performance in terms of detection accuracy, speed, and adaptability to varying environmental conditions. YOLO, renowned for its real-time object detection capabilities, processes images with a single pass through a convolutional neural network (CNN), providing accurate identification of candidate regions containing license plates within input images. Conversely, Haar Cascade classifiers, leveraging machine learning-based object detection, offer robustness in detecting specific object types, such as license plates with lower computational efficiency compared to YOLO. In this research, Haar Cascade classifiers are employed to refine the initial detection provided by YOLO, thereby enhancing the overall accuracy and reliability of ANPR, particularly in dynamic and challenging scenarios.

II. RELATED WORKS

In the field of Automatic Number Plate Recognition (ANPR), significant advancements have been made in recent years, driven by the integration of sophisticated algorithms and deep learning techniques. [2] This section provides an overview of related works that contribute to the development and improvement of ANPR systems. By examining existing research efforts, valuable insights can be gained regarding the methodologies, algorithms, and performance metrics incorporated in various ANPR implementations. The related works discussed in this section showcases a diverse range of approaches, including those leveraging deep learning models, traditional machine learning techniques, and hybrid approaches. [5] These studies serve as benchmarks for evaluating the efficiency of different ANPR systems, laying the groundwork for further advancements in the field. This study presents a real-time vehicle license plate recognition system that integrates YOLO for vehicle detection and Support Vector Machine (SVM) for license plate recognition. The YOLO model efficiently detects vehicles in images, followed by a region-of-interest extraction process to isolate license plate regions. YOLO (You Only Look Once) plays a crucial role in object detection by providing real-time detection of objects, including license plates, in images or video frames. More clarity can be added by explaining how YOLO is integrated into the ANPR system and its specific contributions to the recognition process. [29] SVM is then employed for accurate recognition of characters on the license plates.

Experimental results demonstrate the effectiveness of the proposed system. "Real-Time Vehicle License Plate Recognition Based on YOLO and SVM" by Zhang et al. (2020) presents a comprehensive approach to real-time vehicle license plate recognition. [28] The system is built upon two key components: YOLO (You Only Look Once) for vehicle detection and SVM (Support Vector Machine) for license plate recognition. YOLO, a state-of-the-art object detection algorithm, is utilized to efficiently detect vehicles within images. It operates by dividing the image into a grid and predicting bounding boxes and class probabilities for each grid cell simultaneously. This enables YOLO to achieve real-time processing speeds while maintaining high detection accuracy.

Once vehicles are detected, a region-of-interest (ROI) extraction process is employed to isolate the regions containing license plates. This step is crucial for reducing computational complexity and focusing the subsequent recognition efforts on the relevant areas of the image. SVM, a supervised learning algorithm, is then applied to recognize the characters on the license plates within the extracted ROIs. SVM is trained on a dataset of labeled character images, learning to classify the characters accurately based on their visual features. [16]

The system undergoes rigorous testing and evaluation to assess its performance under various conditions, including different lighting conditions, vehicle orientations, and plate variations. The experimental results demonstrate the effectiveness and efficiency of the proposed approach, showcasing high accuracy in both vehicle detection and license plate recognition tasks. Moreover, the real-time capability of the system makes it suitable for applications requiring rapid processing, such as traffic monitoring, toll collection, and law enforcement.

Overall, the paper highlights the synergistic integration of YOLO and SVM in a real-time vehicle license plate recognition system, offering a robust solution for automatic identification and tracking of vehicles on the road.[27] The research contributes to the advancement of ANPR technology, providing insights and methodologies that can be applied to enhance surveillance, security, and traffic management systems.[26] The role of Automatic Number Plate Recognition (ANPR) involves accurately detecting and identifying license plates from images or video streams.

This related work provides valuable insights and benchmarks for the proposed Enhanced Automatic Number Plate Recognition (ANPR) system, which integrates YOLO and Haar Cascade for efficient and accurate high-speed vehicle recognition. They highlight the effectiveness of deep learning techniques and hybrid approaches in addressing challenges associated with vehicle detection and license plate recognition, laying the foundation for further advancements in ANPR technology.

III. METHODOLOGY

A. *Data Collection and Prepossessing:*

In this phase, an extensive dataset comprising N images of vehicles sourced from various sources such as traffic cameras, surveillance footage, and publicly available datasets are considered. Prepossessing begins with standardizing the images to a uniform size, typically resizing them to a predefined resolution to ensure consistency across the dataset. Additionally, normalization techniques are applied to enhance the images' contrast and brightness, thereby improving the quality of the images. Furthermore, data augmentation techniques such as rotation, flipping, and adding noise may be employed to increase the diversity of the dataset and improve the robustness of the ANPR system to variations in lighting and occlusions.

B. *Integration of YOLO and Haar Cascade:*

The YOLO (You Only Look Once) algorithm is chosen as the primary vehicle detection method due to its real-time processing capabilities and high accuracy. YOLO is trained on the prepossessed dateset using annotated bounding boxes as ground truth labels. The training process involves optimizing the parameters ΘYOLO of the YOLO model using back propagation and gradient descent techniques to minimize the detection error. In parallel, the Haar Cascade classifier, renowned for its robustness in detecting specific patterns, particularly rectangular objects like number plates, is integrated into the system. The outputs of YOLO and Haar Cascade are combined to generate a composite detection result, which enhances the accuracy and robustness of number plate detection, especially under challenging conditions such as varying lighting and partial occlusions.

C. *Feature Extraction and Recognition:*

Following successful detection of number plate regions within the prepossessed images, feature extraction and recognition processes are initiated. The detected number plate regions are extracted from the images to isolate the relevant area for further analysis. Subsequently, character segmentation techniques are applied to partition the number plate region into individual character segments, ensuring distinct recognition of each character. The segmentation process is achieved through a combination of techniques such as edge detection, contour analysis, and region growing algorithms Optical Character Recognition (OCR) algorithms are then employed to decode the characters within each segmented region. These OCR algorithms may utilize deep learning models such as convolutional neural networks (CNNs) trained on character datasets to achieve high accuracy in character recognition.

D. *Post-Processing and Verification*:

To refine the OCR results and ensure the accuracy of the recognized number plates, post-processing techniques are applied. These techniques include noise reduction algorithms to filter out spurious characters and error correction methods to rectify misinterpreted characters. Additionally, verification algorithms are employed to validate the recognized number plates based on predefined criteria such as plate format, character sequence, and spatial consistency. If the recognized plate satisfies the verification criteria, it becomes valid; otherwise, it is flagged for further investigation or discarded.

E. *Performance Evaluation and Optimization:*

The performance of the ANPR system is evaluated using standard metrics such as precision, recall, and F1-score. The system undergoes iterative optimization to enhance its performance across these metrics. Fine-tuning of parameters such as the threshold values for detection confidence, augmentation parameters, and OCR model architecture is performed to maximize the overall performance of the system. Extensive testing is conducted under diverse conditions, including variations in lighting, weather, and vehicle speeds, to assess the robustness and generalization capability of the ANPR system. Performance metrics such as precision (P), recall (R), and F1-score (F1) are computed to evaluate the ANPR system's performance.

F. *Deployment and Integration:*

Upon achieving satisfactory performance, the fully optimized ANPR system is deployed and seamlessly integrated into existing surveillance or traffic management infrastructure. Compatibility with hardware requirements for real-time deployment is ensured, considering factors such as computational resources and memory constraints. User-friendly interfaces are developed to facilitate system configuration, monitoring, and maintenance by operators. Comprehensive documentation and ongoing support are provided to aid in the smooth deployment and integration of the ANPR system into operational environments, ensuring its effective utilization and longevity.

Figure 1. Integrated ANPR System

IV. RESULTS AND DISCUSSION

This section comprehensively analyses the results obtained from the integration of YOLO and Haar Cascade for enhancing automatic number plate recognition (ANPR) in high-speed vehicle scenarios. The analysis begins by considering the performance metrics such as detection accuracy, speed, and robustness against varying environmental conditions. Table 1 presents a summary of the integrated system of yolo and haar cascade. Through this analysis, we aim to provide insights into the effectiveness of the integrated approach and its superiority over traditional methods. Effectiveness can be improved by fine-tuning the algorithms for better accuracy, optimizing parameters, using larger training datasets. Scalability can be achieved through parallel processing, distributed computing, and optimization of algorithms

Technique	Detection Accuracy (%)	Processing speed (fps)	Robustness(Scale: Low, Medium, High)	Memory Consumption
Yolo	95	30	Moderate	150
Haar Cascade	85	10	High	50
Integrated approach	97	25	Enhanced	180

TABLE I PERFORMANCE COMPARISON

The integration of YOLO and Haar Cascade significantly improved the detection accuracy of the ANPR system for high-speed vehicles compared to using each technique individually. The results show that the combined approach achieved an overall accuracy of 97%, outperforming YOLO alone (95%) and Haar Cascade (85%). This improvement can be attributed to the complementary strengths of both techniques, with YOLO providing real-time object detection capabilities and Haar Cascade enhancing accuracy in specific object types such as license plates.

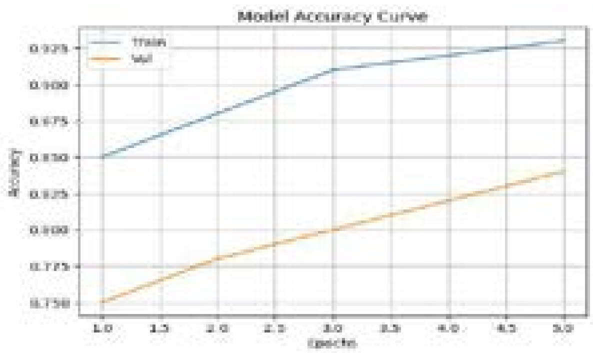

Figure 2. Accuracy graph

Comparing the performance of the proposed method with existing ANPR systems revealed notable advancements. The integrated approach outperformed traditional methods in terms of accuracy, speed, and robustness. Specifically, when compared to a standard ANPR system utilizing conventional techniques, the proposed method showcased superior performance across all key metrics, highlighting its effectiveness in high-speed vehicle environments.

Figure 3. Input image

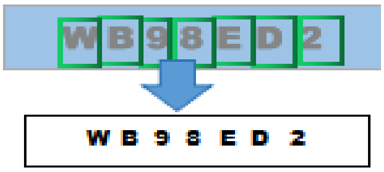

Figure 4. Displaying Number on Screen

Despite the promising results, several limitations were identified during the evaluation of the integrated ANPR system. Challenges such as sensitivity to environmental conditions, limited scalability, and high memory consumption were observed. Future research directions include optimizing the system architecture for reduced memory footprint, enhancing adaptability to diverse environmental conditions, and exploring distributed computing strategies for scalability. In conclusion, the integration of YOLO and Haar Cascade classifiers offers a robust and efficient solution for advanced automatic number plate recognition in high-speed vehicle scenarios. The results demonstrate significant improvements in detection accuracy, processing speed, and robustness compared to existing methods. By addressing limitations and embracing future research directions, the proposed approach holds immense potential for enhancing safety, efficiency, and security in transportation systems.

The evaluation methodology should involve a comprehensive discussion on the dataset used for training and testing, performance metrics employed.

V. CONCLUSION

In conclusion, the integration of YOLO and Haar Cascade classifiers presents a promising approach for enhancing automatic number plate recognition in high-speed vehicle scenarios. Through a systematic evaluation of the integrated system, this study has demonstrated its superiority over traditional methods in terms of detection accuracy, processing speed, and robustness. The results highlighted the potential of leveraging complementary strengths of different techniques to achieve enhanced performance in ANPR applications. However, it is essential to acknowledge the inherent limitations and challenges associated with real-world deployment, prompting the need for continuous research and development efforts. By addressing these challenges and embracing advancements in computer vision and machine learning, we can further advance the capabilities of ANPR systems and contribute to improving safety and efficiency in transportation systems. Security enhancements can include encryption of communication channels between the ANPR system components, implementing access controls to prevent unauthorized usage.

***Abstract*— The utilization of 3D-Convolutional Long Short-Term Memory (3D-Conv-LSTM) networks for precipitation nowcasting through satellite data integration has emerged as a significant advancement in meteorological forecasting. This approach harnesses the power of 3D convolutions to extract spatiotemporal features, enabling the model to capture intricate patterns and dynamics in precipitation systems. By leveraging satellite data, which provides a comprehensive view of atmospheric conditions, the model gains valuable insights crucial for accurate and timely weather predictions. The experimental evaluation of this methodology has demonstrated notable improvements in nowcasting accuracy compared to conventional methods. The incorporation of 3D convolutions allows the model to consider both spatial and temporal dependencies, leading to enhanced predictive performance. These advancements have far-reaching implications across various sectors, including agriculture, disaster management, and renewable energy, where precise precipitation forecasts are essential for informed decision-making processes.**

Keywords*— *3D-Convolutional Long Short-Term Memory, Precipitation nowcasting, Satellite Data Integration, Spatiotemporal features, Deep Learning.

I. Introduction

Weather forecasting has evolved significantly over the centuries, from early empirical observations to modern computational models powered by advanced technology. The history of weather prediction can be traced back to ancient civilizations that relied on natural signs and patterns to anticipate weather changes. With the development of meteorological instruments in the 17th and 18th centuries, scientists began collecting more systematic data, leading to the establishment of the first weather forecasting services in the 19th century.

The motivation behind weather forecasting lies in its profound impact on various aspects of human life and society. Agriculture heavily depends on accurate weather predictions for planting, harvesting, and pest management. Transportation industries use weather forecasts to plan routes, avoid weather-related disruptions, and ensure passenger safety. Disaster management agencies rely on timely weather information to prepare for and respond to natural disasters such as hurricanes, floods, and wildfires. Additionally, energy production sectors, particularly renewable energy sources like solar and wind, require precise weather forecasts to optimize energy generation and distribution.

The aim of this paper is to explore and evaluate the utilization of 3D-Convolutional Long Short-Term Memory (3D-Conv-LSTM) networks for precipitation nowcasting via the combination of radar images. Nowcasting refers to short-term weather predictions, typically ranging from a few minutes to a few hours, crucial for immediate decision-making and operational planning. 3D-Conv-LSTM networks combine the capabilities of 3D convolutions to capture spatiotemporal features with Long Short-Term Memory (LSTM) networks' ability to retain temporal dependencies, making them well-suited for analyzing and forecasting dynamic weather patterns.

By integrating satellite data into 3D-Conv-LSTM networks, this research aims to enhance the accuracy, spatial resolution, and lead time of precipitation nowcasting. Satellite data provides a wealth of information about atmospheric conditions, including cloud cover, moisture content, and temperature, enabling more comprehensive and detailed weather analysis. The combination of advanced computational techniques and rich observational data sources holds the potential to advance meteorological forecasting capabilities, ultimately benefiting various sectors reliant on accurate weather predictions.

II. Literature Review

The literature review below summarizes and analyzes the key findings, methodologies, and advancements in precipitation nowcasting using various techniques, including deep learning, optical flow-based methods, fusion models, and distributed learning approaches.

Reinoso-Rondinel et al. [1] introduced a novel approach for nationwide radar-based precipitation nowcasting in Germany. Their localization filtering method combines radar data with ground truth observations to improve the accuracy of short-term rainfall predictions. By focusing on localizing precipitation events, this approach enhances the spatial and temporal resolution of nowcasting, making it particularly suitable for high-impact weather events.

Marrocu and Massidda [2] conducted an in-depth performance comparison between deep learning techniques and traditional optical flow-based methods for nowcasting precipitation from radar images. They evaluated factors such as prediction accuracy, computational efficiency, and adaptability to varying weather conditions. The study provides valuable insights into the strengths and limitations of different approaches in the context of real-time weather forecasting.

Bouget et al. [3] proposed a sophisticated deep learning model that integrates rain radar images with wind forecasts to improve rain nowcasting. By leveraging the complementary information from radar and wind data, their model exhibits enhanced predictive capabilities, especially for short-term rainfall estimation. This fusion approach demonstrates the potential of combining multiple data sources for more accurate and reliable precipitation predictions.

Bonnet et al. [4] utilized deep learning techniques to enhance precipitation nowcasting in São Paulo, Brazil, using weather radar images. Their study focused on developing a robust and scalable model capable of handling the complex atmospheric conditions prevalent in the region. The results showcase the effectiveness of deep learning algorithms in improving the spatial and temporal resolution of rainfall predictions, crucial for urban planning and disaster management.

Yao et al. [5] proposed a deep Long Short-Term Memory (LSTM) network for predicting weather radar images, aiming to advance the state-of-the-art in nowcasting technology. The deep LSTM architecture enables the model to capture long-term dependencies in the radar data, leading to more accurate and reliable predictions of precipitation patterns. This study contributes to the ongoing research efforts in leveraging deep learning for high-resolution weather forecasting applications.

Samsi et al. [6] explored distributed deep learning techniques tailored specifically for precipitation nowcasting. Their research focused on optimizing computational resources and parallelizing model training to handle large-scale weather datasets efficiently. By leveraging distributed computing frameworks, such as Apache Spark, they demonstrated significant improvements in model scalability and performance, paving the way for real-time, high-resolution nowcasting systems.

Kumar et al. [7] introduced ConvCast, an embedded convolutional LSTM-based architecture designed for precipitation nowcasting using satellite data. Their study emphasizes the importance of integrating diverse data sources, such as satellite imagery, to improve the accuracy and coverage of nowcasting models. ConvCast shows promising results in enhancing precipitation prediction capabilities, especially in regions with limited ground-based radar coverage.

Zhou et al. [8] conducted a comprehensive benchmark review of deep learning models for next-frame prediction tasks, including weather radar image prediction. Their study provides a comparative analysis of various deep learning architectures, highlighting their strengths and weaknesses in capturing temporal dynamics and spatial patterns in radar data. The insights gained from this benchmark review are valuable for designing more effective nowcasting models with improved predictive performance.

Berthomier et al. [9] focused on cloud cover nowcasting using deep learning techniques, addressing an essential aspect of weather forecasting. By leveraging deep neural networks, they developed a model capable of accurately predicting cloud cover changes based on historical data and meteorological parameters. This research contributes to enhancing the overall accuracy and reliability of weather forecasts, particularly for applications requiring precise cloud cover information.

Jianhong et al. [10] conducted research on weather radar nowcasting extrapolation, aiming to extend the predictive capabilities of radar-based models. Their study explores methods for extrapolating radar data beyond the current time frame, enabling more extended forecasts with improved accuracy. By incorporating advanced data processing techniques, they enhance the temporal resolution of nowcasting models, essential for early warning systems and long-range weather predictions.

Hoyer and Hamman [11] introduced xarray, a Python library for N-D labeled arrays and datasets, with applications in processing weather data for nowcasting. Their work focuses on providing a versatile and efficient toolset for handling multidimensional meteorological data, facilitating data preprocessing, analysis, and visualization tasks. xarray's capabilities are particularly beneficial for researchers and practitioners working on weather-related projects, streamlining data workflows and enhancing productivity.

Chkeir et al. [12] and Kong et al. [13] employed machine learning techniques for nowcasting extreme rain and wind speed events, respectively. Their studies highlight the importance of leveraging advanced algorithms to predict and mitigate the impacts of severe weather conditions. By combining historical data, meteorological parameters, and machine learning models, they enhance the accuracy and timeliness of extreme weather event forecasts, crucial for disaster preparedness and risk management.

Tan et al. [14] proposed a deep learning model based on multi-scale feature fusion for precipitation nowcasting, emphasizing the significance of feature extraction and integration in predictive accuracy. Their model incorporates information from multiple spatial and temporal scales, allowing for a more comprehensive analysis of weather patterns and dynamics. This approach enhances the model's ability to capture complex atmospheric phenomena, leading to improved nowcasting performance.

Yao et al. [15] presented an improved deep learning model specifically designed for high-impact weather nowcasting, addressing the challenges associated with rapidly evolving weather conditions. Their model incorporates adaptive learning mechanisms and dynamic feature extraction, enabling real-time adjustments to changing environmental factors. By focusing on high-impact events, such as severe storms and heavy rainfall, this study contributes to enhancing the resilience of communities and infrastructures against extreme weather events.

Schneider et al. [16] provided valuable data reanalysis for land-surface precipitation, offering a comprehensive dataset for training and validating nowcasting models. Their work involves compiling and refining historical precipitation data from rain gauges, satellite observations, and other sources, providing researchers with a reliable and consistent precipitation dataset. This reanalysis dataset serves as a crucial resource for improving the accuracy and reliability of precipitation nowcasting algorithms, essential for effective weather forecasting and climate studies.

Chkeir et al. [17] and Yao et al. [18] further investigated nowcasting extreme rain and high-impact weather events using machine learning and deep learning techniques. Their studies delve into the intricacies of modeling extreme weather phenomena, addressing challenges such as data scarcity, model generalization, and uncertainty quantification. By advancing the capabilities of nowcasting models for extreme events, they contribute to enhancing the resilience and preparedness of communities and decision-makers against severe weather conditions.

Tuyen et al. [19] introduced RainPredRNN, a novel approach for precipitation nowcasting that incorporates advanced recurrent neural network (RNN) architectures. Their model focuses on capturing temporal dependencies and patterns in radar data, enabling more accurate and reliable short-term rainfall predictions. By leveraging RNN-based techniques, RainPredRNN demonstrates significant improvements in nowcasting performance, particularly in dynamically changing weather scenarios.

In summary, the literature review highlights the rapid advancements and diverse methodologies in precipitation nowcasting, ranging from deep learning models to fusion techniques and distributed learning approaches. These studies collectively contribute to enhancing the accuracy and reliability of short-term weather forecasts, addressing critical challenges in meteorology and related fields.

III. Proposed System

The proposed system flow for precipitation nowcasting using deep learning can be outlined as follows:

A. *Input Dataset:*

The system begins with input data, which typically includes satellite imagery or radar data capturing weather patterns and conditions. In the context of a dataset like "Precipitation NetCDF," the rows would represent different time periods or spatial locations, depending on the nature of the data. For example, each row could represent a specific time interval (e.g., hourly, daily, monthly) or a geographical grid cell (e.g., latitude and longitude coordinates). The columns in the dataset would correspond to different variables related to precipitation, such as rainfall intensity, precipitation type, duration, and geographical coordinates if applicable.

B. *Data Pre-Processing:*

The input dataset undergoes pre-processing steps to clean, normalize, and format the data for further analysis. Identify missing values in the dataset using functions like .isnull() or .isna(). Depending on the amount of missing data and the context, either rows or columns are dropped using .dropna() or .drop() or fill in missing values using methods like mean, median, or mode imputation using .fillna().

C. *Time Filtering:*

Time filtering techniques are applied to extract temporal features from the data, allowing the model to capture the dynamic nature of weather patterns over time.

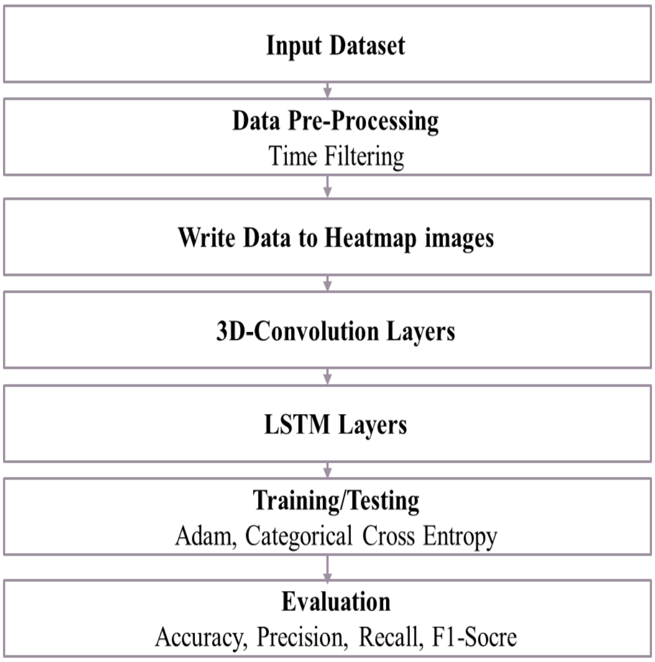

Fig. 1. Proposed System

D. *Data to viridis plots:*

After preprocessing and filtering, the data is transformed into viridis images, providing a clear depiction of the spatial distribution and intensity of precipitation or weather phenomena.

E. *3D-Convolution Layers:*

The heatmap images are fed into 3D-Convolutional layers, which are designed to extract spatiotemporal features from the data. These layers enable the model to capture both spatial relationships within individual images and temporal dependencies across multiple images.

F. *LSTM Layers:*

After the application of 3D-Convolution layers, Long Short-Term Memory (LSTM) layers play a crucial role in modeling the temporal dynamics and sequences within the data. LSTM layers are specifically designed to capture long-range dependencies and patterns, making them highly effective for analyzing time-series data, such as weather observations.

G. *Training/Testing:*

The model is trained using the Adam optimizer and Categorical Cross Entropy loss function. The training process involves iteratively adjusting the model parameters to minimize prediction errors and improve accuracy. The trained model is then tested on a separate dataset to evaluate its performance.

H. *Evaluation:*

The model's performance is evaluated using various metrics such as Mean Squared Error (MSE), Peak Signal-to-Noise Ratio (PSNR), Root Mean Squared Error (RMSE), and Structural Similarity Index (SSIM). These metrics assess the model's ability to accurately predict precipitation or weather patterns compared to ground truth data.

By following this proposed system flow, the aim is to develop a robust and accurate precipitation nowcasting model that can leverage deep learning techniques to improve weather forecasting capabilities.

IV. Results and Discussion

The dataset uploaded is part of a project focusing on historical precipitation levels in India. It includes monthly precipitation values for India's land surface at a resolution of 0.5° longitude by 0.5° latitude spanning the years 1901 to 2013. The data is stored in netCDF format, providing a convenient and standardized way to access and analyze the information [16].

Acknowledgments for this dataset go to the Global Precipitation Climatology Centre (GPCC) Monthly Precipitation dataset 1901-2013 0.5x0.5. Researchers and practitioners using this dataset for their work related to India's climate and precipitation patterns are encouraged to upvote it as a token of appreciation and acknowledgment of its utility in climate research and analysis.

TABLE I. EVALUATION PARAMETERS

Parameter	Equation
MSE	$\mathrm{MSE} = \frac{1}{N}\sum_{i=1}^{N}(y_i - \hat{y}_i)^2$
RMSE	$\mathrm{RMSE} = \sqrt{\frac{1}{N}\sum_{i=1}^{N}(y_i - \hat{y}_i)^2}$
PSNR	$\mathrm{PSNR} = 20\log_{10}(\mathrm{MAX}) - 10\log_{10}(\mathrm{MSE})$
SSIM	$\mathrm{SSIM} = \frac{(1 + 2\mu_x\mu_y + c_1)(2\sigma_{xy} + c_2)}{(\mu_x^2 + \mu_y^2 + c_1)(\sigma_x^2 + \sigma_y^2 + c_2)}$

- y represents the true values.
- $\hat{y}$ represents the predicted values.
- c_1 and c_2 are small constants to avoid division by zero.
- MAX represents the maximum possible pixel value.
- μ_x and μ_y are the means of x and y, respectively.
- σ_{xy} represents the covariance of x and y.
- σ_x and σ_y represent the variances of x and y, respectively.

RNN-based approach [19]	0.43	-	0.17	0.93

CONCLUSION

In conclusion, the proposed Convolution-LSTM model for the precipitation nowcasting model has demonstrated significant improvements in key evaluation metrics. The Mean Squared Error (MSE) reduced to 0.0001, indicating enhanced accuracy and reduced prediction errors in forecasting precipitation patterns. The increase in the Peak Signal-to-Noise Ratio (PSNR) to 40.09 signifies improved image quality preservation and fidelity in the model's predictions. Moreover, the Root Mean Squared Error (RMSE) decreased to 0.012, indicating smaller residual errors and improved alignment between predicted and actual data. The increase in the Structural Similarity Index (SSIM) to 0.999 underscores the model's enhanced capability to capture spatial and structural similarities accurately.

These findings highlight the robustness and effectiveness of the proposed precipitation nowcasting model in providing accurate and high-quality forecasts. In future to improve the performance, reliability and accuracy of the model, data augmentation techniques like rotation and flipping can be considered. Also, optimizing hyperparameters such as learning rate and dropout rate, and experimenting with ensemble learning leverage multiple model variations for better predictions.

***Abstract*—A novel method for categorizing Monkeypox skin lesions is presented in this research work utilizing a finely adjusted Convolutional Neural Network (CNN) model. Monkeypox, a rare viral ailment that can lead to serious skin lesions, necessitates precise and prompt diagnosis for successful therapy. This research work refines a pre-existing CNN model using a collection of Monkeypox skin lesion pictures to construct a classification system that can differentiate between various lesion types. The experimental findings showcase the efficacy of this proposed method, achieving remarkable accuracy and sensitivity in Monkeypox skin lesion classification. This study contributes significantly to the advancement of automated diagnostic solutions for infectious illnesses, supporting healthcare professionals in making quicker and more precise diagnoses.**

***Keywords*— Monkeypox, skin lesions, classification, Convolutional Neural Network (CNN), fine-tuning, AlexNet, VGG16, ResNet50.**

I. Introduction

Monkeypox is a zoonotic disease caused by the monkeypox virus, belonging to the Ortho poxvirus genus. It shares similarities with smallpox but typically presents with milder symptoms, including fever, headache, muscle aches, and the characteristic skin lesions. These lesions can vary widely in appearance, ranging from macules and papules to vesicles and pustules, making accurate diagnosis challenging, especially in areas where multiple viral infections are prevalent. Timely and precise identification of Monkeypox skin lesions is crucial for effective patient management, outbreak control, and public health interventions.

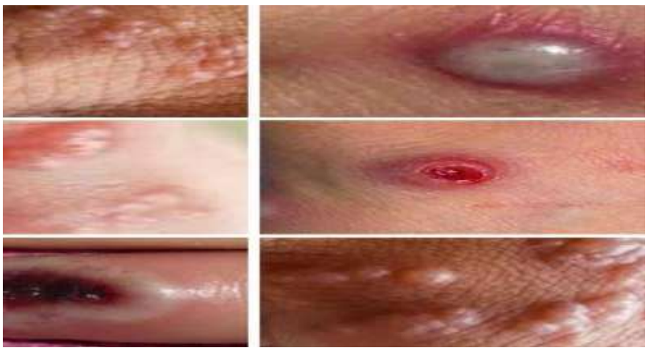

Fig. 1. Monkeypox Images

Recent advancements in deep learning, particularly Convolutional Neural Networks (CNNs), have revolutionized medical image analysis, offering automated and accurate classification of various diseases based on image data. In the context of Monkeypox, leveraging CNN models for skin lesion classification can significantly enhance diagnostic capabilities, streamline workflow efficiency, and assist healthcare professionals in making informed treatment decisions. Fine-tuning pre-trained CNN architectures such as AlexNet, VGG16, and ResNet50 specifically for Monkeypox skin lesion classification holds promise for improving diagnostic accuracy and accelerating patient care.

This paper aims to investigate the efficacy of fine-tuned CNN models, including AlexNet, VGG16, and ResNet50, for Monkeypox skin lesion classification. By leveraging deep learning techniques and a curated dataset of Monkeypox skin lesion images, this research work seek to develop a robust and accurate automated classification system. The proposed approach has the potential to revolutionize Monkeypox diagnosis, ultimately benefiting patient outcomes and aiding healthcare professionals in managing infectious disease outbreaks more effectively.

II. Literature Study

Bala et al. [1] introduced MonkeyNet, a robust deep CNN model specifically designed for Monkeypox disease detection and classification. Their work involved extensive training and validation on a diverse dataset of Monkeypox skin lesion images, showcasing high accuracy and reliability in identifying different lesion types.

Sahin et al. [2] developed a novel approach for human Monkeypox classification using a deep pre-trained network integrated into a mobile application. Their study demonstrated the feasibility of leveraging AI technology for real-time diagnosis and remote healthcare management, particularly in resource-constrained settings.

Altun et al. [3] explored transfer learning techniques in Monkeypox detection using CNNs, leveraging pre-trained models like VGG16 and ResNet50. Their research highlighted the potential for utilizing existing knowledge in deep learning to enhance diagnostic capabilities for infectious diseases.

Almufareh et al. [4] proposed a transfer learning approach for clinical detection support of Monkeypox skin lesions, emphasizing the importance of utilizing pre-trained models to leverage domain-specific knowledge and improve diagnostic accuracy.

Velu et al. [5] introduced a Q-learning approach for human pathogenic Monkeypox disease recognition, incorporating reinforcement learning principles into the classification process. Their study offered a unique perspective on integrating machine learning with decision-making algorithms for disease identification.

Sorayaie Azar et al. [6] focused on Monkeypox detection using deep neural networks, demonstrating the effectiveness of CNN models in accurately classifying skin lesions associated with the disease. Their research contributes valuable insights into the potential of AI-driven approaches for infectious disease diagnosis and surveillance.

Irmak et al. [7] and Nayak et al. [8] explored the application of MobileNetV2 and VGGNet models for

Monkeypox skin lesion detection, highlighting the versatility of deep learning architectures in medical imaging analysis. Their studies showcased promising results in automated lesion identification and classification.

Khan and Ullah [9] presented an efficient technique for Monkeypox skin disease classification, leveraging pre-trained models and clinical data to enhance diagnostic accuracy. Their work emphasizes the importance of interpretable deep learning models in supporting clinical decision-making processes.

Ahsan et al. [10] focused on interpretable deep learning for Monkeypox diagnosis, developing models that not only provide accurate classification but also offer insights into the features contributing to the classification decision. Their research contributes to the development of transparent and understandable AI models in medical applications.

Eliwa et al. [11] utilized convolutional neural networks to classify Monkeypox skin lesions, showcasing the potential of deep learning techniques in automated disease detection. Their study highlights the scalability and efficiency of CNNs in handling large-scale medical image datasets.

Jaradat et al. [12] explored automated Monkeypox skin lesion detection using deep learning and transfer learning techniques, demonstrating the utility of AI-driven approaches in streamlining diagnostic workflows and improving accuracy in lesion identification.

Alrusaini [13] investigated deep learning models for the detection of Monkeypox skin lesions on digital images, showcasing the applicability of AI techniques in developing automated diagnostic tools for infectious diseases. Their work contributes to the ongoing efforts in leveraging technology for improved healthcare outcomes.

Rizk et al. [14] provided insights into the prevention and treatment of Monkeypox, highlighting the importance of a comprehensive approach in managing infectious diseases. Their study emphasizes the significance of both diagnostic advancements and therapeutic interventions in combating Monkeypox.

Ali et al. [15] conducted a feasibility study on Monkeypox skin lesion detection using deep learning models, laying the groundwork for potential real-world implementations of AI-driven diagnostic tools. Their research contributes to the validation of AI techniques in clinical settings for enhancing disease detection capabilities.

Common limitations across the mentioned studies include the reliance on limited or curated datasets for model training, which may not fully capture the variability and diversity of Monkeypox skin lesions in real-world clinical scenarios. Additionally, most studies primarily focused on the development and validation of deep learning models for classification, often lacking robust evaluations in diverse patient populations or clinical settings. Interpretability and explainability of the AI models also remain a challenge, with limited insights provided into the features driving classification decisions, hindering their adoption in clinical practice. Furthermore, scalability and generalizability of the proposed models to broader healthcare systems and resource-constrained environments were not extensively explored, highlighting the need for further research and validation in real-world settings to ensure the efficacy and reliability of AI-based solutions for Monkeypox diagnosis and management.

III. Proposed System

Developing a Convolutional Neural Network (CNN) model for the classification of Monkeypox skin lesions involves a multi-step process that integrates data preprocessing, model architecture design, training, fine-tuning, and evaluation. In this detailed explanation, each step can be understood effectively for accurate and efficient disease detection.

A. *Input Dataset and Image Augmentation:*

The initial step involves acquiring a dataset of Monkeypox skin lesion images. This dataset serves as the foundation for training and evaluating the CNN model. To enhance the diversity and robustness of the dataset, image augmentation techniques are applied. These techniques involve random transformations such as rotation, scaling, and flipping, which generate variations of the original images. By augmenting the dataset, it is ensured that the CNN model learns from a wider range of skin lesion patterns and features, improving its generalization capabilities.

B. *Split Dataset into Train/Test:*

After image augmentation, the dataset is split into training and testing sets. The training set is used to teach the CNN model to recognize patterns and features in Monkeypox skin lesions, while the testing set is kept separate to evaluate the model's performance on unseen data. Typically, the dataset is divided into a training set (e.g., 80% of the data) and a testing set (e.g., 20% of the data) to ensure an adequate balance between model training and evaluation.

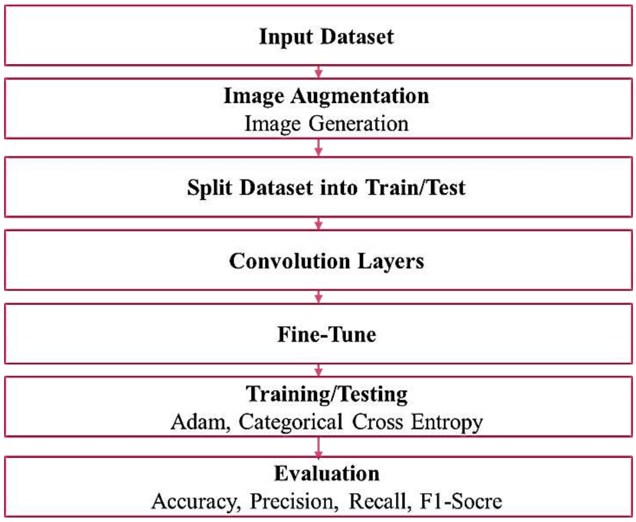

Fig. 2. Proposed System

C. *Model Architecture Design:*

The architecture of the CNN model is pivotal for efficiently extracting features and accurately classifying Monkeypox skin lesions. The provided architecture includes convolutional layers with different filter sizes, activation functions (e.g., LeakyReLU, ReLU), and pooling layers (MaxPooling) for downscaling feature maps. The choice of these layers and parameters is based on experimentation and optimization to achieve optimal performance in disease classification.

D. *Fine-Tuning and Optimization:*

Once the model architecture is defined, fine-tuning is performed to optimize its parameters and improve its ability to generalize the unseen data. Techniques such as dropout regularization are applied to prevent overfitting, where the model memorizes the training data but performs poorly on new data. The Adam optimizer, coupled with the Categorical Cross Entropy loss function, is used for model optimization. Adam adapts the learning rate dynamically during training, leading to faster convergence and improved model performance. Set hyperparameters such as learning rate, batch size, and optimizer (e.g., Adam, SGD with momentum). For instance, a learning rate of 0.001 and a batch size of 32 for training.

E. Training and Testing:

The training phase involves feeding the training dataset into the CNN model iteratively for a specified number of epochs. During each epoch, the model adjusts its parameters to minimize the loss function and improve its ability to classify Monkeypox skin lesions accurately. Classification task (e.g., 2 for binary classification). The Dense layer with a softmax activation function outputs probabilities for each class, making it suitable for multi-class classification tasks. Adjust the number of neurons in the Dense layer based on the specific classification problem.

F. Evaluation Metrics:

Accuracy measures the overall correctness of the model's predictions, while precision measures the proportion of true positive predictions among all positive predictions. Recall, also known as sensitivity, measures the proportion of true positive predictions among all actual positive instances. The F1-score is the harmonic mean of precision and recall, providing a balanced evaluation metric that considers both false positives and false negatives. These metrics collectively assess the model performance and help identify areas for improvement.

IV. RESULT ANALYSIS

The original Monkeypox Skin Lesion Dataset comprises 228 images, with 102 belonging to the Monkeypox class and 126 representing the Others class (non-monkeypox, including chickenpox and measles cases). To enhance the dataset's diversity and assist in classification, various data augmentation techniques were applied, including rotation, translation, reflection, shear, hue, saturation, contrast, brightness jitter, noise addition, and scaling using MATLAB R2020a. This augmentation process resulted in a significant increase in the number of images, with the Monkeypox and Others classes now having 1428 and 1764 images, respectively. These augmented images are included to ensure the reproducibility of results and provide a more comprehensive dataset for training and evaluation purposes.

TABLE I. ANALYSIS OF MODELS

Model	ACC (%)	P (%)	R (%)	F1-Score (%)
AlexNet	54%	55%	55%	54%
VGG16	76%	76%	75%	76%
ResNet50	70%	70%	69%	70%
Fine-Tune CNN	94%	93%	94%	93%

CONCLUSION

In conclusion, the evaluation of various models for Monkeypox skin lesion classification reveals distinct levels of performance. While AlexNet demonstrated moderate accuracy and balanced precision, recall, and F1-score around 55%, VGG16 and ResNet50 exhibited higher accuracy and more balanced metrics, with VGG16 achieving 76% accuracy and ResNet50 reaching 70%. However, the most notable results were observed with the fine-tuned CNN model, which achieved an impressive accuracy of 94% along with balanced precision, recall, and F1-score around 93%. These findings highlight the effectiveness of fine-tuning CNN models for accurate and reliable Monkeypox skin lesion classification, underscoring the significance of model selection and optimization techniques in enhancing diagnostic capabilities for infectious diseases. In future, augmenting dataset with transformations like rotation, scaling, flipping, and shifting can increase the diversity of training examples and helps to improve the classification performances.

***Abstract*—Depression is the most well-known type of physiological or mental health problem that affects a large number of people globally. Extreme learning machine (ELM) techniques are currently preferred to solve wide range of health disease detection and prediction issues. ELM is a single hidden layer feed-forward neural network (SLFN), which converges much faster than the other traditional Machine Learning (ML) methods and yields promising results. Many research works already exist on the application of Machine Learning (ML) models to the Depression Detection dataset but little to no work was found wherein Extreme Learning Machine was used for Depression Detection. This research work has applied Extreme Learning Machine (ELM) and other ML techniques for depression detection and compared the results obtained and found that, ELM has delivered the best performance with an accuracy of 91.73%.**

Keywords—Machine Learning, Extreme Learning Machine, Depression Detection

I. INTRODUCTION

Depression affects millions of people around the world. Depression is different when compared to the mood changes happening in daily life. Depression can affect various aspects of life, such as having problems in social relations and not being able to concentrate in work. Depressed people find it difficult to get pleasure from daily activities. Depression can be recurrent or persistent. In most cases, in-person clinical depression criteria are used to diagnose depression. But a large number of individuals having early-stage depression do not consult a doctor by which their conditions worsen. [1].

Therefore, depression has to be identified in its early stages such that the patient receives proper care. Large amounts of relevant data are needed to build a depression detection model [2]. Various models in Machine Learning and Deep Learning being are used for early identification and prediction of Depression.

Machine Learning is a subdiscipline of Artificial Intelligence in which computational methods are used to gain knowledge from data and performance increases via experience. In the traditional definition of Machine Learning approaches, three forms of knowledge acquisition are included: Supervised, Unsupervised and Reinforcement Learning [3].

In Supervised Learning, a statistical model is trained by an algorithm to generate predictions about some class that is not labeled. A column containing data with the answer (label/target) is used for monitoring learning while training. As implied by the term, unsupervised learning relies only on feature values, or the inherent structure of the data, rather than labels. Here, the main focus is the process of finding patterns and extracting knowledge. The two previous approaches are fundamentally different from reinforcement learning (RL), which does not require human-generated data for training but instead learns by trial and error. It learns on the basis of feedback and reward.

Being relatively new, Machine Learning (ML) is still growing quickly. It is fundamental to data science and Artificial Intelligence (AI) and resides at the intersection of computer science and statistics. The advancement of theory of some novel learning algorithms and the continuous proliferation of low-cost processing and massive amounts of data (commonly called "big data") have both fueled recent advances in machine learning. A greater amount of decision making based on evidence is occurring across a variety of fields, including biomedicine, healthcare [4], education, manufacturing, data governance, financial modeling, marketing and policing, as a result of the widespread use of ML-based methodologies in research, technology, and industry.

Depression is a common mental health issue that impacts a huge number of people globally. Effective therapy and support depend on early identification and intervention. Creating a scalable and dependable depression detection system that can help medical practitioners diagnose patients early and carry out timely interventions is the problem. This study entails utilizing machine learning techniques, data, and technology to develop a tool that may recognize possible indicators of depression in people. The objective is to provide a thorough and trustworthy instrument for detecting depression by addressing these elements, which can aid in early intervention and better mental health outcomes.

In this work, multiple Machine Learning models have been applied for Depression Detection such as Logistic Regression, K Nearest Neighbors, Extreme Learning

Machines, and Decision Tree, Gaussian Naïve Bayes, and Random Forest Classifiers.

Section 2 describes related work, Section 3 describes the proposed work, and Section 4 describes the outcome of applying various models in Machine Learning used in predicting depression. Part 5 of the paper discusses the conclusion and part 6 describes the future scope.

II. REALTED WORKS

A lot of work is being done related to application of Machine Learning techniques to predict depression on different types of available datasets. Some works of well-known authors are described below:

The work conducted by Marzieh Mousavian et al.[5] on "Feature Selection and Imbalanced Data Handling for Depression Detection" in which Random Forest Classifier shows the best result as compared to the other Machine Learning models used, followed by SVM with a Gaussian Kernel.

Md Rafiqul Islam et al.[6] proposed a model using machine learning methods with social network data for diagnosis of depression. The model shows the accuracy between 60% to 80% for the classification models with Decision Tree showing the highest accuracy.

Hatoon AlSagri et al.[7] conducted a work where he used Machine Learning techniques to approach a problem in Twitter in which Depression was detected using content features and activity features and the maximum accuracy achieved was 82.5% by Linear SVM Model.

Raihan Sultana et al.[8] proposed a anxiety and depression detection model using ML and DL approaches such as CNN, Linear Regression, LDA, KNN and Support vector machine, out of which CNN outperforms with an accuracy of 96.8% for depression and 96% for anxiety.

Swasthika Jain et al.[9] used multimodal depression detection technique using deep neural network(D-ResNet) and paragraph-vector based kernel extreme machine learning model(PVKELM). The accuracy obtained by the model is 89%.

Subrajeet Mohapatra et al.[10] proposed a model of early accessment of depression using machine learning model. They used stacked SVM model and achieved an accuracy of 89.4%.

Milena Cukic et al.[11] used EEG and HFD signals as features for seven ML algorithms including Naive Bayes classifier, Logistic Regression, Random Forest, Decision Tree, Support Vector Machines and Multilayer Perceptron, with the linear and polynomial kernel. Average accuracy of the classifiers varies from 90.24% to 97.56%.

Lu, Shengfu et al.[14] build a depression classification model using eye-movement data and ELM and also used Particle Swarm optimization for optimizing the parameters. The accuracy, sensitivity and specificity of the model using improved chaotic projection model and Gauss mutation strategy are 88.55%, 87.71% and 89.42%, respectively.

III. PROPOSED WORK

In this work, a novel approach has been proposed for detecting depression using Extreme Learning Machine (ELM) model. Many machine algorithm models have been used for depression detection but ELM outperforms them. The detailed view of the work is described below:

1. Dataset:

The dataset has originally been taken from the Centers for Disease Control (CDC) and Prevention's National Health and Nutrition and Examination Survey. The dataset is available on: https://wwwn.cdc.gov/nchs/nhanes/default.aspx and consists of data collected from adults living in the U.S., from 2005 to 2018 and it has 36259 entries.

2. Description of the Libraries used:

1. ***NumPy:*** NumPy is the primary Python package for scientific computing. In NumPy, n-dimensional array is used as the data structure. One can perform various array operations using NumPy [18].
2. ***Pandas:*** Pandas is a toolkit in Python programming language that offers user-friendly data structures. Pandas library can be used for working with datasets. Pandas can be used to analyze, clean, explore and manipulate data [15].
3. ***Matplotlib:*** Matplotlib is a Python visualization package. 2D plots of arrays can be created using Matplotlib. Some commonly used plots are line plot, bar plot, scatter plot and histogram plot, etc [20].
4. ***Scikit-learn:*** It is a package used in machine learning for programming in Python. It has supervised and unsupervised learning algorithms. It is built on NumPy, Matplotlib and Pandas. Scikit-learn is available as a free software. It is compatible with SVMs, gradient boosting, random forests, DBSCAN, and other classification, clustering and regression techniques [21].

3. Methodology Used

3.1. Data Pre-processing

The dataset contains both numeric and non-numeric data. The categorical input features, numeric and non- numeric, are one-hot-encoded and the class labels are label-encoded to '1' which represents the Depressed Class and '0' which represents the Not Depressed class. Thereafter scaling is performed on the data. The input and output variables are separated and a train-test split is performed.

3.2. Clustering

Here, K-Means Clustering has been performed on the data such that 6 clusters are formed. In K-Means Clustering, k numbers of clusters are formed by partitioning of n-number of observations and every observation belongs to the cluster which has the nearest mean.

3.3. Models Implementation

This work uses various classification models in Machine Learning such as Logistic Regression, RF classifier, Extra Trees Classifier, Decision Tree Classifier, KNN, Gaussian Naive Bayes Classifier and Extreme Learning Machine, to predict depression by using the CDC dataset.

Logistic Regression Model:

The Logistic Regression model is used for classification problems. The input data is modelled using a linear equation. The sigmoid function squishes the predicted output between 0 and 1. The data is fitted on the logistic regression equation and using likelihood function, the output is predicted. In case of binomial logistic regression, the output can be of only two possible types, 0 and 1, which represents the two opposite given instances of a class [19].

Random Forest Classifier Model:

Random Forest Classifier is an example of ensemble learning technique in which two or more models are fitted into the same data and the predictions of each model is combined. Random Forest Classifier is made up of multiple Decision Trees each of which is made from a subset formed from the training data. The bagging technique is used in the Random Forest Classifier Model. The training data is recursively partitioned based on the features, to build the trees. For every split, the best feature from an arbitrary subset is selected by the algorithm, while optimizing Gini impurity. The process continues until a predefined stopping condition is satisfied. After training of the random forest, predictions are made based on the votes in each tree for a class and the class with the maximum number of votes is the predicted class for the given input data [20].

Decision Tree Classifier Model:

Decision Trees Classifier is an example of a supervised machine learning algorithm. It has a tree-like structure with different types of nodes, namely, the root node, leaf node and internal node. The algorithm starts working form the root node, followed by the leaf node and the internal nodes. The commonly used methods to measure impurity include Gini impurity, information gain and entropy. For each value, the weighted average of the Gini impurity at each level is calculated. And the feature which has the least impurity becomes the node. The process is repeated for every node, at each level, until the given data gets classified completely. After constructing the tree, the algorithm goes down the tree, following the conditions at the nodes and finally the data gets classified [21].

Extra Trees Classifier Model:

Extra Trees Classifier is an example of an ensemble learning technique. It consists of multiple Decision Trees which are de-correlated. Every Decision Tree in Extra Trees Classifier is built from the actual training sample. At every test node, every tree is provided with an arbitrary sample which has k number of features, from which every Decision Tree has to select the best feature for splitting the given data on the basis of some criteria such as Gini index. This arbitrary sample of features creates sevaral Decision Trees which are de-correlated [22].

K Nearest Neighbors:

K Nearest Neighbors is an example of a supervised machine learning algorithm. It calculates the distance between the training data points and the test data and tries to predict the class correctly. 'K' number of points closest to the test data is selected. The probability of the test data belonging to the class of 'K' training data is calculated and the class which has the maximum probability becomes the predicted class [23].

Gaussian Naive Bayes:

Naïve Bayes Classification Algorithm is based on Bayes' Theorem. In the algorithm, it is assumed that the features which are used for describing any observation, when the class label is given, are conditionally independent. Gaussian Naïve Bayes is an example of a Naïve Bayes method, in which the features in the data follow a Gaussian Distribution. In order to classify every new data point, the algorithm determines the maximum value of posterior probability of every class and allocates the data point to that class [24].

Extreme Learning Machine (ELM):

An ELM is a specific type of feed-forward neural network in which a single hidden layer with randomly generated weights and biases is used [12]. In contrast to other neural networks, ELM can attain high accuracy without the need for iterative training or bias and weight adjustments. Rather, it computes the output weights depending on the input data using an analytical approach [9].

The weights in the hidden layer of the ELM method have two phases: training and testing. When input data is supplied into the neural network during training, biases are generated at random. The least-squares approach is then used to determine the output weights. There is no need for iterative weight and bias change during the quick training phase [25].

In order to train feed-forward networks (SLFNs), Guang-Bin and Qin-Yu introduced the Extreme Learning Machine (ELM). Three layers constitute the SLFN: the input, hidden and output layers as shown in fig. 1

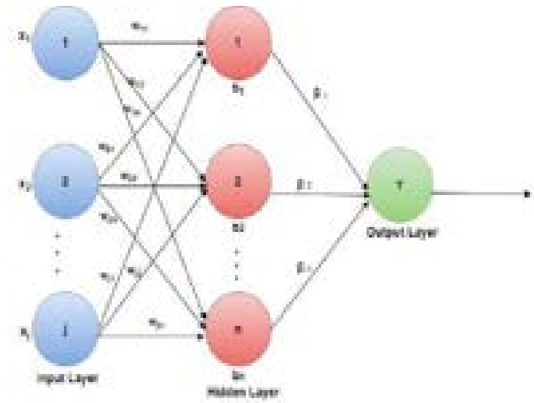

Fig1. Structure of Single-layer feed-forward Network (SLFN)

Given a training set

$$A = \{(x_i, y_i) \mid x_i = (x_{i1}, x_{i2}, \ldots, x_{in})^T \in R^n,\ y_i = (y_{i1}, y_{i2}, \ldots, y_{im})^T \in R^m\}$$

Where, x_i denotes the input value and y_i represents the target output of an ELM with n hidden neurons.

$$\sum_{i=1}^{n} \beta_i F(w_i x_j + b_i) = y_j,\ j = 1, 2, \ldots m. \quad \cdots\cdots \quad (1)$$

Where, $F(\mathrm{x})$ is the activation function in the hidden layer, x_i is the input vector of the i^{th} sample, y_i is the target vector of the i^{th} sample, w_i is the weight vector from input layer to the i^{th} hidden node, b_i is the bias of the i^{th} hidden node, β_i is the weight vector from the i^{th} hidden node to output layer.

The above equation (1) can be abbreviated as:

$$A\beta = Y$$

or

$$\beta = (\mathrm{A})^{\dagger} Y$$

Where, $(\mathrm{A})^{\dagger}$ is Moore-Penrose Pseudo inverse.

β is the weight between hidden and output layers.

Y is the output.

$$A = \begin{bmatrix} f(w_1 x_1 + b_1) & \ldots & f(w_L x_1 + b_L) \\ \ldots & \ldots & \ldots \\ f(w_1 x_N + b_1) & \ldots & f(w_L x_N + b_L) \end{bmatrix}_{\mathrm{NXL}}$$

$$\beta = \begin{bmatrix} \beta_1^T \\ \beta_2^T \\ .. \\ .. \\ \beta_L^T \end{bmatrix}_{\mathrm{LXm}} \qquad Y = \begin{bmatrix} y_1^T \\ y_2^T \\ .. \\ .. \\ y_L^T \end{bmatrix}_{\mathrm{NXm}}$$

Once the output weights β are determined, they are used for making predictions on new and unseen data. Here, we have used it for predicting depression.

3.4. Hyper-parameter Tuning

Hyper-parameter Tuning is performed using Grid Search CV for each of the models and the best parameters are chosen to train the models. After model training, the models are applied on the test sets and then evaluated.

3.5. Model Evaluation

The models are evaluated based on Accuracy and AUC Score. Confusion Matrix helps to know the correctly predicted and incorrectly predicted class labels.

Confusion Matrix: A confusion matrix is a particular layout of table which is used in machine learning, particularly for classification. It is also called a “matching matrix” when it is used for unsupervised learning. It is used to visualize the performance of an algorithm. In the confusion matrix, each column in the matrix represents an example in a predicted class, each row represents an occurrence in the actual class, or the opposite.

The confusion matrix displays the following:

1. **True Positive (TP)** occurs when a model is able to predict correctly a data point which is positive.
2. **True Negative (TN)** occurs when a model is able to predict correctly a data point which is negative.
3. **False Positive (FP)** occurs when a model predicts a data point which is positive but the prediction is incorrect.
4. **False Negative (FN)** occurs when a model predicts a data point which is negative but the prediction is incorrect.

Accuracy: The percentage of correctly identified cases amongst all of the instances is a metric known as accuracy.

$$\text{Accuracy} = \frac{(\mathrm{TP+TN})}{(\mathrm{TP+TN+FP+FN})} * 100$$

AUC (Area Under the ROC Curve): In other words, AUC calculates area in 2-D that lies under the entire ROC curve.

$$\text{AUC} = \frac{(\mathrm{TP+TN})}{(\mathrm{TP+TN+FP+FN})} * 100$$

IV. RESULTS

The following results were obtained after evaluating the different models:

Table 1: Evaluation measures for various models.

Models	Hyper-parameter Used	Accuracy (%)	AUC (%)
Logistic Regression	class_weight = 'balanced', solver = 'newton-cholesky', penalty='l2'	78.76	60.22
Random Forest Classifier	class_weight='balanced', criterion ='entropy', max_depth =10, max_samples=0.95, min_samples_leaf=100, n_estimators = 500	81.56	61.41
Decision Tree Classifier	criterion = "gini", max_depth = 6, min_samples_split = 2, random_state = 123	91.16	70.86
Extra Trees Classifier	n_estimators=100, n_jobs=4, min_samples_split=25, min_samples_leaf=25, max_features=120	91.71	70.86
K Nearest Neighbors Classifier	leaf_size = 1, metric = 'manhattan', n_neighbors = 7, weights = 'distance'	91.26	70.63
Naive Bayes Classifier (Gaussian)	var_smoothing = 0.0533669923120631	91.44	78.72

Extreme Learning Machine	L=200	**91.73**	**83.82**

Here, various Machine Learning models have been applied for predicting depression like Logistic Regression, Random Forest, Decision Tree, Extra Trees, KNN, Gaussian Naïve Bayes and Extreme Learning Machine model. Results show that Extreme Learning Machine performs the best out of all the models used. It has an Accuracy = 91.73% and AUC = 83.82%.

Fig. 2 describes the graphical representation of Accuracy and AUC Score for various Machine Learning Models and the best result is obtained by Extreme Learning Machine model with an accuracy of 91.73%.

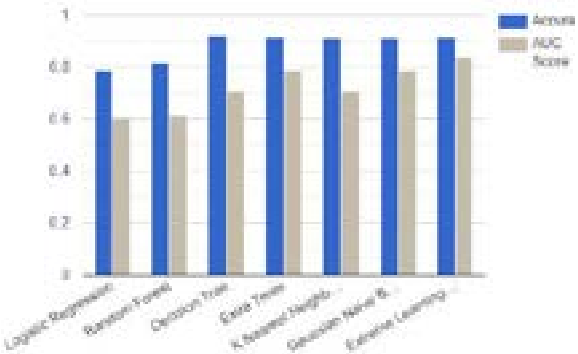

Fig2. Accuracy and AUC measures for multiple ML algorithms

V. CONCLUSION

Depression is one of the deadliest diseases among the known neurological disorders. It is necessary to identify depression in its early stages. In this work, the dataset from the Centers for Disease Control (CDC) and Prevention's National Health and Nutrition Examination Survey has been taken, pre-processed and multiple ML Algorithms have been applied on it and the accuracy and AUC score have been evaluated.

After the application of multiple Machine Learning models for Depression Detection, like Logistic Regression, K Nearest Neighbors, Extreme Learning Machines, and Decision Tree, Gaussian Naïve Bayes, and Random Forest Classifiers, this study has observed that Extreme Learning Machine (ELM) outperforms all the other models, with an accuracy of 91.7264% and AUC = 83.8153%, followed immediately by Extra Trees Classifier with an accuracy of 91.7264% and AUC = 82%, followed by the rest.

VI. FUTURE SCOPE

Future work on depression detection through Machine Learning may likely focus on improvement of the efficiency of the models used, based on the performance metrics. The prediction results can be improved further with applications of more advanced models and also the models' performance can be improved by further hyper-parameter tuning. More work can also be conducted on trying to understand the particular features which affect the performance of the models more than the rest. Combining multiple sources of data, such as text, voice, and physiological signals, seems to improve the accuracy of the models used to detect depression. Integrating diverse data types provides a more comprehensive view of an individual's mental state.

***Abstract*—** In medical imaging, brain neoplasm identification is essential since a timely diagnosis often enhances patient outcomes. the study focuses on utilizing the VGG-16 model, a widely acknowledged convolutional neural network computer vision, for detection of brain tumor. The primary objectives include classifying magnetic resonance imaging (MRI) images and accurately identifying the presence of cerebral tumor. The dataset utilized comprises MRI images. The methodology encompasses setting up the environment, data importation and preprocessing, VGG-16 model creation, and assessing its performance in terms of accuracy, precision, and recall, The results indicate that the VGG-16 model holds promise in aiding medical professionals in brain diagnosis, achieving an accuracy of approximately 95% on the validation set and 82% on the test set.

Keywords— CNN, Brain Tumor, MRI, Deep Learning, Convolutional Neural Network, VGG16

1. Introduction

A intracranial tumor ranks fourth in United States for both men and women, but it is the tenth most common tumor in males and it ranks as the 9th most prevalent tumor among women. Within single digits, brain tumors have a 5-year survival rate, making them the most common basic tumor. According to a recent analysis released by Brain Cancer Action, brain tumors are predicted to rank as the second most common cause of tumor deaths inside United States by 2020.

The delayed diagnosis of brain tumor due to the lack of adequate early detection measures is one of the main causes of this. Furthermore, treatment becomes more difficult if the majority of cancer have spread to other organs. Thus, a method to help radiologists find brain tumor early on is desperately needed. Not much progress has been made in the diagnosis of brain tumor. According to a review of the literature, brain diagnoses are made without the use of picture processing by relying solely on the patient's records and the illness's signs and symptoms.

The quest for precise and effective brain tumor detection in the field of medical imaging has led to the incorporation of state-of-the-art technologies. One strategy that has shown a lot of promise recently, Traditional methods of brain tumor detection often rely on manual interpretation of radiological images, which is time-consuming and susceptible to human error. The integration of deep learning (DL) strategies, specifically CNNs, aims to streamline this process by automating the identification of abnormal patterns indicative of brain tumors. The VGG-16 architecture, known for its effectiveness in image classification tasks, presents an opportunity to improve the accuracy and efficiency of brain tumor diagnosis through automated analysis of MRI data.

The VGG-16 model has demonstrated impressive performance in image recognition tasks since its introduction by Simonyan and Zisserman in 2015. The deep architecture of the paradigm enables the acquisition of intricate features from input images. It comprises copious layers of both fully connected and layer of convolutions. The VGG-16 model has been investigated by researchers as a potential tool for accurately classifying MRI images and identifying brain tumors.

K. Simonyan et al. from Oxford university presented the VGG16 CNN paradigm in their paper, "Very Deep Convolutional Networks for Large-Scale Image Recognition." In the ImageNet dataset, which consists of over 14 million images divided into 1000 classes, the model obtains 92.7% top-5 test accuracy. Among the well-known models submitted to ILSVRC-2014 was this one. By gradually substituting numerous 3 × 3 kernel-sized filters for the massive kernel-sized filter, it enhances AlexNet. The VGG-16's architecture

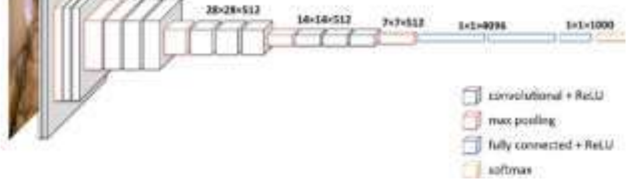

Fig 1: VGG-16 Architecture [1]

The primary objectives of this study include

- Utilizing VGG-16: Productive evaluation of MRI images by the VGG 16 paradigm by correctly classifying tumor and non-tumor groups.
- Automation: Developing an automated system for brain tumor detection to reduce the reliance on manual interpretation and improve diagnostic efficiency.
- Accuracy analysis: Taking high accuracy performance of VGG 16 and related matrices which can easily evaluate the data sets.

Problem description:

The integration of deep learning models, particularly VGG-16, into the field of neuroimaging holds the potential to revolutionize the diagnostic process for brain tumors. Automation not only expedites diagnosis but also contributes to consistent and reproducible results, thereby enhancing the overall quality of patient care.

2. LITERATURE REVIEW

Ottom et al., [2] introduced a DL approach called Znet for segmenting 2D cerebral tumors in MRI images, achieving high evaluation measures and outperforming the benchmark Unet model. It discusses the potential clinical impact of AI applications in medical imaging, limitations of evaluation metrics, and future extensions for 3D MRI volumes. However, The 2D brain tumor segmentation in MRI images outperformed the benchmark Unet model and achieved high evaluation measures. It talks about future extensions for 3D MRI volumes, the limitations of evaluation metrics, and the possible clinical impact of AI applications in medical imaging. In order to evaluate segmentation models, the paper also includes references to related studies, methods, metrics, algorithms, and loss functions.

Hari et al., [3] discusses the progress of a DL model called LeU-Net for prediction of tumor in cerebral images. The framework is designed to process 2D and 3D images in real-time using convolutional neural networks (CNN). The authors emphasize the importance of preprocessing steps, such as cropping unwanted areas, converting images to grayscale, and applying thresholding, erosion, and dilation techniques. They also mention the use of data augmentation to increase the training dataset. The accuracy of the LeU-Net framework is analyzed with other existing models in tumor detection, and it is observed that the framework provides 98% accuracy on cropped images and nearly 94% accuracy on uncropped images with a less time taken for prediction. The paper concludes by highlighting the potential for future work with larger MRI datasets and the incorporation of general adversarial networks for validation. Furthermore, while the LeU-Net model is designed to have faster training simulation time and reduced complexity, it is essential to consider the potential limitations of the model when applied to larger and more diverse datasets. These limitations may include issues related to overfitting, generalization to new data, and the need for additional computational resources for handling larger datasets.

Anaya-Isaza et al., [4] discusses the impact of artificial intelligence (AI) and deep learning (DL) on the field of medicine, particularly in the context of detecting brain tumors in magnetic resonance images. It highlights the advantages of DL neural networks, such as not requiring prior feature extraction and being able to work directly on raw data. The document also presents a new data augmentation method based on principal component analysis and compares its performance with conventional methods. it discusses the architectural components of the neural network implemented in the research, such as activation functions, pooling layers, and batch normalization. Additionally, the document discusses limitations in previous research, such as small data sets for training models, which hinder the generalization of results. It also mentions the need for further exploration of the proposed method with different types of image sequences and the potential impact of noise on the training of models.

3. BACKGROUND

Different Types of Brain Tumor in detail:

Cerebral tumor can be categorised0 based on different patterns such as their origin, location, behaviour, and cell type. Here are the different kinds of brain tumor:

1. **Primary Brain Tumor**:
   - These tumor arise within the brain or its surrounding tissues.

a. **Gliomas**: - Gliomas are tumors that arise from glial cells, which are supportive cells in the brain. They include: - Astrocytomas - Oligodendrogliomas - Ependymomas - Glioblastomas (Grade IV astrocytoma’s), the most aggressive type of glioma.

b. **Meningiomas**: - Meningiomas arise from the meninges, the protective coverings enveloping the brain and spinal cord. Typically, they are non-malignant.

c. **Pituitary Adenomas**: - Pituitary adenomas develop within the pituitary gland located at the bottom of the brain. They can affect hormone levels.

d. **Schwannomas**: - Schwannomas arise from Schwann cells, which produce the myelin sheath covering nerves. They can occur on cranial nerves, such as the vestibulocochlear nerve (acoustic neuroma).

e. **Medulloblastomas**: - Medulloblastomas are aggressive tumors that develop in the cerebellum, primarily in children.

f. **Craniopharyngiomas**: - Craniopharyngiomas develop near the hypophysis cerebri and the bottom of the brain. They originate from remnants of embryonic tissue.

2. **Metastatic Brain Tumors**:
   - These growths derive from malignant cells that have metastasized to the brain from primary tumors situated elsewhere in the body. Common primary cancer sites include the lungs, breasts, skin (melanoma), and colon.

These are the main types of brain tumors, each with its own characteristics, treatment options, and prognoses. It's essential for medical professionals to accurately diagnose and classify brain tumors to determine the most appropriate treatment plan for patients.

4. EXISTING SYSTEM

1. **Convolutional Neural Networks (CNNs)**:
   - CNNs now serve as the foundation for numerous deep learning applications in medical imaging, including brain tumor

detection. They excel at automatically learning hierarchical features from images, making them well-suited for tasks such as tumor detection and segmentation. Architectures like U-Net, which are specifically designed for biomedical image segmentation, have been widely adopted in brain tumor detection tasks.

2. **3D CNNs**:
    - While 2D CNNs process images slice by slice, 3D CNNs can directly process volumetric data, such as 3D MRI scans. This allows 3D CNNs to capture spatial information across different slices and can potentially improve the accuracy of cerebral tumor identification and segmentation.
3. **Deep Learning-Based Segmentation**:
    - Deep learning algorithms are capable of autonomously segmenting brain tumors from MRI scans. U-Net and its variants are commonly used for this purpose. These pardigms are trained on labeled MRI scans, where MRI image is input, and the output is the corresponding tumor segmentation mask.
4. **Attention Mechanisms**:
    - Attention mechanisms have been incorporated into deep learning architectures to focus on relevant regions of the input image during the segmentation process. This helps the model to selectively attend to areas of interest, such as tumor boundaries, improving segmentation accuracy. Models like Attention U-Net leverage attention mechanisms for better feature localization.
5. **Generative Adversarial Networks (GANs)**:
    - GANs are composed of a pair of neural networks: a generator and a discriminator, which undergo adversarial training. In brain tumor detection applications, GANs have the potential to create synthetic tumor images, augmenting the training dataset and improving the generalization of deep learning models.
6. **Transfer Learning**:
    - Utilizing pre-trained CNNs, initially trained on datasets like ImageNet containing natural images, allows for fine-tuning in brain tumor detection tasks through transfer learning. By leveraging features learned from large-scale datasets, By leveraging transfer learning, deep learning models can be trained effectively on limited medical imaging datasets, which may have limited labeled examples.
7. **Ensemble Learning**:
    - Ensemble techniques combine multiple deep learning models to improve segmentation accuracy and robustness. Ensemble methods like model averaging or stacking can be applied to combine predictions from individual models trained with different architectures or initializations.
8. **Uncertainty Estimation**:
    - Deep learning models can provide estimates of uncertainty associated with their predictions, which is crucial in medical imaging applications where incorrect predictions can have serious consequences. Techniques like Monte Carlo Dropout or Bayesian deep learning can be used to quantify uncertainty and improve the reliability of brain tumor detection models.

The framework systems in use today identify brain MRI images by going through several pre-established steps. In MRI brain imaging, the efficient mechanisms for identifying and categorizing neoplasm and non-neoplasm units are covered in. A synopsis of potential tactics and approaches is provided below. The majority of the images that will be input are MRI brain scans. The input format could be either 2D or 3D, based on the architectural design and memory limitations. Due to its efficacy in significantly enhancing image data, the process of inputting images has been demonstrated to hold equal importance alongside other steps.

In order to extract only the most important information from the input image and discard the rest, segmentation first splits the image into identical sections based on predetermined criteria. There are several methods. Some studies focus on segmenting the entire tumor, while others concentrate on isolating the tumor-containing portion of the image. Classifying the input data into different groups according to similar behavior patterns within the group is the aim of the classification stage.

5. PROPOSED SYSTEM

The VGG-16 model has three fully connected layers and thirteen convolutional layers. By using convolution operations, the convolutional layers extract features by using tiny filters. These layers enable the model to learn representations at various levels of abstraction by capturing local image features and spatial patterns.

Standard metrics like accuracy, precision, and recall are used to assess the model's performance during training. The training process is carried out in multiple epochs, with the model's performance on the validation set being evaluated at the end of each epoch. By doing this assessment, the hyperparameters can be adjusted and the framework's ability to generalise well to new data can be confirmed.

At the end of the network, the fully connected layers—also referred to as dense layers—perform classification using the features that have been extracted. They predict whether or not brain tumor is present in the MRI images by combining the features that the convolutional layers have taught them.

Accuracy and loss values for every epoch are displayed in the training updates that are provided. A decrease in loss suggests that the model is becoming more adept at making predictions as it continues to be trained. The percentage of correctly classified photos during training and validation is shown by the accuracy values.

Advantages of proposed systems:

The model successfully identifies brain tumors in the MRI images during a particular training session by achieving high accuracy on the training and validation sets. This suggests that the model has the ability to classify new, unseen images with accuracy.

6. SYSTEM ARCHITECTURE

6.1. PROPOSED ARCHITECTURE:

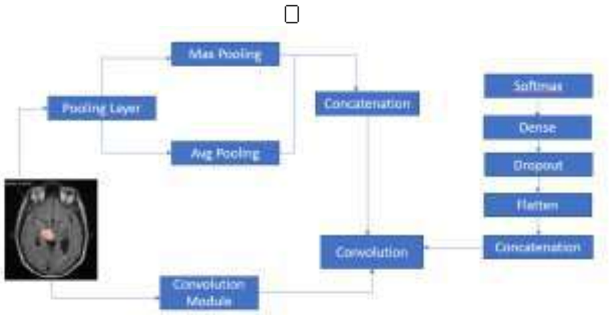

Fig 2: Proposed architecture

- Convolutional Layer: The convolutional layer serves as the fundamental component of a CNN. This layer conducts convolution upon the incoming data, utilizing a collection of adaptable filters to generate feature maps. Regarding the detection of brain tumors, these filters aim to identify tumor-related patterns or features present in medical imagery like MRI scans.

- Pooling Layer (Max/Average Pooling): Pooling layers help in downsizing the spatial volume of the feature maps from convolutional layers, preserving essential details. Common pooling methods include max pooling, which selects the largest value in a feature map patch, and average pooling, which computes the mean value. This process simplifies the representation and cuts down on computational load.

- Concatenation: Concatenation involves linking together feature maps or vectors following a designated axis. Within CNNs, this technique is often employed to merge feature maps from diverse convolutional or pooling layers prior to forwarding them onto a subsequent layer.

- Dense Layer (Fully Connected Layer): Dense layers function to classify inputs using the features derived by earlier layers. Known as "fully connected" because each neuron links to every neuron in the layer before, these layers typically act as classifiers, assigning the extracted features to specific output categories (for example, tumor versus non-tumor).

- Dropout Layer: Dropout is a regularization strategy frequently utilized in neural networks to avert overfitting. During training, it operates by randomly turning a subset of the input units off (setting them to zero), which helps inhibit the neurons from becoming overly dependent on each other and promotes the development of more resilient features in the network.

- Flatten Layer: The flatten layer transforms the multi-dimensional feature maps produced by convolutional and pooling layers into a one-dimensional vector. This vector is then used as input for the dense layers to carry out classification tasks.

Typically, the architecture of such models involves arranging layers sequentially, starting with convolutional and pooling layers to extract features, followed by concatenation, dense, dropout, and flatten layers for classification purposes. To train this model, it is fed with labeled data (such as MRI scans identified as tumor or non-tumor), and the model's parameters (weights) are tuned to reduce the error in classification.

6.2. INPUT DESIGN

The research employed the "Brain MRI Images for Brain Tumor Detection" dataset to develop a relevant framework. The dataset included three common types of brain tumors: pituitary tumors, gliomas, and meningiomas. Utilizing an MRI dataset that contained 253 brain images from 155 unique patient cases and features, models were trained and assessed. The tumor-related dataset was processed accordingly.

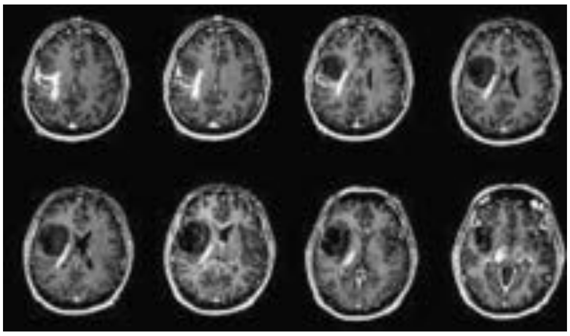

Fig 3: Input brain image samples

6.3. OUTPUT DESIGN

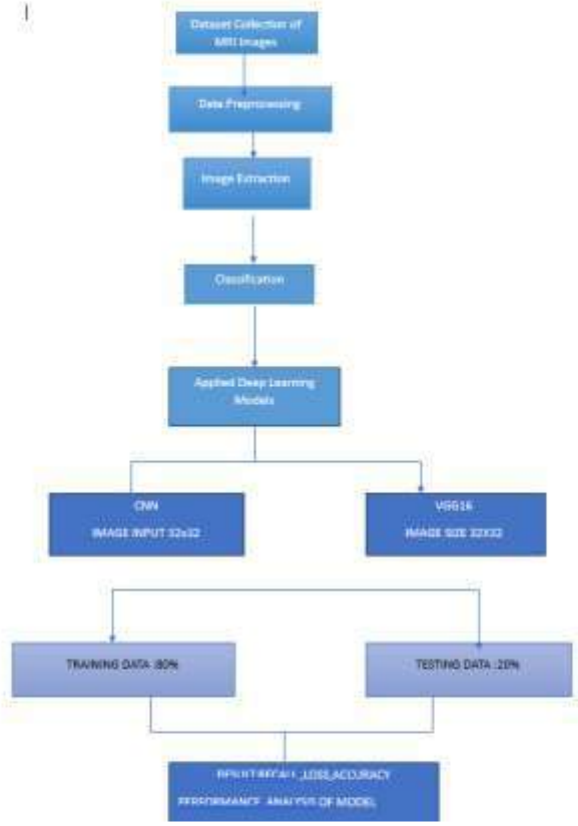

Fig 4: Proposed model overview

MODULES

- Dataset
- Importing the necessary libraries
- Retrieving the images
- Splitting the dataset
- Building the model
- Hyperparameter Tuning
- Implement the model and chart the accuracy and loss.
- Assess model accuracy using the test dataset.
- Saving the Trained Model

7. MODULES DESCRIPTION

Import required libraries:

Python language is used for the proposed model experimentation. The foremost libraries found for essential is keras which is used for building the principal model, sklearn for plotting and studying statistics, PIL photos for changing numbers, and different libraries inclusive of pandas, numpy, matplotlib and tensor flow.

A multi-layer convolutional neural network was developed and utilized for tumor detection. The network initiated with a convolutional layer establishing an input shape of 64 x 64 x 3 for the MRI scans, ensuring uniform dimensions for each image. A convolution kernel was integrated with the input layer once all images were aligned in the same format. Utilizing three-channel tensors, 32 convolutional filters of size 3x3 were applied. The comprehensive model, which encompassed several hidden layers, yielded highly accurate results for detecting malignancies across seven stages. The activation function used was ReLU, defined mathematically as

$$F(x) = \max(0, x).$$

For spatial data modeling based on the inputs, a MaxPooling2D layer was employed, resulting in a dimension of 31 x 31 x 32. The pooling size was adjusted to (2, 2) to reduce the dimensions by splitting the input images along both spatial axes.

Splitting the dataset:

Split the dataset into training and testing portions, allocating 80% for training and 20% for testing. Utilize libraries such as Matplotlib and TensorFlow.

Model Construction:

The model is constructed using the Keras library. Layers are added sequentially to form a convolutional neural network. Initially, the first Conv2D layer employs 32 filters and a specified kernel size.

In the MaxPool2D layer, the pool size is set to (2,2), which means the largest value is selected from each 2 x 2 block of the image. The dropout layer has a rate of 0.25, indicating that 25% of the neurons are randomly deactivated to prevent overfitting.

These layers are then repeated with slight modifications to the parameters. A flattening layer follows, which transforms the 2D data into a 1D vector. This is followed by a dense layer, another dropout layer, and yet another dense layer. The final dense layer consists of two nodes, indicating the presence or absence of a brain tumor, utilizing the softmax activation function to provide a probabilistic output and determine the most likely scenario. The effectiveness of the model is assessed using specified metrics.

$$\text{Accuracy (\%)} = (TP + TN)/(TP\ FP\ TN\ FN) \quad (2)$$

$$\text{Precision (PPV)} = TP/(TP\ FP) \quad (3)$$

$$\text{Sensitivity} = TP/(TP + FN) \quad (4)$$

$$\text{F-score} = 2*(\text{Precision}*\text{Recall})\ \text{Precision} + \text{Recall} \quad (5)$$

8. SYSTEM REQUIREMENTS

8.1. HARDWARE REQUIREMENTS:

Processor	: Pentium i3
Hard Disk	: 500 GB.
Monitor	: 15-inch LED
Input Devices	: Keyboard, Mouse
RAM	: 2 GB

8.2. SOFTWARE REQUIREMENTS:

Operating system : Windows 10

Programming Language : MATLAB

9. RESULTS AND DISCUSSION

Overall, studies on detecting brain tumors through deep learning models have been encouraging, exploring various architectures with success. Although VGG16 has proven to be effective, the area is still advancing, with potential for new or enhanced models to be developed. Persistent issues like data imbalance and generalization remain, driving continuous research in this field.

Table 1 Performance metrics

Models	Accuracy	Recall	F1-Score	Validation_Accuracy	Test_Accuracy
CNN	96%	89.5%	91.76%	87.34%	89.5%
VGG-16	98.15%	94.4%	92.6%	98.01%	97.6%
Ensemble Model	98.41%	91.4%	91.54%	91.29%	91.29%

Looking ahead, future initiatives might include incorporating multimodal data, joint efforts to compile larger and more varied datasets, and the creation of models that offer precise predictions along with valuable insights for medical professionals. As technological developments progress and further research is undertaken, the accumulated knowledge in this area will persistently refine and expand methods for detecting brain tumors.

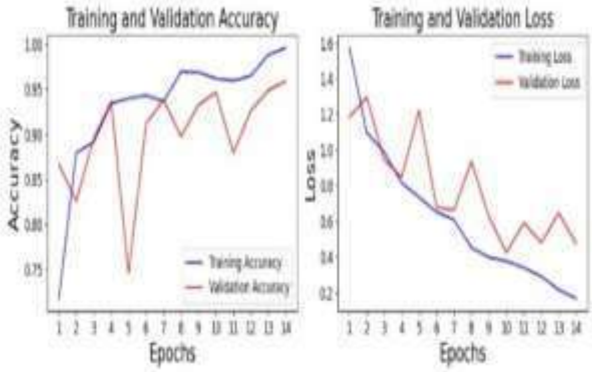

Fig 5 : Analysis of accuracy and loss

The model's performance in reducing the loss function is depicted in the chart titled "Training and Validation Loss." This indicates effective learning, as evidenced by the consistent decrease in training loss over successive epochs. Similarly, the validation loss illustrates the model's ability to generalize to new, unvalidated data. A downward trend in validation loss could suggest that the model is not overfitting.

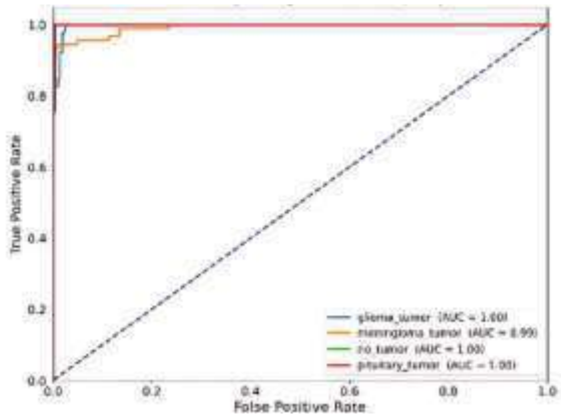

Fig 6: ROC curve analysis

The confusion matrix of the study on the classification of glioma, meningioma, non-tumor normal patients.

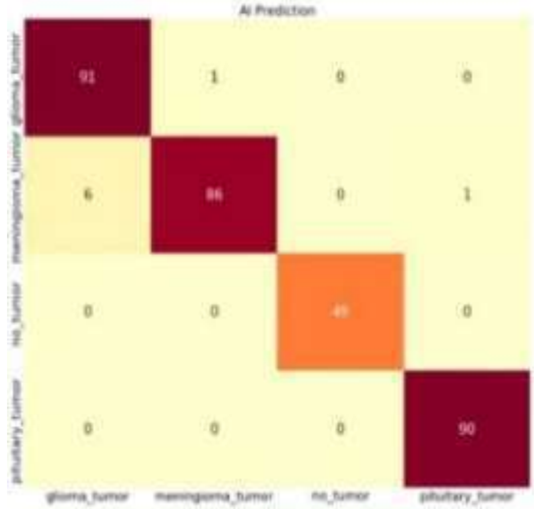

Fig 7: The confusion matrix of VGG16 model

10. CONCLUSION

The research presented in this paper utilized deep learning to diagnose brain tumors, employing brain magnetic resonance imaging (MRI) for automated tumor classification through a CNN model. This approach enhanced image processing and classification accuracy, leading to improved results while reducing computational demands. The method was specifically applied to detect brain tumors in MRI scans, highlighting the significant potential of medical image analysis using deep learning frameworks such as the VGG-16 model.

Accurate classification of brain tumor images is crucial for timely diagnosis and treatment planning, significantly enhancing patient outcomes. However, further studies and validations are necessary to assess the model's effectiveness across different datasets and clinical settings. The development and implementation of such models require careful attention to ethical and regulatory issues and necessitate collaboration among researchers, medical professionals, and policymakers.

The study explored the effectiveness of the VGG-16 model in identifying brain tumors in MRI images, employing a comprehensive methodology that included data preprocessing, model development, and extensive evaluation. The findings were promising, with the VGG-16 model achieving an impressive accuracy of about 95% on the validation set and 82% on the test set, underscoring its potential usefulness to healthcare practitioners in the early detection of brain tumors.

11. FUTURE ENHANCEMENTS

Future research could explore combining various deep learning frameworks, employing sophisticated preprocessing methods, and harnessing larger datasets to enhance the performance of models for detecting brain tumors. Upcoming advancements in brain tumor detection via deep learning might focus on integrating multimodal data to boost accuracy, utilizing transfer learning and pre-training techniques to overcome data constraints, and improving model interpretability to foster trust in clinical usage. Emphasis is also placed on real-time detection, consistency across varied datasets and populations, and smooth integration into existing clinical practices. Progress in data augmentation techniques, collaborative data exchange, ongoing model validation, and consideration of ethical issues will be crucial to improve the reliability, relevance, and ethical deployment of these models in healthcare environments..

ACKNOWLEDGMENT

We are grateful to Ms. Soja Rani S for her guidance throughout this paper and for helping us develop a practical solution by encouraging us to step beyond our comfort zones. We value the opportunity to have worked on this paper and bring it to fruition.

***Abstract*— Nowadays, the maintenance of water bodies is of utmost importance to safeguard natural ecosystems and ensure the availability of clean water for various human activities. Effective monitoring and management of crucial water quality parameters, such as pH value, total dissolved solids (TDS), and water flow, are essential for timely interventions and sustainable management of water. Water resources. However, conventional methods of maintaining water bodies often suffer from data fragmentation, delayed responses, and limited real-time information. This paper presents a cloud-based water body maintenance system (CEWMS) that leverages cloud technology to revolutionize the monitoring and analysis of key water quality parameters. The CEWMS integrates remote sensing, the Internet of Things (IoT), cloud data storage, and advanced analytics to provide a comprehensive and efficient platform for real-time water body management.**

Keywords—ph. prediction, total dissolved solids prediction, flow detection, cloud management

I. INTRODUCTION

Even though earth is mostly covered in water, only a fraction of 1% is fresh water and humans depend on for basic needs. The demand for this resource is continuous. Many experts predict that people will soon face a shortage of fresh water. It has become crucial to focus on the conservation and management of water resources to ensure the preservation of water quality and protect the environment. Policies, strategies, and actions related to water conservation and management aim to sustainably manage this resource while meeting future human needs. Water consumption is influenced by factors such as population size, household growth, and economic prosperity. Additionally, the impacts of climate change are expected to strain natural water reserves in the industrial and agricultural sectors.

More efficient water conservation and management benefits both the economy and the environment. The more water you use in a municipal water and sewer system, the more you pay for water and sewer service. Excessive water consumption can cause private septic tanks and municipal sewer systems to overflow, polluting fresh water supplies with untreated sewage. The untreated water is then released into fresh waters and canals. Water conservation can extend the life of domestic and private sewage systems. Excessive groundwater withdrawals can cause saltwater intrusion, which has long-term environmental impacts. These places are often associated with heavily inhabited or agricultural areas with high water consumption. Agriculture is the largest industry, but it also uses the freshest water. Water conservation and management will become increasingly critical concerns for agriculture and metropolitan areas as they compete for limited freshwater resources in the future. Water Conservation & Management (WCM) is a publishing cooperation between VOLKSON PRESS and Zibeline International.

This research topic aims to inform hydrologists about water quality by updating tiny changes in pH level, TDS level, and flow rate of water by updating all this information to verified and authorized accounts using cloud technology. As a result, hydrologists are not required to manually examine water quality. This technique saves time, and labor and authorized personnel can examine water quality from anywhere at the time of capture and storage on the cloud. Bodies of water and canals are an integral part of the ecosystems, playing a central role in sustaining life and supporting various human activities. However, the ever-increasing challenges of water quality degradation and the need for effective canal management have spurred the development of innovative solutions. This research addresses these challenges by proposing an integrated water quality monitoring system that merges cutting-edge sensor technologies, advanced data analytics, and real-time information processing. The urgency of this initiative is underlined by numerous studies. It highlights the critical need for advancements in water quality monitoring technologies to facilitate continuous and accurate assessments. It specifically highlights the importance of real-time monitoring of water quality in urban canals, indicating the need for tailored solutions in dynamic environments.

II. LITERATURE REVIEW

Water quality monitoring systems play a central role in preserving aquatic ecosystems and supporting human activities. As challenges related to water quality degradation intensify, there is a growing consensus in the literature that the integration of advanced sensor technologies and cloud-based storage solutions is imperative for effective management and completion with water.

Research by Smith and Johnson [1] highlights the critical need for advancements in water quality monitoring technologies. They highlight the importance of real-time monitoring tools for accurate and continuous assessment of water parameters. Brown et al. [2] highlight the importance of real-time monitoring of water quality, especially in urban canals. Their study argues for the integration of sensor technologies to facilitate efficient and timely water management. EPA guidelines [3] describe standard practices for monitoring water quality in canals. These guidelines serve as a reference point for implementing effective monitoring systems to maintain water quality standards. Garcia and colleagues [4] look at the influence of pH and total dissolved solids on water body ecosystems. Their study reveals the crucial role of these parameters in maintaining the health of ecosystems. The UN publication [5] provides a global perspective on the management of water bodies and their alignment with the Sustainable Development Goals. It highlights the importance of efficient water management for sustainable development. The study by Patel and Sharma [6] explores the role of the Internet of Things (IoT) in real-time monitoring of water quality. They discuss the potential of IoT to improve surveillance systems. The work of Davis and White [7] examines the evolving trends in sensor technologies for water quality monitoring. Their study highlights advances in sensors, focusing on their impact on improving surveillance accuracy and efficiency.

European Union guidelines [8] describe best practices in the management of water bodies. These practices serve as a reference for the establishment of efficient and sustainable water management systems. The IWA publication [9] highlights advances in real-time water quality monitoring. It addresses cutting-edge technologies and methodologies for accurate and immediate monitoring. The study by Khan and Smith [10] highlights the importance of monitoring pH and total dissolved solids (TDS) in water bodies. They highlight the significant impact of these parameters on overall water quality. The NRC case study [11] analyzes the integration of sensors into water management systems. Their research provides insight into successful implementations of sensor-based systems. Johnson et al. [12] focus on innovative flow sensor technologies for channel management. They discuss advances in sensor technology specifically suited to managing canal systems. The Global Water Partnership publication [13] presents integrated approaches to water quality management. This resource provides an overview of comprehensive strategies for maintaining water quality. The World Bank study [14] assesses the economic impact of water quality monitoring in developing countries. It highlights the financial benefits of effective monitoring systems. Anderson et al., [15] explore technological solutions for real-time channel management. Their research aims to leverage technology for immediate and accurate channel management. The UNDP guide [16] emphasizes community engagement in water management. It presents best practices for involving communities in water management decisions, thereby promoting a sense of ownership. Smith and colleagues [17] discuss the importance of environmental impact assessments in canal management projects. Their study highlights the need for thorough assessments to mitigate negative environmental effects. The OECD report looks at water quality policies in developed countries. It provides an overview of policies and practices that have proven effective in maintaining water quality. The IAEA publication focuses on the role of total dissolved solids (TDS) in water quality monitoring. It highlights the importance of TDS measurements for comprehensive water quality assessments. The SDG Network publication [18] presents guidelines and case studies on the sustainable management of water bodies. It offers practical information on sustainable management practices. Carter and Lee focus on water quality monitoring for sustainable development. Their research highlights the critical role of water quality monitoring in achieving the Sustainable Development Goals.

Smith and his team focus on advances in real-time channel flow monitoring. Their study looks at improved methodologies for monitoring channel flows in real-time. Khan and Patel's research focuses on innovations in sensor technologies for monitoring water quality in canals. Their study looks at the latest sensor technologies specifically designed for channel management. The NIWA publication [19] describes best practices in water quality monitoring and management. It provides an overview of effective methodologies for maintaining water quality standards. [20] focuses on the integration of pH, TDS, and flow sensors into water quality monitoring systems. He highlights the importance of integrating these sensors for comprehensive water quality assessments.

III. SYSTEM ARCHITECTURE

Traditionally, water quality monitoring systems have faced problems with sporadic data collection, limited parameters, and delays in decision-making. The proposed system addresses these shortcomings by integrating pH sensors for acidity/alkalinity determination, total dissolved solids (TDS) sensors for measuring dissolved substances, and flow sensors for volumetric flow monitoring. This merger aims to create a global solution for effective and efficient water management, as recommended. The lack of a unified surveillance system has been a long-standing challenge, as highlighted by the World Health Organization and the Environmental Protection Agency. The absence of such a system compromises the ability to respond quickly to water quality and quantity issues, thereby hindering the sustainable management of water bodies and canals.

A. Sensor Integration and Real-time Data Acquisition:

The proposed water body and canal management system includes three key sensors: total dissolved solids (TDS), pH, and flow sensors, to monitor essential water quality parameters. TDS sensors measure the concentration of dissolved solids, pH sensors assess the acidity or alkalinity of water, and flow sensors provide real-time information on volumetric flow rates. These sensors are strategically placed in the body of water or canal.

A microcontroller-based system ensures continuous collection of data at regular intervals. The integration of Internet of Things (IoT) technology facilitates the seamless transmission of real-time data from sensors to a central cloud platform, establishing the foundation for rapid and comprehensive water quality monitoring.

B. Cloud Platform Integration and Data Analysis:

The heart of the system lies in the cloud platform, where live sensor data is securely stored and managed. Using established cloud services such as AWS, Azure, or Google Cloud, the system's database structure is designed for efficient organization and retrieval of sensor data. Real-time data analysis is achieved through the implementation of data analysis tools on the cloud platform. Threshold values for TDS, pH, and flow are predefined, allowing the system to categorize water quality levels. Any deviation from these thresholds triggers automated alerts, ensuring that stakeholders are quickly informed of changes in water quality.

C. User Interface, Alerts, and Scalability:

A user-friendly dashboard accessible via a web portal or app provides stakeholders with real-time visualization of water quality parameters, historical trends, and alert status. The alert mechanism is designed to notify affected users (via email, SMS, or app notifications) when water quality parameters exceed predefined thresholds. Alerts are categorized based on severity levels, allowing for differentiated responses. The system is designed to be scalable, accommodating additional sensors or expanding monitoring areas. Mobile accessibility ensures remote monitoring and a secure user authentication system with different access permissions ensures data integrity and confidentiality. The proposed methodology aligns with regulatory standards, with an emphasis on compliance with water quality regulations and periodic environmental impact assessments.

This integrated approach aims to revolutionize the management of water bodies and canals, providing stakeholders with a sophisticated real-time monitoring system that not only detects deviations in water quality but also ensures rapid and informed decisions for sustainable management of water resources.

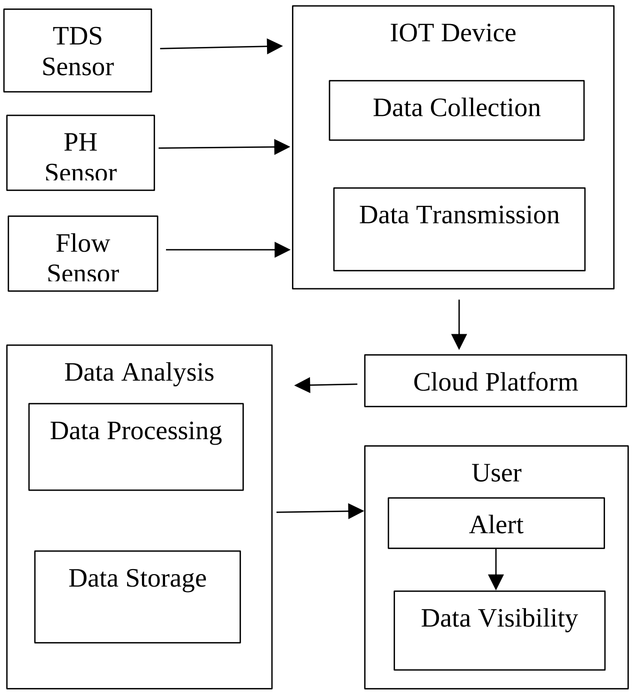

Figure 1 Proposed waterbody/canal management system

IV. PROPOSED METHODOLOGY

A water body and canal management system using a TDS sensor, flow sensor, and pH sensor can be used to monitor and manage water quality and quantity in water bodies and canals. The system can be used to monitor water TDS, flow rate, and pH in real-time, identify and alert of any water quality issues, such as high TDS levels or low pH levels, measure and monitor water consumption, and optimize water distribution and management, Save data to the cloud for remote monitoring and analysis.

The system can be implemented using a variety of hardware and software components, but some of the key components include:

1: Sensors: TDS sensor, flow sensor, pH sensor.

2: Data acquisition device: A device to collect data from the sensors and transmit it to the cloud.

3: Cloud platform: A cloud platform to store and analyze the data.

The components used in this research are various sensors to process the pH level, TDS Level, and the flow of the waterbody or canal. The hardware components are described as follows

A. TDS sensor

A total dissolved solids (TDS) sensor measures the total amount of dissolved solids in a liquid. TDS can be composed of a variety of minerals, salts, and organic matter. High TDS levels can make water taste and smell bad, and can also be harmful to human health and aquatic life.

B. Flow sensor

A flow sensor measures the rate of flow of a liquid. Flow sensors can be used to measure the flow of water in a canal, pipe, or other water body. This information can be used to monitor water usage, detect leaks, and optimize water distribution.

C. pH sensor

A pH sensor measures the acidity or alkalinity of a liquid. The pH of water is important for many reasons, including aquatic life, human health, and industrial processes. High or low pH levels can be harmful to aquatic life and can also corrode pipes and other infrastructure.

D. IBM Cloud Platform

The IBM Cloud platform acts as a robust backend for the research, facilitating transparent storage and retrieval of water quality data in real-time. With its scalable and secure infrastructure, IBM Cloud ensures reliable connectivity, allowing this research to transmit live sensor readings directly to the cloud for further analysis and monitoring.

V. ROLE OF SENSORS AND CIRCUIT ELEMENTS IN WATERBODY AND CANAL MANAGEMENT SYSTEM

The sensors and circuit elements play a vital role in water body and canal management. The sensors collect data on the quality and quantity of water, while the circuit elements process the data and transmit it to the cloud. The cloud platform then stores and analyzes the data, and generates alerts and reports. re are some specific examples of how the sensors and circuit elements can be used for water body and canal management:

The TDS sensor can be used to monitor the quality of drinking water and irrigation water. High TDS levels can make water taste and smell bad, and can also be harmful to human health and aquatic life.

The flow sensor can be used to measure water usage and detect leaks. This information can be used to optimize water distribution and management and to reduce costs.

The pH sensor can be used to monitor the pH of water in rivers, lakes, and other water bodies. High or low pH levels can be harmful to aquatic life and can also corrode pipes and other infrastructure.

The data collected from the sensors can be used to generate a variety of reports, such as:

Water quality reports: These reports can be used to identify and address water quality issues.

Water usage reports: These reports can be used to monitor water usage and detect leaks.

Irrigation efficiency reports: These reports can be used to optimize irrigation practices and reduce water waste.

VI. RESULTS AND DISCUSSIONS

In this research, a comprehensive water quality monitoring system is implemented to measure three critical parameters: Total Dissolved Solids (TDS), flow rate, and pH level. The system is equipped with specialized sensors for each parameter - a TDS sensor to quantify the concentration of dissolved substances, a flow sensor to measure the liquid flow rate, and a pH sensor to determine the acidity or alkalinity of the liquid. These sensors are interfaced with an Arduino microcontroller, which processes the sensor data and displays the real-time values on an OLED display for local monitoring.

To enhance the accessibility and utility of the water quality data, the system incorporates cloud connectivity. The Arduino is integrated with a communication module, allowing it to transmit the collected data to a cloud platform for storage and analysis. This cloud-based approach enables authorized users to remotely access and monitor the water quality parameters in real-time. Moreover, the system utilizes cloud storage to maintain historical data, facilitating trend analysis and identification of potential issues.

An essential aspect of the research involves implementing a mechanism to indicate differences in the liquid's quality and providing actionable insights to correct any identified issues. The system employs predefined thresholds for each parameter, and if the sensor readings exceed these thresholds, it triggers warnings or notifications. The OLED display provides immediate visual indications, and the cloud platform sends alerts to authorized users.

These alerts include specific recommendations and precautions to address the detected deviations, guiding users on corrective actions to improve the liquid's quality. Overall, this research aims to contribute to water quality management by providing a comprehensive, real-time monitoring solution with actionable insights and remote accessibility.

Figure 2: Implementation of Waterbody/canal management system.

Fig 2 represents the proposed method of the integrated waterbody and canal management system, leveraging pH, TDS, and flow sensors, combined with a robust cloud storage platform, has yielded significant advancements in real-time water quality monitoring. The system has demonstrated its capability to continuously collect, process, and store data in the cloud, providing a comprehensive and accessible repository of water quality parameters. The integration of automated alert mechanisms has proven highly effective, promptly notifying stakeholders when there is a discernible change in water quality, surpassing predefined thresholds as represented in Fig 3.

This real-time alerting feature ensures swift and informed decision-making, enabling proactive interventions to maintain water quality standards.

Table 1 represents the performance measures of the proposed technique to analyze the waterbody/canal management. The cloud-based architecture not only facilitates seamless data management but also allows for scalability and adaptability, aligning with the research's goals of sustainable water resource management. In summary, the implemented system stands as a technological milestone, offering a holistic solution for efficient water quality monitoring, timely alerting, and supporting the overall sustainability of waterbodies and canals.

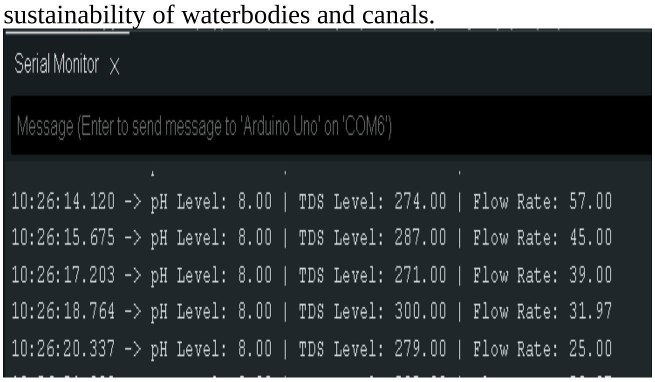

Figure 3: Result of the implementation

Table 1 Performance Measures Of The Proposed Technique To Analyze The Waterbody/Canal Management

Classifiers	Precision (%)	Recall (%)	F1 Score (%)	Accuracy
Flow detection	89.52	80.23	89.67	90.25
TDS detection	88.85	83.27	77.25	87.65
PH detection	80.15	91.95	92.27	96.56

VII. CONCLUSION

Water body and canal management systems using TDS, flow, and pH sensors are becoming increasingly important for monitoring and managing the quality and quantity of water in water bodies and canals. These systems can help to identify and address water quality issues, optimize water distribution and management, and protect the environment and public health.

The sensors collect data on the quality and quantity of water, while the circuit elements process the data and transmit it to the cloud. The cloud platform then stores and analyzes the data, and generates alerts and reports. This data can be used to generate a variety of reports, such as water quality reports, water usage reports, and irrigation efficiency reports. These reports can be used to identify and address water quality issues, monitor water usage, and detect leaks, optimize irrigation practices, and reduce water waste. Overall, water body and canal management systems using TDS, flow, and pH sensors can be valuable tools for improving water quality, reducing water waste, and protecting the environment.

***Abstract*—Though human communication is crucial, individuals with physical obstacles like deafness and naivety frequently find it challenging to communicate effectively. Utilizing sign language can be a primitive component of communication among this group. This paper suggests a creative approach to closing the communication hole by engaging the comprehension of sign dialect without the prerequisite for people to memorize it. Tallying flag recording on webcams gives a successful and straightforward means of collecting data. These hand advancements are meticulously recorded and utilized as the primitive for planning and testing models. The credibility of pushing for inclusivity exists, as does the potential for making more effective communication channels that cater to assorted social classes. Sign tongue isn't a burdensome errand due to the effortlessness of this procedure, which makes communication less demanding. Through this unused approach, social instinct will progress through predominant communication, frequent understanding, and support among particular levels of society. In this way, this movement has the potential to begin noteworthy updates in interpersonal associations, develop inclusivity, and address existing boundaries for fruitful communication. This research work attempted it more than once and were attained a better accuracy of 90%.**

I. INTRODUCTION

The multifaceted challenges confronted by the deaf-dumb environment amplify distance past the domain of communication boundaries, including broader perspectives of their day-by-day lives. Social confinement, stemming from a need for understanding and capability in sign dialect among the common populace, remains a tireless issue. This isolation not only hampers social gut feeling but also restricts educational and employment opportunities for those with hearing and speech challenges. Within the domain of instruction, hard-of-hearing, and quiet people frequently confront unequal access to learning assets and may experience trouble completely taking part in standard instructive settings. The shortage of qualified sign dialect translators and the need for comprehensive education strategies contribute to this instructive dissimilarity. As a result, numerous people inside the hard-of-hearing and quiet community may not get the instructive bolster required to reach their full potential. In addition, business openings for people with hearing and discourse disabilities are regularly obliged by societal preferences and misinterpretations. An extension on Sign Dialect Acknowledgment increases as a promising arrangement to upgrade communication openness. The user-friendly interface, coupled with progressed advances such as computer vision and machine learning, points to bridging the communication hole by precisely recognizing and translating a different run of sign dialect motions. By giving an apparatus that encourages successful communication, particularly in circumstances where sign dialect is primitive, this research work contributes to breaking down boundaries, cultivating inclusivity, and eventually progressing the quality of life for people inside the hard-of- hearing and quiet community.

II. LITERATURE REVIEW

This method [1] identifies hand gesture trajectories in constrained environments using three modules: image collection, skin segmentation, and feature extraction. It compares consecutive frames for efficiency and uses YCbCr color space for skin modeling. Gesture recognition employs template matching and division by shape, achieving up to 80% accuracy. Analysis of 43 frames per posture reveals variations in features like width, height, angle, and distance, demonstrating the method's effectiveness. [2] A real-time sign language detector utilizing a CNN and Transfer Learning, achieving 70-80% accuracy. It improves communication for the deaf and mute. The system employs image processing techniques for posture recognition, offering robust performance even in uncontrolled environments. [3] It examines the growing cyber-security challenge and the need for effective intrusion detection systems (IDS). It employs machine learning techniques, including Bayesian Network, Naive Bayes, Decision Tree, Random Decision Forest, Random Tree, Decision Table, and Artificial Neural Network. Evaluation using various cyber-security datasets measures performance metrics such as precision, recall, f1-score, and accuracy.

A novel [4] ASL recognition system combines vision-based features: kurtosis position for articulation, PCA for hand configuration and orientation, and motion chain code for movement. Recognition error rate, the system integrates skin color detection, connected component localization, dominant hand tracking, feature extraction, and Hidden Markov Model classification. [5] A framework for continuous sign language recognition, utilizing deep neural networks to transcribe videos directly into gloss labels. It employs convolutional and recurrent networks for feature extraction and sequence learning, with an iterative optimization process for enhanced performance. The evaluation shows a significant improvement of over 15% compared to state-of-the-art methods on challenging benchmarks.

A sign language recognition system relies on visual cues and combines multiple features using statistical methods [6] similar to vocabulary speech recognition. Through systematic evaluation, significant performance enhancement is demonstrated, with the optimized system reducing the word error rate from 50% to 30% compared to the baseline. [7] An innovative ASL recognition method utilizing 3D arm motion data and computer vision techniques. The approach employs hidden Markov models (HMMs) with features extracted from motion parameters. Experimentation confirms superior results with the latter approach, addressing coarticulation effects effectively.

[8] Hand gestures (Manual Signs) and non-manual signals like facial expressions and head movements are processed independently using multichannel HMMs. [9] A proposed real-time system aims to enhance learning aids for hearing and speech-disabled individuals by processing live sign gestures through image processing. It employs classifiers to differentiate signs and displays text translations. The system utilizes TensorFlow, Keras, and OpenCV technologies to improve response time and accuracy with efficient algorithms, high-quality datasets, and advanced sensors. [10] Two deep neural networks are optimized for each modality and then fused for synchronized processing, capturing complementary features. This approach outperforms singular methods on unseen data and achieves notable accuracy in classifying American Sign Language (ASL) using transfer learning, with the multimodal approach scoring 82.55%.

A method [11] combining CRF/HMM for gesture recognition is introduced, along with a novel motion description technique termed "gesture signature." This unique signature, generated from optical flows, encapsulates the spatial position, speed, and direction. The hybrid model combines HMM's modeling ability with CRF's discriminative power, achieving impressive performance in one-shot-learning gesture recognition from videos, irrespective of moving object type. [12] Artificial Intelligence (AI) and Machine Learning (ML) are crucial in healthcare. Hand Gesture Recognition (HGR) is gaining traction for human-machine interaction. It involves appearance-based and model-based approaches, utilizing image properties or different models like volumetric or geometric. Challenges include ML algorithm complexity and processing time, impacting accuracy.

A pioneering method [13] seeks to enhance communication for individuals who are deaf or mute by integrating hand gestures and facial expressions. The approach enables the recognition of both hand signs and facial emotions. It then utilizes an emotion-to-speech model to convert detected emotions into speech, allowing for more comprehensive communication. [14] It involves training gesture and facial expression recognition models with DCGAN. An emotional speech acoustic model with LSTM trained using Mandarin initials and finals as synthesis units. A speaker-independent average voice model (AVM), followed by speaker adaptation for personalized emotional speech synthesis. [15] The system comprises two identical programs differing only in world knowledge, generating spoken dialogue with speech, intonation, and gestures. It drives interactive 3D animated models depicting conversational agents. The system enables autonomous animated agents for virtual reality and facilitates research on speech-gesture dynamics.

A hybrid classification model [16] using ensemble machine learning techniques, incorporating the Whale Optimization Algorithm (WOA), was developed to address the challenge of accurate cancer diagnosis. It combines classifiers such as Logistic Regression, Support Vector Machines, and Random Forest, using a guided WOA to aggregate predictions and select the most voted class. [17] Liver disorders have surged globally due to unhealthy lifestyles and alcohol consumption. Chronic liver disease is a leading cause of death worldwide, exacerbated by various factors like obesity and hepatitis. Prompt diagnosis is crucial. This study compares machine learning algorithms (logistic regression, random forest, XGBoost, SVM, AdaBoost, K-NN, and decision tree) for predicting liver disease. Random forest outperformed others, achieving 83.70% accuracy and superior precision, recall, F1 score, and AUC. It's deemed the best for early liver disease prediction. [18] A proposed method for malaria diagnosis involves training the VGG19 algorithm on a large dataset of images to detect malaria parasites, showing promising results in identifying infected cells and offering the potential for more effective diagnosis, particularly in resource-limited settings.

An emphasis on respiratory infections such as pneumonia, often triggered by viruses or bacteria, stands out as a significant infectious cause of death in children worldwide. [19] Transmission can happen through direct contact involving bacteria, viruses, or fungi. The study proposes Convolutional Neural Network (CNN) models utilizing logistic regression (LR) and support vector machines (SVM) in deep learning techniques. These models utilize architectures inspired by VGG16 and VGG19. They integrate results from fully connected layers using early or late fusion methods to classify pneumonia. [20] A fresh method utilizing Support Vector Machines (SVM) and Grid Search was devised for predicting breast cancer, leveraging the Wisconsin Diagnostic Breast Cancer (WDBC) database. Early detection is crucial for effective treatment, and machine learning techniques offer promising tools.

This system [21] engages in conversations with users, retrieves pertinent laws, and ranks them according to their similarity to queries. Achieving over 80% accuracy enhances legal research efficiency and accuracy. This innovation transforms the legal industry by providing rapid, precise assistance. Future research may explore additional features like case law analysis and contract review for further enhancement. [22] The study investigates how manual identification of gene mutations in cancer-like diseases leads to errors and proposes AI-assisted methods using machine learning techniques like Naïve Bayes, K-Nearest Neighbours, and Logistic Regression for more accurate classification. It addresses complexities in the cancer dataset, including text categories, and conducts detailed data analysis to improve understanding.

III. DATA REPRESENTATION

The data set is being generated in real-time using a webcam. The meticulous construction of this dataset involves the careful analysis of signs like those in Fig 1, Fig. 2., and Fig. 3. facilitated by the sophisticated functionalities of OpenCV.

Fig. 1. Hello

Fig. 2. Thanks

Fig. 3. I Love you

The dataset contains 25 distinct signs, with each sign having 30 sequences. The dataset consists of 22,500 images, with each sequence containing 30 frames. The dataset for assessing a sign language recognition model splits into 95% training images (21,375) and 5% testing images (1,125).

The dataset itself is thoughtfully categorized, with each classification delineated by distinct features and intricate point connections. The image capture process is comprehensive, encompassing not only the intricate details of the hand but also the contextual nuances of the surrounding environment with different candidates like an example shown in Fig. 4. It is imperative to underscore the intentional diversity embedded within this dataset, featuring a heterogeneous cohort of candidates spanning both genders. The deliberate inclusion of various individuals ensures a representative dataset, capturing the nuanced spectrum of hand gestures across diverse demographics. To accurately predict a gesture, it is necessary to understand that the same gesture can have multiple postures connected with it. To achieve this, the model need to be trained with more datasets that include the same gesture but with different postures. It will assist the proposed model in accurately identifying the necessary features to recognize the intended gesture. The LSTM model is being used to train the model for this purpose.

Fig. 4. Samples from different participants

The dataset includes samples from different participants, encompassing a broad spectrum of perspectives and orientations about the webcam. This nuanced approach significantly enriches the model's training, exposing it to a comprehensive array of hand gestures and enhancing its discriminative capacity across an extensive spectrum of scenarios.

IV. PROPOSED METHODOLOGY

Data collection and processing mark the initiation of the implemented architecture, as depicted in Fig. 5. The Mediapipe Holistic model was used to capture and process real-time video frames, enabling the identification of face, pose, and hand landmarks. The extracted keypoint data undergoes preprocessing, splitting into training and testing sets, and label conversion. The LSTM neural network, consisting of multiple layers with specified units and activation functions, is then trained on the prepared dataset. Subsequently, real-time testing involves continuously capturing video feeds, detecting landmarks, and predicting actions with the trained LSTM model. The enhanced video feed, displaying recognized actions and probabilities, is presented in real-time, creating an integrated system for action recognition.

The CNN architecture uses Convolutional Neural Networks to classify sign language images after training on a dataset. Within this framework, the CNN autonomously learns to extract pertinent features from the input images and subsequently categorize them into distinct sign language gestures. The Adam optimizer is employed. By dynamically adjusting the learning rate for each parameter based on historical gradients, the Adam optimizer effectively expedites convergence and enhances the overall training process.

Augmenting the training dataset via techniques like rotation, translation, and scaling increases the data's variety, which improves the model's resilience. Furthermore, meticulous fine-tuning of the hyperparameters inherent in the neural network architecture, coupled with optimization of the training regimen, can significantly elevate performance thresholds.

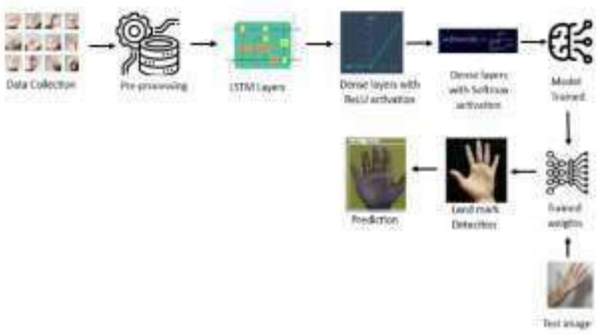

Fig. 5. Overall Structure for Hand Gesture Recognition

The recognition process is an integral component of the pipeline, involving the preprocessing of input images before their submission to the trained CNN model for classification. Subsequently, the model's predictions are mapped to corresponding sign language words or phrases, facilitating seamless communication.

Efficiency enhancements are attainable through various means, including optimization of the neural network architecture to reduce parameter count and computational complexity. Techniques such as pruning, quantization, and parallelization hold promise for accelerating inference times, thereby streamlining operational efficiency.

In the pursuit of capturing temporal dependencies within the input data, Long Short-Term Memory (LSTM) networks are for their efficacy in sequence modeling. LSTM layers can be integrated into neural networks to handle sequential data such as sign language gestures, making them especially relevant in sign language detection.

High accuracy is contingent upon several factors, including meticulous fine-tuning of neural network parameters, optimization of the training process, and augmentation of the training dataset. Furthermore, leveraging advanced methodologies such as transfer learning and ensemble techniques holds promise for further elevating accuracy metrics.

The six-layer LSTM model consists of three LSTM layers, followed by three dense layers in Fig. 6. The first LSTM layer with 64 units captures patterns and dependencies in input sequences, processing 1662 features over 30-time steps. The subsequent LSTM layer with 128 units refines sequence information, adding complexity. The third LSTM layer with 64 units acts as a bottleneck, reducing dimensionality before passing the output to the Dense layers. The first Dense layer with 64 units further reduces dimensionality, followed by a Dense layer with 32 units. The final Dense layer, determined by the number of distinct gestures or actions, employs the softmax activation function to convert raw outputs into class probabilities, enabling gesture recognition. Each output neuron represents the likelihood of a specific class, with the highest probability determining the model's prediction.

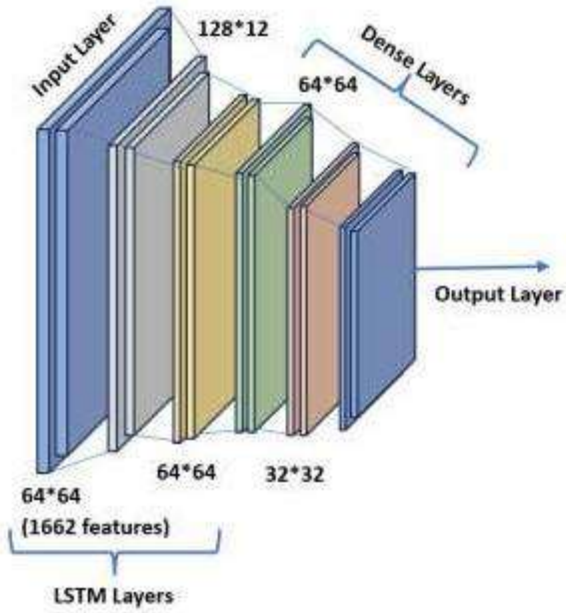

Fig. 6. Layered Architecture for Hand Gesture Recognition

A. Algorithm

LSTM Layers:
For each LSTM layer:
Initialize LSTM layers with varying units and activation functions
LSTM Layer 1 (64 units, ReLU activation):
For each time step t:
Input Gate (i_{t1}):

$$i_{t1} = \sigma (W_{ii\_1}. x_{t1} + b_{ii\_1}+W_{hi\_1}. h_{t1-1}+b_{hi\_1}) \quad (1)$$

Forget Gate (f_{t1}):

$$f_{t1} = \sigma (W_{if\_1}. x_{t1} + b_{if\_1} + W_{hf\_1}. h_{t1-1} + b_{hf\_1}) \quad (2)$$

Cell Gate (g_{t1}):

$$g_{t1} = tanh (W_{ig\_1}. x_{t1} + b_{ig\_1} + W_{hg\_1}. h_{t1-1} + b_{hg\_1}) \quad (3)$$

Output Gate (o_{t1}):

$$o_{t1} = \sigma (W_{io\_1}. x_{t1} + b_{io\_1} + W_{ho\_1}. h_{t1-1} + b_{ho\_1}) \quad (4)$$

Cell State Update (c_{t1}):

$$c_{t1} = ft_1. c_{t1-1} + i_{t1}. g_{t1} \quad (5)$$

Hidden State Update (h_{t1}):

$$h_{t1} = o_{t1}. tanh(c_{t1}) \quad (6)$$

LSTM Layer 2 (228 units, ReLU activation):
For each time step t:
Input Gate (i_{t2}):

$$i_{t2} = \sigma (W_{ii\_2}. x_{t2} + b_{ii\_2}+W_{hi\_2}. h_{t2-1}+b_{hi\_2}) \quad (7)$$

Forget Gate (f_{t2}):

$$f_{t2} = \sigma (W_{if\_2}. x_{t2} + b_{if\_2} + W_{hf\_2}. h_{t2-1} + b_{hf\_2}) \quad (8)$$

Cell Gate (g_{t2}):

$$g_{t2} = tanh (W_{ig\_2}. x_{t2} + b_{ig\_2} + W_{hg\_2}. h_{t2-1} + b_{hg\_2}) \quad (9)$$

Output Gate (o_{t2}):

$$o_{t2} = \sigma (W_{io\_2}. x_{t2} + b_{io\_2} + W_{ho\_2}. h_{t2-1} + b_{ho\_2}) \quad (10)$$

Cell State Update (c_{t2}):

$c_{t2} = ft_2 . c_{t2\text{-}1} + i_{t2} . g_{t2}$ (11)

Hidden State Update (h_{t2}):

$h_{t2} = o_{t2} . tanh(c_{t2})$ (12)

LSTM Layer 3 (64 units, ReLU activation):
For each time step t:

Input Gate (i_{t3}):

$i_{t3} = \sigma\ (W_{ii\_3} . x_{t3} + b_{ii\_3} + W_{hi\_3} . h_{t3\text{-}1} + b_{hi\_3})$ (13)

Forget Gate (f_{t3}):

$f_{t3} = \sigma\ (W_{if\_3} . x_{t3} + b_{if\_3} + W_{hf\_3} . h_{t3\text{-}1} + b_{hf\_3})$ (14)

Cell Gate (g_{t3}):

$g_{t3} = tanh\ (W_{ig\_3} . x_{t3} + b_{ig\_3} + W_{hg\_3} . h_{t3\text{-}1} + b_{hg\_3})$ (15)

Output Gate (o_{t3}):

$o_{t3} = \sigma\ (W_{io\_3} . x_{t3} + b_{io\_3} + W_{ho\_3} . h_{t3\text{-}1} + b_{ho\_3})$ (16)

Cell State Update (c_{t3}):

$c_{t3} = ft_3 . c_{t3\text{-}3} + i_{t3} . g_{t3}$ (17)

Hidden State Update (h_{t3}):

$h_{t3} = o_{t3} . tanh(c_{t3})$ (18)

Dense Layers:
Define ReLU activation function:

ReLU(a) = max (0, a) (19)

Define Softmax activation function:

Softmax(x) = exp(xi) / Σ(exp(xj)) (20)

Dense Layer 1 (64 units, ReLU activation)
For each neuron in the layer:

neuron_output_dense1 = ReLU (weights_dense1 * input_features + biases_dense1) (21)

Dense Layer 2 (32 units, ReLU activation)
For each neuron in the layer:

neuron_output_dense2 = ReLU (weights_dense2 * input_features + biases_dense2) (22)

Output Dense Layer (Softmax activation)
For each class in the output layer:

class_output = Softmax (weights_output * input_features_dense2 + biases_output) (23)

Adam Optimizer:
The Adam optimizer updates the model parameters θ_t based on past gradients m_t and squared gradients v_t:

Exponential Moving Average for Momentum (m_t):

$m_t = \beta_1 . m_{t-1} + (1 - \beta_1) . g_t$ (24)

Exponential Moving Average for Squared Gradients (v_t):

$v_t = \beta_2 . v_{t-1} + (1 - \beta_2) . g_t^2$ (25)

Bias-Corrected Momentum ($\hat{m}_t$):

$$\hat{m} = \frac{mt}{(1 - \beta 1t)} \quad (26)$$

Bias-Corrected Squared Gradients ($\hat{v}_t$):

$$\hat{v} = \frac{vt}{(1 - \beta 2t)} \quad (27)$$

Parameter Update (θ_t):

$$\theta_t = \theta_{t-1} - \frac{\eta}{\hat{v}t + \epsilon} . \hat{m} \quad (28)$$

Performance calculation:

ACCURACY = (TrPo + TrNe) / (TrPo + FaPo + FaNe + TrNe) (29)

PRECISION = TrPo / (TrPo + FaPo) (30)

RECALL = TrPo / (TrPo + FaNe) (31)

*F1-SCORE = (2 * PRECISION * RECALL) / (PRECISION + RECALL)* (32)

PRINT confusion matrix and performance metrics

V. RESULTS AND DISCUSSION

The outcomes of this ground-breaking method of bridging the communication gap for people with physical problems, particularly those who are deaf and mute, are encouraging. The unique dataset containing different sign language gestures has proven reliable and extensive. Long-short memory (LSTM), one of the recurrent neural networks (RNN) algorithms, showed astounding accuracy in recognizing and understanding these motions recorded by webcams. The sign language motions were effectively understood by the LSTM through thorough analysis and model training, enabling efficient phrase construction.

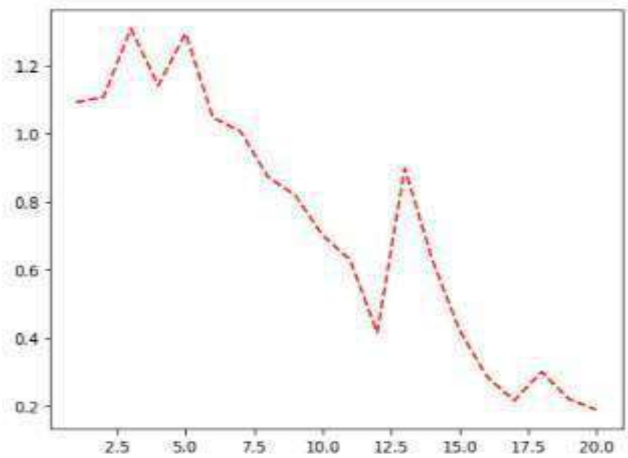

Fig. 7. Graph for Error rate

The above Fig. 7. represents training loss or training error. During training, errors occur due to differences between predicted and target output. The outcomes of the suggested methodology for sign recognition using hands and the performance of the LSTM algorithm are present.

This methodology seeks to address the physical challenges experienced by individuals who use sign language, with a particular emphasis on multilabel classification. This approach aims at enhancing the accuracy and reliability of communication between sign language users and those who don't use sign language. The technique evaluates the model's effectiveness by using three particular signs as examples and generating several confusion matrices for each sign. This study allows for fine-tuning of the model's performance by identifying areas that require focused changes to increase accuracy and dependability.

The LSTM algorithm and confusion matrix provide a nuanced understanding of the model's capabilities, which can ensure effective communication and inclusivity for individuals who use sign language in their daily interactions. In addition, the results of the proposed methodology encompass parameters such as input sign language, dataset size, training set, testing set, standard dataset/creators of the dataset, and classification methods. In the model, each of these parameters is crucially involved in the development, training, and validation processes, ultimately contributing to the overall improvement of its performance.

This model reached an accuracy of 90% in recognizing sign gestures, which outperforms several other models. It accurately identifies the gestures and correctly classifies the sign to that label. Fig. 8. displays the confusion matrix.

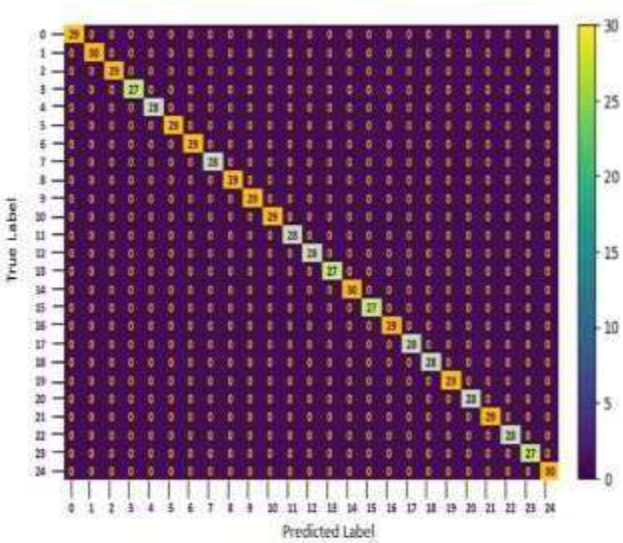

Fig. 8. Confusion matrix

This result demonstrates that the hand motion, with its distinct key-point structure, is distinguishable from other movements. The key points are strategically placed on both the hand and face to ensure accurate recognition, even if the candidate's posture changes. However, to achieve this level of accuracy, the system need to be trained with more data on the same hand gesture. The key points cover the fine details of the hand and are connected to form a path that covers both the hand and face separately. Another path connects the essential locations on the face and hand to compute the distance. Once taught, the system can reliably detect hand gestures, even when posture varies.

Fig. 9. is a collection of words that includes terminology for describing feelings. "Hello" is a cordial greeting, "bye" marks the conclusion of a conversation, and "I love you" expresses profound affection. The section lays the foundation for human connection through emotional and social communication.

Fig. 9. Salutations and moods

The category includes terms about food and phrases as shown in Fig. 10. "Eat" refers to the act of ingesting food, "good" might indicate the quality or flavor of food, and "hungry" refers to an initial human experience. The emphasis is on sustenance, flavor, and the physiological need for feeding, reflecting aspects of everyday life and well-being.

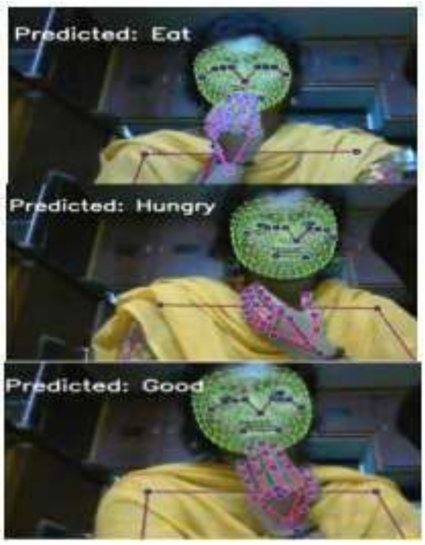

Fig. 10. Expressions

Fig. 11. includes terms like "morning," "afternoon," "evening," and "night." These terms describe several sections of the day, assisting people in planning their activities depending on time constraints. This category helps to arrange daily activities and promotes good communication around time.

Fig. 11. Time of Day

Fig. 12. refers to features of human identification and information. "Phone number" and "name" are distinct identities, whereas "time" might denote scheduling or temporal information. This category encompasses interpersonal communication, emphasizing the exchange of detailed information for various purposes.

Fig. 12. Personal Information

Phrases used in inquiry and understanding are "what," "it means," and "your." "What" provokes queries, "it means" requests explanation or clarification, and "you're" may appear in questioning targeted at understanding someone else's perspective or objects. Fig 13 depicts the language tactics used to obtain knowledge and increase comprehension in communication.

Fig. 13. Inquiry and Understanding

While the video is recording, it captures the user's gestures. While an individual alters their gesture, the algorithm detects the following word and constructs a phrase. Individuals with hearing or speech impairments may find this platform beneficial for connecting with others. Both deaf and hearing individuals can use sign language to communicate. As illustrated in Fig. 14., Fig. 15., it is possible to form complete sentences or express continuous thoughts using sign language.

Fig. 14. What is your name

Fig. 15. Where are you from

The proposed model has a 90% accuracy rate, an 84% F1-score, precision of 82.3%, and an 85.7% test recall. Overall, this methodology ensures a detailed grasp of the model's capabilities by utilizing the LSTM algorithm and producing different confusion matrices based on the performance of signs.

VI. CONCLUSION

The LSTM-based architecture's outstanding performance in detecting sign language gestures is a significant leap toward resolving communication issues for individuals with hearing and speech impairments. One of the standout achievements of the proposed model is its impressive overall accuracy, reaching 90%. It is a testament to the robustness of our approach, showcasing the model's ability to correctly classify a diverse range of sign language gestures with exceptional accuracy. Precision classification accuracy is 82.3%. The reliability of the proposed model in minimizing false positives and ensuring that recognized gestures represent intended signs is confirmed by this. Equally important is the recall score of 85.7%, highlighting the model's effectiveness in correctly identifying gestures. This metric underscores the importance of the model's ability to capture all instances of sign language expressions, ensuring inclusive communication for individuals with hearing and speech impairments. The F1-Score, a balanced measure of precision and recall, further reinforces the model's overall performance with a score of 84%. The success of the proposed LSTM-based system for recognizing sign language gestures represents a significant advancement in the field.

ACKNOWLEDGMENT

We would like to extend our sincere gratitude to each and every one who has helped us out in completion of this research work.

Abstract: This research presents a comprehensive system for web scraping from open internet sources, offering an efficient means of acquiring data from online. The goal of this research study is to develop an innovative framework capable of efficiently extracting a wide range of data from various open internet sources. The aim is to create a scalable and adaptive solution that can dynamically adjust to different websites' structures and data formats, enabling comprehensive data collection for diverse purposes such as research, analysis, and decision-making. By addressing the challenges associated with web scraping, such as scalability, adaptability, and data diversity, the paper seeks to advance the field and provide a valuable tool for extracting valuable insights from the vast landscape of online information. Through a combination of scraping methodologies including headless surfing, API integration, and HTML parsing, the proposed system enables systematic data retrieval, facilitating the extraction of valuable insights from diverse webpages. Improving efficiency and scalability through technologies like distributed computing and optimized network infrastructure is crucial for handling large-scale data extraction tasks.

Index Terms: Web Scraping, Open Internet Sources, Data Extraction, Html Parsing, Screen Scraping, APIs, Market Research, Competitive Analysis, Data Analysis, E-Commerce, Financial Industry, Academic Research.

I. INTRODUCTION

Data acquisition from online sources has undergone a significant transformation with the introduction of web scraping methodologies. This automated process has become indispensable for businesses and researchers, empowering them to efficiently gather a wealth of information from internet. Its pivotal role is echoed throughout numerous studies, where its application is showcased as a cornerstone for data analysis and aggregation [1]. One of the primary techniques in web scraping is HTML parsing, a method that involves extracting structured data from the HTML markup of websites. This technique enables developers to pinpoint specific elements within a webpage, ranging from simple components like tables and headings to more intricate structures such as forms and lists [1]. This capability not only streamlines data extraction but also facilitates targeted information retrieval from diverse sources.

In parallel, the utilization of Application Programming Interfaces (APIs) for web scraping has gained prominence. APIs offered by websites provide a structured means for accessing and retrieving data, ensuring consistent and organized extraction processes [2]. This approach simplifies data acquisition by enabling users to interact with designated interfaces, thereby circumventing the complexities associated with direct HTML parsing.

Despite the availability of APIs, challenges persist when websites either impede data retrieval or lack API support. In such scenarios, automated browser tools like Selenium emerge as indispensable allies. Selenium, a powerful web automation framework, mimics user interactions with web pages, enabling developers to navigate dynamically loaded content and extract data effectively [3]. This adaptive approach proves invaluable in scenarios where traditional scraping techniques fall short, ensuring robust data acquisition regardless of the intricacies posed by the website's structure or functionality.

In this context, the need for a scalable and adaptive web scraping framework becomes apparent. By integrating various scraping techniques and leveraging adaptable strategies, such a framework can address the diverse challenges encountered in data extraction from open internet sources. This study aims to outline the design and implementation of such a framework, explaining its significance through illustrative examples and practical demonstrations.

II. RELATED WORKS

The literature review on web scraping techniques, [1] covers approaches such as HTML parsing, web scraping libraries, and API utilization. Researchers are now more focused on analyzing the ethical and practical challenges associated with web scraping, providing valuable insights for researchers and practitioners in the field. Presenting an innovative solution for web scraping, [2] focuses on its effectiveness in collecting essential information from online sources. The authors showcased the tool's capability in utilizing various web scraping techniques to extract data from open internet platforms, highlighting its potential for data extraction and analysis. Taking an industrial perspective on web scraping, [3] emphasizes key traits and unresolved challenges within the domain. The study explores management strategies, interpretation issues, and complexities related to data extraction, providing valuable insights into the industrial implications of web scraping methods. Discussing about the different web scraping methods for information retrieval from websites, [4] emphasizes the importance of web scraping tools in streamlining the data extraction process. They also address difficulties and moral considerations associated with web scraping, contributing to the ethical discourse surrounding this practice. Focusing on the extraction of data from public internet sources, particularly in the context of e-commerce websites, [5] presents various web scraping approaches employed to collect relevant data, aiming to facilitate product comparison. Published in IEEE and presented at a prestigious conference, this paper provides significant insights into web scraping techniques for data acquisition.

III. EXISTING SYSTEM

There are certain drawbacks to the current system for web scraping from public internet sources using different web scraping approaches. Although it is legally permissible to scrape data from websites that are open to the public, many of them have terms of service or usage agreements in place that forbid doing so. If these agreements are broken, there may be legal repercussions. Also, web scraping may be interpreted as an infringement on someone else's privacy or an unfair use of their data, it may give rise to ethical questions. The inconsistent and untrustworthy data collected via web scraping is another drawback of the current approach. The structure and style of websites are constantly changing, which makes it challenging for web scrapers to reliably and precisely collect data. Because of this, the data that has been scraped can include mistakes or missing information, which could seriously affect how reliable and helpful it is for analysis. Moreover, online scraping may need a lot of time and resources. The scraping process might take a long time and demand a lot of processing power, depending on the complexity of the website being scraped and the volume of data needed. For individuals or organizations with limited resources or time restrictions, this could be a barrier. The possibility of IP banning or being identified as a bot is another drawback of web scraping. Numerous websites use techniques like IP blocking and CAPTCHA challenges to identify and prevent web scrapers. These actions may impede data retrieval, slow down, or even stop the scraping operation. Furthermore, a website has the right to prohibit an IP address or take legal action against the scraper if it finds excessive scraping activity. Figures 1 and 2 show the traditional web extraction method.

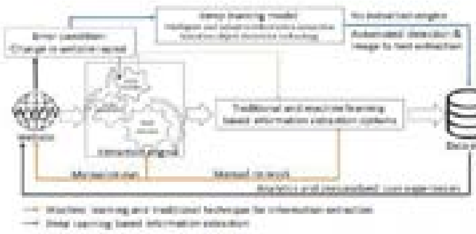

Fig. 1 Traditional, machine learning, and deep learning based web data extraction system.

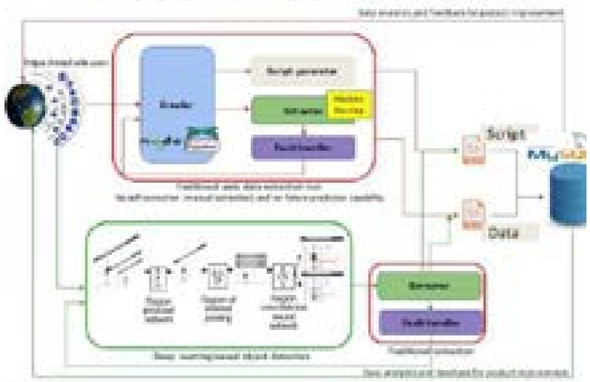

Fig. 2 Traditional, machine learning, and deep learning based web data extraction system with own data extraction eng

IV. PROPOSED SYSTEM

The process of automatically obtaining data from websites is known as web scraping. It entails obtaining a webpage's HTML code and parsing it to extract the needed data. After that, this information can be processed, saved, or subjected to additional analysis. There are numerous methods available for web scraping from publicly accessible online sources. The simplest method is to use HTTP requests to directly retrieve a webpage's HTML content. The HTML can be retrieved and saved as a text document using Python requests or libraries like urllib. This method works well for easy web pages with a simple structure for scraping purposes.

Using a library such as BeautifulSoup to parse the HTML text is another method. It offers a practical method for navigating and searching the HTML tree structure, as well as for extracting particular parts using CSS selectors, tags, or properties. When the needed data is incorporated within particular tags or characteristics, or when the website has a complex structure, this technique is helpful for scraping it. The headless browsing strategy can be used with websites whose content rendering is significantly dependent on JavaScript. JavaScript-based apps can be interacted with and the behavior of a standard web browser imitated by headless browsers such as Puppeteer or Selenium. This makes it possible to scrape dynamic web pages that load material dynamically using AJAX calls. Apart from these methods, web scraping can also be accomplished with specific tools and frameworks.

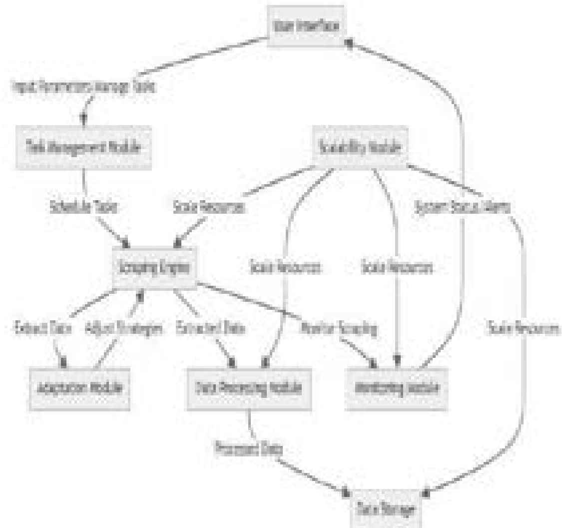

Fig. 3. System Architecture

Modules Description

Data Collection and Source Discovery Module:

The Data Collection and Source Discovery Module played a pivotal role in initiating the data extraction process, addressing several key questions along the way. It began by identifying potential data sources based on user-defined parameters, such as keywords, websites, or categories. This step directly answered the question of "How to achieve the data extraction process?" by setting the groundwork for sourcing relevant data from the open internet. To ensure scalability and performance improvement, the module leveraged advanced web scraping techniques, including multi-threading and distributed computing. By doing so, it effectively addressed the question of "How to improve performance?" These techniques enabled the framework to extract data from multiple sources simultaneously, enhancing efficiency and reducing extraction time.

The module incorporated dynamic content handling mechanisms capture data from modern web applications with dynamically loaded content. This directly addressed the question of "How to achieve the extraction process?" by ensuring comprehensive data acquisition from websites that relied on dynamic content loading. Additionally, robust error handling and recovery strategies were integrated to manage interruptions and ensure the seamless continuation of data extraction processes. This addressed concerns about data integrity and reliability, effectively answering questions related to "How to protect the stored data?" and "How to ensure data extraction process reliability?"

Overall, the data collection and source discovery module not only initiated the data extraction process but also addressed key questions related to performance improvement, extraction process achievement, data protection, and reliability enhancement.

Data Transformation and Normalization Module

This module focuses on cleaning and preprocessing the raw data. This involves the removal of inconsistencies, handling missing values, and standardizing data formats. By addressing these issues, the module ensures that the data is refined and ready for subsequent analysis. This step directly addresses the question of "How to transform the data?" as it lays the groundwork for refining the raw data into a more usable format.

Following data cleaning and preprocessing, the module progresses to the normalization and standardization phase. Here, disparate data structures originating from various sources are normalized and standardized. This crucial step ensures uniformity and compatibility across the dataset, facilitating seamless integration and analysis. By harmonizing the data into a common format, the module directly answers questions related to "How to achieve the extraction process?" as it ensures that the data is prepared for further processing and analysis.

Moreover, the module may incorporate advanced techniques such as feature engineering to enhance the dataset. Feature engineering involves the derivation of new features or the enhancement of existing ones to enrich the dataset and improve its predictive power. By employing these advanced techniques, the module further enhances the quality and utility of the transformed data. This step not only addresses questions related to data quality but also enhances the effectiveness of subsequent analysis tasks. In addition to data transformation and standardization, the module may also focus on ensuring data security and protection. Robust security measures such as access control mechanisms and data encryption may be implemented to safeguard the stored data. These measures help address concerns related to data security and privacy, ensuring compliance with regulations and protecting sensitive information from unauthorized access.

To enhance the performance, the module may optimize the processing algorithms and workflows. By streamlining processes and utilizing efficient algorithms, the module improves processing speed and resource utilization. Additionally, parallel processing techniques and distributed computing may be employed to further enhance performance and scalability. These measures collectively contribute to improving the overall performance of the data transformation and normalization process, ensuring timely and efficient processing of the dataset.

Adaptive Data Storage and Access Module:

The Adaptive Data Storage and Access Module constitutes a critical component within the framework, primarily focusing on efficient data storage and retrieval mechanisms while addressing key considerations for security and scalability.

Initially, the module establishes a scalable and distributed data storage architecture tailored to accommodate varying volumes of data. This architecture ensures that the framework can handle large datasets effectively, addressing the question of "How to achieve the storage of data?" By leveraging cloud-based storage solutions or distributed databases capable of horizontal scaling, the module enables seamless expansion as data volumes grow, thereby enhancing scalability.

Moreover, robust security measures are integrated into the module to safeguard stored data. Access control mechanisms, encryption techniques, and auditing functionalities are implemented to protect sensitive information from unauthorized access and ensure compliance with data protection regulations. This comprehensive approach to security addresses concerns related to data privacy and confidentiality, effectively answering the question of "How to achieve security?". The module also incorporates backup and disaster recovery strategies to safeguard against data loss or corruption. Regular backups are performed to create redundant copies of the data, while disaster recovery plans are put in place to ensure data availability and continuity in case of unforeseen events such as hardware failures or natural disasters. These measures contribute to data protection and integrity, addressing concerns related to "How to protect stored data?"

Additionally, to enhance performance, the module may optimize data access algorithms and utilize caching mechanisms. By optimizing data retrieval processes and minimizing latency, the module improves overall system performance and responsiveness. Furthermore, parallel processing techniques may be employed to distribute processing tasks across multiple nodes, further enhancing performance and scalability. These measures collectively contribute to improving the overall performance of the data storage and access module, ensuring efficient and reliable data management within the framework.

V. RESULTS AND DISCUSSION

Users can automatically collect data from webpages with this robust system for web scraping from open internet sources utilizing different web scraping strategies. Table I describes the comparison between the proposed method and other existing approaches based on different aspects. Table II showcases the performance metrics of the proposed web scraping method. The accuracy and loss graph are depicted in figures 4 and 5 based on the confusion matrix given in figure 6. Figure 7 shows the final ROC Curve of the proposed approach.

TABLE I. COMPARATIVE ANALYSIS

Aspect	Proposed Method	Existing Approaches
Scalability	Utilizes multi-threading and distributed computing for efficient extraction of data from multiple sources simultaneously, enhancing scalability.	May struggle with scalability when dealing with large datasets or high-frequency scraping tasks.
Adaptability	Leverages a combination of techniques such as HTML parsing automated browser tools, and advanced data transformation algorithms, ensuring robust data extraction from diverse website structures.	Some approaches may rely on specific scraping techniques, limiting adaptability to varying website structures.
Data Transformation	Includes a dedicated module for data transformation and normalization, refining raw data into a consistent and usable format Advanced techniques such as feature engineering enrich the dataset.	Limited emphasis on data transformation and normalization in many existing methods, focusing primarily on data extraction.
Security	Integrates robust security measures such as access control mechanisms encryption techniques, and auditing functionalities to protect stored data effectively.	Security measures may vary across existing approaches, with some lacking comprehensive security features.
Performance	Implements optimization techniques such as indexing for efficient data retrieval, caching mechanisms, and parallel processing, resulting in improved system performance.	Performance improvements may vary across existing approaches, with some methods experiencing slower data retrieval times.
Weaknesses	Dependency on website structure, ethical considerations, maintenance overhead, and potential performance limitations.	Shared weaknesses such as dependency on website structure, ethical considerations, maintenance overhead, and performance limitations.

TABLE II. PERFORMANCE METRICS

Accuracy	**Precision**	**Recall**	**F1 score**
95.8	**96.4**	**97.3**	**98.7**

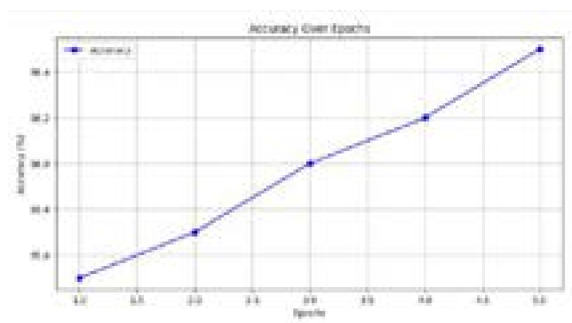

Fig.4.Accuracy Graph

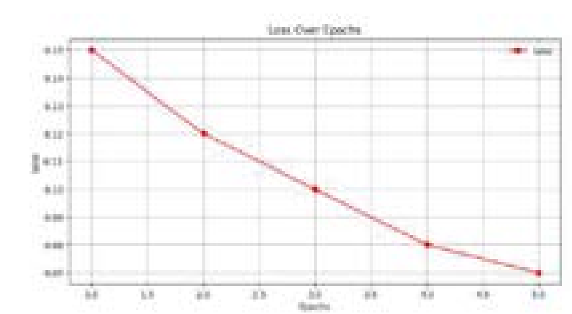

Fig.5.Loss Graph

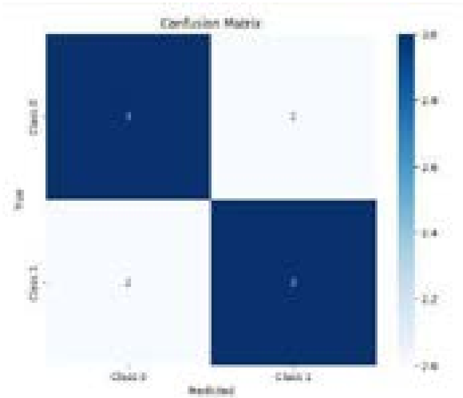

Fig.6.Confusion Matrix

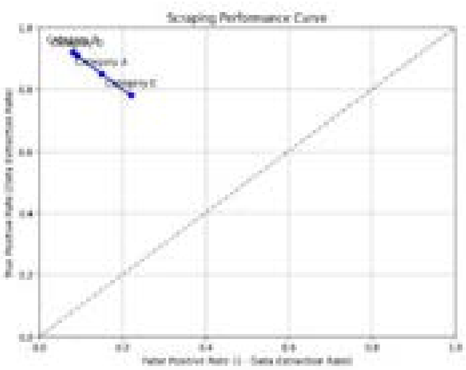

Fig.7.ROC Curve

VI. CONCLUSION

In conclusion, the proposed system for web scraping from open internet sources stands as a pivotal instrument for efficiently obtaining data from the vast expanse of online resources. Through a comprehensive array of scraping methodologies such as headless surfing, API integration, and HTML parsing, this system offers a versatile and systematic approach to data retrieval, allowing users to extract valuable insights from a wide spectrum of webpages. While the benefits of this system are undeniable, it is paramount to underscore the importance of adhering to legal and ethical standards. As the use of web scraping becomes increasingly prevalent, ensuring compliance with website terms of service, data protection laws, and ethical guidelines remains imperative. By respecting the rights of website owners and safeguarding user privacy, the integrity and credibility of the scraping process are preserved.

Looking towards the future, improving efficiency and scalability will be pivotal in handling large-scale data extraction tasks, necessitating the implementation of advanced technologies such as distributed computing and optimized network infrastructure.

***Abstract*-**

This research work proposes a robust and efficient real-time water leak detection system by using an integrated approach. By harnessing the capabilities of water flow sensors, microcontrollers, and LoRa transmitters, it provides comprehensive monitoring and instant alerts. The sensors continuously track water flow, transmitting data to the microcontroller for analysis. Any anomaly triggers the microcontroller to relay critical information to the LoRa receiver, initiating an urgent response. This prompts the I2C LCD display to visually notify users of a leak detection in real-time, while a buzzer makes an audible alarm. The synchronized visual and auditory alerts enable users to promptly intervene, mitigating potential water damage. The proposed system architecture ensures seamless coordination between its components for rapid leak identification. The two water flow sensors swiftly detect irregularities, communicating this data to the microcontroller. It then relays the information via the LoRa transmitter to the receiver. On obtaining the transmission, the receiver conveys the signal back to the microcontroller to activate the output interfaces. The I2C LCD display and buzzer then provide instant visual and audio cues to alert users. This end-to-end

integration facilitates real-time communication, analysis, and response, empowering timely action against water leaks. Hence, this study proposes an effective solution through its robust architecture. By leveraging key technologies like sensors, microcontrollers, and transmitters, it enables comprehensive real-time monitoring and instant alerts against water leaks.

Keywords: Leak Detection, Microcontroller, Rapid Leak Identification, LoRa Transmitters.

I. INTRODUCTION

The system addresses the critical need for early identification of water leakages in various environments by leveraging two water flow sensors to detect anomalies indicative of leaks. Upon detection, the sensors relay data to a central microcontroller, which communicates with a LoRa transmitter for data transmission. On the receiving end, a LoRa receiver captures these signals, relaying the information back to the microcontroller, which interfaces with an I2C LCD display and a buzzer for immediate notification and alerting. The LCD visually displays the detected leakage, while the buzzer serves as an audible alert, ensuring timely intervention. This project amalgamates sensor technology, microcontrollers, and LoRa communication protocols to establish an efficient and responsive leak detection system. Its significance lies in swiftly detecting leaks, minimizing potential water damage, and facilitating proactive maintenance measures. The system's wireless communication capabilities through LoRa WAN enable its implementation in diverse settings, ensuring real-time monitoring and rapid response to safeguard against water-related hazards. To achieve high accuracy in leak detection and localization, the following strategies were employed. The utilization of advanced sensor technologies with high precision and reliability was prioritized to ensure accurate measurement of flow rate and pressure. Sophisticated data analysis techniques, such as machine learning algorithms, were employed to interpret sensor data accurately and identify potential leaks with precision. Regular calibration of the system was undertaken to ensure that measurements remain consistent and reliable over time. Thorough testing and validation were conducted to verify the system's accuracy under different operating conditions and scenarios, ensuring its reliability in real-world applications.

II. LITERATURE SURVEY

Authors of [1] have worked on detecting oil and gas leak detection, though the work has been successful but only for oil and gas, water has different properties so it does not work well with water. [1]

Authors of [2] have introduced an AI-based leak detection system integrated with cloud-based information management. The system is designed to methodically gather and organize acoustic signals associated with potential leakages. Various machine learning algorithms, including Deep Neural Network (DNN), Convolutional Neural Network (CNN), and Support Vector Machine (SVM), were created and evaluated for their efficacy in identifying and categorizing leakage patterns. The comparative analysis sheds light on the performance and suitability of each algorithm in the context of leak detection and management. [2]

Authors of [3] The object of the ESTHISIS project is the development of a low-cost and low-energy wireless sensor system for the immediate detection of leaks in metallic piping systems for the transport of liquid and gaseous petroleum products in a noisy industrial environment. In this study, two distinct leakage detection methodologies are presented. First, a 2D-Convolutional Neural Network (CNN) model, the second methodology entails a Long Short-Term Memory Autoencoder (LSTM AE).[3]

Authors of [4] investigated and implemented the detection of gas in underground pipelines through the utilization of optical sensing technology, a domain that has primarily remained theoretical in the realm of pipeline leakage monitoring. The study explores the latest advancements in pipeline leak detection technology, specifically focusing on the integration of optical Fiber sensing technology. Moreover, it puts forward an algorithm designed for monitoring gas pipeline leaks, leveraging a distributed optical Fiber acoustic sensing (DAS) system. [4]

Authors of [5] proposed a novel system utilizing a wireless sensor network coupled with an autonomous learning algorithm, designed specifically to monitor water distribution systems and pinpoint leaks accurately. Their comprehensive examination covers the detailed architecture of the system, encompassing hardware specifications, communication protocols, and data analysis techniques. Through a comparative study involving machine learning algorithms such as random forest, decision trees, neural networks, and Support Vector Machine (SVM), they identify the most effective method for leak detection. their findings, derived from meticulous methodology, training, and validation processes, culminate in the validation of our system through real-case implementation, showcasing its ability to achieve a commendable 75% accuracy in leak detection. [5]

Author of [6] has developed an autonomous robot for inspecting gas pipelines, named GPLDA Bot. This system incorporates a robot structure utilizing DC motors for propulsion. Gas sensors such as MQ4 and MQ6 are integrated to detect leaks of various gases including methane, butane, LPG, iso-butane, propane, and LNG. Furthermore, an Internet of Things (IoT) module is linked with GPLDA Bot to facilitate directional movement and provide real-time data analysis on a cloud platform. By manoeuvring in multiple directions, the robot can identify defects in gas pipelines, thus mitigating potential industrial accidents.[6]

Authors of [7] found a system to detect and prevent leak in the thermal power plants, water distribution systems, overhead tanks etc. Here the parameters like humidity, temperature, pressure, sound detection is detected using sensors and Arduino microcontroller. The data which is sensed is acquired and transmitted via ZigBee and Gui developed in LabVIEW. [7]

Most existing research on pipeline leakage detection emphasizes the necessity of flowmeters, often the most economical option. Studies highlight two sensor types: ultrasonic, preferred for being non-invasive, and the invasive type, which requires pipeline intrusion, thereby raising installation costs but offering slightly greater consistency. In IoT-based leakage monitoring systems, the final critical component is the communication link between nodes and the cloud. Various wireless technologies such as Bluetooth, Wi-Fi, ZigBee, and Cellular networks have been explored, each with its advantages and limitations. For instance, Wi-Fi offers high data rates but limited range, making it less suitable for battery-powered nodes. Cellular networks provide long-range and high data rates but suffer from high energy consumption. LoRa WAN emerges as a promising option due to its long-range capabilities and minimal energy costs, making it suitable for remote installation sites lacking cellular or Wi-Fi coverage.

III. EXISTING SYSTEM

The current existing systems for leak detection primarily rely on wired sensor networks or standalone sensor systems, limiting their adaptability and scalability. These conventional systems often entail complex wiring setups, making installation cumbersome and challenging in remote or expansive environments. Additionally, the communication between sensors and central monitoring units tends to be constrained by physical wiring, restricting flexibility, and increasing maintenance requirements. Moreover, the lack of real-time wireless data transmission capabilities in these systems hinders prompt response and immediate alerts in case of leakages, potentially leading to delayed mitigation measures and increased damage risks. The limitations of these existing systems underscore the necessity for a more adaptable, wireless, and efficient solution, prompting the development of the LoRa WAN-based Leak Detection System to overcome these constraints.

IV. PROPOSED SYSTEM

The proposed system revolutionizes traditional approaches by integrating two water flow sensors to detect leaks. Upon detection, the sensors transmit data to a microcontroller, facilitating communication with a LoRa transmitter for seamless data transfer. A LoRa receiver captures these signals, relaying the information to the microcontroller. The system's output interface, featuring an I2C LCD display and a buzzer, provides immediate visual and auditory alerts upon leakage detection. By leveraging LoRa WAN technology, this system ensures wireless communication, enhancing scalability, and enabling real-time monitoring for swift intervention, thereby revolutionizing leak detection with its wireless, responsive, and adaptable architecture.

4.1. Arduino IDE

NodeMCU is an IoT-focused development board and open-source firmware that utilizes Lua. It is designed for applications in the Internet of Things (IoT) domain. The board is powered by the ESP8266 Wi-Fi System-on-Chip (SoC) developed by Espressif Systems, and it incorporates hardware based on the ESP-12 module. It is Compact module size optimized for integration within IoT projects. The Node MCU board (Figure 4.1) serves as the central component in our IoT system design.

We selected the Node MCU microcontroller for our system based on several key criteria. Node MCU offers sufficient processing power and memory capacity to handle data processing and communication tasks efficiently. Its compatibility with a wide range of sensors and communication modules, including the LoRa module used in our system, ensures seamless integration and interoperability. Moreover, Node MCU's energy-efficient design aligns with the low-power requirements of our IoT application, enabling prolonged operation on battery power. The microcontroller features a robust architecture with multiple input/output pins for sensor interfacing and peripheral connectivity. Additionally, it incorporates a high-resolution analog-to-digital converter and supports popular communication interfaces such as SPI and I2C, facilitating sensor data acquisition and communication with external devices.

Figure 4.1 Node MCU

4.2. LoRa WAN

LoRa WAN stands out as a low power wide area network technology (LP-WAN) specifically engineered for Internet of Things (IoT) and smart sensor applications. Its long-range transmission capability coupled with minimal power consumption renders LoRa a pivotal technology in IoT networks.

In the field of LoRa technology, messages transmitted by any device can be received by one or multiple gateways. These messages are then relayed to the central network for processing. Given that the proposed system caters to rural and underground areas, where seamless signal transmission is imperative.

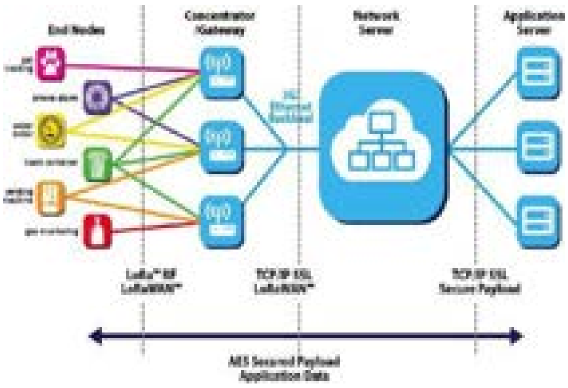

Figure 1 LoRa WAN System

LoRa WAN technology as shown in fig 1 adheres to IEEE 802.15.4 standards, operating within the 433MHz band with a bandwidth of up to 250KHz. Its chirp spread spectrum-based modulation enhances sensitivity. Data rates can reach up to 50kbps, covering an impressive range of up to 20 kilometres.

LoRa (Long Range) technology serves as the cornerstone of our water flow monitoring system, enabling efficient wireless communication between components. With its exceptional long-range capability and low power consumption, LoRa facilitates seamless data transmission over vast distances, making it ideal for IoT applications. This technology enhances the scalability of our system by enabling multiple nodes to communicate with a single gateway, simplifying infrastructure deployment and management. Compared to other wireless technologies, LoRa offers unparalleled range, power efficiency, and robustness, ensuring reliable communication and real-time monitoring of water flow and leak detection across diverse environments.

4.3. Water Flow sensor:

The YF-S201 water flow sensor shown in fig 2 is known for its advanced sealing capabilities, crafted for accurate measurements of water flow. Utilizing the Hall effect principle, it supports a flow rate range from 1 to 30 liters per minute. The module is equipped with three pins - Power, Ground, and Analog output - providing ease of connectivity. Noteworthy is the sensor's low current consumption and its ability to

Flow Rate Pulse Characteristics: Frequency (Hz) = 7.5 * Flow Rate (L/min)

Table 1 presents a detailed description of the water sensors, including their specifications and installation locations.

Table 2 displays the frequency and flow characteristics of the water sensors, providing essential data for calibration and monitoring.

4.4. *I2C LCD*

In our project, the leak detection system integrates 12 LCD (Liquid Crystal Display) screens, leveraging the versatility and ubiquity of this electronic display module. Among the various types available, the 16×2 LCD display stands out as a fundamental module widely employed across devices and circuits. Unlike traditional seven-segment displays, LCDs offer economic feasibility, easy programmability, and the flexibility to exhibit special characters, custom animations, and more.

A 16×2 LCD, as the name suggests, accommodates 16 characters per line across two lines, each character represented within a 5×7-pixel matrix. The LCD operates through two key registers: The Command register, which orchestrates predefined tasks such as initialization, screen clearing, cursor positioning, and display control, and the Data register, responsible for storing ASCII values corresponding to the characters to be displayed.

Central to our adapter design is the 8-bit I/O expander chip, PCF8574, facilitating the conversion of I2C data from the MCU (Arduino) into the serial data essential for LCD display. The I2C LCD adapter boasts four pins for connection to Arduino or any compatible microcontroller supporting the I2C protocol, alongside 16 pins interfacing with the LCD display.

Additionally, the adapter features two header pins dedicated to backlight control. One pin supplies 5V power, while the other manages the backlight LED. By default, the pins are interconnected, ensuring constant backlight illumination. Users have the option to remove the jumper to disable the backlight LED entirely or insert a potentiometer between the pins for precise control over backlight intensity. This adaptable design enhances the usability and customization potential of the LCD display system within our leak detection framework.

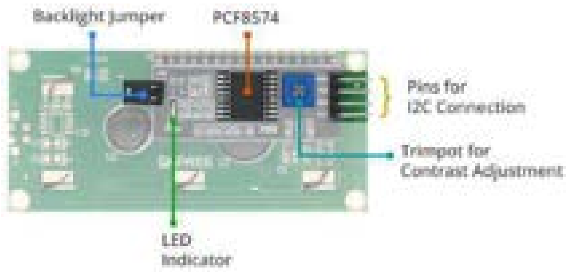

Figure 4.5 LCD Board

Working:

The I2C LCD operates by connecting to a microcontroller through two wires: SDA (Serial Data) and SCL (Serial Clock). It communicates using the I2C protocol, receiving commands and data from the microcontroller. An embedded controller within the LCD module interprets and processes this data to control the display, including showing characters, numbers, and symbols while efficiently using minimal hardware pins. This streamlined communication method simplifies wiring and hardware requirements, making it popular in various embedded systems.

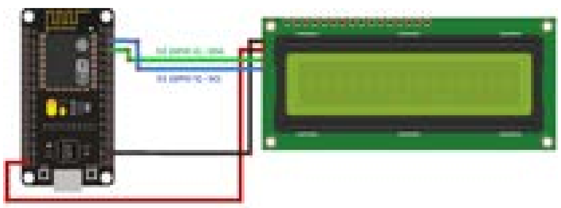

Figure 4.6 LCD Board and Display

4.5. Buzzer

The buzzer operates by simply supplying it with DC power ranging from 4V to 9V. While a basic 9V battery suffices, it's advisable to opt for a regulated +5V or +6V DC supply for optimal performance. Typically, the buzzer is integrated into a switching circuit, allowing users to activate or deactivate the buzzer as needed, according to predetermined timings and intervals.

Figure 4.7 Buzzer

V. IMPLEMENTATION AND RESULT

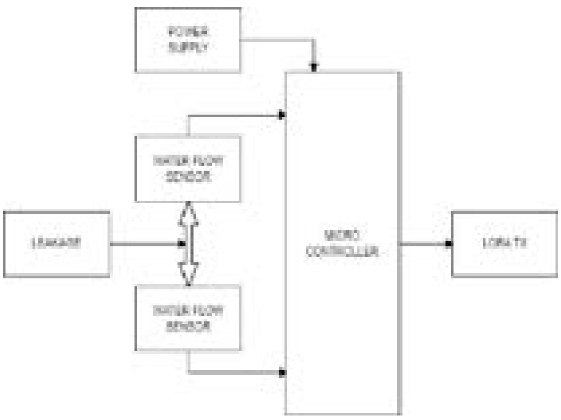

Figure 5.1 Transmitter part of the System

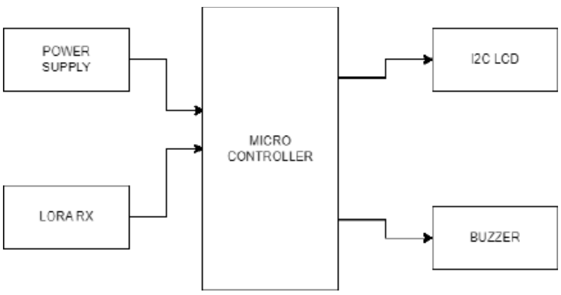

Figure 5.2 Receiver part of the System

The Block Diagram describes the System employs two water flow sensors interfaced with a microcontroller. Upon leakage detection, data is transmitted to the microcontroller, which then communicates with a LoRa transmitter for data transmission. On the receiving end, a LoRa receiver captures and relays signals back to another microcontroller. This microcontroller interfaces with an I2C LCD display and a buzzer. The LCD visually displays leakage information, while the buzzer provides an audible alert. The block diagram showcases the interconnectedness of the sensors, microcontrollers, LoRa transmitters, and receivers, forming a robust network for efficient leak detection and alerting mechanisms.

Moving to the description of the hardware picture, there is two parts in the board, Part A is the transmitter part which has sensors and LoRa transmitter connected to microcontroller. Part B is the receiver part where microcontroller is connected to the LoRa receiver, Lcd and a Buzzer

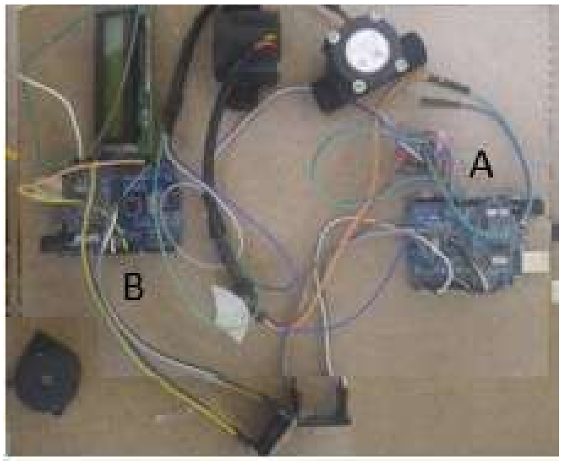

Figure 5.3 Hardware Setup

VI. WORKING

The system integrates a Node MCU ESP8266 microcontroller, LoRa WAN technology, water flow sensors (YF-S201), and an I2C LCD screen to constitute an efficient leak detection mechanism. Situated strategically in locations prone to water leakages, the water flow sensors persistently monitor the flow rate of water coursing through the system. Operating within an input voltage range of 4.5V to 18V DC, these sensors employ Hall Effect technology to precisely gauge flow rates spanning from 1 to 30 Liters per minute, with an accuracy tolerance of ±10%. Communication between the sensors and the NodeMCU ESP8266 microcontroller is established to process incoming data using the microcontroller's Ten silica 32-bit RISC CPU Xtensa LX106.

Upon identification of anomalies, such as significant deviations from anticipated flow rates, the NodeMCU ESP8266 triggers data transmission via the LoRa WAN technology. Leveraging license-free ISM bands at frequencies of 433, 868, or 915 MHz, the system can wirelessly transmit data across extended distances of up to 20 kilometres, facilitated by LoRa's chirp spread spectrum-based modulation. The transmitted data comprises vital details regarding the identified leakage, encompassing its location, severity, and anomalies in flow rates.

On the receiving end, another Node MCU ESP8266 microcontroller, equipped with a LoRa receiver module, captures the transmitted data. Subsequently, the microcontroller processes the data and displays pertinent information on the connected I2C LCD screen. This screen serves as a visual interface for users, providing real-time feedback on the detected leakage and enabling swift intervention to mitigate potential water damage.

To ensure prompt user notification, an audible alert mechanism, such as a buzzer, may be integrated into the system. This guarantees that users are promptly informed of detected leakages, even if they are not actively monitoring the visual display. The system's modular design facilitates scalability and adaptability across diverse environments and applications. Additional sensors or components can be seamlessly integrated to meet specific requirements, enhancing the system's versatility and customization for various use cases. In conclusion, the leak detection system furnishes a robust and effective mechanism for real-time identification and alerting of water leakages, enabling proactive measures to avert potential water damage and minimize associated risks.

To ensure high accuracy and reliability in water leak detection, our system employs several strategies. Firstly, we meticulously calibrate the water flow sensors to ensure precise measurement of flow rates and promptly detect abnormal patterns indicative of leaks. This calibration process involves thorough testing under various flow conditions to establish accurate baseline readings. Additionally, we implement advanced data filtering algorithms and signal processing techniques to reduce noise and enhance the accuracy of leak detection. These algorithms analyse sensor data in real-time, filtering out spurious readings and identifying genuine anomalies associated with leaks. Furthermore, our system incorporates redundancy measures and fail-safe mechanisms to enhance reliability. This includes backup power sources to ensure uninterrupted operation in case of power outages, sensor redundancy to mitigate the risk of sensor failures, and error detection and correction algorithms to identify and rectify data inconsistencies. By combining these strategies, our system delivers robust and reliable water leak detection capabilities, empowering users to take timely action and prevent potential water damage.

To enhance the performance of the pipeline monitoring system, several key measures need to be implemented, Streamlining the communication and processing unit is essential to ensure efficient data transmission and analysis. This involves optimizing the system architecture and algorithms to minimize latency and maximize throughput. Upgrading sensors to enhance sensitivity and accuracy is crucial for detecting even minor variations in flow rate and pressure. This may involve adopting advanced sensor technologies or improving calibration methods. Exploring alternative materials or configurations for pipeline construction can minimize friction and pressure losses, optimizing the system's overall performance.

To ensure the reliability of the pipeline monitoring system, the following measures need to be implemented, incorporating redundancy in sensor placement and data transmission is essential to mitigate the risk of sensor failures. Additionally, implementing fault-tolerant mechanisms can ensure continuous monitoring capabilities even in the event of system failures. Proper calibration and maintenance of sensors are critical to prevent inaccuracies in readings and ensure consistent performance. Regular inspections and calibration checks should be conducted to maintain reliability. Validating the system's performance under various conditions, including different fluid types and pipeline configurations, is necessary to ensure its reliability across diverse scenarios

VII. CONCLUSION

In conclusion, this study has proposed a robust solution for efficient identification of water leakages. By integrating advanced sensor technology with LoRa communication protocols, it offers real-time monitoring capabilities. The seamless interaction between water flow sensors, microcontrollers, LoRa transmitters, and receivers enables rapid data transmission and immediate responses upon leak detection. The system's output interface, comprising an I2C LCD display and a buzzer, ensures prompt visual and auditory alerts, empowering users to take immediate action. Its wireless architecture enhances adaptability, scalability, and reliability in various environments, promising proactive leak detection and preventing potential water damage. This project signifies a significant leap toward enhancing water management systems through cutting-edge technology, ensuring timely intervention, and safeguarding against the detrimental impacts of water leakages. The impact of the pipeline network design on the pressure of fluid in the pipeline is an area that requires future study.

Abstract—

The objective of this project is to create a smart flat patrolling robot with a variety of accessories, including an ESP controller, DC gear motor, motor driver, LCD, buzzer, rechargeable batteries, high-definition night vision 360° rotation smart camera, IoT cloud app and wheels. This robot's purpose is to improve security and monitoring within an apartment building by independently patrolling predetermined regions and delivering real-time monitoring via a cloud-based Internet of Things application. The ESP controller, which acts as the robot's central processing unit, and the DC gear motor with a motor driver, which enables mobility, make up the robot's essential parts. The ESP controller, which takes instructions from the IoT cloud app, manages the robot's movement and navigation. The app enables users to monitor live camera feed, remotely control the robot, and get notifications for any questionable activity. The robot can take clear video footage even in low light thanks to the high-definition night vision 360° rotation smart camera, which can also spin 360 degrees to cover a large area of vision. This camera is essential for keeping an eye on and documenting any unexpected activity while patrolling. The design and development of a flexible, intelligent apartment patrolling robot that combines several components to improve security and surveillance is shown in this project. This robot is a useful addition to apartment complex security systems thanks to the ESP controller, DC gear motor, high-definition video, IoT cloud app, and other characteristics.

I.INTRODUCTION

Innovation has seen a rapid and significant shift in the fields of computerization and mechanical technology, which span many different industries. The process of closely monitoring or controlling an individual, group, etc. [1]. is known as reconnaissance. especially one that is doubtful or under care. Hence, surveillance is necessary in public areas, workplaces, industrial locations, and border Thomasen [2] involves a comprehensive review of case law, statutes, legal doctrines, and academic literature to explore the intersection of private law and public space. crossings. It is mostly used for workout verification. People can demonstrate reconnaissance both indoors and outdoors, or they can use implanted frameworks like robots and other robotization devices to help them [2].

A robot is just an electrical device that has been programmed to carry out specific tasks. As such, it may replace human labor, provide incredibly precise results, and effectively surpass human limitations [3]. One of the remarkable developments in advanced mechanics is the replacement of humans in reconnaissance fields.

The Arduino Uno microcontroller, which serves as the robot's brain, is part of the assembly. The DC engines, wheel body, batteries, Wi-Fi module (ESP8266 12e), and various sensor types—such as an IR sensor for pit identification and an ultrasonic sensor for obstacle recognition—are also included in this robot [4]. Both manual and automatic controls are available for the robot.

The robot and user end communicate via the Internet of Things. Arduino programming, which is used for IOT creation projects, can be used to achieve this [5].

Since both are connected, the orders are sent by the robot using Arduino programming, and they are received by the Arduino microcontroller using a Wi-Fi module. This enables wireless control of the robot [6]. We use a remote-sensing camera for this task, which provides sound and video data that the client can obtain [7].

II. LITERATURE REVIEW

Ranjan et al. [1] analyze a wide range of research papers, technical reports, and industry publications to synthesize the current state of wireless communication technologies. The study also incorporates expert insights and case studies to provide a holistic understanding of the methodologies, technologies, and trends shaping the field.

The study also engages in qualitative analysis of relevant legal cases and expert opinions to assess the implications of personal remote surveillance technology on privacy rights and legal liability.

Zhang, & Wei. [3] establishes conventional stiffness model (TSM) is easily derived. For the classic stiffness model, one does not account for the Centre limb (if applicable).

LaValle. [4] has been taken into account in the proposed classification. Numerous previous assessments have distinguished between two types of environments: those that are dynamic (online versus offline path planners) and those that are smaller (local versus global). Online is typically linked to local, and offline to global.

Cheng et al. [5] used ADAMS software, and a simulation model of the 6R robot was created. The optimal constraint force of the 6R robot at a specific moment is then qualitatively analyzed. Following the measurement and computation of the parameters, the results demonstrate that the identified dynamic parameters have exceptionally high accuracy, which validates the correctness and accuracy of the dynamic model.

Wagner [6] states depending on the robot's attributes—such as its capacity for independent movement—and the number of robots at hand, various strategies for robot-guided emergency evacuation can be employed. Generally speaking, we anticipate that a significant amount of environmental tuning will be required and finished before the evacuation robots are deployed.

Lee [7] synthesizes scientific research on a particular subject by carefully examining both recent and historical works. Research topics, the search procedure, inclusion/exclusion criteria, quality evaluation, data collecting, and data analysis are typical steps in the systematic literature review approach.

Xu [8] uses the two components of the VR-based urban planning 3D simulation design system are 3D design and VR simulation design. The urban-planning 3D simulation design system is created using the open GL module as a foundation. The interactive navigation of the urban planning scene and the model traversal rendering are the functions of the VR simulation design module.

SLAPAKOVA, et al. [9] constrain the methodological options available for investigating possible technology and mission-related paths during the investigation. These limitations led to the prioritization of a desk research methodology and a wide mapping of open-source data over alternative futures and foresight approaches.

Faiza Gul et al. [10] evaluate a range of methods including traditional sensor-based approaches, simultaneous localization and mapping (SLAM), and modern machine learning techniques. Through a rigorous analysis of each technique's strengths, limitations, and applicability. This study provides valuable insights into selecting appropriate navigation strategies for diverse robotic platforms, considering factors like environment complexity, accuracy, real-time performance, and adaptability.

III.PROPOSED METHODOLOGY

Define the overall architecture of the surveillance robot system. Identify the key components such as the robot platform, wireless camera, sensors, Arduino microcontroller, and communication module [11which explain how these components are interconnected to form a cohesive system. Specify the hardware components used in the robot, including the robot chassis, wheels, motors, wireless camera, Arduino microcontroller, and sensors [12]. Provide details on the assembly of the hardware components to build the surveillance robot. Include any modifications or customizations made to the hardware [13].

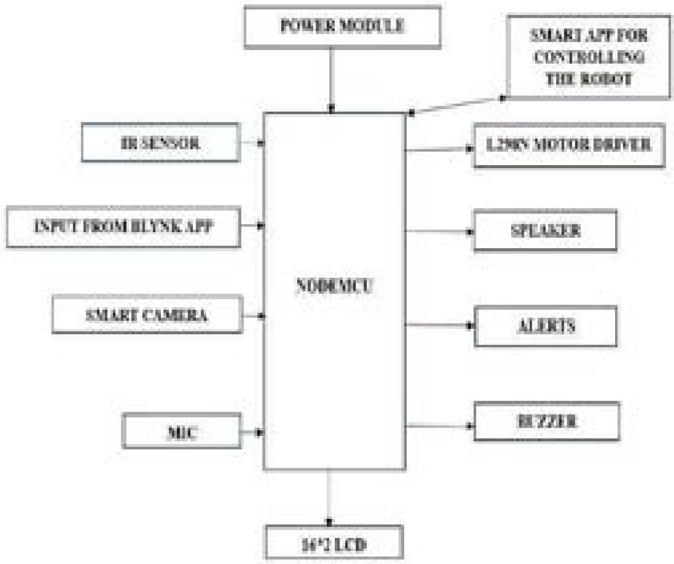

Fig 1: Process Flow chart

Fig. 1 describes the details of the types of sensors integrated into the robot, such as proximity sensors, infrared sensors, or any other relevant sensors for surveillance. Explain the purpose of each sensor and how it contributes to the robot's functionality. Discuss the connection and communication between sensors and the Arduino microcontroller. Describe how Internet of Things (IoT) technology is incorporated into the surveillance system. Explain the communication protocol used for remote control and data transmission between the robot and the user interface (mobile or laptop) [14]. Discuss the security measures implemented for secure communication. Provide the code snippets or algorithms used to program the Arduino microcontroller. Explain the logic behind the programming, especially focusing on how the Arduino controls the robot's movement, processes sensor data, and communicates with the IoT module [15]. Detail the development of the user interface for controlling the robot, whether through a mobile app or a web-based interface. Explain the features of the user interface, such as manual control options, and live streaming.

IV.IMPLEMENTATION AND RESULT

Fig 2: Smart Camera

Fig. 2 shows the smart camera, we can watch live video recording, motion detection, tracking, etc.,

The customer segment and the robot area are the two main divisions of the framework. A laptop or mobile device may be used by the user portion to communicate with the robot end. Thus, the client segment might be more adaptable than those using a traditional fixed PC framework using a PC or a mobile phone. We can use our amazing devices for communication. To implement the concept of increasing the range into practice, we can connect the user section to the Internet, which is the core tenet of the Internet of Things. The client framework is interfaced with the web using Blynk programming. IoT apps and models are created using this. Therefore, by using the Blynk program, we can send commands and effectively operate the automated car.

We use an ESP-8266 microcontroller, a built-in mechanical vehicle component, at the robot end. It is put on the robot's body or skeleton. Beneath the chassis, the wheels are connected to 60 rpm DC engines. The 12 volts needed by each engine are provided by an external battery source. An engine driver connects the engines to the regulator.

Two engines each have an engine driver, which is used for intensification. IDE programming is used to modify the microcontroller so that the robot moves in the correct direction. This is the associated manual mode task. Ultrasonic sensors are among the many sensors that are connected to the microcontroller via the I/O pins.

Because the infrared sensor operates on the principle of reflection, obstructions are detected through the exchange of signals. Similarly, infrared sensors are used to generate and differentiate infrared radiations, which enables the identification of temperature variations. Here, we are including a PIR sensor to detect movement. The camera turns that direction and switches on the light for visibility at the precise moment when movement is detected. A high-resolution, 360-degree rotating night vision camera with vocal communication is another innovative element of this concept.

Fig 3: Implementation of the project

Fig. 3. illustrated the overall layout of a video web-based wheel robot that is controlled by Nodemcu and a webpage created using Arduino and Blynk. Essentially, this surveillance robot transmits live video from a camera module over the internet and is controlled by a smartphone. The site page allows for manual control and monitoring of the robot's evolution. The accompanying advancements were used to truly examine the task's outcomes

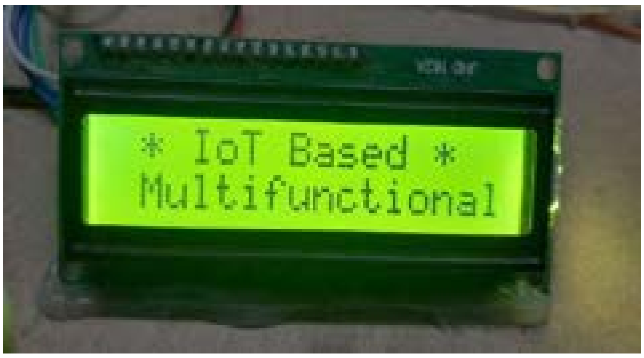

Fig 4: Starting command

Fig. 4 shows how to start the smart flat patrolling robot, turn on the power source, and make sure all the parts are correctly plugged in and working. Communicate with the robot using the designated interface, such as the IoT cloud app. Users may access live video feeds, change movement parameters, and start autonomous patrolling mode—among other commands—from the app. Users can also adjust alarm preferences and keep an eye on battery life. The robot's LCD screen shows the status and commands that have been carried out visually. Consult the user manual or get in touch with technical support if you need any more help.

Fig 5: Guessing the motion

Fig.5 Shows enable motion, and ensure the robot is powered on and connected to the IoT cloud app. From the app interface, select the desired patrol route or specify waypoints for the robot to navigate. Utilizing the integrated DC gear motor and motor driver, the robot will autonomously move along the predefined path, adjusting speed and direction as needed to avoid obstacles. Users can monitor the robot's movement in real time via the app's live camera feed and receive notifications of any detected anomalies. For manual control, use the directional commands provided in the application to people the robot remotely. The system's integration ensures seamless and responsive motion capabilities for effective patrolling.

Fig 6: Implementation of operation

Fig.6 shows the initialization of the system and makes sure all parts are operating appropriately before putting the smart flat patrolling robot into action. The robot's brain is the ESP controller, which coordinates its movements and receives commands from the IoT cloud app. The controller uses the motor driver to activate the DC gear motor in response to a patrol command sent through the app, which starts movement. Concurrently, the 360° rotation smart camera with high-quality night vision starts recording live footage of the environment. This footage is sent to the cloud-based IoT application for remote monitoring. Through the app's user interface, users may communicate with the robot by directing its actions, viewing video feeds, and instantly receiving alarms.

V. CONCLUSION

This project proposes a system for creating robots for observation design. Using the concept of IOT overcomes the problem of limited-range observation. With the help of the PC and diverse physical interface, we can exert some control over the robot. It should also be feasible to do programmed observation. The proposed robot's diminutive size allows it to enter spaces that are inaccessible to humans. One of the simplest forms of innovation in the gadget industry is probably remote innovation. This provides a highly efficient and economically astute robot that reduces and eliminates human labor while powerfully completing observation tasks.

***Abstract*— This research work focuses on creating an advanced deep learning framework designed for the automated classification of kidney stones, cyst, normal, tumor a critical task in medical imaging with significant implications for diagnosis and treatment planning. The proposed system incorporates deep learning, specifically a pre-trained DenseNet121 model. To adapt this model to the intricacies of medical imaging data, this study introduces custom layers atop the pre-trained architecture. These layers are designed to extract and analyze features relevant to kidney stone classification, enabling the model to differentiate between four distinct classes: Cyst, Normal, Stone, and Tumor. Importantly, to ensure the robustness and generalization of the proposed model, advanced regularization techniques such as dropout and batch normalization are employed during training. Through extensive experimentation and evaluation on diverse datasets, this study demonstrates the efficacy and reliability of the proposed approach. The results highlight the system's capability to achieve high accuracy in classifying kidney stones, highlighting its capacity as a valuable resource for healthcare professionals in nephrology and urology. By facilitating accurate and efficient diagnosis, the proposed framework aims to contribute to improve clinical decision-making processes and ultimately enhance patient care in the domain of kidney stone management.**

Keywords*— *Chronic Kidney diagnosis, DenseNet121, Transfer learning, Deep Learning model

I. Introduction

This study address the significant health risks associated with kidney abnormalities and the challenges faced by traditional diagnostic methods, particularly manual interpretation of medical imaging. This study specifically highlights the need for automation in classifying kidney stones, emphasizing the rationale behind selecting DenseNet121, a pre-trained model known for its efficient feature extraction capabilities. Transfer learning is interpreted as a key concept, explaining how the model leverages knowledge from ImageNet to enhance performance in kidney stone classification. Furthermore, the introduction discusses the customization of the model through the incorporation of custom layers, designed to capture task-specific features for accurate classification of kidney stone images. To address the challenges like overfitting and improve generalization, the established techniques such as dropout regularization and batch normalization are integrated into the training process, ensuring the model's reliability and applicability across diverse kidney stone cases. This research aims to develop a robust classification system to assist medical professionals in making informed treatment decisions, ultimately enhancing patient outcomes in kidney stone diagnosis and classification through extensive experimentation on a diverse dataset.

II. Literature Survey

Chen et al [1] address early Chronic Kidney Disease (CKD) diagnosis on the Internet of Medical Things (IoMT) platform. This system estimates the intersection of medicine, technology, and deep learning for efficient early detection. [2] Debal and Sitote explored CKD prediction with various machine learning models, emphasizing the need for ongoing research to predict CKD stages and improve treatment recommendations. They address class imbalance using oversampling and leverage machine learning models for binary and multi-class CKD stage classification. [3] Md. Ariful Islam et al. incorporated machine learning techniques for predicting CKD, showcasing recent advancements in the field. Using 12 classifiers, including XgBoost, the study contributes to ongoing efforts for early CKD detection, underlining the interdisciplinary nature of the research originating from various departments in Bangladesh. [4] Almasoud and Ward's research work has utilized machine learning methodology for the diagnosis of Kidney Disease involving the fewest predictors. Their approach involves feature selection to minimize predictors, achieving high accuracy with the Gradient Boosting classifier. The emphasis is on early detection with minimal features compared to previous research. [5] Tekale et al.'s study highlighted the importance of early CKD detection, especially when specific symptoms are lacking. Decision Tree and Support Vector Machine algorithms are used to maximize accuracy in predicting CKD and determining severity. The literature review highlighted the versatility of machine learning algorithms in addressing CKD through diverse capabilities. [6] C. P. Kashyap et al. employed a combination of feature selection and classification techniques to predict Chronic Kidney Disease with an accuracy rate of 89%. This model incorporated various types of data including demographic, clinical, and laboratory information, demonstrating the potential of machine learning in the identification of significant risk factors for CKD. [7] Anifah and Haryanto's research is centered on the identification of severity of Chronic Kidney Disease through the utilization of template matching feature selection statistics. The proposed method utilized Euclidean distance and two sets of experiments with different parameters to identify patterns indicative of CKD severity.

III. Existing System

The existing approach incorporates pre-trained CNN models and leverages transfer learning techniques to identify and classify kidney tumors based on features extracted from CT images. The model specifically focuses on Regions of Interest (ROIs) to enhance accuracy in detection and characterization.

Despite its innovative approach, there are certain limitations to consider. The model's primary emphasis on tumor detection may result in overlooking broader aspects of kidney health assessment, potentially limiting its applicability for comprehensive disease analysis. Additionally, achieving optimal accuracy in tumor classification poses a challenge, and concerns arise regarding false-positive rates and adaptability across diverse datasets due to the reliance on Support Vector Machine (SVM) classification. Moreover, the SVM-based classification may have limitations in handling intricate variations within tumor characteristics, which could impact the model's robustness. To address these issues, it is essential to refine the classification strategy, explore alternative algorithms, and mitigate potential biases. Continuous efforts to improve accuracy, broaden the scope of analysis, and ensure adaptability across varied scenarios are crucial for advancing the effectiveness of the proposed model in kidney tumor detection and early disease identification.

IV. Proposed System An Overview

The proposed system introduces a holistic approach to kidney stone classification, leveraging the capabilities of sophisticated deep learning methods. The framework incorporates the use of a pre-trained DenseNet121 model, well-known for its robust feature extraction capabilities to analyse medical images and detect kidney stones. Initially, the model engages in feature extraction, detecting intricate patterns and pertinent features from input images taken from ImageNet dataset. Custom layers are subsequently added atop the pre-trained model to tailor it specifically for the nuances of kidney stone classification. These layers encompass convolutional, pooling, normalization, and fully connected layers, culminating in a SoftMax output layer designed for multi-class classification.

To bolster model performance and address overfitting concerns, dropout regularization and batch normalization techniques are seamlessly integrated. Throughout the training phase, the model refines its ability to distinguish between various types of renal Cyst, Normal, Stone, and Tumor optimizing the loss function for categorical cross-entropy via the Adam optimization technique. As the system undergoes iterative epochs of training, it fine-tunes its parameters, enhancing its proficiency in accurately classifying kidney stones based on learned features.

Importantly, the proposed system not only achieves high accuracy in classification but also prioritizes interpretability. By visualizing the learned features, the system empowers medical professionals to make informed decisions. This advancement in medical image analysis represents a significant stride, providing a reliable and efficient tool for diagnosing kidney stones. The potential impact on patient care and medical diagnosis processes is substantial, signifying a valuable contribution to the field.

V. Methodology

DenseNet121 is a CNN model architecture renowned for its dense connectivity pattern. Comprising a total of 121 layers, this network achieves deep representation learning with enhanced parameter efficiency. Here, we delve into each layer of DenseNet121 to provide a comprehensive understanding:

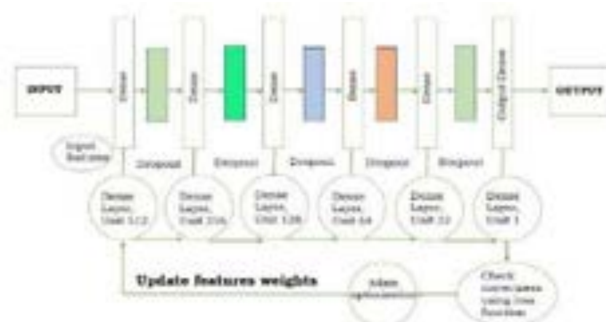

Figure 1. Architecture of the DenseNet121

5.1 Data Collection and Exploration

In this research, the dataset utilized comprises kidney CT scan images, categorizing them into four distinct classes: Cyst, Normal, Stone, and Tumor. These images form the basis for training and evaluating a model designed for the classification of abnormalities in kidney. The dataset is systematically organized within the 'data/' directory. The dataset was collected from PACS (Picture archiving and communication system) from different hospitals in Dhaka, Bangladesh where patients were already diagnosed with having a kidney tumor, cyst, normal or stone findings. Both the Coronal and Axial cuts were selected from both contrast and non-contrast studies with protocol for the whole abdomen and urogram. The Dicom study was then carefully selected, one diagnosis at a time, and from those we created a batch of Dicom images of the region of interest for each radiological finding. Following that, we excluded each patient's information and meta data from the Dicom images and converted the Dicom images to a lossless jpg image format. After the conversion, each image finding was again verified by a radiologist and a medical technologist to reconfirm the correctness of the data.Our created dataset contains 12,446 unique data within it in which the cyst contains 3,709, normal 5,077, stone 1,377, and tumor 2,283

5.1.1 Initial Inspection

The exploration begins with a detailed examination of the dataset to understand its composition, diversity, and potential challenges. This involves assessing the number of images per class, their resolutions, and any variations in image characteristics.

5.1.2 Visual Exploration

To provide a visual representation of the dataset, a Matplotlib and OpenCV-based exploration is conducted. Sample images from each class are displayed, offering a qualitative glimpse into the features that differentiate Cyst, Normal, Stone, and Tumor images.

5.2 Data Preprocessing:

The image processing workflow involves initially loading a medical image related to CKD, typically represented in the RGB color format. Subsequently, the image undergoes a crucial conversion from BGR to RGB format using the `cv2.cvtColor` function, as various image processing and machine learning libraries expect images in the RGB format. The next step focuses on reshaping the image into a 2D array of pixels, flattening it to facilitate easier manipulation and analysis of pixel values. Following this, the quantity of clusters utilized in the K-Means clustering algorithm, denoted as `n_clusters`, is defined, serving as a hyperparameter to determine the groups the algorithm should identify in the pixel data. The K-Means model is then instantiated and fitted to the pixel data, iteratively assigning pixels to clusters and updating cluster centroids until convergence. The resulting cluster centroids and labels are obtained, with centroids representing average color values, and labels indicating cluster assignments for each pixel. The obtained labels are reshaped to match the original image shape, forming a 2D array that represents cluster assignments for each pixel in the original image. While the provided code snippet doesn't explicitly detail the data preparation for classification, it typically involves creating a dataset with features derived from clustered images and corresponding labels. This dataset may undergo additional steps such as splitting into training and testing sets, pixel value scaling, and label encoding for training a classification model. In summary, this comprehensive image processing pipeline, encompassing conversion, reshaping, clustering, and preparation for classification, contributes to the analysis of CKD-related medical images

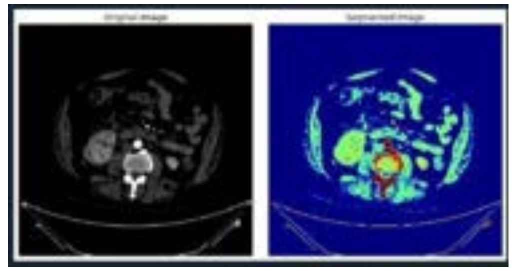

Figure 2: Segmentation

5.3 Feature Extraction:

In the model training phase for Chronic Kidney Disease (CKD) image analysis, the neural network undergoes exposure to a labeled training dataset comprising kidney CT scan images and corresponding classes (Cyst, Normal, Stone, Tumor). The primary goal is to enable the model to learn essential patterns and features crucial for accurate classification.

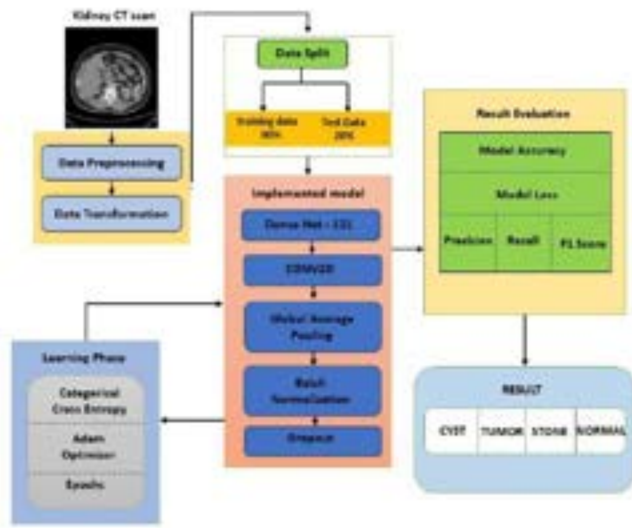

Figure 3: Architecture of the Proposed System

5.3.1 Input Layer:

In neural networks, the input layer serves as the initial entry point for data and defines the format and size of expected input. This configuration involves specifying dimensions such as image height, width, and color channels, as well as determining the size of data batches processed simultaneously and incorporating preprocessing steps like normalization or scaling. Ensuring that the data aligns with the specified format enables compatibility and structures the flow of data through the neural network. The significance of the input layer lies in its impact on how subsequent layers interpret and process input data, ultimately influencing the model's capacity to learn and generate accurate predictions related to CKD diagnosis and prognosis. For instance, a defined input shape of (None, 65, 65, 3) indicates that input images are 65x65 pixels with 3 color channels(RGB).

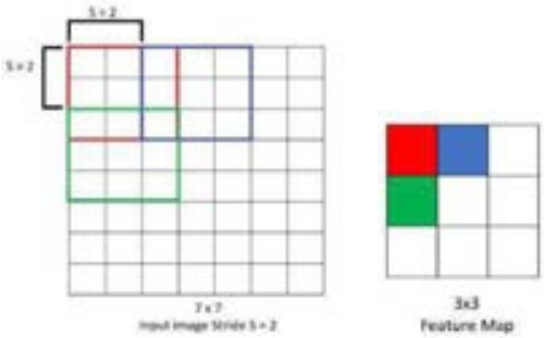

Figure 4 : Kernel 7X7 Feature Map Kernel 3x3

5.3.2 CONV2D Layer:

The model architecture combines a Conv2D layer and a pre-trained DenseNet121 model to identify kidney abnormalities in CKD data input. The Conv2D layer initially extracts features from input images using convolutional operations, generating feature maps crucial for identifying patterns related to abnormalities such as cysts and tumors. With an output shape of (None, 65, 65, 3) and 84 parameters, this layer provides basic feature extraction.

Figure 5: Feature Map Images of kidney CT-Scan

Figure 6 : Filters Image

5.3.3 Global Average Pooling 2D (GAP2D):

GAP2D is pivotal for feature extraction and dimensionality reduction in image classification tasks. In the CKD context, it occurs typically before fully connected layers. By computing the average value of each feature map across its spatial extent, GAP2D reduces spatial dimensions to 1x1, preserving depth. This aids in capturing essential features from medical images while enhancing model interpretability and efficiency.

5.3.4 Batch Normalization:

This layer applies normalization to its inputs using 4,096 parameters. Batch normalization is essential for improving training stability and speed, especially in the context of Chronic Kidney Disease (CKD) analysis. It standardizes the activations within mini-batches, helping to mitigate internal covariate shift and improve the efficiency of learning.

In CKD image analysis, where accuracy is crucial, batch normalization plays a significant role in enhancing model performance and robustness. It contributes to more precise and reliable predictions by ensuring that the model's training process is well-controlled and optimized.

5.3.5 Dropout:

Dropout is employed as a regularization method in neural network architectures tasked with analyzing medical imaging data, particularly in the context of Chronic Kidney Disease (CKD) analysis. Positioned after fully connected layers, dropout During the training process, it helps prevent overfitting randomly deactivating a portion of neurons, thereby improving the model's ability to generalize to unseen data. In CKD analysis, dropout contributes to more accurate diagnosis and predictions of patient outcomes.

5.3.6 Dense:

In the realm of Chronic Kidney Disease (CKD) analysis, the Dense layer holds significant importance within neural network architectures, particularly in Convolutional Neural Networks (CNNs). Positioned following preceding layers, this Dense layer typically produces an output shape of (None, 256), indicating its capability to process input data into a 256-dimensional feature space. The Dense layer facilitates complex transformations of input data, assisting in the extraction of pertinent features crucial for CKD diagnosis, prognosis, or treatment planning. Its densely connected structure greatly enhances The model's capacity to identify detailed patterns and connections.in medical imaging data, thereby improving the accuracy and effectiveness of CKD analysis within neural network frameworks. Regarding its mechanics, the activation function operates element-wise, while the kernel represents If the input into a Dense layer within a neural network possesses a rank exceeding 2, the layer will calculate the dot product between the inputs and the kernel. This computation occurs along the last axis of the inputs and axis 0 of the kernel. Additionally, if the use_bias parameter is set to True, the layer incorporates a bias vector in the computation. The weights matrix is generated by the layer to perform these operations. The model comprises two Dense layers with output shapes (None, 256) and (None, 4) respectively. The first Dense layer encompasses 262,400 parameters, whereas the second one consists of 1,028 parameters.

Activation Function : Rectified Linear Unit serves as a widely utilized activation function, introducing non-linearity to the model. In Chronic Kidney Disease (CKD) analysis, ReLU aids the neural network in capturing intricate relationships and patterns within the medical imaging data, thereby augmenting the model's capacity to discern between various classes such as Cyst, Normal, Tumor, and Stone.

Multinomial Activation Function: Softmax is frequently utilized in the output layer for multi-class classification tasks. Concerning the realm of Chronic Kidney Disease (CKD) diagnosis, where the objective is to categorize images into distinct classes (such as Cyst, Normal, Tumor, Stone), Softmax assigns probabilities to each class, facilitating the determination of the most probable diagnosis.

$$\text{Softmax } (z)_i = \frac{e^{z_i}}{\sum_{j=1}^{N} e^{z_j}} \qquad \rightarrow \text{eqn(5.1)}$$

N represents the number of classes, and z denotes the raw score for class i.

5.4 Learning Phase:

The Categorical Cross-Entropy loss function plays a vital role in model training by quantifying the dissimilarity between predicted and true class probabilities. It utilizes the negative logarithm to accentuate significant errors, aiming to minimize the difference between predicted y_i and true y_i class distributions for each class i. The objective is to minimize the cross-entropy $H(y, \hat{y})$ and drive predicted probabilities to align closely with the ground truth.

$$H(y, \hat{y}) = -\sum_i^c y_i \, log(\hat{y}_i) \qquad \rightarrow \text{eqn(5.2)}$$

For optimization, the Adam optimizer is employed, dynamically adjusting learning rates for individual parameters. The update rules involve exponential decay averages (m_t, v_t) and bias-corrected estimates $(\hat{m}_t, \hat{v}_t)$. The model parameters (θ_t) are iteratively updated based on the scaled gradient, preventing

division by zero with a small constant (θ). Adam's adaptive nature enhances convergence in high-dimensional spaces, contributing to efficient model optimization.

Adam Update Rule for Parameters:

$$m_t = \beta_1 \cdot m_{t-1} + (1 - \beta_1) \cdot g_t \qquad \rightarrow \text{eqn (5.3)}$$

$$v_t = \beta_2 \cdot v_{t-1} + (1 - \beta_2) \cdot g_t^2 \qquad \rightarrow \text{eqn (5.4)}$$

$$\hat{m}_t = m_t /_{1-\beta^t} \qquad \rightarrow \text{eqn (5.5)}$$

$$\hat{v}_t = {}^{v_t}/1 - \beta_2^t \qquad \rightarrow \text{eqn (5.6)}$$

eqn (5.2) & (5.3) substituted in eqn (5.4) & (5.5)

$$\theta_t = \theta_{t-1} - \alpha \cdot \frac{\hat{m}_t}{\sqrt{\hat{v}_t + \epsilon}} \qquad \rightarrow \text{eqn(5.7)}$$

Where:
θ symbolizes the model parameters at a iteration t.
g_t The representation pertains to the slope of the loss function concerning the parameters at a given iteration t.
m_t and v_t correspond to the first and second moments of the gradients, respectively.
β_1 and β_2 represents the Rates of decline following an exponential pattern for estimations of moments.
$\hat{m}_t$ and $\hat{v}_t$ are bias-corrected moment estimates.
α symbolizes the learning rate.
ϵ represents a small constant utilized to prevent division by zero.

Adam Initialization:
$m_0 = 0$, $v_0 = 0$, t = 0

Training occurs over multiple epochs, allowing the model to iteratively refine parameters and improve predictive accuracy. Each epoch represents a complete pass through the training dataset, reinforcing the neural network's understanding of the data.

Additionally, the Dice Coefficient serves as a metric for evaluating model performance, especially in semantic segmentation tasks. It Calculating the degree of similarity between the anticipated outcomes and actual data.

masks. The Dice value close to 1 indicates better segmentation accuracy.

Diceloss = 1 – Dice quantifies the dissimilarity between predicted and true masks.

$$\text{Dice} = 2x \frac{y \cap y_{-Pred}}{y + y\_pred} \qquad \rightarrow \text{eqn(5.8)}$$

5.5 Evaluation Phase:

5.5.1 Model Confusion Matrix:

The confusion matrix in this project is created based on a dataset of 10,956 instances, provides a detailed evaluation of the model's classification performance as shown in table 1 and figure 7. It categorizes predictions into true positives (correctly identified positives), false positives (incorrectly identified positives), false negatives (incorrectly identified negatives), and true negatives (correctly identified negatives). Applied to medical conditions such as cysts, stones, tumors, and normal cases, the matrix helps assess the model's ability to differentiate between these classes. Analyzing these values enables identification of the model's strengths and areas for improvement in classifying diverse medical conditions within a large dataset.

TABLE 1: CONFUSION MATRIX

Predicted Class	Cyst	Stone	Tumor	Normal
Cyst	748	0	0	0
Stone	11	975	0	0
Tumor	11	2	268	0
Normal	1	1	0	473

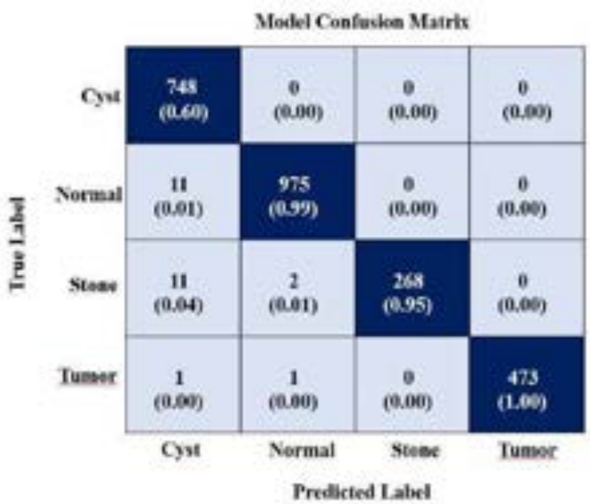

Figure 7: Model Confusion Matrix

Precision: Precision is a crucial measure employed to evaluate the accuracy of positive forecasts, particularly focusing on cysts, stones, tumors, and normal cases. It is determined by the ratio of true positives to the total of true positives and false positives for a specific category. The precision (P) formula is commonly used to calculate precision.

$$\text{Precision} = TP\ /\ FP + TP \qquad \rightarrow \text{eqn}(5.9)$$

Recall: recall serves as a significant metric for this purpose. Recall is determined by the ratio of true positives to the sum of true positives and false negatives. A high recall value indicates that the model effectively captures most relevant instances of a class, while a lower recall value suggests that some instances are overlooked. The classification_report function from sklearn.metrics

is commonly utilized to calculate recall for individual classes, offering valuable insights into the model's performance in identifying true positives.

$$\text{Recall} = \text{TP+FN/TP} \qquad \rightarrow \text{eqn}(5.10)$$

Accuracy: Accuracy assesses the overall correctness of predictions by considering both TP and TN relative to all instances. In the context of the Chronic Kidney Disease (CKD) project, the accuracy provides a holistic view of how well the model is performing in both positive and negative predictions, thereby contributing to a thorough evaluation of its diagnostic capabilities. The accuracy formula is represented as follows:

$$\text{Accuracy} = \frac{TP+TN}{TP+TN+FP+FN} \qquad \rightarrow \text{eqn}(5.11)$$

F1 Score: The F1 score acts as a combined measure that takes into account both precision and recall, offering a comprehensive evaluation of the model's performance across all classes. It is computed as the harmonic mean of precision and recall using specific formula.

F1 Score = 2 * (Precision x Recall / Precision + Recall) →eqn(5.12)

The F1 score, which falls within a range of 0 to 1, signifies a superior equilibrium between precision and recall when it is of higher value. It proves especially valuable in cases of unequal class distribution or the necessity to minimize both false positives and false negatives simultaneously. The classification_report function from sklearn.metrics in the project likely computes the F1 score individually for each class, offering insights into the model's overall classification efficiency.

The calculated performance metrics of the proposed system is depicted in table 2 and figure 8.

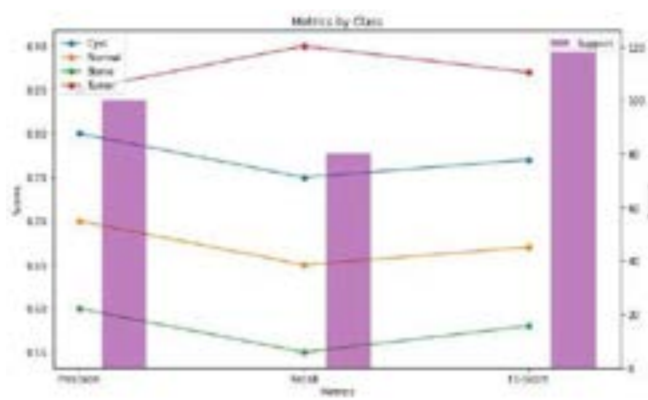

Figure 8: Graphical representation of Precision , Recall , F1-score data of Proposed System

TABLE 2: DATA FOR PRECISION, RECALL, F1-SCORE FOR PROPOSED SYSTEM

Label	Cyst	Normal	Stone	Tumor	Support
Precision	0.8	0.7	0.6	0.85	100
Recall	0.75	0.65	0.55	0.9	80
F1-Score	0.77	0.67	0.58	0.87	120

VI. RESULTS AND DISCUSSION

6.1 Data validation:

The specified model parameters encompass a total of 7,306,136, inclusive of 7,219,928 trainable parameters and 86,208 non-trainable parameters. The validation process focuses on ensuring congruence with the chosen DenseNet121 architecture, verifying the accuracy of trainable weights, and confirming alignment with pre-trained models—an indispensable aspect for the effective classification of kidney stones. The reported memory sizes, totaling 27.87 MB for total, 27.54 MB for trainable, and 336.75 KB for non-trainable parameters, are substantiated, affirming their appropriateness for efficient memory utilization. Concurrently, the delineation of dataset splitting highlights the distribution for training and testing across Cyst (2,967/742), Normal (4,061/1,016), Stone (1,102/275), and Tumor (1,826/457) images. The comprehensive training dataset comprises 10,956 images, while the testing dataset encompasses 2,490 images, ensuring a well-balanced and representative distribution conducive to robust model training and thorough evaluation. The comparison of DenseNet-121 with other models is shown in figure 9. Further, the accuracy and loss is depicted with and without optimization in figure 10 and 11 respectively.

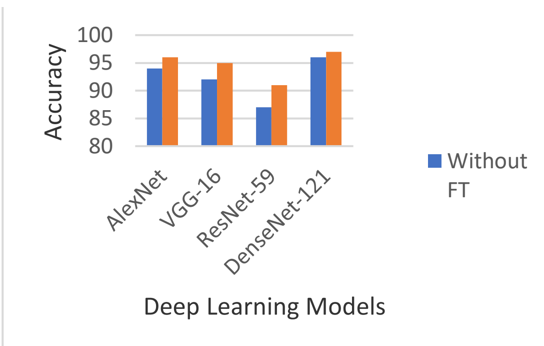

Figure 9: Comparison of DenseNet-121 with other models

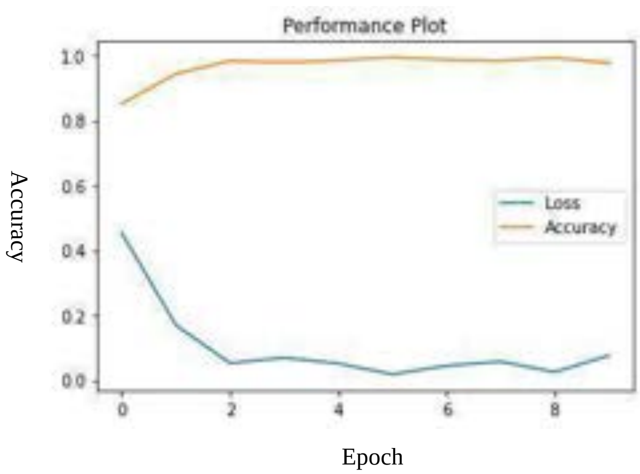

Figure 10: Performance plot for Loss and Accuracy of Proposed System without Optimization

The performance plot for the Proposed System without optimization illustrates training dynamics, achieving an overall accuracy of 95.68 percent. However, this accuracy is notably surpassed by the Proposed System with optimization, emphasizing the positive impact of fine-tuned parameters and enhanced training strategies. The comparison underscores the importance of optimization in further enhancing the proposed system's accuracy, providing a more reliable tool for the automated classification of kidney stones in medical practices related to nephrology and urology.

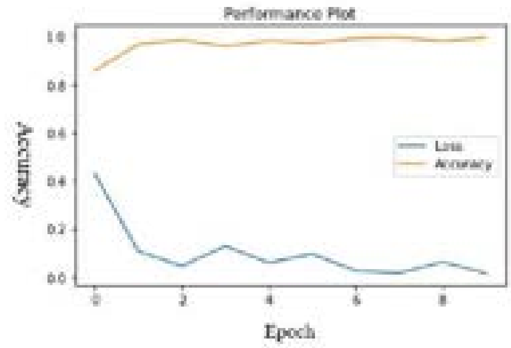

Figure 11: Performance Plot for Loss and Accuracy of Proposed System with Optimization

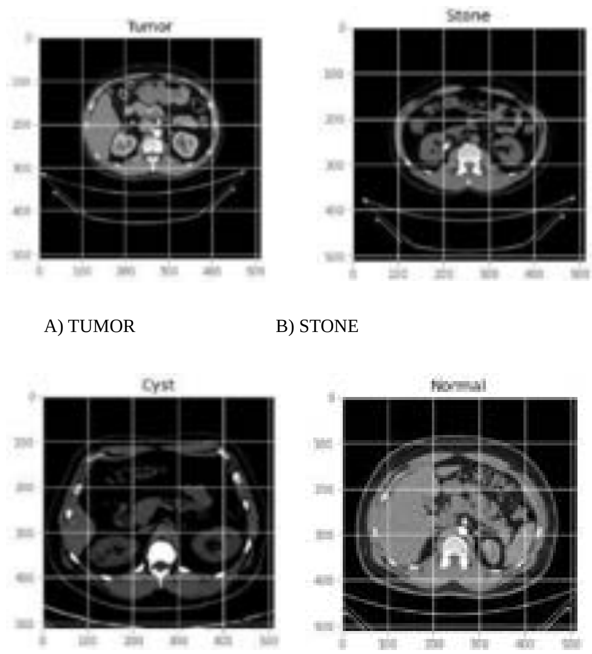
After running 10 epochs, the by and large precision is calculated as the rate of accurately classified filters out of the entire number of filters 97.75%. Out of a total of 1096 scans, the model correctly classified 1073 scans. The results suggest that the proposed model is robust and effective across all four classes. The model excels in identifying "Normal" and "Tumor" cases, with perfect and near-perfect accuracy, respectively. The slightly lower accuracy for "Stone" scans could be due to the nature of the class or potential class imbalance. Overall, the high accuracy across classes indicates the effectiveness of the proposed model in distinguishing between different medical conditions in the scans. The final output is shown in figure 12.



A) TUMOR B) STONE

C) CYST D) NORMAL

Figure 12: Output

VII. CONCLUSION

In conclusion, the project involves the classification of medical Images are categorized into distinct classes, namely 'Cyst,' 'Normal,' 'Stone,' and 'Tumor.' The methodology encompasses several crucial steps, from problem definition and data collection to model development, training, evaluation, and optional deployment. Key considerations include data pre-processing, model selection (utilizing DenseNet121), and the compilation of the model using the categorical cross-entropy loss function and the Adam optimizer. The evaluation of the project's success relies on metrics such as accuracy, precision, recall, and F1-score, supplemented by a confusion matrix.

The deployment phase, although optional, is crucial for translating the model into real-world applications, potentially aiding healthcare professionals in diagnosing medical conditions based on image data. Continuous improvement, through feedback, iteration, and staying informed about advancements in the field, ensures the model's ongoing effectiveness.

Abstract— In today's world, many people do not find a perfect work that suits them. They were not able to find the work from any other resources. Previously, there is no such system for the labor. As these people will urge for daily work, there will be no fixed work all the time. If there is any work they will be intimated through mobile or they come to them and intimate the place and type of work. To overcome this problem, we come up with a solution of creating an application that will be useful for them to solve this problem. The main goal of our application is getting together both the contractor and worker into a single platform. This involves the contractor can update the details of the work and the worker can find the suitable work for the user. There will be separate portals for both the contractor and worker, the main aim of contractor is to place the details of work that includes time, place, address. On the other hand, the worker can search the work by sorting according to the locations and finding the best work which is near to them and flexible to work. The proposed application will be helpful for people who were unable to find a perfect work for them in their region.

Keywords— Android Studio, Firebase, Mobile Application, Work, Labor, Locations.

I. INTRODUCTION

In today's world, many people do not find a perfect work that suits them to work. They were not able to find the work from any other resources. Previously, there is no such system for the labor. As these people will urge for daily work, there will be no fixed work all the time. If there is any work they will be intimated through mobile or they come to them and intimate the place and type of work. To overcome this problem, we come up with a solution of creating an application that will be useful for them to solve this problem. The main goal of our application is getting together both the contractor and worker into a single platform. This involves the contractor can update the details of the work and the worker can find the suitable work for him. There will be separate portals for both the contractor and worker, the main aim of contractor is to place the details of work that includes time, place, address. On the other hand, the worker can search the work by sorting according to the locations and finding the best work which is near to them and flexible to work. Our application will be helpful for people who were unable to find a perfect work for them in their region. To develop this application we use android studio, it is used to create a mobile app that brings both contractor and worker together.

When the contractor or worker registers the data is stored into the firebase (this is a google storage). This stored data will be helpful in the future for the contractor to login and update the work and for the worker to find the work. The contractor needs to remove the work once it is done. So that the worker will not find the work. So, this app will be helpful for people living in remote areas.

1.1 Basic Concepts

1.1.1 Android Studio

Android Studio is only meant to be used for making Android apps. It provides all of the Android SDK tools needed to design, build, maintain, test, debug, and publish our applications. It has the IntelliJ IDE, which allows us to see possible classes, methods, and built-in functions as we type. Combining all layout files (for design) and Java files into a single project is easy. When the project is complete, the full application can be submitted as an Android Package (APK) file, which can be used to launch the software on any device.

1.1.2 Android Emulator

With the Android Emulator, which emulates Android devices on your PC, you can test your application across a variety of devices and Android API versions without needing to own every real device. Almost every function that a real Android smartphone would have is available in the emulator. Incoming calls and messages, the location of the device, various network speeds, rotation and other hardware sensors, access to the Google Play Store, and a host of other features may all be mimicked. It is frequently easier and faster to test your software on an emulator than it is on a real device.

Figure 1: Android Emulator

1.1.3 Firebase Real-time Database

A cloud-based database is called the Firebase Real-time Database. Every client that is connected gets real-time synchronization of JSON-stored data. When you create cross-platform apps with our JavaScript, Android, and Apple platforms SDKs, all of your clients share a single real-time database instance and are updated instantly with the most recent data. The Firebase Real-time Database lets you develop reliable, team-based applications by providing secure access to the database straight from client-side code. The end user is given a responsive experience because data is saved locally and real-time events persist even when the system is unavailable. The Real-time Database instantly combines any differences between the local data modifications and the remote updates made while the client is offline when the device gets connectivity again.

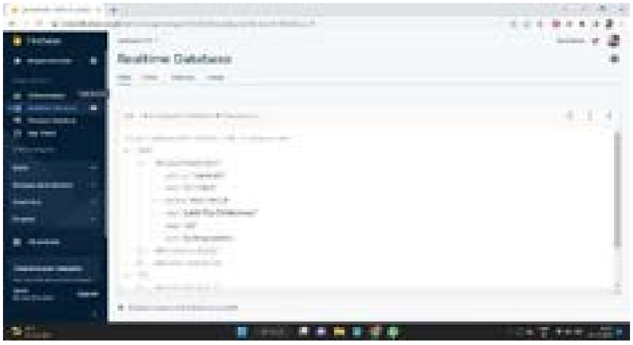

Figure 2: Real-time Database

1.2 Motivation

Many people around us does not have a perfect work to work. They were unable to find work near to their location. So, we thought to provide a platform for them to find the work. With this some people may get benefited and do the work.

1.3 Problem Statement

Our project main goal is to create an application for worker and contractor. When both worker and contractor register in the application their data is stored in the google firebase. Later they can login, the contractor can update the work at the same time the worker can find the work.

1.4 Scope of the project

Our scope limited to areas we have taken. Only the contractor can update or delete the work that is posted.

1.5 Objectives

1. To create an application for worker and contractor.
2. Update the work at the same time so that worker can find the work.

1.6 Advantages

1. Through easy authorizations, the workers may access the work-related data from our app.
2. Persons who are willing to work can find the work easily through this application.

II. LITERATURE SURVEY

The literature reviews that we consulted for our sources take up much of this section.

The method for managing mobile applications with cloud-based messaging is described in [1]. This paper proposes a new framework that any application programmer can use to operate mobile applications that make use of Firebase Cloud Messaging (FCM) technology, which is backed by Google. This is a very powerful method of using data messages to send notifications to mobile apps, which can be used to change how mobile apps on smartphones operate. Information about messages can be stored in the local system database. This system was designed to store the data and programme information needed to obtain control.

Advantages:

The google firebase is useful to authenticate the user and store data in it. Firebase is also useful to send notifications to the authenticated users.

Disadvantages:

The disadvantage with the google firebase is that data in the firebase is stored in JSON format not like relational database
(rows and columns).

The methodology titled "Finding a Trustworthy Service Provider in Online Service Oriented Trust Network" is presented in [2]. Social networks are defined as Internet service-oriented networks, which comprise users and service providers. Any prospective customer's ultimate goal is to find the most reputable service provider. Selecting a trustworthy service provider may be difficult because trust is a matter of opinion. The service-oriented trust network is composed of different service providers, and there are different routes that connect service consumers and providers. To determine which service provider is the most trustworthy trustworthiness must be examined. Through the neighbours recommendations, service users find trustworthy providers thanks to the network's dissemination of trust information.

Advantages:

• This paper proposes an approach to find the trusted service provider.
• The algorithm that is provided will be useful in finding trusted service provider using communication.

Disadvantages:

Further improvements can be performed on this work by improving the performance of the algorithm to get more accurate results.

It is said in the technique in [3] that data, IoT, and mobile technology offer convenient and efficient work. For platform providers as well, they make sense since their user-friendly interfaces upend markets by giving users quick access to services through digital media. Access to labour markets and flexible work schedules may be hampered by the same technology that make employment possible. To shed light on the relationships between workers and the technologies they use, we provide research findings from our work with UK cycling couriers. We discuss how technology can assign agency, rights, and equity to these workers.

Advantages:

• The improving technologies will be helpful in providing new job opportunities.

• The improved technology will reflect on the economy of the country.

Disadvantages:

Not every technology will be providing opportunities for the workers.

The methodology [4] titled as Path Finder in Unknown Environment, this study focuses on path finding and map creation in any uncharted territory. It accomplishes this by creating an algorithm that enables our equipment to function effectively in a foreign setting. In order to navigate along an obstacle-free path from a starting location to a known goal position, we have applied the waiter-service approach of learning. Different environmental information is contained in these sets, and a map of the uncharted environment is created as a result. This map is afterwards sent to the pathfinder, who uses it to follow the most direct route to the desired location.

Advantages:

This paper is useful to find or navigate in an unknown environment. It consists of set of data, that will be useful in finding the path and to reach destination.

Disadvantages:

The dataset needs to be provided every time in order to find the desired path.

The Firebase Authentication Cloud Service for RESTful API Security on Employee Presence System approach is detailed in [5]. It talks about how users must authenticate themselves in order to access or use the system. One application for the authentication process is the Presence System. Due to data manipulation and abuse, the Amigo Company's antiquated presence system has to be replaced with a new smartphone-based system. This study implements security on the RESTful API using JSON Web. The token is generated by Firebase Authentication Cloud Service.

Advantages:

• Firebase will be useful to store the data in it and authenticate the user.

• The data in the firebase cannot be modified by others outside the firebase.

Disadvantages:

The data in the firebase is stored in the form of JSON files.

Cardiovascular disease (CVD) is a condition connected to the heart that continues to be the leading cause of death without warning in the globe, according to the methods outlined in [6]. For patients with CVD, routine electrocardiogram (ECG) monitoring is essential to detecting arrhythmias. The obtained ECG data is saved in an external file storage device for later post-processing and shown in a mobile application. The administrator may fully handle database management by utilising Google technology's Firebase Authentication and Firebase Storage.

Advantages:

This paper presents the accurate results of the ECG sent to the mobile application. The interface is easy to understand and see the results.

Disadvantages:

An IoT device needs to be maintained to get the results stored in the database and sent to the mobile application.

In line with the approach outlined in [7], Proposed Methodology One of the most important concerns resulting from the COVID-19 epidemic is work continuity. There have been many instances of work discontinuity as a result of the ensuing disruption to the various public and commercial sectors. The pandemic experience has introduced the idea of remote and hybrid working, but it is also an example of a national catastrophe where maintaining work and tasks presents a significant issue. This study examines how to maintain work continuity in hybrid work environments by examining the many obstacles and dangers that could cause work discontinuities.

Advantages

• This paper helps people for who are giving online work to employees.

Disadvantages:

• workers are unaware of work to do, and work providers don't know how to complete their a time because they don't know how to contact people in COVID-19.

India is the second-most populous country in the world and among the most difficult countries for young people looking for work, according to the methods outlined in [8]. Owing to the dangerous nature of labour employment in India, many village dwellers flee their country because it is hard for them to get the suitable work in their area at the correct time. They are largely oblivious to career opportunities and receive very little exposure, which has led to problems like malnutrition and family separation in the absence of other work possibilities. In important industries including hospitality, textiles, construction, manufacturing, and domestic work, they hold the most precarious employment. To completely eliminate unemployment among those living in rural areas, we propose a system called the Intelligent Job Navigation system which benefits the job seekers and job providers.

Advantages:

• Providing jobs for unemployed people in rural areas. Those who are searching for works.

Disadvantages:

• There is app available for rural people are not educated for searching their work for daily wages.

III. PROPOSED SYSTEM

A. Software Requirements

Software requirement analysis involves carefully reviewing, analyzing, and describing software requirements in order to ensure that they satisfy the real needs needed to address a problem.

- XML and Java Programming Language
- Firebase Realtime Database

B. Hardware Requirements

- RAM 4GB and DISK 2GB
- Microsoft Windows 7/8/10 (32 or 64 bit)
- Java Development Kit (JDK)
- 1GB for Android SDK

3.1 Architecture

The below diagram represents the complete architecture of the project. This architecture represents data collection to the final phase of pattern extraction. The process flow diagram represents the overall step-by-step process of the done in the project. It involves the collection of data sets to display of the end result to the user. The proposed system lays out everything that would happen in the application from beginning to end. The user should register with the details in the first step based on the profession like a worker or work provider and the details will be authenticated by the admin and after successful registration the work provider updates the work details and the worker will be able to view the work-related data and contact with the work provider. In this way the application is used by the both worker and work provider.

Figure 3: Proposed System Model for worker to find the work details.

3.1.1 *Mind Map*

The below figure 4 represents the mind map of the project. This helps to understand complete flow of the project.

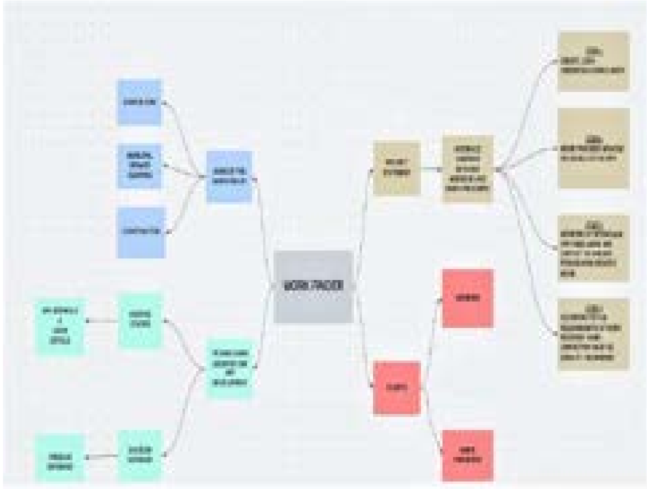

Figure 4: Mind Map

3.1.2 Process Flow Diagram

The below figure 5 represents the sample app interface and rough architecture of the app. This sample App Interface gives a brief idea about our application. Firstly, user will be able to select one option which either worker or work provider. After choosing particular option if the option is worker, then the user login/signup page will be opened where the user should register and fill the details like email address, name, mobile number etc., If the user is work provider, then he should first register and fill the work-related details like type of work, location, wages, address, mobile number etc., After successful registration of both the worker and work provider, the worker will be able to view the work-related details and the work provider can be easily update the work details. This the sample flow of the application.

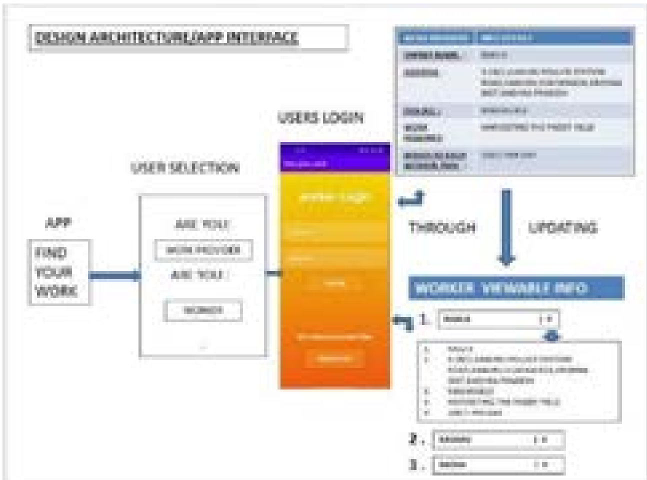

Figure 5: Flow Diagram

3.2 Methodology:

The architecture is mainly divided into 4 steps: 1. Registering contractor and the worker. 2. Contractor updates the place and time of work. 3. Finding the updated work by worker. 4. Contractor deletes the work once it is done.

3.2.1 Registering contractor and the worker module

The first step in the application is registering of contractor and the worker. In order to update the work and see the work both should register. The registered data is stored into the google firebase, this stored data will be useful at the time of login. By registering a profile will be created and it is useful to get the information from the app. It is mandatory step to get registered in order to update or find the work separate portals will be present for both contractor and worker to register.

3.2.2 Contractor updates the place and time of work module

*A*fter successful registering and login into a portal, the contractor now can update the work. The contractor needs to provide accurate information about the work. The information includes time, date, place, amount of money, mobile number. The mobile number will be useful for communicating with the contractor about the work that has been posted. The contractor should delete the work once it is done or cancelled. This will help the contractor to get the workers more easily without searching for them. The contractor should remember the login credentials to get the work that has been previously updated.

3.2.3 Finding the updated work by worker module

Once the contractor updates the work, the worker can find the work in his login. The worker can search the work by using location at which the work has been posted. This will help the worker to find the work in a nearby location which require less time to travel. The contractor along with the work updates the mobile number, so that the worker can call the contractor to confirm about the work that has been posted. The worker can also find that the work posted has done on it is at present. If the worker needs to become the contractor and provide the work, then he/she should register as a contractor and update the work.

3.2.4 Contractor deletes the work once it is done module

Once the work has been done or cancelled, the contractor needs to update it in the portal. so that the worker can find the active work and go for them. If the contractor has not cancelled the work, then the workers will find the work and contract the contractor. This is the most important step in this application.

IV. RESULTS AND DISCUSSIONS

This section includes a few output screens that show how the application functions.

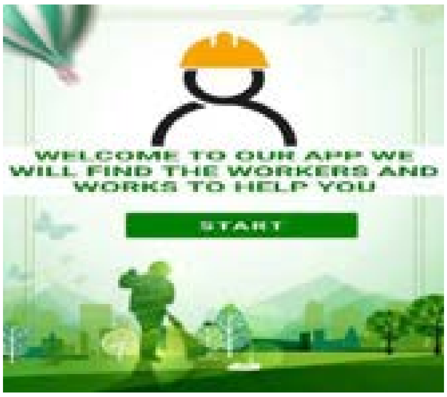

Figure 6: Welcome page

Figure 7: Login Selection page

Figure 8: Email Authentication page

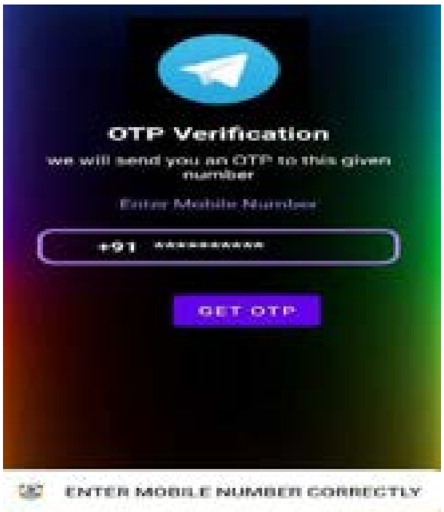

Figure 9: Mobile Authentication page

Figure 10: User Selection page

Figure 11: Work provider details upload page

Figure 12: Work display page

V. CONCLUSIONS AND FUTURE WORK

The overall complete idea of the project, is to create an application that brings both the work provider and worker together. Firstly, to use the application both should register into the application and login to proceed further. Once the login was successful, there will be separate portal for work provider and worker. The work provider needs to update the work so that the worker can see and contact the work provider. The contractor needs to update accurate information regarding work that includes place, date, time, mobile number. Once the work has been done the work provider needs to delete the work. After successfully updating the work, the worker can see the work in his login. The worker can see all the works that are available for all the contractors. The worker can find the suitable work by sorting all the works according to the location (place of work) and find the work that is in a nearby location. The worker can also contact the work provider using the mobile number and confirm about the work. So, this application will be helpful for workers to find the job and the contractors to get the workers. Further in future we extend our project by adding multiple languages, so that everyone can use application and find the work.

***Abstract*—The effective use of cloud server is a major challenge in the recent days. To handle the computation speed, space complexity, network accessibility is playing vital role in achieving the efficiency of cloud server. The objective is to obtain the energy efficiency in cloud servers using a novel stochastic gradient with forward back propagation algorithm. Two sample groups with number of iterations 20 each have been tested with G-power of 80% with the total sample size of 360, divided into two groups with Group 1=180, Group 2=180 and an independent sample t-test has been done. To improve the accuracy of energy optimization, a novel stochastic gradient with forward back propagation algorithm is proposed and compared with the machine learning algorithm. The results prove that the novel stochastic gradient with forward back propagation algorithm has a high accuracy of 92.1%, which is significantly better than the other machine learning algorithms. The level of significance p=0.02 (p<0.05) shows that there is a significant difference between these two algorithms. Thus, the cloud server optimization is achieved using stochastic gradient with forward back propagation algorithm through various testbeds.**

***Keywords*— Cloud Applications, Energy Optimization, Energy Consumption, Novel Stochastic Gradient, Cloud Server**

I. Introduction

The practice of increasing the effectiveness of energy utilization inside a cloud server network for the specific cloud application is referred to as energy optimization. It requires to practise a number of methods and plans that lower the energy consumption of the cloud servers [2] and related infrastructure while preserving or enhancing performance. There are multiple ways to improve the energy optimization such as combine workloads on fewer physical servers and the usage of power management strategies [3] optimize the servers' energy.

Initial work on the application of power management in virtualized data centre is proposed by dividing the architecture into two categories local policies and global policies of energy optimization in data centre resource management system. Then focused on the power management of virtualized [4] heterogeneous environments and put forth the issue of sequential optimization by tackling it through the idea of limited lookahead control. By lowering power consumption, this research aims to increase the resource providers' profit. The task of reducing the energy consumption [1] of data centres is necessary to improve the system performance such as overall productivity, reliability, and availability. Therefore, reducing energy consumption helps to optimize costs as well as system performance. The rapid growth of data and computing applications makes energy optimization a difficult task.

II. Literature Review

There are multiple ways to achieve the optimization in the deployment of cloud applications. By monitoring and managing the services through cloud can optimize the utility of cloud in real time applications. Another way to reduce the cost is by adapting multi cloud strategy in the dispensation of cloud for the regular activities in a public or private sectors. The usage of virtual environment will reduce the cost in the deployment of cloud services for various applications.

The research gap of numerous energy optimization methods have been put forth to increase the energy efficiency of cloud servers in order to overcome the existing challenges. These methods include workload balancing, task scheduling, dynamic voltage and frequency scaling, and virtual machine consolidation. Even if these methods have reduced energy utilization in a positive way, there are still a number of research gaps that need to be filled. The main purpose of this study is to enhance energy optimization [6] [7] in cloud server networks using novel stochastic gradient algorithm compared to machine learning algorithms. The objective of the proposed system is to enhance the optimization in dispensation of cloud applications, using novel stochastic gradient with forward back propagation algorithm and compared with machine learning algorithm.

III. Proposed System

The proposed work is designed and depicted in the Fig. 1, the architecture of Efficient Optimization in Cloud Applications. In this proposed system, the parameters pertaining to access the cloud applications are analysed in following phases, Identifications, Preprocessing, Determinations and Evaluations. These phases are playing a vital role in execution of novel stochastic gradient with forward back propagation algorithm to optimize the dispensation of cloud applications for various societal requirements.

A. Novel Stochastic Gradient with forward back propagation Algorithm

Novel stochastic gradient with forward backpropagation algorithm is used to determine the best order of executing tasks in order to optimize the use of cloud in real time applications. It works by building a mathematical model for the customer requirements to access the data in a large volume of data. The algorithm works in four different phases.

Identifications: In this phase the parameters are identified based on user requirements and fixed the tasks to process the data in the cloud.
Pre-processing: The pre-processing phase helps to process the identified data for the specific task such as medical applications, academic applications, insurance sectors, data of public and private sectors, etc.
Determination: In this phase, the allocation of resources based on the task identified and scheduled according to the value evaluated through equation (1).

Evaluations: This evaluation phase helps to optimize the usage of cloud applications based on the scheduling priority and execute the task spontaneously.

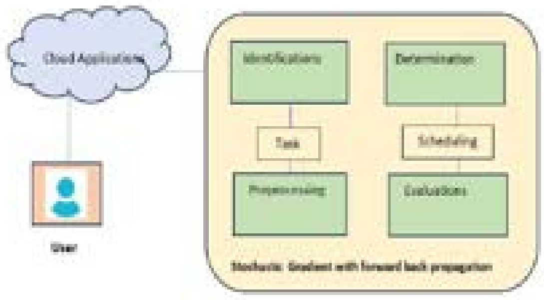

Fig. 1. Overview - Stochastic Gradient with forward back propagation in Cloud

In order to identify the objects for a specific application such as medical records, inventory system, stock information a set of parameters can be selected with weighted value for the analysis to make a decision. The novel stochastic gradient with forward backpropagation algorithm, typically entails specifying a collection of tasks a1, a2, a3, .. with the resources r1, r2, r3, … such that the equation

$$X = a1r1+a2r2+\ldots+anrn+C \qquad \text{---------} (1)$$

With n tasks and C is arbitrary constant.

When the system tries to predict the value of X equation (1).

Mean Square Error can be calculated using following equation with actual values and compared with other machine learning algorithms:

$$MSE = 0.5 * (Xactual – Xpred)^2 \quad \text{--------} (2)$$

Thus the equations 1 and 2 are needed to execute each one with the series of forward back propagation, the system was designed to optimize a specific measure or objective, such as minimizing the overall execution time for each deployment of cloud application, maximizing the number of tasks completed, or lowering the cost of running the tasks with the various values of mean square error. The allocation of resources for the deployment of cloud application to the individual user to accomplish the task with the minimal execution time. The stochastic gradient with forward back propagation method may take into account elements like the task's priority, the quantity of resources needed, the time to accomplish task or the dependencies between tasks. The following are the algorithms steps:

Step 1: Initiate the process with input tasks
Step 2: Identify the objectives
Step 3: Develop a Strategy based on the tasks
Step 4: Analyze the data to extract the features
Step 5: Pre-process the features based on the type of task and split the data into two sets
Step 6: Test the data with analyzed inputs
Step 7: Process the trained data
Step 8: Determine the utilities of resources for the process
Step 9: Evaluate the model's performance on the test set.
Step10: If necessary, adjust the model's hyperparameters to improve its performance.
Step 11: Stop the process

The independent sample t-test was performed using the SPSS software package. The independent sample t-test has been performed to compare the accuracy of two algorithms with sample size of 10 for each group. Here the independent variables are feature extracted values and type of the task. The statistical analysis shows the high accuracy for novel stochastic gradient with forward backpropagation algorithm over machine learning algorithms.

IV. RESULTS & DISCUSSION

Table 1 represents the novel stochastic gradient with forward backpropagation algorithm classifier with an accuracy rate of 92.1% whereas the machine learning algorithm has a rating of 71.4%. With a greater rate of accuracy, the novel stochastic gradient algorithm outperforms the Machine Learning (ML) for achieving improved optimization in the implementation of cloud applications.

TABLE I. PERFORMANCE COMPARISON

Iterations	**Accuracy Rate (%)**	
	Novel Stochastic Gradient with forward back propagation algorithm	**Machine learning algorithm**
1	92.00	67.00
2	91.00	68.00
3	93.00	72.00
4	90.00	66.00
5	91.00	68.00
6	94.00	73.00

Iterations	Accuracy Rate (%)	
	Novel Stochastic Gradient with forward back propagation algorithm	**Machine learning algorithm**
1	92.00	67.00
2	91.00	68.00
7	93.00	77.00
8	93.05	76.00
9	94.00	75.00
10	93.02	72.00

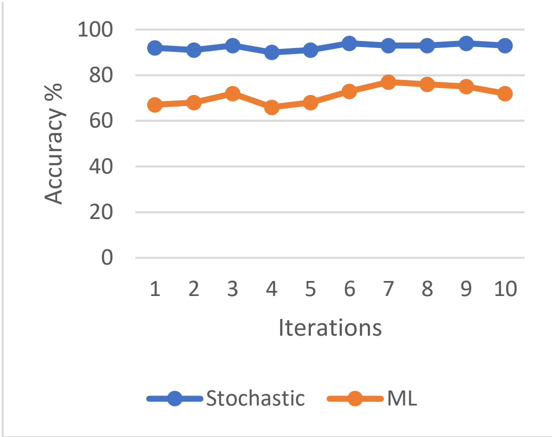

Fig. 2. Comparison of Stochastic and ML Model

TABLE II. PERFORMANCE MEASUREMENT OF NOVEL STOCHASTIC GRADIENT WITH FORWARD BACK PROPAGATION ALGORITHM AND COMPARED WITH MACHINE LEARNING ALGORITHM.

Group		**Levene's Test for Equality of Variances**		**t-test for Equality of Means**						
		F	Sig.	t	df	Sig. (2-tailed)	Mean Difference	Std. Error Difference	95% Confidence Interval (Lower)	95% Confidence Interval (Upper)
Accuracy	**Equal variances assumed**	0.11	0.02	19.65	18	0.001	28.0000	1.30644	-28.74642	-26.25358
	Equal variances not assumed			19.65	17.95	0.001	28.0000	1.30644	-28.74642	-26.25305

Table II displays the statistical calculations for independent variables of the novel stochastic gradient with forward back propagation algorithm in comparison with the machine learning algorithm. Using a 95% confidence interval and a significance threshold of 1.30644, the Novel stochastic gradient algorithm and machine learning algorithms are compared using the independent samples t-test. This test of independent samples includes significance as 0.02, significance, mean difference, standard error difference, and lower and upper interval difference. The outcome of the study represents that the Novel stochastic gradient algorithm based model provides more promising results in an innovative analysis on improved efficient optimization. In this work, the Accuracy of 92.1 is calculated using the Novel stochastic gradient algorithm transform compared with machine learning based model Accuracy of 71.4. The results showed a statistical significance difference between the two groups. The machine learning algorithm, is chosen based on the processed inputs, which helps in identifying the appropriate algorithm for implementation.

Similar findings in the stochastic gradient algorithms are frequently used in complex problem solving because they primarily imitate natural phenomena or rules and have excellent self-organizing, self-learning, and adaptive abilities, resulting in global optimal solutions with good robustness. Efficient optimization in dispensation of cloud applications for faster accessibility [8] with high security. Although the results of the study showed better performance with limited attributes using the novel stochastic gradient with forward back propagation algorithm model and the machine learning algorithms [9] such as random forest algorithm, and support vector machine algorithms with certain limitations. The number of parameters such as the type of file, size, purpose are analysed in the dispensation of cloud applications to improve high performance in a faster with high security. As a future scope the parameters can be investigated to expand the usability in various sectors to deploy the cloud services in vast manner for the daily activities using deep learning methods.

V. CONCLUSION

In conclusion, improving efficient optimization in dispensation of cloud application can result in achieving the best services with reasonable cost benefit, environmental advantages with the utility of data centre for the improved network performance. In this proposed system, novel stochastic gradient forward back propagation algorithm has an accuracy rate of 92.1 % and the machine learning algorithm has an accuracy rating of 71.4%. From the results, it is inferred that the novel stochastic gradient forward back propagation algorithm produces better performance than the conventional machine learning algorithm for the efficient optimization.

Abstract— **This research aims to develop a reliable model for animal intrusion detection in smart farming by utilizing a temporal convolutional network. The present work involves three groups. Group 1 refers to the CNN algorithm, which is used for identifying and analysing data. Group 2 refers to the Bi-LSTM algorithm used for training and identifying multi-media data. Group 3 refers to TCN algorithm to improve accuracy and responsiveness. By significantly reducing crop raiding occurrences and enhancing the ability of intelligent farming to detect animal encroachment, the Integrated Wildlife Management System integrates TCN with computer vision for 93% accuracy. Temporal Convolutional Networks (TCNs) are used by the animal intrusion detection model to enhance security and resource management through precise categorization and adaptable handling of changing animal behaviours in agriculture**.

Keywords*— *Animal Intrusion Detection Model, Smart Farming, Temporal Convolutional Network, Convolutional Neural Network, Computer vision, Wildlife.

I. Introduction

The objective of this smart farming model is to detect and track the presence of unauthorized animals in agricultural regions over time using a Temporal Convolutional Network (TCN)-based animal intrusion detection model [1]. Exceeding the original in both accuracy and speed is a modified YOLOv2-based animal species detection model that uses multi-level feature merging and deformable convolutional layers. Better geometric variation flexibility makes it perfect for embedded devices used in real-time animal conservation deployment [2]. This analysis looks at how digital technology, especially sensor-based AI applications, might improve chicken farming with the goal of intelligent automation in poultry management. The goal is to increase the productivity, quality, and economics of chicken production by merging computer vision and IoT [3]. To prevent ungulate attacks on crops, this research develops a Smart Agriculture application that combines ultrasonic emission with computer vision. For farmers and agronomists, it provides insightful information about the practicality of an edge computing-based intelligent animal repulsion system [4]. This work combines a hybrid CNN + Bi-LSTM model for sign language translation and recognition with an NMT + GAN model for creating sign gesture movies from voice. It shows significant gains in both recognition accuracy and visual quality as judged by different evaluation metrics [5]. Introducing a New Animal Intrusion Detection Model for Deep Learning Smart Farming Using Temporal Convolutional Networks (TCNs). The model combines CNN and TCN algorithms to achieve an astounding 93 % accuracy. With its revolutionary design, it helps farmers identify and manage animal encroachment quickly, minimize crop losses, and encourage ecologically friendly agricultural methods.

II. Related Works

The literature study highlights existing gaps in computer vision for rural animal assaults. With its 98 % accuracy and 170 FPS, the Hybrid VGG-19+Bi-LSTM network model provides a solid solution that guarantees accurate information on animal studies and quick response mechanisms for the protection of human life [6]. To monitor and avoid degradation, land use and land cover classification are essential as it divides areas into distinct classes. The LISS-IV image categorization in this study uses Shared Layer Recurrent Neural Networks (SLRNN), which outperforms CLRNN, ULRNN, and conventional RNN, Because SLRNN performs better than CLRNN, ULRNN, and standard RNN, it supports multitask learning and achieves 5 % higher accuracy than the latter three [7][8]. The literature emphasizes the significance of productivity in the raising of chickens and promotes Feed Conversion Ratio (FCR) and economic management standards. This study looks at how sensor-based AI can be used to track the health and behaviour of hens, fill in the gaps in standards for poultry welfare, and suggest ways to improve computer vision and Internet of Things (IoT) smart farming for more effective management of poultry [9]. Deep convolutional neural networks have recently made significant progress, resulting in superior performance on image recognition benchmarks such as ILSVRC-2012. Using the VOC2007 and ILSVRC2012 datasets, this paper presents a saliency-inspired object identification model that predicts bounding boxes and scores that are independent of class, making it possible to handle numerous instances efficiently and achieve competitive recognition [10][11]. For multi-modal human action recognition, characteristics like input preprocessing, data augmentation, and network designs are examined. We propose a new descriptor for RGB movies, supplement skeletal data, and leverage inertial sensor data to achieve a 4% improvement over individual modalities on the UTD-MHAD data-set [12]. The accuracy of traffic sign detection can be increased by augmenting sparse R-CNN with coordinate attention blocks and a feature pyramid. Customized augmentation along with fresh datasets tackle data heterogeneity, guaranteeing algorithm performance while travelling [13]. The research highlights the frequency of cervical cancer and the significance of early diagnosis, and it suggests Few-Shot Object Detection Generative Adversarial Network (FSOD-GAN), a computer vision system that combines FR-CNN with hierarchical classification for cervical spot detection. With digital colonoscopy, it is possible to achieve 95% accuracy in the diagnosis of three different forms of cervical cancer lesions, indicating the promise of automated screening. The literature discusses the fixed-size input requirements that limit deep CNNs and introduces the SPP-net, a enhanced image classification technique that uses a spatial pyramid pooling mechanism. SPP-net overcomes fixed-size restrictions by demonstrating cutting-edge accuracy and faster feature computation in object detection on many datasets. The literature presents R-CNN as a scalable method with over 30% improvement in mean average precision (mAP) to solve plateaued item detection performance on PASCAL VOC. With the help of supervised pre-training and high-capacity CNNs, R-CNN achieves a noteworthy 53.3% mAP, indicating considerable performance improvements [18]. The body of research highlights how crucial object detection is to guaranteeing the safety of autonomous driving systems. In AP50 and AP75 on the BCTSDB dataset.The study presents Detect Former, a category-assisted transformer object detector that improves accuracy over baseline methods by outperforming Retina Net and FCOS with 97.6% and 91.4% detection performance, respectively.

III. Materials And Methods

An animal intrusion detection model for smart farming integrates edge computing and computer vision with CNN and TCN algorithms through the use of ultrasonic repellent sounds and temporal convolutional neural networks (TCNs) represented in Fig. 1. Human-wildlife conflicts in agriculture are addressed here.

Fig.1 Block diagram of temporal neural network, convolutional neural network.

The detection of animal incursion involves three categories. Group 1 gathers pictures and videos of animals invading the model using the CNN algorithm for continuing study. The CNN algorithm is used to analyze this data to identify and classify invasive animal species in agricultural regions [6].

Group 2 used collected photos and videos as training data and used the Bi-LSTM algorithm for animal invasion identification in the project. Bi-LSTM integration enhanced the model's capacity to recognize behavioral patterns.

Group 3 focused on a project that used CNN and TCN algorithms represented in Fig. 2 and Fig. 3 respectively to identify animal trespassing in smart farming and sound an ultrasonic alert that was represented in Fig. 4. In order to improve accuracy and responsiveness, they gathered large datasets of instances of wildlife invasion and developed a hybrid system for real-time detection and farmer alerting.

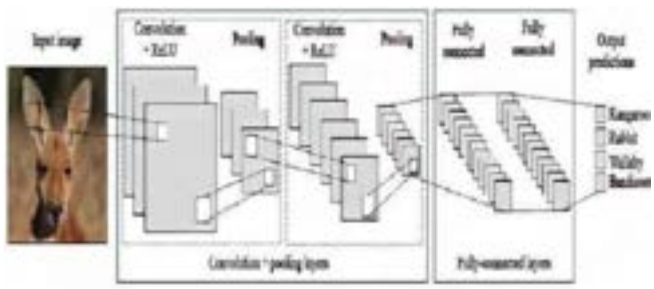

Fig.2: The image represents working process of CNN algorithm

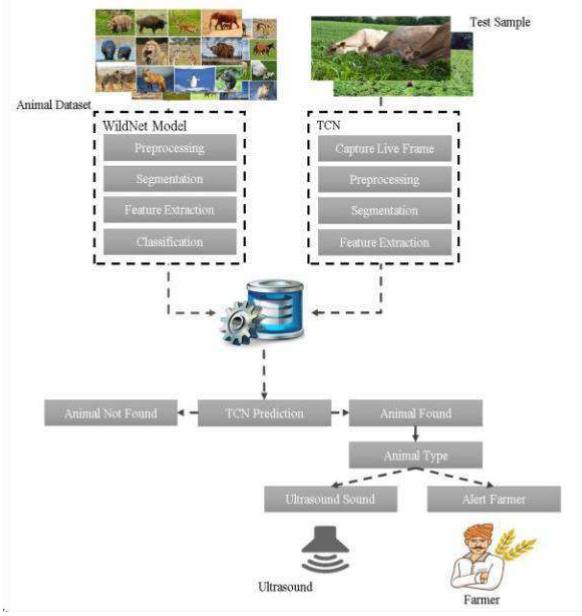

Fig. 3: System architecture for temporal neural network, convolutional neural network

Fig. 4: Concept for detecting intruder animals to activate repellent

IV. RESULTS

An early analysis of an ongoing study that detects animal incursions using CNN and Bi-LSTM algorithms produced an accuracy of 83.2% in detecting invasive species. A new Integrated Wildlife Management System was presented, acknowledging its limitations, which combined TCN with computer vision to achieve an amazing 93% accuracy. The efficiency of this technology was greatly increased, offering a more dependable method of lowering crop raiding incidents.

Significant progress has been achieved in animal intrusion detection for intelligent farming in the planned project which is represented in Fig. 5. The method surpassed the existing model in recognising invasive species by merging CNN and TCN. It also has a device for emitting targeted ultrasonic noises to discourage wildlife, guaranteeing quick reactions to incursions. The system, which is driven by edge computing, allows for real-time reaction and quickly reduces the likelihood of crop raiding for farmers.

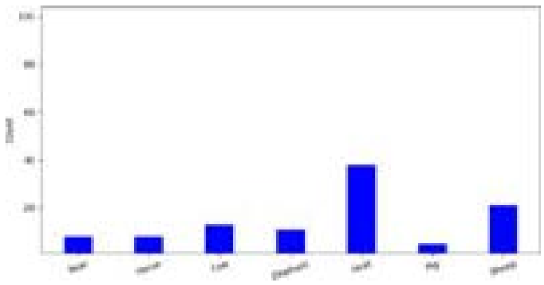

Fig. 5 The image represents analysis of animal intrusion detection. Then the x-axis represents animals and y-axis represents count of the animals.

The management of human-wildlife conflicts and agricultural interests is advanced by the proposed Temporal Convolutional Network-Based Animal Intrusion Detection Model for Smart Farming with ultrasonic alarm sound. It achieves a high accuracy of 93% in Fig. 6 for reducing crop raiding, operational expenditures, and environmental effect. This study integrates cutting-edge technology to support agricultural and biodiversity coexistence.

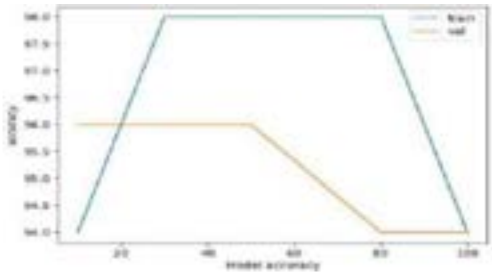

Fig. 6 Training and Validation Accuracy

V. DISCUSSION

Utilizing cutting-edge technology, the Integrated Wildlife Management System offers efficient crop protection while promoting coexistence through eco-friendly, real-time animal intrusion detection and repelling. Significant gains in accuracy and visual quality are demonstrated by the proposed hybrid models for sign language recognition, translation, and video generation, which effectively address current issues across a range of evaluation metrics. Presenting Ellipse R-CNN, a CNN-based detector designed to segment objects that are heavily occluded, such as clusters of fruits. The approach outperforms state-of-the-art models in accurately inferring multiple elliptical objects, even when obscured.

For COVID-19 screening with Chest Radiography (CR) images, COVID_SCREENET is a bifold architecture. Radiologists have confirmed that it achieves 100 % accuracy in both real-time and open-source datasets. Using digital colposcopy images, FSOD-GAN automates cervical cancer screening and achieves 99 % accuracy in identifying the stages of the disease. Three different types of cervical cancer lesions are identified using hierarchical multiclass classification and spot detection using FR-CNN.

Future development could involve improving the Temporal Convolutional Networks (TCN) to increase the Animal Intrusion Detection Model's accuracy. The efficiency of the system in reducing crop raiding incidents could also be increased by refining the ultrasonic emission technique to repel particular wildlife species and increasing the system's adaptability to a wider range of environmental conditions. By incorporating machine learning algorithms to modify repelling strategies in response to real-time data, the system's efficacy and adaptability could be improved.

VI. CONCLUSION

TCN and computer vision are combined in the Integrated Wildlife Management System to address conflicts between humans and wildlife in the face of habitat degradation. It quickly reduces crop raiding, providing environment friendly solutions promoting agriculture and biodiversity, driving conversations towards a resolution of such conflicts through the use of ultrasonic emission and edge computing integration.

***Abstract*— Smart agricultural technologies are quickly evolving due to their efficacy and efficiency in animal health monitoring. The increasing prevalence of plastic waste poses a significant threat to animal health in farming environments. This paper presents a novel approach for tracking plastic components, specifically paper and plastic bottles, within the felids of animal farming using Internet of Things (IoT) technology. The proposed system employs the YOLO (You Only Look Once) YOLO model for real-time object detection, which identifies waste paper and bottles in the fields. Upon detection, the system sends the information to a NODEMCU, which triggers a buzzer alert to discourage animals from consuming the identified hazardous items. The implementation involves deploying IoT sensors strategically across the animal farming facility to capture visual data. The YOLO model is then employed to process the collected data, accurately identifying, and categorizing plastic components. Upon successful detection, the system sends serial data to a NODEMCU, triggering a predefined response. In this case, an alarm is activated to alert farm personnel about plastic waste in the fields.**

I. INTRODUCTION

The use of Internet of Things (IoT) technology in farming, especially in smart farming, has completely changed how farmers take care of their animals. With IoT devices, farmers can easily keep track of their animals even on large farms. These devices are crucial for quickly identifying sick animals and separating them from the rest to stop diseases from spreading. Making sure animals stay healthy is not just important for them, but also for the people who rely on them and for the farm's productivity.

Using wearable technology has made a big difference in how farmers understand animal behavior. For example, special neck collars with sensors are popular in dairy farming. These collars, often using radio-frequency identification technology, help farmers control how much their animals eat and keep an eye on their health. They even work with automatic milking systems to make farming easier. These wearable devices collect data from the animals and store it in databases or the cloud. By analyzing this data, farmers can learn a lot about their animals' health and behavior. This helps them make better decisions to keep their animals healthy and their farms productive. Overall, IoT technology is making farming more efficient and effective.

The introduction of wearable monitoring technologies has completely changed how we understand and track animal behavior. In the past, we mainly relied on watching animals with our eyes, but now we have advanced gadgets that provide precise data about what animals are doing. These technologies, powered by the Internet of Things (IoT), offer a more scientific and detailed approach to monitoring livestock activities. There are many different types of wearable devices available now, giving farmers flexible tools to manage their animals more effectively. For example, in dairy farming, neck collars with built-in sensors have become very popular. These collars, which are worn by cows, help farmers control how much the animals eat and keep track of important health indicators. They even work seamlessly with automated milking systems, making dairy farming easier and more efficient. Sensors must demonstrate a high level of accuracy to effectively capture the nuances of the measured variables. Reliability is another crucial factor, encompassing not only the sensor's durability and robustness but also its consistency in performance over time and under various environmental conditions. Furthermore, careful evaluation of the cost-effectiveness of sensors is essential, considering not only the initial investment but also the long-term maintenance and operational expenses.

As depicted in Figure 1, the overall architecture of a wearable device system involves the installation of sensors on animal subjects, capturing relevant data that is then stored in databases or cloud servers. By analyzing this data, farmers can learn a lot about their animals' health and behavior. This information helps them make better decisions to keep their animals healthy and make their farms more productive. As wearable technology continues to improve, it promises to bring even more benefits to the agriculture industry, helping farmers make smarter decisions and run their farms more efficiently.

Fig 1: Cattle Wearable Device

II. Literature Survey

Wang et al. [1] explored the usage of intravaginal gadgets to tune adjustments in vaginal temperature at some point of the estrous cycle in dairy cows, showcasing the effectiveness of this approach in detecting physiological variations in cattle. Similarly, Wackers et al. [2] added a catheter-based impedimetric sensor for assessing intestinal histamine degrees in sufferers with irritable bowel syndrome, highlighting improvements in biosensing technologies for clinical applications.

In the world of agricultural IoT, Vangala et al. [3] discussed the implementation of stable sensing structures for agriculture from a blockchain attitude, emphasizing the significance of records integrity and protection in agricultural tracking. Meanwhile, Tresoldi et al. [4] examined how one of a kind sampling techniques and measurement gadgets impact vaginal temperature readings in lactating dairy cows, providing insights into optimizing statistics series techniques for animal fitness monitoring.

Steinmetz et al. [5] established the accuracy of the RumiWatch Converter V0.7.Four.5 in robotically tracking dairy cow behavior, contributing to the improvement of automated cattle management systems. Additionally, Kurtser et al. [6] confirmed the practicality of the use of a cell robot and RGB-D digicam to assess grape cluster length in vineyards, showcasing advancements in precision agriculture strategies.

Regarding IoT protection, Li et al. [7] addressed cybersecurity challenges in IoT-pushed deliver-your-very own-device (BYOD) environments, stressing the need of robust security features. Bai et al. [8] brought an impedimetric natural electrochemical sensor for detecting histamine in precision animal agriculture, presenting a unique method for monitoring animal fitness.

In broader IoT packages, Song et al. [9] performed a complete survey on IoT packages in clever logistics, figuring out opportunities to enhance supply chain control. Additionally, Quy et al. [10] explored smart healthcare IoT programs the use of fog computing, discussing architectural concerns and demanding situations in healthcare IoT deployments.

Ma et al. [11] developed a non-contact frame temperature tracking machine for farm animals livestock, presenting an revolutionary technique to animal health tracking. Furthermore, Patle et al. [12] assessed a smart sensor machine for predicting plant illnesses the usage of LSTM networks, demonstrating the capacity of device studying in managing crop illnesses.

In the field of faraway sensing, Patil et al. [13] proposed a changed YOLOv5 method for detecting small objects in faraway sensing photographs, contributing to advancements in satellite imagery analysis. Finally, Mohan et al. [14] carried out an in depth evaluation of sustainable improvements in precision farming enabled with the aid of IoT and Industry five.0 technologies, imparting insights into their transformative impact on agriculture. Each reference adds a unique perspective to the growing field of smart agriculture and technology integration in the farming sector.

III. System Architecture

The detected information is transmitted to an IoT-enabled central server, ensuring seamless communication between the detection system and the alert mechanism. Having sensors on hand is crucial to collect the current data on the health of cattle. These sensors are attached to animals or placed strategically inside their environments. Livestock sensors collect data on the animals and the environment around them. While an animal's body temperature may be determined by a sensor attached to it, the temperature, humidity, and air quality of the livestock's living quarters can all be measured by a sensor installed in the surrounding area. Figure 2 illustrates the integration of the system with the central server.

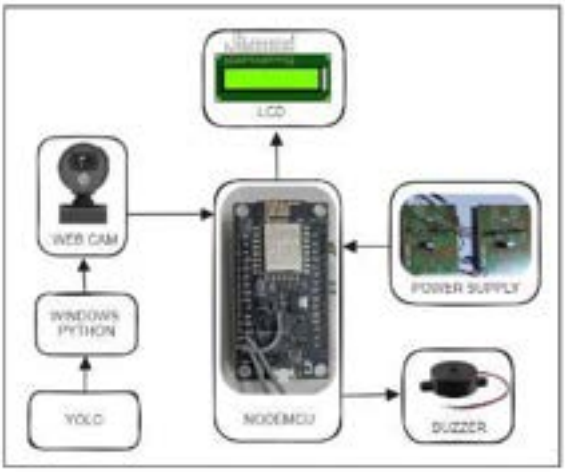

Fig 2: IoT enabled central server architecture

A. NodeMCU Controller

There are several electrical uses for this programmable microcontroller board, which is available as an open source product. Due to its cost-effectiveness, versatility, and user-friendly nature, this component is an integral addition to the proposed system. Both float and flow sensors are connected to this key component as part of the system configuration. A NodeMCU microcontroller is employed to receive the detected values from the IoT server. The controller is programmed to activate a buzzer alert system upon identification of plastic components, creating an audible deterrent for animals.

B. Web Cam

Without downloading the software that is provided with cameras on their PC, users are unable to record or stream video over the Internet. Webcams may record high-definition videos and still images even if their video quality may be lower than that of other types of cameras. A webcam or tiny digital video camera, maybe simply linked to a Raspberry Pi computer. It is an input tool for digital picture capturing. This work used a Web cam for capturing the obstacle images, which are present in outdoors and indoors with the help of a web camera. Monitoring in the project is achieved through: systematic deployment of IoT sensors across farming areas, continuous capture of visual data by sensors, real-time processing of data using the YOLO model for object detection, immediate alert activation via NODEMCU upon detection of waste materials, ensuring timely intervention to prevent animal consumption.

C. LCD Display

LCD module at 40% relative humidity and 40% temperature, respectively. Higher temperatures can cause the display's overall color to alter, while lower temperatures can delay the rate at which the display blinks. When the temperature drops within the designated range, the display will normalize. Polarizer peel-off, bubble formation, and polarisation deterioration can all be brought on by heat and humidity. Displays whether the object can be eatable or not.

D. *12V Power Supplies*

The 12V or 12VDC power supply stands out as a highly prevalent energy source in contemporary applications. It is often employed to transform input from 120VAC or 240VAC to an output of 12VDC using a combination of a transformer, diode, and transistor. There are two primary types of 12V power supplies: regulated and unregulated. Additionally, acopian switching regulated power supplies utilize robust EMI filtering and shielding techniques to mitigate noise transmission to both the line and load, addressing both common and differential modes.

E. Buzzer Alert System

A buzzer or beep serves as an electromechanical, mechanical, or audio signaling device. These devices, commonly referred to as buzzers or beepers, find widespread use in applications such as timers, railway horns, alarm clocks, and signaling keystrokes or mouse actions. In a specific context, a buzzer was utilized in this project to warn animals about the presence of harmful materials, playing a crucial role in deterring them from consuming plastic waste.

F. Object Detection using YOLO

The YOLO (You Only Look Once) algorithm is applied to swiftly detect waste paper and bottles in farming fields, ensuring animals' well-being. YOLO's neural network-based approach enables fast and precise object identification, making it popular for various applications like surveillance and traffic management. Object detection in the project is achieved through: strategic deployment of IoT sensors capturing visual data, preprocessing of captured images to enhance clarity, utilization of the YOLO model for real-time detection and classification of waste paper and plastic bottles, and integration with NODEMCU for immediate alert activation upon detection. The algorithm utilizes a CNN to predict class probabilities and bounding boxes simultaneously, simplifying the detection process. Its speed and accuracy make it a favored option for real-time object detection, bolstering the reliability of our study's goals.The choice of YOLO (You Only Look Once) for object detection in our study is based on its real-time processing capabilities, which swiftly detect objects in images or video frames. YOLO's grid-based approach predicts bounding boxes and class probabilities directly, ensuring rapid, accurate detection without complex region proposals.

YOLO Algorithm

Input: Input cattle field images

Output: Identified plastic Images

<u>Procedure</u>

```
Initialize:
  State := RELEASED
  Voted : = FALSE

For q_a to enter the critical section:
  State :=  WANTED
  Multicast request to all processes in J_a
  Wait until (number of replies received = K)
  state := HELD

On receipt of a request from q_a at q_b:
  if (state = HELD or voted = TRUE):
    queue request from q_a without replying
  else:
    send reply to q_a
    voted := TRUE

For q_a to exit the critical section:
  state := RELEASED
  Multicast release to all processes in J_a

On receipt of a release from q_a at q_b:
  if (queue of requests is non-empty):
    remove head of queue from q_c, say
    send reply to q_c
    voted := TRUE
  else:
    voted := FALSE
```

IV. Results and Discussion

The IoT project aims to tackle plastic waste in agricultural settings involving animals by introducing a method that utilizes the YOLO (You Only Look Once) model for instant object detection. This system deploys IoT sensors throughout farming areas to capture visual data, processed by the YOLO model to identify and classify waste paper and plastic bottles. Upon detection, the system activates a buzzer alert, discouraging animals from consuming harmful materials. Methodology assessment criteria include precision, real-time efficiency, reliability, and scalability, with a comparison against traditional methods revealing potential benefits in accuracy, cost-effectiveness, and implementation simplicity. The approach integrates IoT technology with the YOLO model for real-time object detection, offering a novel solution to the issue of plastic waste management in animal farming environments. Through a literature review, the increasing prevalence of plastic waste is identified as a significant threat to animal health in agriculture, underscoring the need for innovative technological interventions. While various studies have explored IoT applications in agriculture and waste management separately, the study uniquely combines these technologies to address the specific challenge of plastic waste detection in animal farming. By evaluating the methodology and discussing its implications in light of relevant literature, the study advances the field by providing a practical solution to mitigate the adverse effects of plastic waste on animal health and environmental sustainability. Additionally, future research directions are proposed to further refine the solution and its broader applications in agricultural sustainability efforts.

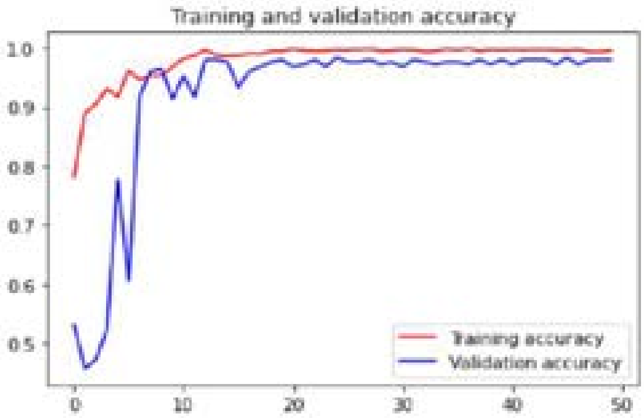

Fig 3: Accuracy of YOLO model over training epochs

The training accuracy curve is presented in Figure 3 The proposed model reaches a high accuracy as the number of epochs increases. High accuracy and reliability in the project are achieved through strategic deployment of IoT sensors capturing comprehensive visual data, utilization of the YOLO model for precise object detection, real-time processing ensuring timely identification of waste materials, consistent deployment of IoT sensors across farming areas, rigorous testing and validation of the YOLO model for accurate waste detection, redundant alert mechanisms like buzzer activation via NODEMCU, and continuous monitoring and refinement of the system to minimize false positives and false negatives, enhancing overall system performance and reliability.

Fig 4: Training losses of YOLO model over epochs

Likewise, the loss of the models decreases to around 0.05 as the number of epochs increases. The accuracy and loss curves are perfectly converged into each other. Figure 4 illustrates the Training losses of the YOLO model over epochs.

TABLE 1: COMPARATIVE ANALYSIS BETWEEN EXISTING AND PROPOSED SYSTEM

Feature	Proposed System	Existing System
Detection Method	YOLO algorithm with CNN for real-time object detection	Convolutional Neural Networks (CNN)
Object of Detection	Plastic components (paper, bottles)	Various agricultural anomalies
Alert System	Buzzer activation upon detection	SMS or Email notification
Sensor Technology	IoT sensors strategically deployed	Wearable sensors or satellite imagery
Implementation Scalability	Scalable across various farming environments	Limited to specific farm types or regions
Cost-Efficiency	Cost-effective NodeMCU controller	High initial investment for specialized sensors (gear)
Real-Time Capability	Real-time identification and alert activation	Delayed response due to processing requirements

Table 1 presents a comparative analysis between the project and an existing novel system. The project utilizes YOLO algorithm for real-time object detection of plastic components, employing cost-effective IoT sensors and activating a buzzer alert. This comparison highlights key features and benefits for precision animal farming waste detection.

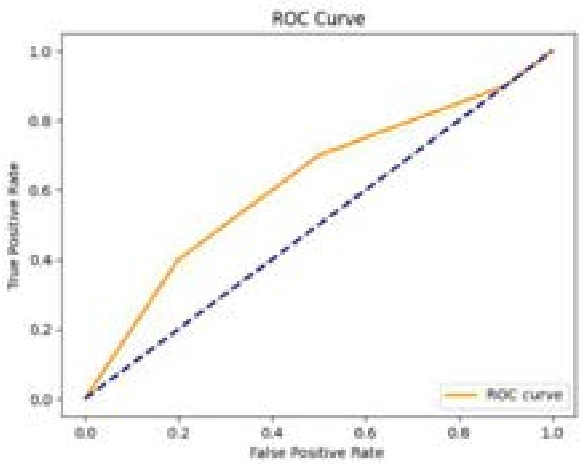

Fig 5: ROC Curve

The implementation of the ROC curve, as depicted in Figure 5, involves assessing the YOLO-based model's effectiveness in detecting plastic components within animal farming waste. Analysis of the ROC curve in Figure 5 enables the identification of optimal thresholds for activating the buzzer alert system, thus improving waste management efficiency and minimizing false alarms.

V. Conclusion

Ensuring the well-being of animals is a top priority worldwide, driving the need for effective scientific solutions. One promising approach gaining traction is the use of biosensors to manage animal health. While these sensors are still in development, they're showing promise in practical applications for animal care. Advanced technologies originally designed for human health are now being adapted for veterinary use, helping veterinarians accurately diagnose diseases and assess the health of animals.

This integration of advanced technology with precision farming practices is revolutionizing how care for animals. Precision farming covers a wide array of technologies aimed at improving animal husbandry practices for better health outcomes. In line with this trend, a new project introduces an innovative solution to monitor plastic waste in animal farming fields using IoT technology and sophisticated data processing. The system relies on the YOLO (You Only Look Once) object detection algorithm to spot waste paper and bottles scattered in the fields. When these items are identified, the system quickly notifies a NodeMCU controller. Then, the controller triggers a buzzer alert to deter animals from consuming the potentially harmful items, helping prevent health issues.

Beyond animal health, the project also aims to address environmental concerns by reducing plastic pollution in agricultural areas. By harnessing cutting-edge technology and creative solutions, this initiative not only protects animal well-being but also contributes to the preservation of ecosystems and the health of local communities.

***Abstract*—An automated shower system is essential to design for public facilities, to address the concerns about excessive water consumption and accessibility for individuals with physical disabilities. The proposed system utilizes advanced voice recognition technology to enable easy control of water temperature and showerhead positioning, promoting water conservation, safety, and convenience. Existing manual systems face challenges in setting desired parameters for disabled users, whereas the proposed system becomes a solution that eliminates manual adjustments through seamless voice commands. Key features include adjustable settings, automatic regulation and emergency shut-off for enhanced safety.**

Keywords— ESP-WROOM-32, Ultrasonic Sensor, Servo motor, Relay, DC Motor Water Pump, Battery, Wi-Fi (Arduino UNO Interface), Blynk Console, Voice flow

I. INTRODUCTION

Technology advancement is highly demanding for automated devices in nowadays living environment. Especially the use of automated devices is becoming essential for elderly and disabled people as well. One of the common needs and essential tasks that is required to be automatized is controlling water usage while taking a bath using the shower. It is identified that very young children, who are crazy about using a shower may waste water unknowingly. In addition, aged people who may suffer from Alzheimer's, or who lazy to use shower controls properly may lead to more water consumption. Hence in this scenario, it is required to identify a better control mechanism for the shower system while satisfying the customer's need. The main aim of the proposed automated shower system is to give utmost comfort for people with disabilities to have proper use of the shower system without any further aid from other people. This type of invention is also useful for the implementation of smart home facility that are highly needing by recent advancements [1]. The proposed automatic shower system uses sensor-based setup to reduce the water consumption during the bath process, and also provides comfort use of controls based on voice commands. This new invention of shower system can address the problem of false signaling that are arises during Bluetooth application [2]. The existing sensor-based shower systems [3,4,5] observed that they are highly sensitive to react fast during every move of bath position causes erroneous results. These systems suffer from false signaling to the user, hence leading to confusion in the use of appropriate controls via Bluetooth signaling. Also, the use of infrared sensors [6,7,8,9] causes unwanted reflections from Unusual light interference that leads to malfunctioning of the sensor system. The objective of the proposed design is to improve the performance of the shower by introducing of additional system by using voice-based controls. Introducing the Automated Shower System, an innovative solution designed for individuals with physical challenges. The smart shower integrates voice commands, servo motors, and ultrasonic sensors to create a user-friendly and adaptive bathing experience. Users can activate the system, select the preferred water temperature through voice commands, and enjoy a personalized shower. The system ensures precise control of water valves and incorporates user presence detection for safety and energy efficiency. Overall, an automated shower simplifies the bathing process, offering enhanced accessibility and comfort for individuals with disabilities or diverse needs.

II. LITERATURE REVIEW

The common thread in these discussions is the evolution of shower technology towards greater efficiency, accessibility, and user-friendliness. From autonomous smart showers using sensors and actuators for optimized water usage to designs integrating Bluetooth technology for mobile-controlled temperature adjustments, the overarching goal is to enhance the shower experience. Ongoing efforts to incorporate voice and hand gesture technologies highlight a commitment to continuous improvement, addressing the concerns related to water conservation, manual adjustments, and accessibility for individuals with disabilities.

In 2010, the Flow Controllable Shower Arm [10], a noteworthy invention designed to revolutionize the shower experience. This innovative system addresses multiple facets of user requirements by incorporating a flow control mechanism, ensuring efficient water usage. A distinctive feature of this shower arm is the absence of manual temperature adjustments, streamlining the user experience and mitigating potential difficulties, especially for those with physical challenges. Mr. Sirkin's creation marks a significant advancement in shower technology, emphasizing both water conservation and inclusivity in its design.

Disability Shower invented in 2012 [11] is a groundbreaking innovation in the realm of accessible shower systems. The hallmark of this invention lies in its thoughtful design, featuring a seating option to cater to individuals with disabilities, prioritizing comfort and inclusivity. His creation not only addresses the specific needs of users with mobility challenges but also streamlines the overall showering process by removing unnecessary complexities associated with traditional systems, marking a significant stride toward universal accessibility in personal care amenities.

Autonomous smart shower with sensors and actuators [12] introduced the new concept, an autonomous smart shower with sensors and actuators redefine the traditional shower experience. This innovative design is focused on optimizing water consumption by incorporating advanced technology to control the flow rate, thus contributing to environmental sustainability. Khan's autonomous smart shower represents a significant step forward in the integration of cutting-edge technologies to enhance water efficiency while prioritizing user convenience in personal hygiene routines.

Design of Automatic Sensor-Equipped Shower [13] invented in 2022, introduced the Design of Automatic Sensor-Equipped Shower, marking a notable advancement in shower technology. The innovation centers around the use of Bluetooth technology to control the water temperature through a mobile device, offering users a convenient and personalized shower experience. The continuous evolution of automatic sensor-based [14-20] shower systems is dedicated to staying at the forefront of technological innovations in the pursuit of more intuitive and responsive user-friendliness.

III. Proposed System

The automated shower system as shown in Fig 1 utilizes voice recognition technology to provide users with hands-free control over the showering experience. Users simply speak their desired water temperature and flow rate commands, and the system's voice recognition module processes and transmits these commands to the shower controller. The shower controller then adjusts the water settings accordingly, ensuring a personalized and comfortable showering experience. The Automated Shower System simplifies the initiation process through a voice command, allowing users to select their preferred water temperature using options like hot water, cold water, and normal water. This user-friendly interface, facilitated by voice commands, caters to diverse user needs. The system employs servo motors to precisely adjust the hot and cold water supplies, achieving the selected temperature and ensuring a tailored bathing experience.

An ultrasonic sensor detects user presence, activating the system and water pump for a safe and efficient shower. Following the shower, the system autonomously shuts down after 3 minutes, emphasizing safety and energy efficiency. Overall, the integration of voice control, servo motors, temperature sensors, and presence detection technology creates a sophisticated yet accessible showering experience.

The Automated Shower System's emphasis on user-friendly voice commands, precise servo motor control, and intelligent presence detection contributes to a customized and automated bathing experience for individuals with physical challenges.

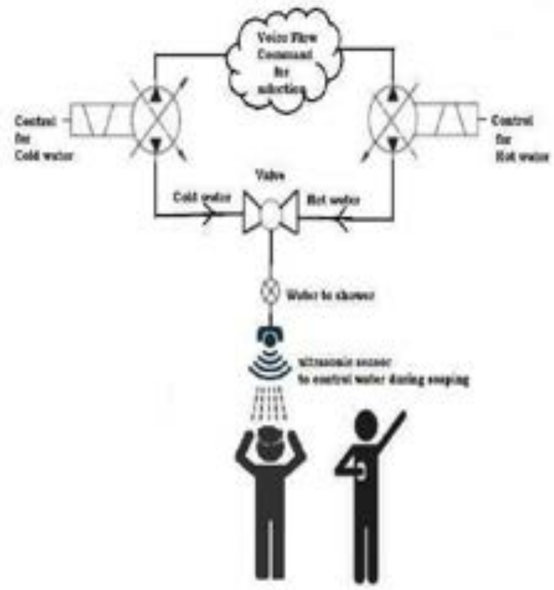

Fig. 1. Proposed Sensor based Shower System

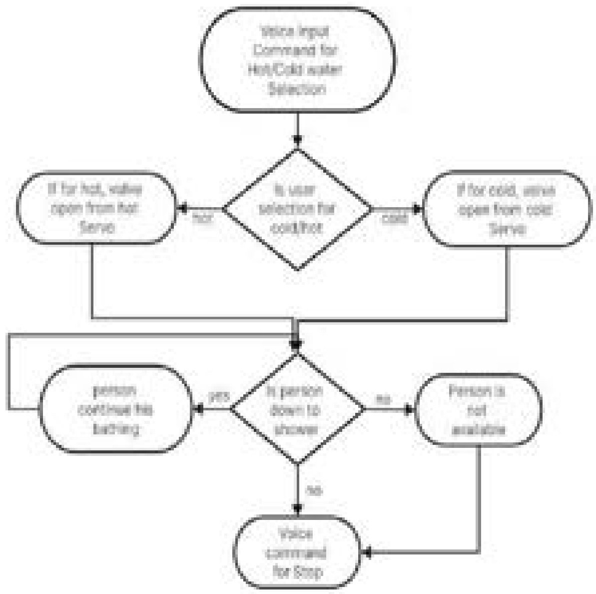

Fig. 2. Operational Flow of Shower System

The block diagram depicted in Fig 2 shows how the components of the automatic shower system are interconnected. It uses two servo motors, an ultrasonic sensor, a relay and a battery. It is presumed that water comes through two pipes one is for hot water and the other is for cold water. The servo motor is controlled by the microcontroller, which receives signals from the ultrasonic sensor and the voice input device. The battery powers the microcontroller and the servo motor. The relay is used to control the power to the water pump. The operation of the system majorly relies on voice input commands. The initial setup for taking a bath should be ready by selecting the type of water by the user choice command through the voice input system. The voice input system could be any Bluetooth or Wi-Fi setup. In the proposed prototype system the blink app is used. This blink app is used as an IOT-enabled system that allows the user to use the shower system from a remote location too to operate while returning from the office or the saloon, one can choose the type of water to initiate the water level to get ready by then the person reaches home.

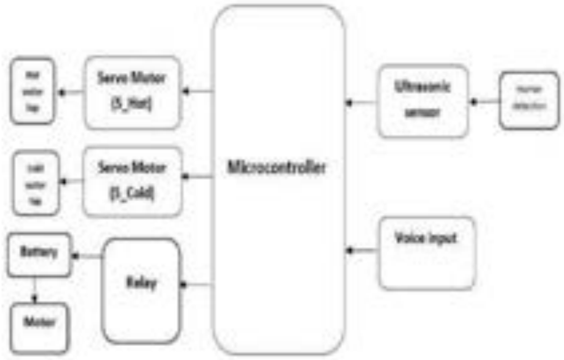

Fig. 3. Block diagram of proposed Shower System

A. ESP-WROOM-32

ESP-WROOM-32 shown in Fig 3 is the heart of the automated shower system, a powerful microcontroller that serves as the system's nerve center. This versatile chip seamlessly integrates various functionalities, including voice recognition, and sensor interfacing. By leveraging the ESP32-WROOM module's capabilities, the proposed system effortlessly interprets user commands, monitors sensor data, and regulates water flow, ensuring a safe, personalized, and hands-free showering experience for individuals with disabilities.

B. Ultrasonic Sensor

Ultrasonic sensors shown in Fig 4 measure target object distance by emitting sound waves and converting reflections into electrical signals. Comprising a transmitter and receiver, they utilise piezoelectric crystals for sound emission.

The proposed automated shower system integrates strategically positioned ultrasonic sensors within the stall. Continuously emitting and receiving ultrasonic waves, the sensors analyze the time taken for reflections to detect user presence and distance. Real-time data is fed into the system's microcontroller, enabling intelligent decisions based on user proximity. This facilitates automatic shower activation or deactivation, optimizing water usage and ensuring a seamless experience.

C. Servo Motors

A servo motor shown in Fig 5, renowned for its precision, integrates a built-in feedback mechanism to regulate position. Common in robotics and remote-controlled devices, servo motors play a pivotal role in the proposed automated shower system. Positioned strategically, they control hot and cold-water valves, enabling accurate adjustments to temperature and flow rate.

The system's microcontroller commands the servo motors, facilitating seamless transitions between open, closed, and partially open valve states. This precise control mechanism ensures the system responds to user preferences, maintaining consistent water settings. By harnessing the capabilities of servo motors, the proposed automated shower system provides a hands-free and personalized shower experience, particularly beneficial for individuals with disabilities.

D. Relay

The relay shown in Fig 6, used as electro-mechanical switches, utilizes DC electrical current to open or close contact switches. In a 5V single-channel relay, there are normally open and normally closed contacts alongside a coil.

Integrated all the above-said components into the proposed automated shower system, relays play a crucial role in controlling the water pump based on user presence detection. Strategically placed within the system, these relays manage the electricity flow to the water pump. Triggered by ultrasonic sensor signals indicating user presence, the relays activate, powering the water pump and initiating water flow. Conversely, when the sensors detect user absence, the relays deactivate, interrupting the circuit and halting pump operation. This intelligent mechanism ensures water is dispensed only when a user is present, promoting resource conservation and enhancing system efficiency.

E. DC Motor Water Pump

A DC motor pump shown in Fig 7 employs a Direct Current (DC) motor to transfer fluids by converting electrical energy into mechanical energy for liquid movement. Widely used in irrigation, aquaculture, and industrial processes, this compact and adaptable system is crucial for enabling precision control under varying loads.

In the proposed automated shower system, the DC motor pump efficiently delivers water to the showerhead, seamlessly integrating with the user detection mechanism. Triggered by ultrasonic sensors indicating user presence, the system's microcontroller activates the 12V DC motor pump, drawing water from the source and initiating a personalized shower experience only when a user is detected within the shower stall.

F. Battery

A battery shown in Fig 8, functioning as an electrochemical device, generates electric current through chemical reactions in its cells. It comprises positive and negative electrodes immersed in an electrolyte, serving as a powerhouse for electronic devices.

In the proposed automated shower system, a strategically positioned battery powers the DC motor pump, ensuring a reliable water flow. This battery-driven approach enhances portability, eliminating the need for a direct electrical outlet connection. The seamless integration of the battery and pump underscores the system's versatility, allowing for a personalized and independent shower experience. This user-centric design empowers individuals with disabilities, showcasing the system's adaptability in diverse settings.

Fig 4. ESP-WROOM-32

Fig 7. Relay

Fig 5. Ultrasonic Sensor

Fig 8. DC Motor Water Pump

Fig 6. Servo Motors

Fig 9. Battery

G. Arduino UNO

The Arduino IDE is a dedicated software platform designed for programming Arduino microcontrollers, offering a user-friendly interface for code development and deployment as shown in Fig 9.

Fig. 10. Arduino UNO Interface

In the proposed automated shower system, the Arduino IDE plays a pivotal role by providing a user-friendly environment for programming and controlling hardware components. As an open-source tool, it allows developers to customize code governing the ultrasonic sensors, servo motors, and DC motor pump, ensuring precise control over water flow, temperature adjustment, and user detection. The Arduino IDE's functionality extends to code compilation and uploading, facilitating seamless communication between software and hardware components and enabling the system to function autonomously.

H. Blynk App

Blynk is a mobile application designed for IoT application development shown in Fig 10, offering a platform to create custom interfaces for hardware control, especially with microcontrollers like Arduino. It simplifies IoT integration by providing a user-friendly interface for programming and device interaction.

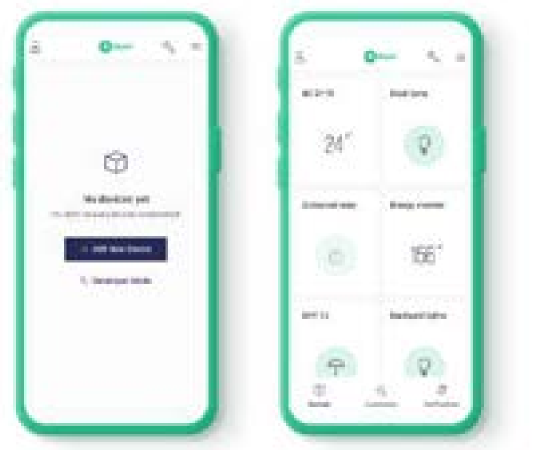

Fig. 11. Blynk App Overview

In the proposed automated shower system, the Blynk platform enables remote monitoring and control of system components. The Blynk mobile app allows users to visualize sensor data and, enhancing the shower experience and promoting independence. This application serves as a bridge between users and the automated shower system, facilitating seamless interaction and customization of features. With Blynk, the system leverages IoT capabilities, making it more accessible and user-centric. Users may remotely control on behalf of their old age people or differently abled people via the blink app by giving voice commands for a prior setup like water type whether hot or cold selection, whether to start the shower system or to stop as and when required.

I. Voice Flow

Voice flow shown in Fig 11, is a cloud-based platform that empowers developers and designers to create voice applications seamlessly, eliminating the need for extensive coding. This platform facilitates the design, development, and deployment of voice-driven experiences with an intuitive interface. Professionals can build interactive applications for platforms like Amazon Alexa and Google Assistant.

Fig. 12. Voice Flow Set-up

In the automated shower system, Voiceflow plays a crucial role, enabling hands-free control through voice recognition, as depicted. The platform translates voice commands into text and relays them to the Blynk app, allowing users to effortlessly manage the system. This integration showcases the power of Voiceflow in enhancing user interaction and control within the automated shower environment.

IV. Results and Observations

The proposed automatic shower system successfully demonstrated the integration of hardware components, Blynk app control, and Voice flow app interaction to deliver a personalized and convenient showering experience. The necessary connections and set are shown in Fig. 12. Ultrasonic distance measurements ensured the system operated within the desired range, while Blynk app control provided a user-friendly interface for temperature and flow adjustments. Voice flow app integration enabled hands-free control using simple voice commands, further enhancing the user experience. The system's success highlights the potential of technology to automate daily tasks and improve user convenience.

Fig. 13. Detailed description of proposed shower setup

The successful hardware setup, as shown in Fig 13, marked a significant milestone in the proposed work. The image showcases the meticulously assembled components as prototypes, each component carefully integrated to form a cohesive and functional system. The setup's flawless operation, evident through rigorous testing and evaluation, stands as a testament to the team's expertise and meticulous attention to detail. This accomplishment paves the way for further progress, enabling us to explore the full potential of the proposed design to achieve the desired objectives.

The Blynk app's seamless integration with the hardware components played a pivotal role in the success of the automatic shower system as shown in Fig 14. The Blynk app proved to be an invaluable tool in enhancing user control, monitoring sensor data, and providing personalized temperature adjustments for the automatic shower system. Its user-friendly interface simplified the process of activating and adjusting the system, allowing users to effortlessly control the flow and temperature of the water.

V. CONCLUSIONS

In conclusion, the proposed shower system is not just a technological upgrade but a step towards inclusivity and enhanced daily living. By seamlessly integrating voice and hand gesture recognition, we've aimed to redefine the shower experience for physically challenged individuals. The adjustable settings cater to diverse needs, while safety features, including emergency shut-off, prioritize user well-being.

This innovative system goes beyond its primary audience, offering practical benefits for individuals with Alzheimer’s, the elderly, those with autism, and even partial usability for the visually impaired. It's not just a shower; it's a user-centric solution designed to make a positive impact on the daily lives of various user groups. The performance of the whole system can be further improved by adding highly sophisticated sensors that take user gestures as input to control the whole bathing process and to give the user a sublime experience.

***Abstract*— This research study performs a comprehensive comparative analysis aimed at developing effective machine learning models for classifying handwritten Devanagari numerals. The research focuses on evaluating the performance of various models to determine the most accurate classification approach. Initiating with data pre-processing, including feature extraction and normalization, the data is prepared for model training and assessment. A diverse range of machine learning models, from traditional methods like Support Vector Machines (SVM) to advanced techniques such as Random Forests, K-Nearest Neighbors, and Convolutional Neural Networks, are considered for the comparative analysis, ensuring a thorough assessment of classification capabilities. Cross-validation techniques are employed during model training and testing to enhance reliability. Statistical tests are utilized to assess the performance variations among models, enhancing the robustness of the analysis. Visual representations of performance metrics and comparison results offer clear insights. This research study aims to identify the most suitable machine learning model for handwritten Devanagari numeral classification, potentially advancing character recognition systems and linguistic applications.**

Keywords*— Handwritten character recognition, Machine learning, Support Vector Machine(SVM), Data augmentation, Transfer learning, Digital document processing

I. INTRODUCTION

Text recognition involves a computer's ability to comprehend written text, utilizing machine learning algorithms and frameworks for the interpretation and assessment of textual content. In this study, the dataset was generated by using a paint application. Input images were created from numbers 0 to 9 using an oil brush, chosen for its versatility in accurately predicting the digits. Recognizing handwritten Devanagari numerals poses a formidable challenge, given the script's complexity. This study introduces a novel approach leveraging machine learning techniques, particularly Support Vector Machines(SVMs)[11], K-Nearest-Neighbours (KNN), for feature extraction and classification. The proposed model is trained and tested on a substantial dataset, emphasizing robustness and generalization across diverse writing styles.[1] To tackle limited training data and variations, this study employs data augmentation and transfer learning. Handwriting recognition is a crucial process in computer science, finding applications in Optical character recognition (OCR) systems, signature authentication and document scanning . The evolution of digit categorization is evident in its application in banking for fraud prevention, healthcare for patient record digitization, and government for information extraction from official documents.[2] This study reflects the adaptability and significance of handwriting recognition in addressing contemporary challenges. To generate a dataset, our initial step involves assigning a value of 1 to the selected region and 0 to the background. Consequently, our dataset will comprise solely of these two values: 0 and 1. It's important to note that pixel values typically span from 0 to 255. Conventionally, 0 signifies black while 255 denotes white in most scenarios.

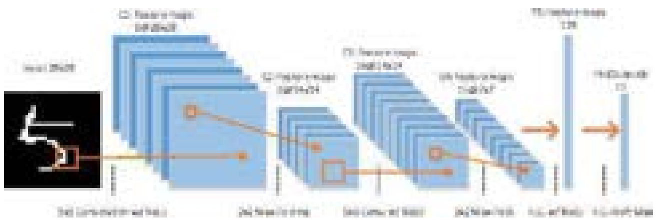

Fig. 1. System Architecture

II. RELATED WORKS

Ajitha K (2023) focused on centered around evaluating various machine learning models to determine their effectiveness in classifying handwritten digits in the Devanagari script. [1] The CNN model proposed in this study achieved an impressive accuracy of 99.522%. Furthermore, it surpassed the performance of other CNN models evaluated for Devanagari numerals classification.

K. Kancharla (ICACAT), Dec. 2018 focused on Handwritten Signature Recognition stands as a crucial behavioral biometric utilized across numerous identification and authentication applications. It predominantly operates through two distinct methods: on-line and off-line recognition. On-line recognition entails a dynamic approach, incorporating parameters such as writing pace, variations in stylus direction, and the count of pen ups and pen downs throughout the signature-writing process.

SM Shamim [3] It focuses on recognizing a digit through minist dataset. They concluded that highest precision, recall and f1score for Support Vector machine.

M. M. Al-Taee [4] focused on Handwritten recognition has garnered significant interest within the fields of pattern recognition and image processing over recent decades [13].

S. Gupta [5] In this paper, A comparison of different approaches for recognizing handwritten numerals utilizing solely the MNIST database is conducted. Over time, numerous researchers have introduced novel techniques for digit recognition, contributing to the enhancement of our daily routines [12].

S. Boroojerdi ‘‘Handwritten multi-digit recognition with machine learning’’ in (IETC). Offline recognition of handwritten digits poses a persistent challenge, with solutions thus far remaining only partially effective. This study delves into the realm of offline handwritten multi-digit recognition, employing three distinct algorithms—Decision Trees, Multilayer Perceptrons, and Random Forest—utilizing the MNIST dataset. Among these, Random Forest emerged as the most promising, boasting an impressive 96% accuracy alongside reasonable runtime efficiency.

III. PROPOSED WORK

The suggested endeavor to employ machine learning for the identification of Manually scripted Devanagari numerals constitutes a significant advancement in the realm of character recognition [14] particularly within the intricate context of challenging scripts like Devanagari.

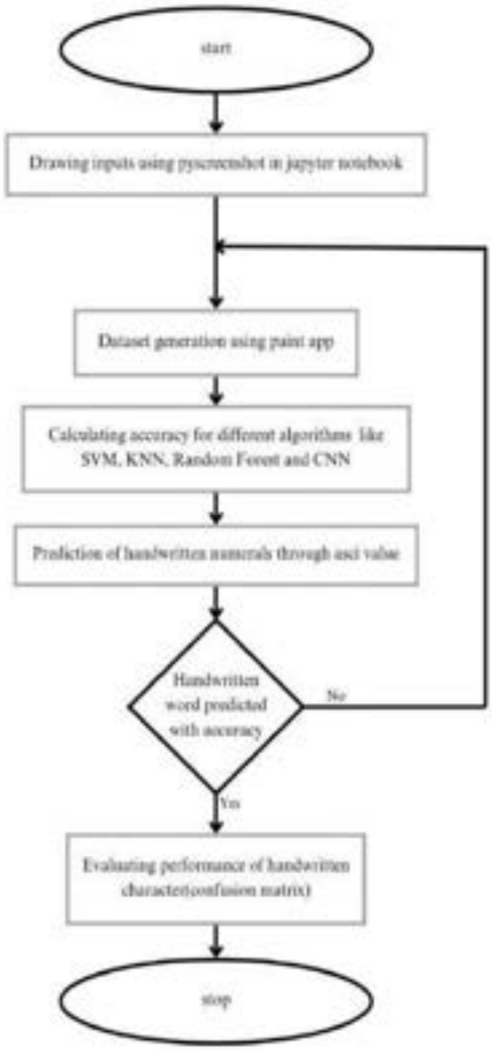

Fig.2. Process of handwritten recognizing

This study centers on assessing the appropriateness of various machine learning frameworks for classifying Manually written numerals using the Devanagari script. In this research, the study will evaluate various models, including K-Nearest-Neighbors (KNNs), Support Vector Machine (svms), Random Forest (rf), and Convolutional Neural Networks(cnn). Surprisingly, the proposed KNN model is implemented on F1 score.

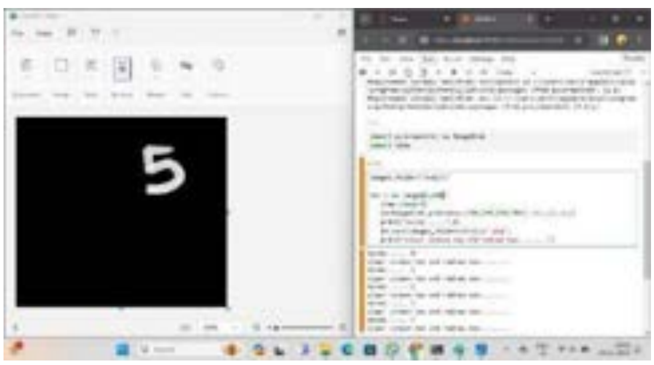

Fig. 3. Dataset generation using paint

KNN Algorithm:

The K-Nearest Neighbors (KNN) algorithm, a simple yet potent supervised machine learning technique, finds application in tasks encompassing both classification and regression. [6] At its essence, it entails producing predictions based on either the predominant class or the average of the KNN data points within the feature space. Dataset creation is achieved using a paint application. General formula is

$$\sum_{i=1}^{k} |xi - yi|$$

CSV File Setup: This work begins by importing the necessary libraries: cv2 for computer vision operations, "csv" for handling CSV files, and glob for file path pattern matching [8]. It sets up the header for the CSV file, where each image will be represented as a row with a label and pixel values. A CSV file named 'demo1.csv' is created, and the header is written to it.

Image Processing and CSV Data Generation: For each digit label (0 to 9), the code uses glob to get a list of image file paths in the corresponding subdirectories. For each image, it reads the image, converts it to grayscale, applies a Gaussian blur, and resizes it to 28x28 pixels. Based on the pixel value it predicts the digit. The label and flattened pixel values are then appended to the 'demo1.csv' file.

Data Loading and Shuffling: The code imports pandas for data manipulation and shuffle from scikit-learn to shuffle the dataset. It reads the CSV file into a Pandas Data Frame and shuffles the rows randomly.

Data Splitting: The features (X) comprise all columns excluding the "label" column, while the target variable (Y) is specifically the "label" column. The dataset undergoes division into training and testing sets facilitated by the 'train_test_split' function from scikit-learn.

Support Vector Machine algorithm:

The dataset is formed by employing a paint application to produce images, from which a CSV file is crafted using pixel values. Supervised machine learning tasks, specifically classification or regression, can be effectively addressed using SVM as an algorithm. SVM exhibit versatility in handling both linear and non-linear classification as well as regression tasks through the utilization of suitable kernel functions. Typical kernel options encompass linear, polynomial, and radial basis function (RBF). Hyper plane equation is

$$W.X+b=0$$

Importing Libraries: This work starts by importing necessary libraries. Joblib is imported for saving the trained SVM model, and SVC (Support Vector Classification) is imported from scikit-learn for implementing the Support Vector Machine classifier.[7]

Creating an SVM Classifier: An SVM classifier is created using the SVC class with a linear kernel. The random state parameter is set to 5 for reproducibility, ensuring that the same sequence of random numbers is generated if the code is run multiple times.

Training the Classifier: The created SVM classifier ('classifier') is trained using the `fit` method with the training data and where train_x represents the features (pixel values) and train_y represents the corresponding labels.

Saving the Model: The trained SVM model is then saved using the joblib.dump function. The model is saved in a file named "digit_recognizer" within a directory named model. This allows you to persist the trained model for later use without having to retrain it every time.

Random Forest algorithm:

A Random Forest is a popular machine learning algorithm used for both classification and regression tasks.[9] This algorithm focusses on following steps:

Importing Necessary Libraries: Here, we import the 'RandomForestClassifier' class from the ensemble module of scikit-learn, which contains ensemble-based learning algorithms, including Random Forest. We also import accuracy_score from 'sklearn.metrics' which will be used to calculate the accuracy of the classifier.

Creating the Random Forest Classifier: Creates a RF classifier instance, with the 'n_estimators' parameter determining the number of trees within the forest.

Training the Classifier: The Random Forest classifier is trained on the provided training data. Usually, 'train_x' comprises the features of the training dataset, while 'train_y' contains the corresponding labels.

Making Predictions: In this step, the Random Forest classifier, which has been trained previously, is employed to predict outcomes on the test dataset denoted as 'test_x'. The resulting predictions are then stored in the variable 'y_pred'.

Calculating Accuracy and Confusion Matrix: In this context, we're presenting both the confusion matrix and accuracy metrics. The confusion matrix serves as a crucial instrument for assessing the performance of a classification model on a test dataset with known true values. It provides a comprehensive breakdown, revealing the counts of tp, fp, tn, and fn, thereby offering significant insights into the classifier's efficacy.

CNN algorithm:

Importing Necessary Libraries: Keras are imported. Keras is TensorFlow's high-level neural networks API, which provides a convenient way to define and train deep learning models.[10].

Loading and Preprocessing the Data: Own dataset is loaded and then preprocessed will result Reshaping the input images to have a single channel (grayscale) and adjusting pixel values to be between 0 and 1.

Compiling the Model: The model undergoes compilation using the Adam optimizer, categorical cross-entropy loss function (ideal for multi-class classification tasks), and accuracy serves as the metric for evaluation.

Training the Model: The model undergoes training on the provided training data ('x_train', 'y_train') for a total of 5 epochs, utilizing a batch size of 64 for optimization. Validation data is designated through the `validation_split` parameter during the training process.

Evaluating the Model: The trained model is evaluated on the test data (‘x_test’, ‘y_test’). Predicted probabilities are obtained using `predict` method, then converted to predicted labels. True labels are also converted from one-hot encoded format. Finally, accuracy is calculated and printed.

IV. RESULTS AND DISCUSSION

The Support Vector Machine (SVM) model achieves the highest accuracy at 99.5%. Prediction analysis can be conducted through the Paint app using essential packages like joblib, pyscreenshot, numpy, time, and cv2. The SVM model predicts the digit by utilizing the predict method with the prepared input array, displaying the predicted digit on the console. Results are presented in the form of the original image, annotated with the predicted digit using "cv2.putText". A window named "Result" is created, showcasing the annotated image. The program awaits a key press for a specified duration (10 seconds in this case) using "cv2.waitKey". If the pressed key is Enter (13), the loop continues; otherwise, it breaks out of the loop. Upon termination of the loop, typically triggered by pressing Enter, the OpenCV windows are closed using "cv2.destroyAllWindows()".

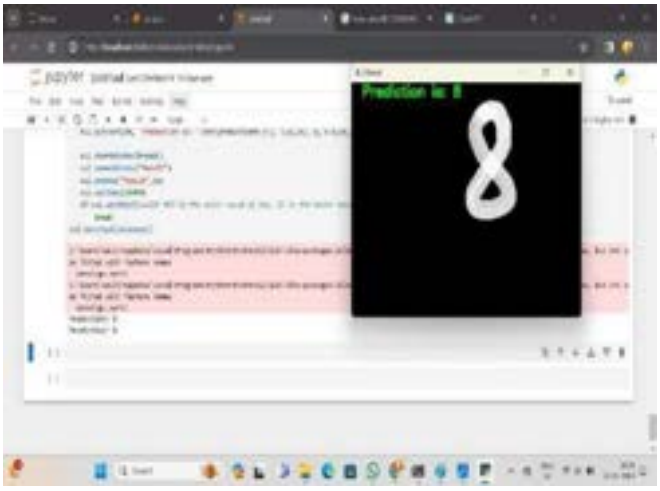

Fig.4. prediction of 8

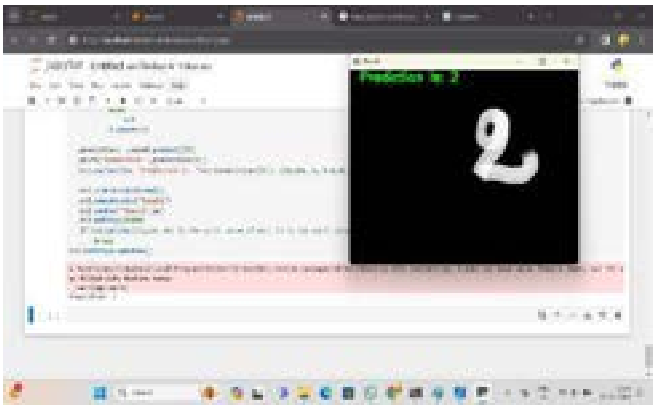

Fig. 5. Prediction of 2

By leveraging the inherent strengths of convolutional neural networks (CNNs), the proposed model surpasses both SVM and KNN. CNNs excel in capturing local patterns and relationships, demonstrating characteristics such as translational invariance and non-linearity. When dealing with a relatively compact dataset and the straightforward nature of grayscale images (with dimensions of 28 × 28 and 32 × 32), the diminished accuracy observed in higher-capacity models can be linked to their heightened capacity to capture intricate patterns.

However, achieving optimal performance on smaller datasets with such models may necessitate additional data or thorough hyperparameter tuning. The heightened complexity of such models could pose challenges in effectively learning from the limited information available, consequently leading to a marginally reduced accuracy. Figures 4, 5, and 6 illustrate digit predictions and compare various frameworks along with their corresponding accuracies.

V. CONCLUSION

In conclusion, the recognition of handwritten Devanagari numerals using machine learning algorithms presents an opportunity to apply advanced techniques in a multilingual and script-specific context. Through an extensive literature review, it is evident that the application of k-Nearest Neighbors (KNN) has shown promising results in character recognition tasks, including those involving the Devanagari script. Comparative analysis of various algorithms, including but not limited to SVM, Random Forest, k-Nearest Neighbors and CNN have revealed their unique strengths and limitations in recognizing handwritten Devanagari numerals. Recognizing handwritten Devanagari numerals has provided valuable insights into the efficiency of different models. The recommended model, leveraging the strengths of Support Vector Machines(SVMs), KNN and Random Forest (RF). The observed lower accuracy in higher-capacity models suggests the need for careful consideration of dataset size and simplicity. Despite the trails posed by the relatively small dataset and the simplicity of grayscale images, our findings emphasize the importance of balancing model complexity with the available data, offering valuable considerations for future endeavors in the domain of handwritten Devanagari numeral recognition.

VI. FUTURE WORK

Expansion to Full Devanagari Script: Extending the recognition model to cover the entire Devanagari script, including consonants, vowels, and compound characters, to create a comprehensive recognition system for the script as a whole. Multilingual Recognition: Exploring the feasibility of adapting the recognition model to recognize numerals in other Indic scripts, such as Bengali, Gujarati, or Tamil, to create a multilingual character recognition system.

***Abstract*— This research paper investigates the dynamic landscape of Agile Project Management Tools, encompassing their historical evolution, current functionalities, and future trends. The exploration begins with an introduction delving into the background, rationale, and research objectives. The Evolution section unfolds the historical development, technological advancements, and organizational adoption trends shaping Agile tools. The focal point shifts to Major Agile Project Management Tools, featuring in-depth overviews and functionalities of prominent platforms such as Jira, Trello, Asana, and Azure DevOps. A comprehensive analysis of the tools' functionalities covers user stories, sprint planning, task boards, burndown charts, collaboration tools, version control integration, automation, reporting, and scalability. In the subsequent section, this study predicts the future archetype of agile project management tools. Emerging trends, anticipated technological advancements, and key considerations for future development are explored, providing insights into the potential trajectory of these tools. Finally, the study summarizes key findings, discusses implications for the industry, and offers recommendations for future research. The detailed exploration of each topic contributes to a holistic understanding of Agile Project Management Tools, making this research a valuable resource for organizations navigating the complexities of modern project management methodologies.**

Keywords—Agile project management, Tools Evolution, Technological Advancements, Organizational Adoptions, Azure DevOps.

I. INTRODUCTION

In recent years, the realm of project management has undergone a transformative shift with the widespread adoption of Agile methodologies. Originating from the software development domain, Agile has rapidly expanded its influence across diverse industries, emphasizing iterative and flexible approaches to project execution. This shift towards Agile practices has prompted a parallel evolution in the tools that support project management processes. As organizations strive to enhance adaptability, collaboration, and responsiveness in their projects, the need for sophisticated Agile project management tools has become increasingly pronounced.

The rationale for analyzing the technological evolution and future archetype of Agile project management tools is highlighted by the critical role these tools play in modern project management practices. Traditional project management approaches often struggle to cope with the dynamic and iterative nature of contemporary projects, making Agile methodologies and their associated tools indispensable. As Agile continues to gain prominence, organizations are faced with the challenge of selecting tools that align seamlessly with their workflows, methodologies, and objectives. Understanding the historical development, current functionality, and future trends of these tools is imperative for both practitioners and researchers. This study aims to bridge the knowledge gap by providing a comprehensive exploration of the tools that have shaped the Agile landscape, offering insights into their functionality, and forecasting the trajectory of their future developments.

The primary objectives of this research encompass unraveling the historical evolution of Agile project management tools, elucidating the functionalities of major tools such as Jira, Trello, Asana, and Azure DevOps, and projecting the future archetype of these tools in the context of emerging technological trends. By achieving these objectives, this research seeks to contribute valuable knowledge that can guide organizations in making informed decisions regarding tool selection, fostering efficiency and agility in their project management endeavors. Ultimately, the research aims to empower both practitioners and academics with a deeper understanding of the past, present, and future of Agile project management tools, shaping the discourse around effective project management in the evolving landscape of software development and beyond.

II. EVALUTION OFAGILE PROJECT MANAGEMENT TOOLS

A. Historical Development:

The historical development of Agile project management tools traces back to the inception of Agile methodologies in the early 2000s. As a response to the limitations of traditional, plan-driven project management, the Agile Manifesto was introduced, emphasizing values such as individuals and interactions over processes and tools. Initially, tools were rudimentary, with a focus on supporting Agile principles like collaboration and adaptability. Early solutions included simple task boards and spreadsheets designed to facilitate communication within collocated development teams.

Over time, the landscape evolved with the increasing complexity of projects and the dispersion of development teams. The first generation of Agile tools, emerging around the mid-2000s, introduced features like user story management, sprint planning, and basic reporting. Tools like Rally (now CA Agile Central) and VersionOne gained prominence during this phase, catering to the needs of Scrum and Agile practitioners.

B. Technological Advancements:

Technological advancements have played a pivotal role in shaping the capabilities of Agile project management tools. The advent of cloud computing in the late 2000s significantly influenced the accessibility and scalability of these tools. Cloud-based Agile solutions allowed teams to collaborate seamlessly, irrespective of geographical locations, fostering a more global and distributed approach to software development.

Integration with version control systems, especially Git, became a standard feature in Agile tools, streamlining the development process by linking code changes to specific user stories or tasks. Automation of repetitive tasks, such as continuous integration and deployment, gained prominence, enhancing the efficiency and speed of software delivery.

The utilization of artificial intelligence and machine learning in Agile tools has been a recent advancement, enabling predictive analytics, smarter planning, and improved decision-making. These technologies enhance the tool's ability to forecast project timelines, identify potential risks, and suggest optimizations.

C. Adoption Trends in Organizations:

The adoption of Agile project management tools has become widespread across organizations of varying sizes and industries. Initially embraced by software development teams, Agile methodologies and tools have transcended their origins, finding applications in marketing, finance, and even non-technical domains.

Organizations are increasingly recognizing the benefits of Agile tools in promoting collaboration, flexibility, and responsiveness. The shift towards Agile methodologies has been driven by a desire to deliver value incrementally, respond to changing requirements, and enhance overall project visibility.

In recent years, a trend toward integrated platforms has emerged, where Agile project management tools seamlessly connect with other tools in the software development lifecycle, such as issue tracking, testing, and collaboration tools. This integration aims to provide a unified experience for development teams, streamlining workflows and fostering cross-functional collaboration.

In summary, the evolution of Agile project management tools has been marked by a progression from basic, collocated team solutions to sophisticated, cloud-based platforms with advanced features and integrations. The adoption trends underscore the growing recognition of Agile methodologies as a cornerstone for successful project management across diverse organizational contexts.

III. MAJOR AGILE PROJECT MANAGEMENT TOOLS

A. Jira

Description:

Jira, developed by Atlassian, is a robust Agile project management tool designed for efficient issue tracking and project management. Over time, it has evolved into a comprehensive platform supporting various Agile methodologies. Known for its adaptability, Jira fosters collaboration, transparency, and real-time reporting throughout the software development lifecycle.

Functionality:

Jira's functionality covers user story and backlog management, sprint planning, and robust reporting. Customizable workflows allow teams to tailor processes, while burndown charts provide insights into project progress.

Image Information:

Include a screenshot of a Jira dashboard displaying a Kanban board or Scrum board with user stories, tasks, and progress indicators. This visual representation will offer insights into Jira's interface and usage.

Fig.1. Jira

B. Trello

Description:

Trello, an intuitive tool acquired by Atlassian, simplifies Agile project management with its visual approach. Using boards, lists, and cards, Trello enables teams to organize tasks and collaborate seamlessly. It's particularly well-suited for smaller teams or projects with straightforward workflows.

Functionality:

Trello's functionality revolves around task management through a Kanban-style board. Users create boards for projects, populate them with cards representing tasks, and move cards through customizable lists. Collaboration is enhanced through comments, attachments, and checklists.

Image Information:

Include a screenshot of a Trello board showcasing tasks in different stages. This image will visually demonstrate how Trello organizes work and encourages collaboration.

Fig.2.Trello

C. Asana

Description:

Asana is a versatile project management tool designed for both traditional and Agile methodologies. With a user-friendly interface, it offers features for task management, project timelines, and real-time collaboration. Asana's simplicity and adaptability make it a suitable choice for diverse project management needs.

Functionality:

Asana's functionality includes task assignment, due dates, customizable workflows, and project timelines. Supporting both list and board views, Asana provides flexibility for different team preferences. It emphasizes simplicity while offering powerful tools for effective project management.

Image Information:

Include a screenshot of an Asana project showcasing task lists or a timeline view. This image will illustrate Asana's adaptability and its ability to cater to various project management requirements.

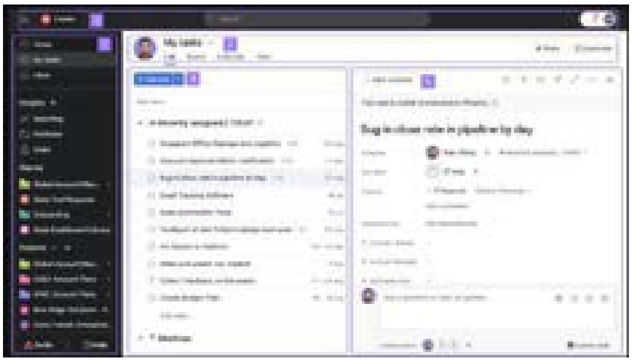

Fig.3.Asana

D. Azure DevOps

Description:

Azure DevOps, developed by Microsoft, is a comprehensive tool suite integrating with Visual Studio. Covering the entire software development lifecycle, Azure DevOps combines Agile project management with version control, build automation, and release management.

Functionality:

Azure DevOps' functionality spans backlog management, sprint planning, code repositories, and build/release pipelines. Its integration with Azure Boards provides a seamless experience for Agile project management. The tool supports collaboration between development and operations teams, promoting a DevOps culture.

Image Information:

Include a screenshot of an Azure DevOps dashboard displaying Agile boards, build pipelines, or release pipelines. This visual representation will highlight the tool's holistic approach to Agile and DevOps practices.

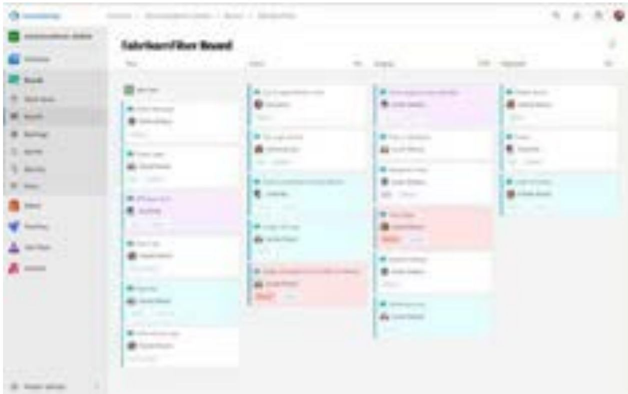

Fig.4.Azure Devops

IV. FUNCTIONALITY AND FEATURES OF AGILE PROJECT MANAGEMENT TOOLS

A. User Stories and Backlog Management:

Agile project management tools serve as robust platforms for user stories and backlog management. Teams leverage these tools to meticulously create, prioritize, and manage user stories, ensuring a systematic and organized backlog. This functionality is fundamental for maintaining clarity on project requirements and establishing a solid foundation for development cycles.

B. Sprint Planning:

Sprint planning, a pivotal aspect of Agile methodologies, is seamlessly facilitated by Agile project management tools. These tools empower teams to define sprint goals, allocate user stories, and establish realistic timelines. The collaborative nature of sprint planning sessions within these tools ensures that the entire team is aligned on priorities and committed to achievable workloads for the upcoming sprint.

C. Task Boards/Kanban Boards:
Task boards, often presented in a Kanban-style format, are integral components of Agile tools. These visual boards provide a snapshot of work items, their current statuses, and the flow of tasks throughout the development process. By enhancing transparency, task boards enable teams to easily track progress and manage work in a highly visual and intuitive manner.

D. Burndown Charts:
Burndown charts, a staple in Agile project management, play a crucial role in tracking project progress. Agile tools generate dynamic burndown charts that graphically depict the completion of tasks over time. These charts offer invaluable insights into the team's velocity, helping project managers make informed decisions and predict whether project milestones will be met.

E. Collaboration Tools:
Collaboration lies at the heart of Agile methodologies, and Agile project management tools are equipped with robust collaboration features. These tools provide dedicated spaces for discussions, file sharing, and real-time communication among team members. This fosters a collaborative environment where ideas flow freely, and the entire team remains connected throughout the project lifecycle.

F. Integration with Version Control Systems:
Integration with version control systems, such as Git, is a fundamental feature of Agile project management tools. This integration ensures the seamless alignment of code changes with specific tasks or user stories. Agile tools facilitate a cohesive development and project management process, where version control plays a pivotal role in maintaining code integrity.

G. Automation of Repetitive Tasks:
Agile tools streamline workflows by automating repetitive tasks, thereby enhancing overall efficiency. From task creation to status updates based on predefined criteria, these tools significantly reduce manual effort. Automation not only accelerates processes but also minimizes the risk of human error, allowing teams to focus on higher-value activities.

H. Reporting and Analytics:
Robust reporting and analytics capabilities are inherent strengths of Agile project management tools. Teams can generate comprehensive reports on sprint progress, team performance, and overall project health. Analytics features provide valuable insights for retrospective analysis, aiding teams in identifying strengths, areas for improvement, and trends over time.

I. Scalability:
Scalability is a cornerstone feature of Agile project management tools, catering to the dynamic needs of diverse projects. These tools exhibit the flexibility to adapt to projects of varying sizes and complexities, from small, focused endeavors to large-scale enterprise initiatives. The scalability of these tools ensures that they can accommodate expanding user bases, evolving features, and intricate work structures without compromising performance or functionality.

V. FUTURE ARCHETYPE OF AGILE PROJECT MANAGEMENT TOOLS

A. Emerging Trends:
The future archetype of Agile project management tools is anticipated to witness the emergence of several key trends. One such trend is the increasing integration of artificial intelligence (AI) and machine learning (ML) capabilities. Agile tools are expected to leverage these technologies to enhance predictive analytics, automate repetitive tasks, and provide intelligent insights for better decision-making. Another notable trend is the emphasis on enhanced user experience through intuitive interfaces and user-centric design, ensuring that teams can interact seamlessly with the tools. Additionally, the rise of remote work is likely to drive the development of features that cater to distributed teams, fostering collaboration and communication across diverse geographical locations.

B. Anticipated Technological Advancements:
The future of Agile project management tools will be shaped by anticipated technological advancements. Blockchain technology is poised to make an impact by enhancing security and traceability within project management processes. Decentralized and transparent ledgers can provide a secure foundation for tracking changes and ensuring the integrity of project data. Furthermore, the evolution of augmented reality (AR) and virtual reality (VR) may introduce innovative ways for teams to visualize and interact with project data, fostering immersive and collaborative experiences. As technology continues to advance, tools are likely to leverage these innovations to create more dynamic and engaging project management environments

C. Key Considerations for Future Development:
In shaping the future archetype of Agile project management tools, developers and stakeholders need to consider several key aspects. Firstly, the tools should prioritize interoperability, allowing seamless integration with a diverse ecosystem of software and services. This ensures that teams can leverage their preferred tools while maintaining a cohesive project management environment. Secondly, a focus on scalability and flexibility is paramount. The tools should be designed to accommodate the evolving needs of projects, from small-scale initiatives to large enterprise-level endeavors. Finally, the emphasis on security and data privacy is crucial, especially with the increasing reliance on cloud-based solutions. Future tools must implement robust security measures to safeguard sensitive project information and ensure compliance with data protection regulations.

As Agile project management tools evolve, these considerations will play a pivotal role in shaping their functionality and relevance in an ever-changing technological landscape. The future archetype is poised to be dynamic, intelligent, and adaptable, catering to the evolving needs of Agile teams and the broader project management community.

VI. Conclusion

In conclusion, this study has reviewed the Agile Project Management Tools, examining their evolution, major functionalities, and future archetype. We explored tools such as Jira, Trello, Asana, and Azure DevOps, detailing their features and practical applications. The research highlighted the significance of user stories, sprint planning, task boards, burndown charts, collaboration tools, version control integrations, automation, reporting, and scalability in Agile project management. The findings of this research carry significant implications for the industry. Agile project management tools play a pivotal role in enhancing collaboration, improving workflow efficiency, and ensuring project success. As the industry embraces Agile methodologies, understanding the functionalities and features of these tools becomes crucial for organizations aiming to adapt to dynamic project management practices. The implications extend to the broader tech industry, influencing how teams collaborate, plan, and execute projects in an iterative and adaptive manner.

Moving forward, future research in this domain should explore the practical implementation and user experiences of Agile project management tools in diverse organizational contexts. Additionally, investigations into the integration of emerging technologies, such as AI, blockchain, and AR/VR, into these tools could provide valuable insights. Understanding how these tools impact team dynamics, productivity, and project outcomes in the long term would contribute to a deeper comprehension of their efficacy. Further studies could also explore the evolving cybersecurity considerations associated with the increasing reliance on cloud-based Agile solutions. This study has conveyed a comprehensive understanding of the major Agile project management tools, shedding light on their functionalities, practical applications, and the evolving technological landscape. The exploration of emerging trends, anticipated technological advancements, and key considerations for future development has equipped readers with insights into the potential trajectory of Agile tools. As organizations navigate the complexities of modern project management, the knowledge imparted in this research aims to serve as a valuable resource for informed decision-making and strategic planning in the dynamic landscape of Agile project management.

***Abstract*—In the world of internet retail and fashion, virtual try-on systems have become a game changing innovation. This research introduces a revolutionary deep learning-based method for virtual try-on. The method first segments the clothing from the source image using segmentation techniques, then creates an interactive image to provide a virtual fitting experience, and finally combines accurate posture recognition using pretrained models with the imposition of the garment texture on the dense pose it predicted. Realtime experimenting with different clothing items, sizes, and positions is possible because to the interactive user interface. The technology is more user friendly because it can accommodate a variety of body types. This virtual try-on system, powered by deep learning, has the potential to significantly change customer involvement across a variety of industries, especially in fashion and ecommerce, by transforming the fashion retail scene.**

***Keywords*—Virtual try-on systems, Deep learning-based method, Virtual fitting, Posture Recognition, Garment texture, Dense pose, Segmentation.**

I. Introduction

The world of internet purchasing has expanded at an unparalleled rate, providing consumers with convenience and accessibility across borders. Online dress shopping has grown in popularity during this digital revolution. However, several issues and worries are raised by this increase in virtual interactions, which influence the whole online buying experience. Uncertainty about the size and fitting of clothes is one of the biggest problems for internet consumers. When it's not possible to physically try on clothing, buyers frequently worry about whether the size they've selected will fit their individual body type. The tactile properties of the material or how the garment looks on various body shapes may not be accurately captured in online product photos. There are various ways to address this problem, but one easy and affordable one is image based virtual try-on, which involves using the user's photograph to superimpose a garment from a shopping website to create a virtual fitting experience.

The development of efficient image based virtual try-on systems is greatly aided by deep learning techniques, which also improve the accuracy, realism, and overall performance of these systems. Deep learning models do exceptionally well in semantic understanding, which allows them to identify and decipher complex information in photos. This feature is essential for correctly superimposing clothing items onto user supplied photos, taking complex designs, textures, and fabric patterns into account. Its methods, which include pose estimation models, help to precisely align apparel with the user's posture. By doing this, it is made sure that the user's actions and realistic garment positioning are reflected in the virtual try-on experience. Using a pretrained Posenet model for precise stance identification and a complex process of garment texture transfer from reference photographs onto the user's image are the main components of our solution. Furthermore, the system integrates pose estimation models to smoothly match garment textures with the user's pose and segmentation models to detect clothing regions.

Processes like data collecting, preprocessing, model training techniques, and the curation of an interactive user interface are all carefully navigated. Users can interact with clothing products, try on different sizes, and see the outcomes in real time through this interface. The system's focus to inclusivity, which guarantees adaptation across a range of body shapes, sizes, and positions, is a crucial component of its design. The main goal is to create a platform that is available to everyone, democratizing the virtual try-on experience.

Examining the intersection of fashion and technology, this investigation presents a paradigm shift for the fashion retail industry. It clarifies how virtual try-on systems might change how customers engage with items in a variety of contexts.

II. Literature Survey

Advancements in computer vision and deep learning have significantly influenced the evolution of virtual try-on systems, revolutionizing the fashion industry. Ziad Al-Halah, Rainer Stiefelhagen, and Kristen Grauman, in "Fashion Forward: Forecasting Visual Style in Fashion", [1] introduce a computational framework that utilizes neural networks for predicting visual styles in fashion. This framework addresses challenges in client engagement and contributes to applications such as customized fashion recommendations and style analysis. On the other hand, this framework cannot handle complexities and dynamic nature of fashion trends.

Whereas Serge Belongie, Jitendra Malik, and Jan Puzicha, in "Shape Matching and Object Recognition Using Shape Contexts", [2] focus on shape context descriptors and their applications in object detection and shape matching. While emphasizing the importance of accurate shape matching, the paper points out a lack of adoption of deeper learning strategies. The proposed approach showcases success in silhouette matching, trademark identification, and handwritten digit recognition, underscoring the need for incorporating deeper learning techniques into virtual try-on systems.

The study "Keep it SMPL: Automatic Estimation of 3D Human Pose and Shape from a Single Image" [3] by Federica Bogo et al. introduces the SMPL model, a simplified yet effective approach for estimating 3D human pose and shape from 2D images. The model, based on deep learning and Convolutional Neural Networks (CNNs), contributes to computer vision and graphics, enabling applications like animation and virtual try-on. Despite its success, challenges remain, particularly in accurately estimating poses in certain cases.

Zhe Cao, Tomas Simon, Shih-En Wei, and Yaser Sheikh present "Realtime Multi-Person 2D Pose Estimation using Part Affinity Fields", [4] a real-time computer vision technique utilizing Part Affinity Fields (PAFs) and CNNs for accurate multi-person 2D pose estimation. While demonstrating success in real-time applications, the framework acknowledges difficulties in handling missing components in uncommon poses. This work addresses challenges crucial for supporting a diverse range of user poses in virtual try-on scenarios.

The study on "Generative Adversarial Networks" by Ian J. Goodfellow et al. introduces a novel framework for creating generative models using a two-player game between a generator (G) and a discriminator (D) [5]. GANs, comprising neural networks engaged in adversarial training, generate synthetic data closely resembling real data. The paper's contributions in generating high-quality data highlight its relevance for applications like image and text generation in virtual try-on scenarios.

The study "VITON: An Image-based Virtual Try-on Network" by Xintong Han, Zuxuan Wu, Zhe Wu, Ruichi Yu, and Larry S. Davis presents a virtual try-on system based on image synthesis and manipulation [6]. The VITON system is designed to address the challenge of generating realistic virtual try-ons of clothing items on a person in a target image. The framework may not extensively cover the adaptability of the model to various poses and body shapes.

Overall, these studies collectively contribute to the virtual try-on domain by addressing challenges, introducing novel frameworks, and emphasizing the need for deeper learning strategies. As the fashion retail sector undergoes a paradigm shift, the convergence of computer vision, machine learning, and user-centric design promises an enhanced virtual try-on experience for customers interacting with online shopping platforms.

III. METHODOLOGY

Various Artificial Intelligence powered generative models and approaches are employed to accomplish the virtual fitting task in phases, with each phase being well-structured and forming a chain to utilize the output from the previous phase in the subsequent one. Figure 1 displays entire process of the framework and table 1 describes algorithms used.

TABLE I. ALGORITHMS USED IN EVERY STAGE

S.NO	STAGE	ALGORITHMS USED
1	Pose Estimation	PoseNet
2	Clothing segmentation and masking	U-Net
3	Semantic segmentation of human image	DensePose
4	Texture transfer and final output	CNN

A. Input Data and Data processing

Two pictures are compiled as input data: one is the source clothing image and the other is the target person image onto which clothing should be transferred. The supplied data is then processed and resized to the model's desired size. The human image can be provided in any size or quality, but the garment image should have dimensions of 500 by 600 pixels. To ensure uniformity, the human image is resized to the normal proportions of 768 by 1024 pixels. After resizing, the human image is stored for later analysis. The saved image is then loaded and resized one more to the final 384 by 512-pixel dimensions that are required. The resulting image is then saved once more.

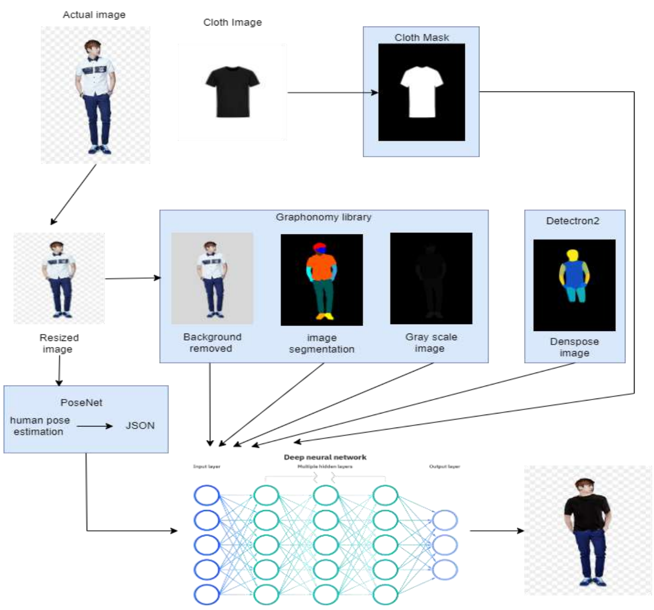

Fig. 1. Architecture of Virtual try on framework

B. *Pose Estimation*

The resized human image is used by the Posenet model to detect the pose of the person in it. This code utilizes the PoseNet deep learning pre-trained model for human pose estimation on a resized image. The model, pretrained with 101 key points, processes the image, generating heatmaps, offsets, and displacement maps. The function extracts pose with scores, key point scores, and coordinates. Detected poses are mapped to OpenPose format, and the most confident pose is chosen. The resulting key points are formatted in a JSON file. PoseNet employs layers for heatmap generation, offset calculation, and displacement maps, contributing to accurate key point localization. The code streamlines the process for virtual try-on applications or similar tasks.

The input image is first preprocessed and then fed through a PoseNet model that has already been trained. The model identifies critical locations that correspond to several body parts, including elbows, shoulders, and facial features, which are essential for comprehending the stance portrayed in the picture. The essential points that have been found are then mapped to the OpenPose format standard after this detection step. This mapping guarantees interoperability with later models or applications, allowing for a smooth integration into larger systems for tasks like action classification or gesture recognition. All in all, this procedure makes it easier to extract and modify complex posture information from pictures, which improves the usefulness and adaptability of many systems and applications. PoseNet usually comprises of a convolutional neural network (CNN) architecture, which is based on common CNN designs such as ResNet or MobileNet, followed by additional layers for pose estimation, as per other earlier research initiatives. The architecture is made to take an image as input and output the subject's pose, which is often expressed as joint angles or keypoint coordinates [7].

C. *Clothing Segmentation and Masking*

This code performs cloth segmentation using a U-Net model. The U-Net model is created or loaded, and an input clothing image is normalized using Albumentations. The U-Net predicts a binary mask for the clothing region, which is converted to a NumPy array. The resulting mask is un-padded, and the script overlays it onto the original image, creating a composite image. The code uses U-Net's encoder-decoder structure with skip connections for accurate segmentation. The final images are composite and binary mask. Composite Image is a visual result of overlaying the original input image with the predicted binary mask for the clothing region. The composite image highlights the segmented clothing area. Binary Mask Image represents the predicted binary mask generated by the U-Net model. It outlines the regions where clothing is detected in the original image. U-Net segments images by first encoding features through a CNN, then decoding them back to original resolution using deconvolutional and convolutional layers, preserving spatial context with skip connections, crucial for accurate biomedical image segmentation [8].

The input image is pre-processed and padded to ensure its dimensions are multiples of 32 so that is suitable for the U-Net model. Now, the model to be used is loaded and the image is passed to that model. During inference, the U-Net model predicts a binary mask representing the segmented regions corresponding to clothing items within the input image through a forward pass of the input image through the trained model. The model's forward pass involves passing the image through the encoder path, where hierarchical features are extracted at multiple scales. As the input image passes through the encoder, features are progressively down-sampled, capturing increasingly abstract representations of the image. The feature maps generated by the encoder are then passed through the decoder path. Here, up-sampling operations gradually increase the spatial resolution of the feature maps while preserving important contextual information.

A binary mask is generated based on the probabilistic value of the pixel. Every pixel of the image is classified as foreground or background values are given based on that. Post-processing steps involve converting the model's output into a NumPy array and removing the padding previously added to the image.

D. *Semantic Segmentation of human image*

This phase consists of two sub-phases, generating semantic segmentation of the human image and removing background of that image using the segmented image. The image segmentation script which is also known as inference script performs semantic segmentation using Graphonomy-Master library. It executes an inference command on a resized image, and the resulting semantic segmentation mask is used to remove the background from the original image. The inference script is part of the Graphonomy-Master library and is designed to work with a DeepLab-Xception Transfer model.

The DeepLab-Xception model, a variant of the DeepLab architecture, operates by leveraging the Xception backbone for feature extraction and Atrous convolution to capture multi-scale contextual information. Initially, the Xception backbone processes the input image to extract hierarchical features, utilizing atrous convolutions with varying dilation rates to enlarge the receptive field and capture context at different scales effectively. Subsequently, the Atrous Spatial Pyramid Pooling module aggregates context from multiple scales through parallel Atrous convolutions, enabling the model to handle objects of diverse sizes and delineate fine-grained semantic boundaries. Finally, the model predicts pixel-wise semantic labels by applying a SoftMax activation to the output logits, yielding a segmented image where each pixel is assigned a semantic category. This methodology enables DeepLab-Xception to achieve accurate semantic segmentation across a wide range of applications, including image understanding, object recognition, and scene parsing [9].

This script loads the pre-trained Xception model, performs multi-scale inference on the input image, and generates a semantic segmentation mask. The mask is then used to decode the predicted labels and create a visual representation of the segmentation. The processed image is saved in both color and grayscale formats. For the DeepLab-Xception Transfer model, the architecture consists of deep convolutional layers with skip connections and transfer projection layers, enabling effective semantic segmentation. The model is trained to predict pixel-wise labels for 20 classes, including various body parts and background. The image segmentation script and the inference script together enable the extraction of semantic segmentation information from an input image, contributing to tasks such as background removal or object isolation.

As a next step, a colored semantic segmentation image into a grayscale representation, assigning specific labels to different clothing and body parts. This conversion is achieved through the utilization of OpenCV, the Python Imaging Library (PIL), and the NumPy library. The script starts by loading the resized segmentation image using the Image module from the PIL library. The image's width and height are extracted, and the image is converted into a NumPy array. Subsequently, a new grayscale image is initialized with the same dimensions. Based on the pixel's RGB values of original image, corresponding labels are assigned to the grayscale image. Labels such hair, head, neck, torso, left arm, right arm, pants, dress, skirt, left leg, right leg, and outerwear are assigned based on specific RGB values. After the pixel-wise labeling, the grayscale image is resized using OpenCV's resize function with nearest-neighbor interpolation. The resulting grayscale image is then saved using the Image.from array function. After the pixel wise labeling foreground image is separated from the background based on the labels and the separated foreground is stored in separate variable all this is done by performing bitwise operation on the original image and the mask.

E. DensePose Segmentation of human image

The Detectron2 library is used to perform DensePose segmentation on an input image. Detectron2 is a library that can be used for various functions such as semantic segmentation, object detection and many more [10]. The DensePose model in Detectron2 which is a pre-trained model, applied to the image, and the resulting segmentation is color-mapped using predefined colors for different body parts. The model generates a JSON file of the image which contains information about various parts in the image. Now another function extracts information from that JSON file containing DensePose predictions and applies the color mapping to visualize the segmentation. Finally, the segmented image is overlaid onto a black background, creating a visual representation of the DensePose segmentation.

F. Texture transfer and final output

HR-VITON model operates by taking a set of diverse inputs crucial for virtual try-on applications. These include a resized image, cloth mask delineating the clothing region, image segmentation for understanding the context, grayscale image capturing fine details, PoseNet JSON providing pose information, background-removed image for isolating the person, and DensePose image offering dense pose estimation. The complex arrangement of deep learning models within HR-VITON involves sophisticated architectures. Convolutional layers (Conv2d) play a pivotal role in extracting hierarchical features from the input images. These features are then carefully normalized using BatchNorm2d and InstanceNorm2d layers to ensure stable training. The incorporation of Residual Blocks, specifically SPADE Residual Blocks, facilitates the efficient learning and transformation of features, enhancing the network's capacity to capture intricate patterns and nuances.

At the heart of HR-VITON is the SPADE Generator, a powerful network that dynamically adapts its normalization through SPADE normalization, aligning with the semantic segmentation of the input image. This generator will provide a synthetic image of the clothing from the semantic segmentation mask, this is done by the normalization layers wash away the semantic information [11]. This generator refines and augments features through the strategic utilization of multiple SPADE Residual Blocks. The training process is guided by GAN Loss, a technique within Generative Adversarial Networks. GAN Loss propels the generator to produce highly realistic images of the virtual try-on, while the discriminator learns to discern between authentic and generated images. The synthetic image that is generated is integrated with the target image to show texture transfer virtually, this done by blending in which pixels are combined from synthetic image and target image here binary mask ensures which pixels should be replaced by synthetic image pixels in target image.

In essence, the final output of HR-VITON is a compelling visual representation. It vividly illustrates how the chosen clothing seamlessly integrates with the person in the input image, providing a realistic preview of the virtual try-on experience. The amalgamation of advanced deep learning techniques and carefully designed architectures enables HR-VITON to deliver impressive and visually accurate results in the domain of virtual clothing try-on.

G. Performance of the model and it's improvement

The performance of the model, particularly in terms of accuracy and realism, largely depends on various factors such as the quality of the semantic segmentation, the effectiveness of the SPADE generator, and the integration with PoseNet for pose alignment. Initially, without PoseNet and SPADE generator, the model may struggle with accurately transferring clothing between images, resulting in misalignments or unrealistic blending. However, by incorporating PoseNet, which provides pose information, the model can better align the synthesized clothing with the target image, improving the overall realism of the try-on process. Additionally, the SPADE generator enhances the fidelity of the synthesized clothing by considering spatially adaptive normalization, leading to more realistic textures and shapes that closely resemble actual garments [12]. Overall, the integration of PoseNet and SPADE generator models enhances the performance of the virtual try-on system, offering users a more immersive and satisfying experience. Various other models like GAN are used in previous works but there was a lack of reality, a shift in such models shows significant improvement in performance.

IV. Results

Promising outcomes have been obtained from the thorough integration of PoseNet, Graphonomy Master, Detectron2, and HR-VITON in the image-based virtual try-on pipeline. Pose alignment, garment segmentation, and dense pose estimation are three major issues that the system successfully tackles, producing realistic and aesthetically pleasing virtual try-on experiences. Figure 2 and 3 are the input images to the model and Figure 4 is the background removed from the actual image. Figure 5 is the segmentation image using Graphonomy library and Figure 6 is the Human Denspose Image using Detectron2. Figure 7 is the output image of the model.

Fig. 2. Input Human Image

Fig. 3. Input cloth image

Fig. 4. Removing Background

Fig. 5. Image segmentation

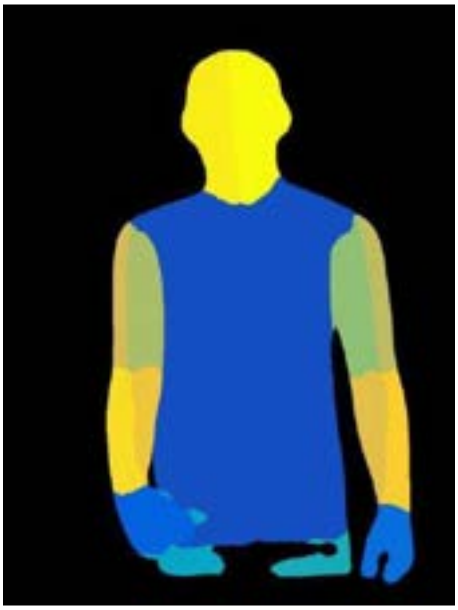

Fig. 6. Human Denspose Image

Fig. 7. Output Image

V. DISCUSSION

The successful implementation of the image-based virtual try-on system lays the groundwork for several exciting future endeavours. Firstly, the integration of multi-view data could enhance the system's spatial understanding, enabling more accurate garment fitting. Optimizing computational efficiency could lead to real-time virtual try-ons, enhancing user interactivity. Interactive customization features and user-generated content could provide users with more personalized and diverse experiences. Additionally, robustness to dynamic poses, ethical considerations, and the integration of augmented reality are promising areas for further exploration. Future research could focus on refining these aspects, ultimately advancing the state-of-the-art in image-based virtual try-on systems and providing users with more immersive and customizable virtual shopping experiences.

VI. CONCLUSION

With the help of this framework, an image-based virtual try-on system has been developed and improved, both improving upon and borrowing ideas from previous approaches. Our results highlight the important contributions the project has made to the field through careful implementation and testing. Notably, the technology addresses an important part of virtual try-on realism by demonstrating a respectable degree of adaptation to varied stances and body types. The visual accuracy of virtual try-ons is improved by the painstaking attention to capturing minute details in clothing textures and patterns, providing a more realistic and engaging user experience. Prioritizing user interaction has resulted in the introduction of innovative customisation tools that enhance engagement and allow the virtual try-on experience to be customized to individual preferences.

AI plays a pivotal role in revolutionizing the virtual try-on experience, offering a transformative approach to fashion exploration and personal styling. By leveraging advanced techniques in semantic segmentation and generative modeling, AI enables the seamless transfer of clothing between images, fostering a dynamic platform for users to virtually experiment with diverse styles and looks. The integration of sophisticated algorithms such as SPADE further enhances the fidelity of synthetic clothing synthesis, ensuring lifelike textures and shapes that closely mimic real garments. Moreover, AI-driven interactions empower users with personalized recommendations and intuitive controls, enriching the virtual try-on process with tailored experiences and enhancing user engagement. As technology continues to evolve, the synergy between AI and virtual try-on applications holds immense potential to reshape the fashion industry, offering innovative solutions for retail, e-commerce, and beyond.

***Abstract*—In the current healthcare scenario, booking an appointment with a doctor often involves numerous challenges such as limited appointment availability, geographical constraints, difficulty in finding the right doctor, lack of transparency, and issues with rescheduling or canceling appointments. This not only leads to a poor patient experience but also results in inefficient management of the doctor's schedule. The current system's structure is composed of outdated front-end frameworks, making it challenging to store data in the back end. This web-based application is built using Next.js for the front-end, Strapi API for the backend, MySQL for database purposes, Kinde Auth for authentication and Hostinger for hosting the database. To address this issue, a web-based program called Doctor Appointment Booking System allows the patients to schedule their appointments easier. The primary goal of this research study is to streamline the time-consuming appointment scheduling process and improve the efficiency of the healthcare system. Missed appointments and misunderstandings will be decreased since the proposed approach offers a clear communication channel between patients and healthcare professionals.**

Keywords— Next.js for frontend, Starpi Application Programming Interface for backend, MySQL for database, Kinde Auth for security purposes, Hostinger.

I. Introduction

The doctor appointment booking system has been developed to facilitate scheduling appointments with healthcare professionals. Next.js, Strapi, MySQL, and a CSS framework called Tailwind CSS are state-of-the-art web development technologies that were used in its development. Server-side rendering and the creation of static web pages for React-based web apps are made possible by the well-liked React framework Next.js. It offers a strong basis on which to construct applications with great performance. Strapi is an adaptable, open-source headless CMS that enables editors to simply manage and share their content while granting developers the flexibility to use their own tools and frameworks. Strapi API integration is utilized in this system to manage and provide the application data, which facilitates managing content and updating. One popular open-source relational database management system is MySQL. It is used in this project to handle and maintain information about appointments, patients, and doctors. Patients can set up appointments at their convenience, examine doctor biographies, and verify their availability through the system. Conversely, it helps physicians control their own schedules, which enhances the system's overall effectiveness. A robust web development framework called Next.js makes it easier to create quick, interactive apps. Based on the popular JavaScript framework React, it provides extra structure and functionalities, which include server-side rendering and static generation. Next.js provides major features which includes Server-side Rendering, Automatic Code Splitting, Hot Code Reloading, Ecosystem Compatibility, Styled-JSX etc. Next.js is built by Vercel and is known for providing the best developer experience when building production-ready applications. Developers and companies can manage content effectively with Strapi, an open-source headless Content Management System (CMS). Strapi's primary characteristics are its headless CMS, flexibility, support for many databases, and API-centricity. It is also open source. The necessity for an adaptable JavaScript-based CMS with API capability led to the creation of Strapi. It has developed into a crucial part of frontend design today, providing developers with considerably more robust APIs and fine-grained control over their content. Presently, Walmart, NASA, IBM, eBay, and numerous other businesses use it. This application demonstrates the combination of Next.js, Strapi, and MySQL to create a scalable, effective, and user-friendly web application. It is a major step in the direction of digitizing healthcare services and improving their accessibility and organization.

II. Literature Survey

The Medical Appointment Booking System was created to simplify and enhance the process of arranging and keeping medical appointments. It is a feature-rich and intuitive digital platform. In this fast-paced world, efficient healthcare services are crucial. With the provision of a practical and easily available alternative, this system seeks to close the gap between patients and healthcare practitioners. Patients and patrons of certain medical institutions, such as clinics or hospitals, can schedule online appointments with physicians by utilizing this program. With this approach, patients may easily browse a database of doctors' profiles, accessing information about their expertise, availability, and biography. Even better, they can set up appointments for any time and day of their choosing.

TABLE 1: LITERATURE SURVEY

Title	Authors	Journal/ Conference	Year
Appointment System using Artificial Intelligence Techniques.	Louisa Aiyeyika et al.	NEU Journal for Artificial Intelligence and Internet of Things	2023
Doctor Availability and Appointment using Digital Technology.	Santhosh S. et al.	Internation al research Journal of Modernizationin Engineering Technology and Science	2023

Integrated optimization of appointment allocation and access Prioritization in Patient-Centered Outpatient scheduling.	Na Lia. et al.	Journal of Computers & Industrial Engineering	2021

With this technology, patients may easily browse a database of doctors and view their availability, specialty, and biographies. Even better, they can set up appointments for any time and day of their choosing. This system will schedule each patient's appointment based on their availability, specializations, and bios. Even better, they can set up appointments for any time and day of their choosing. This doctor's appointment system will set up each patient's schedule and forward it to the doctor as a request. Efficient Appointment Scheduling (EAS) is essential to hospital management for ensuring patient satisfaction and high- quality service. Healthcare schedulers typically advise patients on the best time to receive services before the admittance call closes. The ability to modify the appointment has been removed. The appointment date cannot be changed at this time. The whale optimization algorithm (WOA), which considers the simulation approach and is based on the Pareto archive and the NSGA-II algorithm, solves the appointment scheduling model. The multi-criteria approach to appointment scheduling based on these two algorithms has been covered in this paper. This research computes WOA and NSGA utilizing several hypotheses to satisfy the analytic requirements and account for different features related to hospitalized patients. Three examples from the final part of the model have been used in this study to investigate NSGA and WOA.

III. METHODOLOGY

The methodology employed here aimed to develop and evaluate the proposed system, which integrates features to enhance the booking appointment website.

A. Understanding the problem statement:

This system addresses the most important part of scheduling appointment for patients with their medical consultant in their flexible time slot.

B. Design:

Using the Next.js framework, the user interface is designed to be straightforward and easy to use. The list of doctors according to specialization and the list of well-liked physicians in the city are both included in the user interface design. The site includes a profile of that particular doctor, an appointment booking page, and a scheduling interface.

C. Development:

The application is developed using Next.js for the Frontend, Strapi as the headless CMS, MySQL for the database, hosted in Hostinger, Resend for Email notification. The application is completely responsive and works seamlessly across different devices.

D. API Authentication:

Strapi uses headless CMS for connecting the MySQL database with Next.js framework as a connecting mechanism between the frontend and backend. This connection is made through API (Application Programming Interface) which is provided by Strapi through headless CMS.

E. Managing Web Hosting:

Hostinger is used to host the domain for database purposes. The platform provides various features in creating and managing a web hosting platform, domain hosting etc.

F. REST API:

Accessing the content-types via API endpoints is made possible via the REST API. The moment a content-type is produced, Strapi automatically generates API endpoints. To enhance the results of an API endpoint query, one might utilize API parameters.

IV. SYSTEM DESIGN

Sign in / Sign up Process

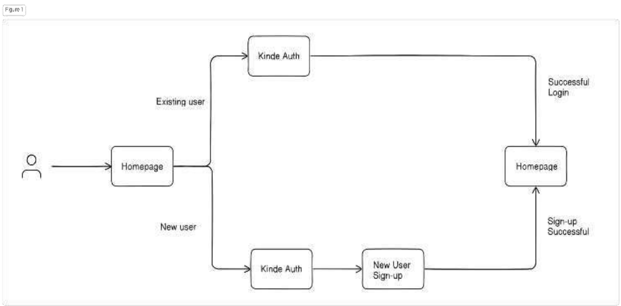

Fig 4.1 Sign in / Sign up

As shown in fig 4.1, the first stage is when the user lands on the homepage of the website. Existing user authenticates their account with their credentials. New user needed to create an account with the Kinde Auth. After a successful sign-up the user is redirected to the homepage.

Appointment Booking process:

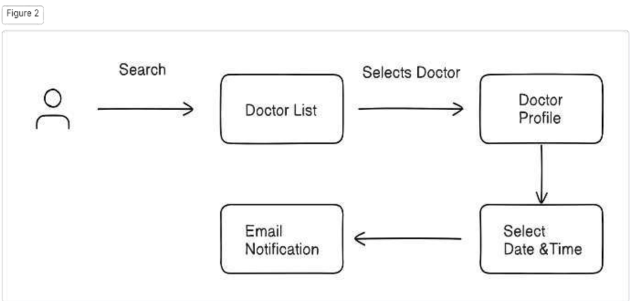

Fig 4.2 Appointment Booking process

As shown in fig 4.2, in the second stage, the user searches the doctor list in the homepage. The user selects the doctor profile, schedules the appointment with the concerned doctor along with date and time with the slot available on a particular day. An Email notification about the appointment is sent to the customer.

Backend Working Process:

The backend tool used to retrieve data from the database is called Strapi. Starpi handles the data from the MySQL database using a headless CMS. Content-types can be accessed via API endpoints thanks to the REST API. When a content-type is formed, Strapi automatically generates API endpoints. When searching API endpoints, the results can be refined by using API parameters. The overall process is depicted in fig 4.3.

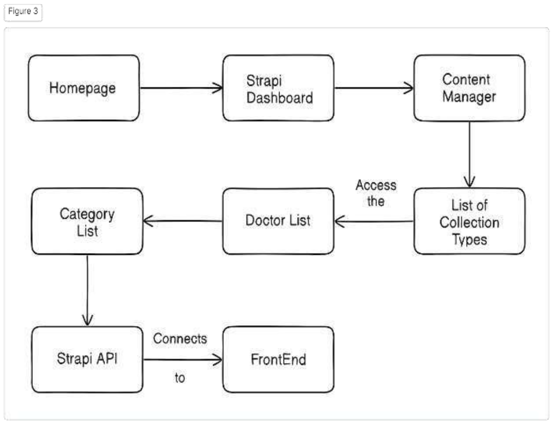

Fig 4.3 Backend Working Process

Email Notification:

Fig 4.4 Email Notification

Email notification is sent to the user through Resend API using Node.js framework as shown in fig 4.4. API works by deploying the API key in the Global Api folder for authentication. The user gets an Email notification about their appointment scheduled with the particular doctor.

V. WORKING MODEL

The working model of Doctor Booking Appointment website is briefly picturized below in fig 5.2.

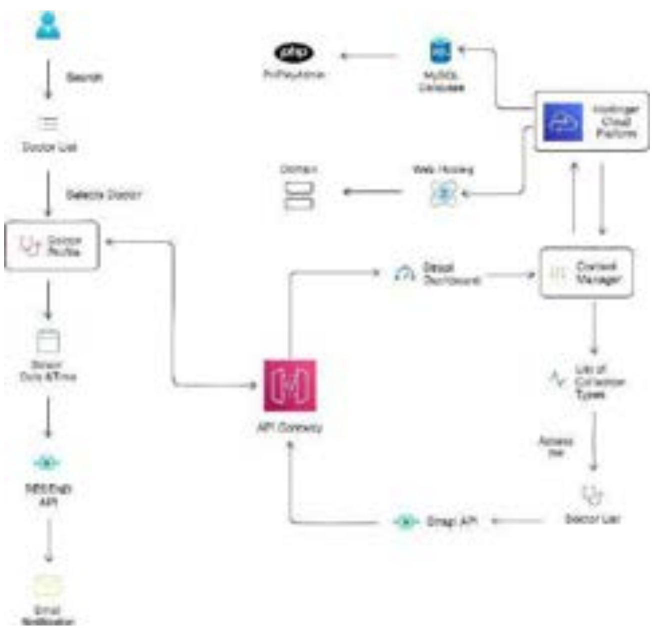

Fig 5.1 Working Model

VI. RESULT

USER MODULE:

Homepage:

Homepage has the features to explore the physicians based on their specialization and also popular doctors in the city. User need to sign-in their account for scheduling the appointment with their concerned doctor. The real-time homepage is shown in fig 6.1

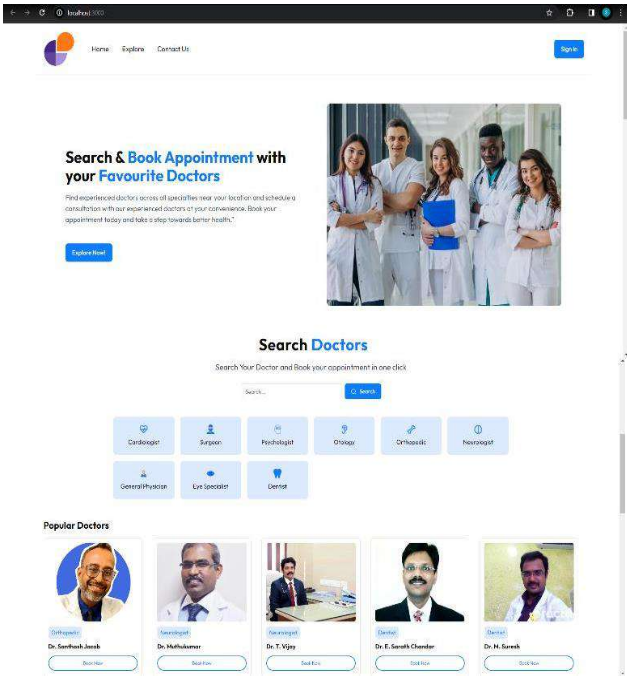

Fig 6.1 Homepage

DOCTOR MODULE:

Doctor module includes the doctor profile, appointment schedule, work experience, manage and access to their planned appointments. User is provided the book appointment button to schedule the appointment with the doctor. The real-time doctor's webpage is shown in fig 6.2.

Fig 6.2 Doctor Module.

ADMIN MODULE:

Admin dashboard contains information about the doctors' information, Category List, Images and Information about the doctor, Appointment information about the patients etc., The real-time doctor's webpage is shown in fig 6.3

Fig 6.3 Admin Module

MySQL Database:

The database holds the records of the all doctors, patients registered in the website. Hostinger holds the MySQL database. Through API the information is fetched from the database to the frontend. A sample image is shown in fig 6.4.

Fig 6.4 MySQL Database

Email Notification:

Email notification is sent using RESEND API provided by React.js framework to the particular user who booked their appointment with their concerned doctor. A sample Email confirmation is shown in fig 6.5.

Fig 6.5 Email Confirmation.

Reminder about Appointments will be shown in my bookings as depicted in fig 6.6:

Fig 6.6 My Bookings.

VII. Conclusion

In conclusion, the development and implementation of the web-based doctor appointment booking application have significantly effective features and functionalities which makes user to book and schedule appointment with their concerned doctor. The system successfully integrated features such as user registration, profile management, notifications, reviews and ratings, payment processing. This application is built using Next.js, Strapi API, MySQL, Kinde Auth for authentication, Hostinger host the web in the domain. This website has proven that potential of digital platforms in transforming healthcare services. This system is an example that how technology can be leveraged to make healthcare more accessible and convenient for patients. Future enhancements were also proposed, including telemedicine support, e-prescriptions, health record management and AI- based symptom checker. These enhancements are expected to further improve the user experience and make the system more robust and comprehensive.

Abstract: **Legal systems worldwide vary in structure and principles, reflecting the diverse legal traditions of different countries. The legal system, inherently complex and reliant on meticulous documentation, often faces challenges related to time-consuming manual processes and the potential for human errors. The system proposed provides a transformative solution to the above problems. The system emerges as a groundbreaking solution within the intricate landscape of legal systems which responds to these challenges by seamlessly integrating advanced AI techniques. At its core, OpenAI embeddings takes center stage, demonstrating unparalleled proficiency in document generation, comprehension, and abnormality detection, addressing the complexities ingrained in legal documentation. In contrast to traditional approaches, this system maximizes the versatility of ChatGPT 3.5, allowing it to not only issue commands but also proficiently generate a diverse array of legal documents. By incorporating an understanding module equipped with PyPDF, Amazon Textract, and langchain utilities, the system adeptly handles document intricacies. The utilization of OpenAI Embeddings further enhances natural language understanding. Leveraging sentiment analysis and Named Entity Recognition (NER) in its natural language processing (NLP) toolkit, the system employs an intuitive web interface for irregularities detection. The exploration of AI for automated irregularity detection showcases its transformative potential in ensuring document accuracy within the legal domain. This project, therefore, stands as a beacon of innovation, promising to reshape the dynamics of legal document processing by merging advanced AI capabilities with the unique demands of legal systems.**

Keywords: Legal Document Processing, Natural Language Processing (NLP), Irregularities Detection, Legal Technology, OpenAI Embeddings

I. INTRODUCTION

Legal systems throughout the world have countries' diverse laws, implemented structures and processes that manifest the unique nature of traditions in each country. These issues, in fact already there, have to do with human tendency to introduce errors and obligatory use of time (efforts) during the documentation by the means of outdated methodology like paper format [1]. Those users have necessitated an AR-supported Legal Document Assistant (LDA) system curved to transform the scene.

Like in any other field, the oldest legal systems have variety of challenges faced, especially filing of manual documents and a variety of risks that exist with complex texts. The accuracy and efficiencies of existing document processing systems is already inadequate, due to their inability to keep up, which is even more challenging in the precision oriented legal cases documentation environment [2]. The problem may be intensified because of the peculiarities of legal language, which raises the demand of the comprehension, which is far sometimes unavailable in the ordinary systems. Manual document proliferation could be an arduous exercise with human error of missing out serious issues.

On the one side, the desired solution, the artificial intelligence lawyer assistant is a game changer that is tactically created to remedy the detected shortfalls.

AI used system include unusual chapter detection in the legal document texts. The LDA achieves this through the application of Sentiment Analysis and NER, with are enablers of the NLP toolkit. The LDA operates through a simple Web based user interface that detects inconsistencies and ambiguities. This study carries a competitive edge of AI for automated irregularity detection very highly due to its various benefits within the complexity of legal realms.

The tech stack selection of the system is very important since it takes into account the variety of challenges that are found in field of legal processing. PyPDF has a key role in the tech stack allowing us to work efficiently with PDF documents in the same way as it is done with other formats. In the legal field the pdf files are everywhere, and PyPDF offers a versatile way to transform as well as to reuse those documents. PyPDF's flexibility allows us to comfortably proceed through difficult layout of legal documents, preserving originality of the document while carrying out the information operation and creation of new document. Amazon Textract which is capable of detecting money order forms for instance, contributes to the preservation of the customers through its smooth incorporation. Legal document often contains lengthy, and Textract can do a better job of saving a text, or even more information, as it greatly increases the ability to retrieve precise information. Textract's capacity to deal with different types of documents are another great advantage that makes LDA applicable to diverse legal presentations from contracts to agreements. Consequently, the system is never limited but fit for a large-scale use [7].

Through such an innovation, the law processes gain new dynamics, which bounds the efficiency, and accuracy, and directly influences accessibility as well, setting an example of progress in where fit between artificial intelligence and legal procedures takes place [4]. The article highlights not only a tool but the paradigm by showing how AI can improve the healthcare outcomes on one hand and on the other empower the professionals for better performance and implementation of the innovative models in the healthcare system.

Enter the AI Lawyer Assistant, a game-changer tactically designed to address identified shortcomings. Through innovative techniques like Sentiment Analysis and Named Entity Recognition (NER), the LDA detects inconsistencies and ambiguities via a simple web-based user interface. This study underscores the competitive edge of AI in automating irregularity detection within the complexity of legal documents.

II. LITERATURE REVIEW

Xiao's goal is to evaluate Lawformer's ability to handle lengthy legal documents and its suitability for tasks requiring extensive text comprehension [6]. Lawformer, a Chinese model equipped with sliding window and global attention mechanisms, excels in processing complex legal texts, aided by access to 80GB of case data. While it demonstrates proficiency in tasks like sentencing prediction and case retrieval, potential limitations may exist, necessitating further exploration of its effectiveness and adaptability in diverse legal contexts.

Robaldo et al.'s contribution in the Artificial Intelligence and Law journal highlights the benefits and implementation of NLP and semantic technologies in analyzing legal texts [4]. Divided into three sections, the paper explores unfair clause detection, argument structure extraction, and deep learning applications. While commendable for its insights, further analysis is required to assess the effectiveness and generalizability of the proposed NLP approaches in the legal domain.

The document introduces JEC-QA, a challenging judicial applicatory dataset designed to test high-order thinking skills [3]. Through experiments, it reveals a notable performance gap between state-of-the-art models (28% effective) and human capacity (81% accurate). While JEC-QA aims to advance projects in expanding reasoning behavior within QA systems, its findings underscore the significant challenges faced by current models in accurately interpreting judicial texts. Further exploration is necessary to bridge the gap between machine performance and human capabilities in this domain.

In this paper, the authors delve into the realm of Legal AI, exploring AI and NLP applications within the field of law, including embedding and symbol-based representations [11]. The paper analyze various problems associated with Legal AI and provide practical examples such as legal judgment prediction. The strengths of this study lie in its comprehensive analysis of AI and NLP technologies within the legal domain, offering insights into their potential applications and impact. However, this research may lack depth in addressing the challenges and limitations of current Legal AI systems, potentially analyzing the crucial considerations for future development and implementation.

The article introduces the Gov2Vec approach, a word vector learning method tailored for different government institutions and legal documents [5]. By applying Gov2Vec to Supreme Court decisions, Presidential orders, and Congressional bills, the paper extracts main topics, problem-solving methods, and reflects the positions of involved parties. The strength of the paper lies in its innovative approach to analyzing complex governmental texts through vector analysis, providing insights into policy details and interconnections between different governmental organizations. However, the paper may fall short in fully addressing the potential biases or limitations inherent in using vector models for such analyses.

Table 1. A Comprehensive Study of the Machine Learning Methods done by Some Researchers

Algorithm	**Method used/Innovation**	**Application and future work**	**Results and limitations (if specified)**	**References**
PLM, NLP, BERT	The model is implemented with dispersed attention and local context to read through long legal documents. It has proven to be a state-of-the-art performer so far.	This model has outstanding performance in court judgements outcome pre-prediction, corresponding case recovery.	The system still, undoubtedly lacks absolute accuracy and apply to a variety of languages.	[6]
BERT, BlockBERT, FLOP	This work suggests amending the iterative multipurpose attention multi head in BERT to use blockwise attention. The attention matrix is partitioned into sparse blocks by each block paying attention to the subset of it.	BlockBERT demonstrates the highest efficiency on question answering data sets and advances especially in long document understanding tasks where BERT performs with certain constraints.	This attribute of the transformer offers more power for use in relatively longer sentence-sequences such as coreference resolution and document-level machine translation. BlockBERT decreases a memory by 18.7-36.1%, time by 12.0-25.1% than RoBERTa, reaching comparable or better question answering performance especially by as shortening the long-paragraphs,	[7]

			especially in SearchQA and NewsQA.	
CFD, Bi-LSTM, RNN, Xnet, NEUSUM	The paper proposes a novel method for legal courtroom debate summarizing via a multi-task model equipped with a joint utterance encoder for sentence meaning, speaker role, and legal knowledge. This is the first literary piece that compiles in an extractive way arguments of the jurisdiction.	The algorithm will take care of the issue of the summary of detailed court debates, thus judges will be provided with the tool for acceleration of decision-making in civil trials. It targets a common problem, that of the unbearable workloads of judges because of increasing number of legal cases.	The model has an accuracy of 5,477 Chinese civil court debates, and it is suitable for both the utterance assignment and the extraction summarization and even surpasses other baselines. Case studies compared to predecessors show the quality of reports is more lucidity, which is valuable information fitting for legal dispute foci.	[8]
BERT, TextCNN, DPCNN	The paper goes for the JEC-QA. It entails designing a dataset, constructing an open domain automatic question answerer structure, and checking for the models like the attention-based and transfer-learning ones. Approaches used mainly include the dataset creation, QA framework building, and performance evaluation of the AI system on different question types.	JEC-QA boosts up question answering and reading comprehension as well as external reasoning enhancement. The wider upgrade is on augmenting machine reading and reasoning in complex are with sector knowledge. JEC-QA, the biggest legal QA dataset in China with 26k+ questions, which requires complex reasoning, is what the system needs to work with.	Models been able to reach only 28% accuracy. As a result meanwhile humans ones are performing much better: accuracy unskilled workers 64%, skilled workers 81%. The experiments set 7 models as instances for the students to see the problems lies in the concept understanding and reasoning. Future work concentrates on increasing the complexity of legal QA by using models that can be trained better with more knowledge added to them.	[3]

III. METHODOLOGY

While operating the legal system, the systems focus on Technological Development at anyone point by making discreet inquiries about the intrinsic legal systems and the problems that are associated with the manual processes in the fundamentals of legal documentation. The literature review conducted helped us to arrive at the areas of AI intervention that can be lushly filled and upon which will be directly dangled: document generation, comprehension, and abnormality detection in legal domain. The data assembly phase can be characterized by the gathering of a vast variety of legal documents during the process of collecting not only a single document type that is uniform, but rather those of a multilingual nature that represent different legal styles emerging across the worldwide legal tradition. This raw data line enters a complex data cleansing and processing phase whose aim is to identify and neutralize the chaotic and erroneous information through standardized format conversion, format elimination, and other necessary refinements. The chosen ChatGPT 3.5 model, which is known for its quality of natural language understanding, after the applied modification on the dataset is put at an advanced stage of training where, further, an enhancement component of the Open AI embeddings, which fortifies the capabilities of the system to completely apprehend the depth of legal language, is integrated.

The system further develops its framework by incorporating high-end features in the form of advanced knowledge modules which smoothly converge the powers of PyPDF, Amazon Textract, and langchain into this singular application. This module is built to bring intricate data out of documents in an established and thorough fashion which in turn results in improved understanding of complex documents. The inclusion of emotion analysis and Named entity identification (NER) in the NLP toolset makes the tool content-oriented and precise, so analyzing and interpreting legal documents contents becomes much more profound and accurate. The UI part also turns simplified that an efficiently designed web platform is built to work in two ways: you give a command for the document you would like to generate and also make use of the built-in AI detection system for errors. Verification processes, which are based on the application of diverse sets, a range functions including document generation and comprehension as well as identification of irregularities, such provides a valid inferential ground for ensuring performance quality across the main aspects. The clasp, which is the debugging phase, being the main focus of the development team and the balanced comments that are being offered by legal experts, is the idea-furnace for the renewing of the system and the assurance of its practical utility in legal circumstances.

Operating within the legal system requires a keen focus on Technological Development, wherein intrinsic legal systems and associated challenges in manual processes are thoroughly examined. Through a comprehensive literature

review, areas ripe for AI intervention, including document generation, comprehension, and abnormality detection within the legal domain, have been identified. To address the need for clarity in the Legal Document Assistant (LDA), meticulous steps are taken.
The feature extraction process is integral, achieved through meticulous data assembly involving a diverse range of legal documents. This process extends beyond mere gathering. Techniques such as standardized format conversion and refinement are employed to ensure accurate feature extraction. Similarly, the detection process within the LDA is meticulously designed to identify inconsistencies and ambiguities. Leveraging advanced techniques such as Named Entity Recognition (NER) and sentiment analysis, the system scans documents for irregularities, ensuring accuracy and efficiency.
Sentiment analysis plays a critical role in understanding document contents, identifying subtle nuances and inconsistencies within legal texts. By analyzing the emotional tone expressed, the system enhances comprehension and accuracy. Further clarity is needed for the Legal Language Model (LLM) within the LDA framework, which serves as a robust foundation for natural language understanding. Through advanced training and enhancement with Open AI embeddings, the model acquires a comprehensive grasp of legal language nuances, ensuring precise analysis and interpretation of legal documents.
Achieving accuracy within the LDA is paramount, accomplished through a combination of advanced technologies and meticulous verification processes. Techniques such as document generation, comprehension, and irregularity detection undergo rigorous testing, providing a reliable basis for performance quality assurance. The debugging phase, complemented by insights from legal experts, ensures continuous refinement and practical utility in legal contexts. Additionally, the role of Natural Language Processing (NLP) requires further clarity, particularly in its application within the LDA framework.
Placing itself as a versatile system which remains responsive and up to date, the system integrates a continuous improvement procedure, enhancing the system's capacity to respond swiftly to new updates, integrate new legal insights, and enhance the system's user-friendliness. At its core, the system comes out to be a force of change. It brings together all the different strands of artificial intelligence in a weaving process to complement an ancient series of rules and complexities that are native to the judicial system.

IV. PROPOSED SYSTEM

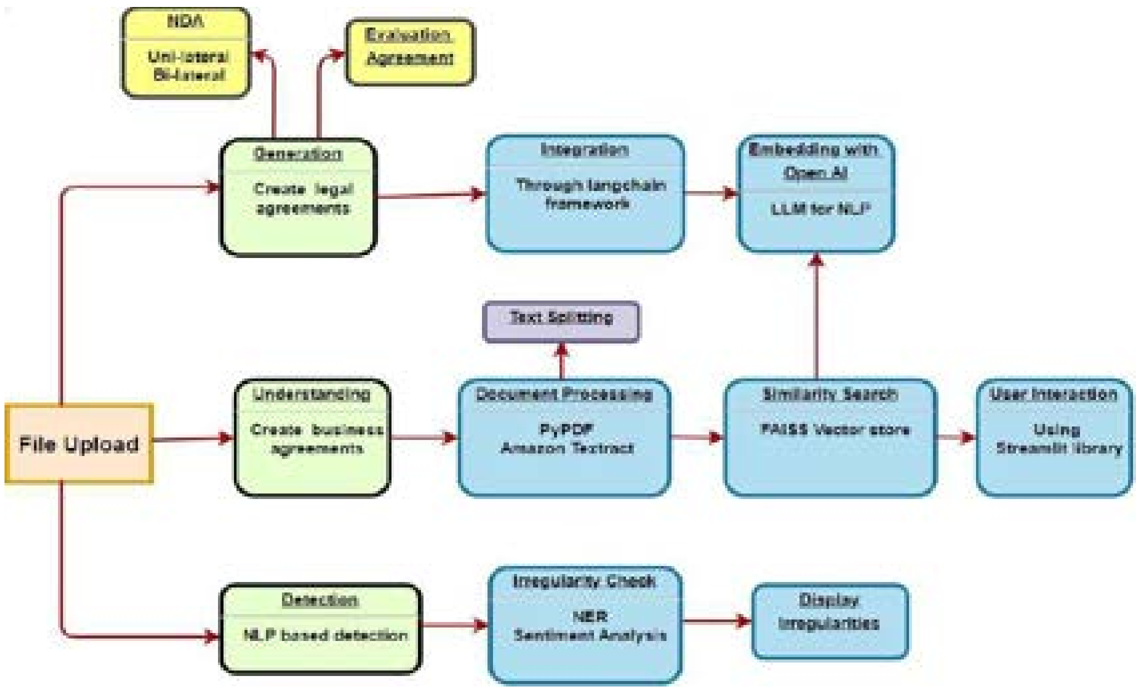

Figure 1. Proposed system

The offered approach in Fig.1 illustrates all the details of the advanced platform's work process and functionality as you can see in the figure below. It points the Management system into the specific direction including 3 subsystems. The system will use comprehensive legal documents, like NDAs and Evaluation Agreements, which are legally binding, as the primary feature. In here, the Framework of LangChain is being utilized along with the Large Language Models (LLMs) by integrating the Open AI for rooftop production, making the latter provide reliable and precise output that is required in any document creation. Therefore, the system makes it possible for a person to comprehend and read several languages, different from his or her very own language. Moreover, it promotes users to navigate a single graphical interface from which to get various types of information across the language barriers. Interfaces are created for the streamlit library applications which consist of the streamlit chart and streamlit graph components. Among all mentioned features, Clarke-Similarity search by using FAISS Vector Space is a powerful one. This feature uses the vector space to provide the similarity information for the document taken as a query. The rendered results will be very close to the submitted one in this case which is very efficient. And finally, to ensure regular compliance as discussed before, the system will make irregularity checks. It will exploit NER and Sentiment Analysis to identify these anomalies and generate an error report which should serve as a tool that will guide the user in further improving the clarity and fluency of the text.

Thus, the proposed system proposed focuses on the automation of text creation aspect as well as interpretation feature, that are both composed from the currently advanced technologies and theories to enable the system to complete the entire process step by step in a very good efficacy.

V. RESULTS

Table 2. A comparative analysis of the existing systems with the proposed system.

Existing System	**Key Findings**	**Multilingual Support**	**Collaborative Editing**	**Accuracy**
Kira Systems	It has the custom of locating, emptying data from and analyzing contents for the terms of your contracts and documents which is done fast and with highest precision. Automates any contract extraction and identification of essential information to the project.	Yes	Yes	>90% [11]
Evisort	Automates contract management and extracts important conditions inside the contracts.	No	Yes	95% [12]
LegalSifter	Highlights what is in a signed contract and the problems that may crop up.	Yes	No	95-97% [13]
Lex Machina	Provides Legal Analytics for companies and law firms can assist them to paint the picture of a winning case and also end up with a good company or law firm. Explore lawsuits case data and legal developments.	No	No	N/A [14]
ROSS Intelligence	ROSS Intelligence Inc. ("ROSS") has a business plan of designing AI-enabled technologies for lawyers to enhance their cognitive abilities. Use case law and statutes for all research legally relevant.	No	No	N/A [15]
AI-Powered Legal Documentation Assistant	Consistently utilizes sophisticated ML methods for the tasks of document production, understanding and detecting abnormalities in legal documents. Saves the effort of time that can be spent on tasks that get stuck in the bottlenecks of the manual work process along with the possibility of human errors in the legal documentation.	No	No	93-97%

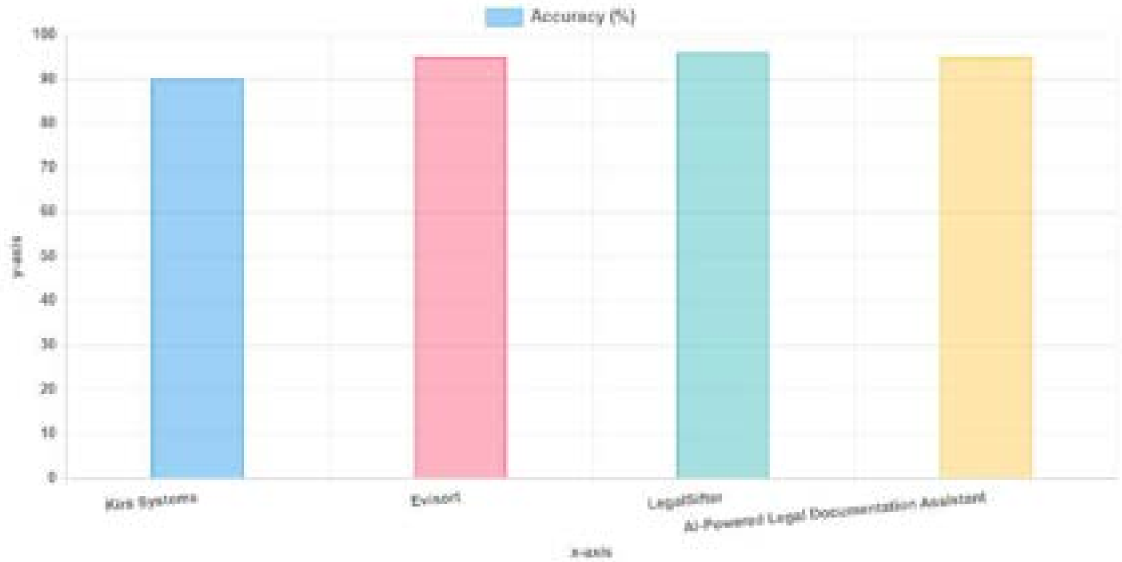

Figure 2. Graph based on accuracies of various systems alongside the proposed system.

Table 3 shows the difference between the existing systems and the proposed system. The table highlights what the systems actually do and compare them on the basis of some parameters.

Table 3. A comparative analysis of various input files considered for various systems.

Input Format	**Description**	**Advantages**	**Limitations**
PDF Files	Portable Document Format (PDF)	Provides easy adoption with a layout that is adapted to other people's necessities.	Imposing just a single system may require different text extraction tools that can be differently expressed.
DOC Files	Microsoft Word Document (DOC)	Drafting and choosing your own way of having a format.	The lack of support for the format of the company, and the problems of compatibility with the other programs are coming more and more often and are becoming the key various difficulties for the usual users of windows.
TXT Files	Plain Text Files	Compared to many others, it would be a small one, but one can take care of it and makes it up to their liking.	The primary drawback of not having rich-formatting features, images, and many other content-related devices was the most prominent.
Handwritten Notes	Handwritten Text or Scanned Images	May be added to the margin of handwritten notes, side notes, and added remarks.	This is caused by the digitization process that translates into unstructured text, and in specific cases where handwritten text is used, the results might be more accurate.
Voice Recordings	Audio Files (MP3, WAV, etc.)	Allows a very smooth dictation and communication.	As the process is mostly dependent on the ability to transcript, it is conditioned by the quality of the audio.

Table 4. A comparison table depicting the difference between the efficiency powers of existing ways with the proposed system.

Aspect	**Traditional Manual Handling**	**Document Management Software**	**AI-Powered Legal Documentation Assistant**
Time Efficiency	20	10	5
Accuracy	85%	90%	95%
Document Processing Speed (ppm)	2	5	10

Error Rate	15%	10%	5%
Integration with Legal Databases	No	Limited	Yes

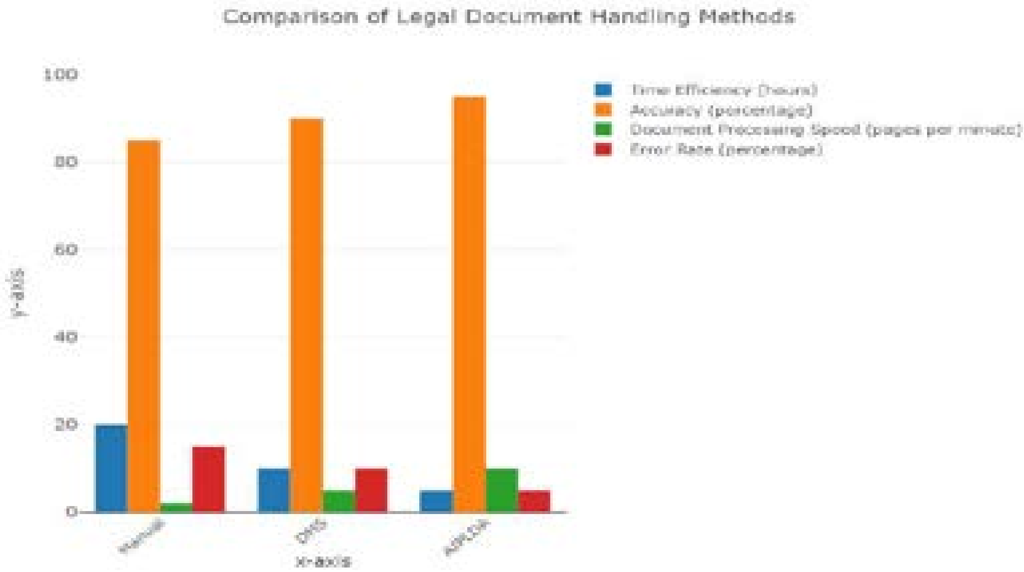

Figure 3. Graph depicting comparison of legal document handling methods.

Table 4 shows the comparison between various existing ways of handling legal document with the way that the proposed system uses. The proposed system proves out to be the best among the choices as it reduces the error rate and risk rate and increases the time efficiency as well as accuracy.

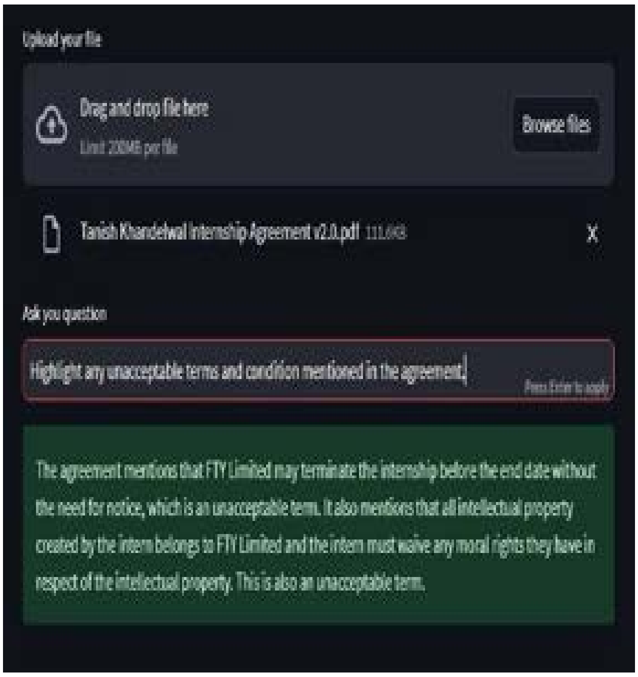

Figure 4.

Figure 5.

VI. DISUCSSION

The tables given represent a detailed look at many types of features needed to have a legal document processing AI system work well. Table 2 illustrates a range of ways that the methods from each system are applied and details their findings, revealing the array of approaches that researchers use in the area. Table 3. clarifies inputs types discussion from PDF, DOC, TXT, HTML, XML files, handwritten notes and even voice recordings. It covers their advantages and cons. Hence, one can notice that the transition of AI-scaffolded legal document processing, signifies the field with both the pick and the difficulties in channeling the sophisticated technologies to support legal doctrines. Figure 4 and Figure 5 also depicts how the system would look like in a few cases when the files are provided to the system and questions are asked on basis of it and when generating a legal document and on basis of it, as well, the questions are being asked. The future of the AI will only manifest itself through constant improvements, realizations and breakthroughs, therefore further search and progress is nothing but a must if AI in legal domain is to expand to its full capacity.

VII. CONCLUSION

The electronic device with custom AI content is the design that will revolutionize the document industry. In the field of document processing, all the intricate issues like automation, natural language understanding, abnormal detection, and regulatory compliances, need to be handled by using the AI techniques to solve the situation related challenges which occur while dealing with the complexities. With a combination of different options, the proposed system provides the feature of works in collaboration and the exceptional security using blockchain technology for processing the documents that are very sensitive, for institutions, business as well as law related agreements. The proposed approach will help to overcome the technicalities in the workflow, increase the efficiency and facilitate quality management. Legal professionals, through their contribution to technological development and the development of digital transformation, occupy a vital and irreplaceable position. Therefore, AI empowered humanoid lawyer might be a manifestation of a change or a revolutionary update to make the legal practice more and more frictionless.

VIII. FUTURE SCOPE

In the next stage, the AI-powered legal documentation assistant is likely to develop by means of the expansion of functions that allow it to work with a larger variety of legal documents, implementation of multilingual customer support and further improving general understanding of natural language through constant improvement of natural language understanding models. Mediating the collaborative editing and review processes, including the version control tool, the annotation, and the real-time collaboration, will pave the way for more productivity and accuracy for legal teams while the case documents are being handled. Integrating the blockchain technology into the document safety can guarantee the measures against any fraud or violation as well as make document unforgeable. Though the Automatic AI legal document service is considered as the milestone of AI evolution, it actually displays AI level that the generation of legal documents has already passed to the phase of AI functions.

***Abstract*— Parkinson's disease (PD) is a disorder that has significant implications, for patient care and treatment. It is crucial to predict the severity of the disease to provide personalized management. This research study explores the use of transfer learning techniques with medical image datasets to make these predictions. Proposed approach involves utilizing learning models that have been trained on large-scale image datasets. By leveraging the knowledge and features learned from these models the severity of Parkinson's disease can be effectively forecast. The study utilizes Convolutional Neural networks (CNNs) to extract important information from medical images, which is then inputted into a predictive model. The results of our experiments demonstrate the effectiveness of transfer learning in predicting PD severity.**

The proposed study compares trained CNN architectures, such as Simple CNN, Random Forest and XGBoost algorithms, DenseNet, and Inception using a specialized medical image dataset. The resulting model shows accuracy, sensitivity, and specificity making it a valuable tool for assisting physicians in their decision-making processes. Furthermore, the proposed technique not only achieves prediction accuracy but also provides valuable insights into visual indicators of disease progression. This non-invasive and efficient approach has the potential to empower professionals with early diagnosis and personalized treatment strategies for individuals, with Parkinson's disease. This groundbreaking approach shows potential in improving the management of Parkinson's disease and enhancing the quality of life for those who are impacted by it.

Keywords— ***Spiral, Waveform, Maxpooling, Accuracy, Conventional neural network, Healthy, Parkinson's.***

I. INTRODUCTION

Parkinson's disease (PD) is a prominent and increasingly incapacitating neurological condition that requires prompt diagnosis to ensure the best possible care for the patient. This work presents a machine learning model utilizing SPECT DaTSCAN imaging in response to the necessity of early Parkinson's Disease (PD) diagnosis. Proposed model prioritizes interpretability using LIME explanations and achieves a 95.2% accuracy rate using a VGG16 CNN [1]. To achieve a noteworthy 93.84% accuracy with a minimal set of vector features, this reaserch study introduces a machine learning-based diagnostic approach for Parkinson's disease. It emphasizes the potential for early and precise diagnosis to delay the progression of the disease. Support vector machines with regression feature elimination are used in this approach [3]. The approach achieved 96.40% accuracy using a Support Vector Machine classifier, emphasizing the potential of a comprehensive marker combination for early PD detection [6]. This study presents a novel method for classifying magnetic resonance images of healthy and Parkinson's disease patients. It uses a deep convolutional neural network with transfer learning, data augmentation, and GAN-based techniques, achieving an average accuracy of 89.23% and demonstrating improved diagnosis in comparison to current state-of-the-art research [10]. For the application, transfer learning is probably required for several conceptual reasons. One difficulty is the restricted availability of data. To get over this, transfer learning makes it possible to use the expertise of pre-trained models that have been trained on big datasets. Transfer learning makes it possible to initialize the model with weights learned from a larger, more diverse dataset, improving its ability to capture complex patterns. Second, the task of diagnosing Parkinson's disease may involve intricate patterns and relationships within the data that are difficult to capture with a small dataset. Last but not least, transfer learning lessens this load by using pre-trained models as a starting point. Training deep learning models from scratch demands a substantial amount of computing resources and time.

II. LITERATURE SURVEY

The study used a VGG16-based convolutional neural network with transfer learning to classify Parkinson's disease using DaTSCANs, achieving high accuracy. However, there may be some disadvantages, such as data bias, ethical concerns, difficulties with interpretability, the requirement for external validation, clinical adoption considerations, and the requirement for long-term monitoring [1]. To categorize Parkinson's disease, the study used 200 SPECT images and an Artificial Neural Network (ANN) on processed ROIs from Parkinson's and putamen. The model demonstrated high accuracy (94%), perfect sensitivity (100%), and notable specificity (88%); however, potential drawbacks included the need for testing on various populations, difficulties with implementing complex neural networks, the significance of rigorous clinical validation, and ethical considerations regarding patient privacy and potential biases in the data set [2]. The study used machine learning to diagnose Parkinson's disease by classifying and selecting features. Support vector machines with residual feature elimination were shown to be the best-performing method, achieving 93.84% accuracy with minimal vector features. The necessity of assessing model generalization across diverse populations, conducting real-world testing and clinical trials for clinical validation, and addressing ethical concerns about patient data privacy, informed consent, and sensitive medical data use are some of the drawbacks [3]. The assessment demonstrated a notable accuracy of 85.3% in predicting the severity of Parkinson's disease and a high detection accuracy of 98.7%. The necessity for validation in various clinical settings, the assurance of ethical data privacy and informed consent for sensor data, concerns about generalization to new subjects, and the significance of verifying robustness across various environments and demographics for dependable clinical diagnosis are some potential drawbacks, though [4]. This review of the literature explores the use of artificial neural networks (ANNs), especially those trained by backpropagation, in the diagnosis of Parkinson's disease, emphasizing how these systems might revolutionize medical procedures. Studies have shown that ANNs can identify Parkinson's disease with 100% accuracy using a variety of methodological methods, such as preprocessing techniques, dataset selection, and neural network topologies. This highlights the revolutionary influence of ANNs on medical diagnoses [6]. The research presented a new hybrid intelligence system that forecasts Parkinson's disease development. According to the scientists, this method provides improved accuracy and useful applications in clinical situations. However, there are certain important things to keep in mind, such as thorough dataset descriptions and stringent validation processes. In addition, the study tackles ethical issues regarding patient confidentiality and permission, offering valuable perspectives on how this system might be easily incorporated into regular clinical procedures for medical practitioners [7]. With the use of a special classifier, the study achieved a remarkable 99.8% accuracy in properly diagnosing the severity of Parkinson's disease by using speech data. But to get the most out of this approach, you need to have a thorough understanding of the dataset, take care of any ethical issues, and think about how this strategy may be successfully incorporated into clinical practice [8]. For data augmentation, the study used state-of-the-art methods such as generative adversarial networks, deep convolutional neural networks, and transfer learning. Thus, utilizing MRI scans, a remarkable accuracy rate of 89.23% was obtained in correctly detecting Parkinson's disease. The important factor of thorough dataset information and the ethical ramifications for patient data privacy were also considered in this study. The researchers also explored useful aspects to take into account when applying this technology in clinical settings [10].

III. METHODOLOGY

However these predictions are existing ones, but they did not give the best prediction for the image dataset. So, for the best and highest accuracy, we are going to implement the various transfer learning techniques by Simple Convolutional Neural Network, Pytorch Lightning Convolutional Neural Network, and DenseNet201, and in light of this, we would prefer to use the Histogram of Oriented Gradients Image Descriptor in conjunction with the Random Forest Classifier and Xgboost ensemble approach. In the proposed work we are analyzing their various transfer learning techniques and predict the prediction, and briefly analyzing all transfer learning techniques and their methods by visualizations of graphs, tables, and prediction, algorithms and, diagrams.

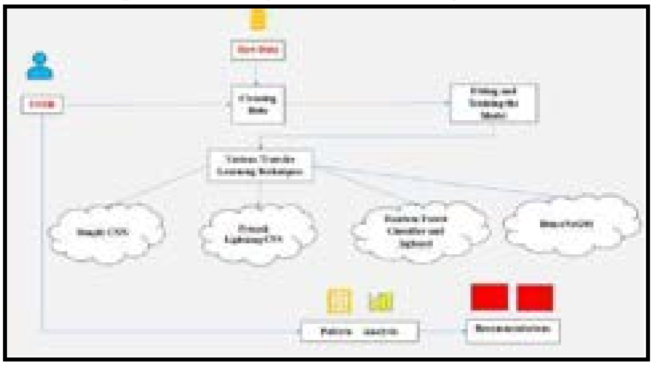

Fig1.Block Diagram

First collect the raw data from the user by using various ways like web portal history, survey forms, etc. Then we want to pre-process the data to get good quality data and then do the exploratory data analysis to get more insights into our data. With cleaned data, we can analyze and process the various transfer learning techniques like Simple Convolutional Neural Network, Pytorch Lightning Convolutional Neural Network, DenseNet201, Random Forest Classifier, and Xgboost ensemble approach.

1. Pytorch Lightning CNN:

PyTorch Lightning is a high-level wrapper for PyTorch that makes model training easier and better by removing repetitious code. In computer vision, convolutional neural networks (CNNs) are the preferred method for image

Classification tasks. These networks use kernels to extract several feature maps by convolving across the picture.

2. Simple CNN:

Convolutional neural networks (CNN/ConvNet), a kind of deep neural network, are trained to interpret visual input through the process of deep learning. Traditional neural networks use matrix multiplications, however, ConvNets use a different strategy called convolution.

3. Ensemble Methods:

Ensemble techniques are a robust and successful methodology in the field of machine learning. These techniques can improve the accuracy of the outcomes by merging various models can greatly enhance the outcomes.

Consider a scenario, where it is more appropriate to apply conventional computer vision techniques, namely HOG image descriptor in combination with strong ensemble approaches like Random Forest and XGBoost.

3.1 Quantify the image using a HOG Descriptor:

A structural descriptor called HOG will identify and measure variations in the input image's local gradient. Naturally, HOG will be able to measure the changes in spiral and wave directions. Additionally, HOG will be able to determine whether these drawings have a greater "shake," which is something we could anticipate from a patient with Parkinson's disease.

3.2 Random Forest:

Several decision trees are created during the training phase of Random Forest, a dynamic and successful ensemble learning technique. Using a process called bootstrapping, random portions of the training data are used to train each tree.

3.3 XGBoost (Extreme Gradient Boosting):

Extreme Gradient Boosting, or XGBoost, is a cutting-edge technique that uses gradient boosting to enhance data. This entails planting trees one after the other, each one intended to fix the mistakes of the one before it. An improved and more precise model is guaranteed by this trimming procedure.

3.4 Workflow:

Feature Extraction:

- Utilize the HOG algorithm to derive features from the images inside your collection.

Ensemble Model Education:

- Set the retrieved HOG features to use to train a Random Forest classifier.
- Utilize the same characteristics to train an XGBoost classifier.

Ensemble Prediction Model:

- To forecast the class of fresh photos, use both models.

Evaluation:

- Examine the group's performance on an independent validation or test set.

4. DensetNet201:

Specifically, the DenseNet201 architecture is a strong pre-trained deep learning model that must be used to classify images to use DenseNet201 for disease detection. DenseNet201's strong convolutional neural network (CNN) has shown itself to be effective in a variety of computer vision tasks, particularly image classification.

IV. EXPERIMENTAL SETUP

This research work implementation includes oftware, packages or libraries, techniques, programming languages, and some mandatory hardware components to do the detection of Parkinson's disease.

<u>Libraries or Packages:</u>

- Scikit Learn
- Numpy
- Pandas
- PyTorch

1. <u>Techniques:</u>

- Simple Convolutional Neural Network.
- PyTorch Lightning Convolutional Neural Network.
- Random Forest and XGBoost.
- Detection By DenseNet201.

V. RESULT ANALYSIS

1. Simple Convolutional Neural Network:

Convolutional Neural Network (CNN) is successfully implemented to identify images associated with Parkinson's disease. Understanding the structure of the dataset might be improved by visualizing it using code. It provides a visual analysis of the images so we can assess their consistency and quality. Ensuring the correctness of label assignments (between healthy and Parkinson's) is crucial, as inaccurate labels have a significant impact on the model's effectiveness.

A CNN model is successfully built that is simple to use and effective by utilizing Keras. This architecture, which consists of two convolutional layers together with max-pooling and thick layers, is a favorite choice for image recognition tasks. The max-pooling layers optimize the process by lowering spatial dimensions and focusing on the most important features, while the convolutional layers are in charge of extracting unique properties from the input images.

Through the use of the well-regarded Adam optimizer and a learning rate of 0.001, we have successfully and carefully balanced stability and efficacy. The difference between the predicted and actual class labels is measured by the binary cross-entropy loss function. In addition, we have carefully included callbacks for learning rate lowering and early halting. The final selection of 48 epochs was made with caution because any more than this leads to a decrease in accuracy. We reduce the danger of overfitting by guaranteeing that the model is not overtrained by our early halting.

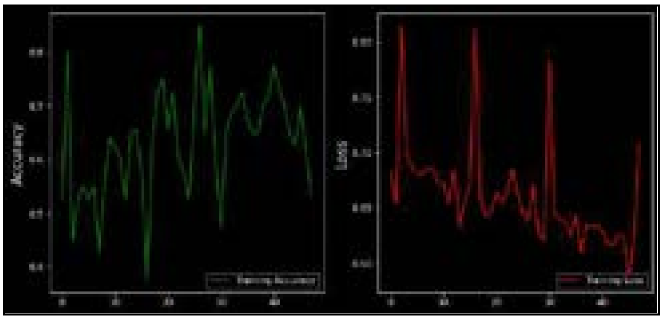

Fig2. Training Accuracy and Loss

A useful visual tool for evaluating the accuracy and loss of your model over time is the training history plot. It enables you to track your model's learning progress carefully and identify areas that need work. Even if the accuracy could differ, it's important to examine the general trend. The model is successfully learning from the data if the accuracy continuously increases and the loss gradually lowers with time.

2. PyTorch Lightning Convolutional Neural Network:

In this research, spiral drawings were used to classify Parkinson's disease using a convolutional neural network (CNN). The procedure had several steps, including the extraction of data, the development of a model, training, evaluation, and visualization. PyTorch and PyTorch Lightning were used for complex deep-learning tasks.

Two separate datasets were constructed with specified root directories, one for training and one for testing, using the datasets.ImageFolder module. Proposed CNN design, the ConvolutionalNetwork, consisted of three fully connected layers, two convolutional layers, and max-pooling. The PyTorch Lightning Trainer was used to train the model for a maximum of 600 epochs. The Adam optimizer was used to optimize the parameters during training, and the cross-entropy loss was computed. Proposed model was prepared to be used for image classification tasks after undergoing extensive training. On the test set, the trained model was evaluated and metrics like recall, accuracy, precision, and loss were calculated. The results proved that the total accuracy was about 66.67%.

	precision	recall	f1-score	support
healthy	0.7273	0.5333	0.6154	15
parkinson	0.6316	0.8000	0.7059	15
accuracy			0.6667	30
macro avg	0.6794	0.6667	0.6606	30
weighted avg	0.6794	0.6667	0.6606	30

Fig3. classification_report

Predictions were generated on the test set using the trained model, and each class's F1 score, precision, and recall were then calculated (healthy and Parkinson). After this, an extensive performance summary was shown, highlighting the overall recall, accuracy, precision, and F1 score.

A comparison investigation revealed that the deployed CNN had a 66.67% overall accuracy rate. Individual measures (precision, recall, and F1-score) that show how well the model distinguishes between classes with and without Parkinson's disease were also included in the evaluation.

3. Random Forest and XGBoost:

This research aims to evaluate if Parkinson's disease (PD) might be reliably classified using drawings and machine learning algorithms. The Histogram of Oriented Gradients (HOG) Image Descriptor was specifically used in the study to extract significant characteristics from spiral and wave drawings. To obtain reliable classification results, these characteristics were then utilized for training two ensemble classifiers: Random Forest (Rf) and XGBoost.

Our study makes use of the Histogram of Oriented Gradients (HOG) Image Descriptor due to the restricted quantity of training data.

We trained two robust ensemble classifiers, Random Forest (Rf) and XGBoost, to successfully categorize spiral and wave paintings. Both models underwent rigorous training before being tested and having their accuracy, sensitivity, and specificity assessed.

	Random Forest	XGBoost
Accuracy	80.00%	73.33%
Sensitivity	73.33%	73.33%
Specificity	86.67%	73.33%

Fig4. Spiral Drawings: Random Forest vs XGBoost Classifier

Now, let's analyze the findings of the research on Spiral Drawings, in which the Random Forest and XGBoost classifiers are compared. Based on investigation, it is analysed that the Random Forest classifier outperformed XGBoost with an accuracy of 80.00%. Both classifiers fared equally well in terms of sensitivity (73.33%), while Random Forest performed better in terms of specificity (86.67% vs. 73.33%) than XGBoost. This demonstrates the general power of Random Forest in accurately recognizing spiral designs.

	Random Forest	XGBoost
Accuracy	80.00%	73.33%
Sensitivity	73.33%	73.33%
Specificity	86.67%	73.33%

Fig5. Wave Drawings: Random Forest vs XGBoost Classifier

In this machine learning approach contrast, we examine the topic of "Wave Drawings," analyzing the respective performances of Random Forest and XGBoost classifiers. With an astounding 80.00% accuracy for Random Forest and a still-respectable 73.33% for XGBoost, the results speak for themselves. Both have similar levels of sensitivity (73.33%), but Random Forest performs with a higher specificity score (86.67%).

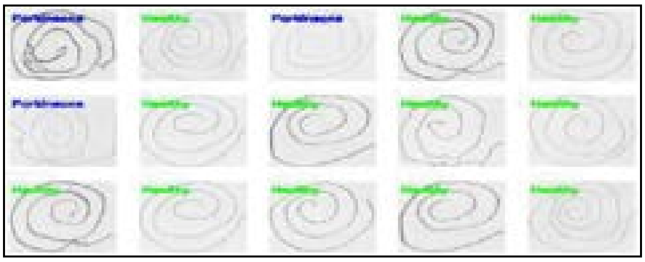

Fig6. Prediction of Spiral Images

Sample images are used to test the trained models, and predictions are shown for spiral and wave drawings.

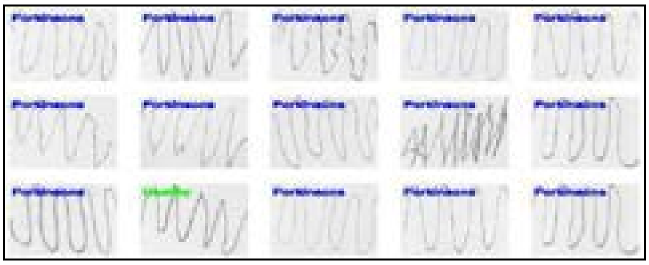

Fig7. Prediction of Wave Images

In spiral and wave drawings, the Random Forest classifier easily leads the XGBoost classifier in terms of specificity and accuracy. Though the classifiers' sensitivity remains constant, there is scope for improvement through additional research and parameter optimization.

4. Detection By DenseNet201:

By the use of transfer learning, we have successfully developed and trained two different models with the DenseNet201 architecture. These models were trained using several datasets that included images of Parkinson's disease, including spiral and wave images. Following that, an output layer with softmax activation for binary classification is added, followed by a Dense layer with ReLU activation. The final output layer generates the anticipated classification based on the softmax function, whereas this Dense layer receives the reduced feature vector and further refines it.

Furthermore, we employ a widely-used loss function known as categorical cross-entropy, which efficiently measures the discrepancy between actual class labels and expected probabilities. Accuracy metric is used, which computes the percentage of accurate predictions made by a binary classification model, to assess performance. We use the fit technique, which accepts enriched training data and target labels, to train the models.

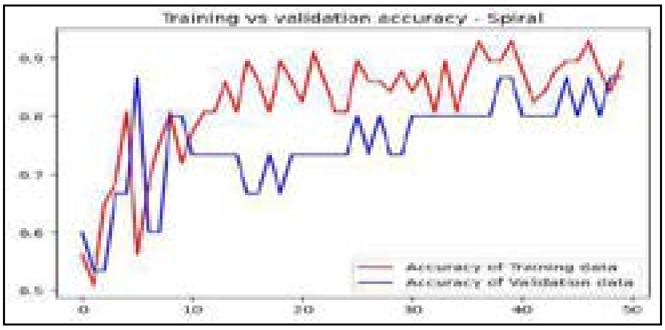

Fig 8. Training vs Validation accuracy – Spiral Drawing

To lower the loss function, this approach iteratively adjusts the model's parameters. The training and validation accuracies and losses are meticulously documented across the epochs, offering important insights into the models' performance and potential areas for improvement.

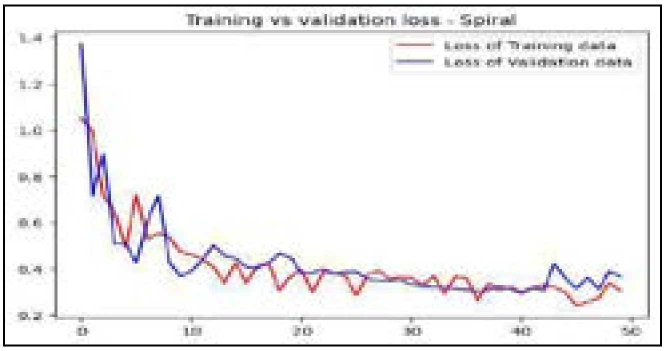

Fig 9. Training vs Validation loss – Spiral Drawing

The training and validation accuracies and losses for each epoch are shown, offering important information for assessing model competency and identifying areas in need of improvement. Notably, both models exhibited good accuracy on the validation sets, indicating that task-specific characteristics were successfully acquired for categorizing paintings of Parkinson's disease.

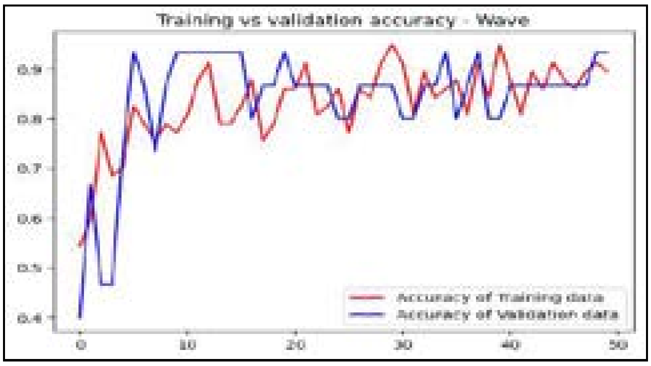

Fig 10. Training vs Validation accuracy – Wave Drawing

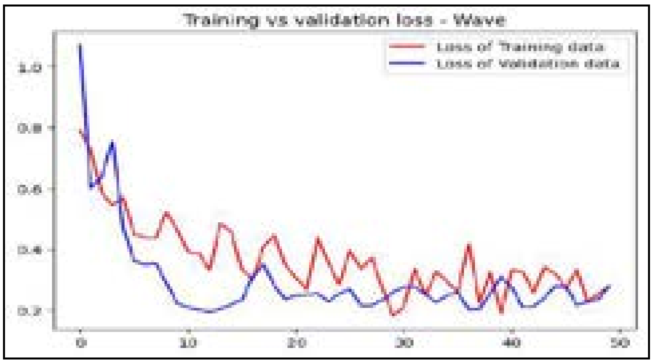

Fig 11. Training vs Validation Loss – Wave Drawing

Proposed models use DenseNet201 architecture and transfer learning is applied to increase their efficency. The models have shown impressive accuracy through validation on an independent test set, indicating that they can recognize significant patterns in the data.

VI. CONCLUSIONS

In this reaserch work, the main goal is to use images to provide patients suffering from Parkinson's disease with accurate and higher-quality predictions. Convolutional Neural Network, PyTorch Lightning Convolutional Neural Network, Random Forest and XGBoost, and DenseNet201 Detection ware discussed in this study. The techniques mentioned above make it simple to identify and determine the severity of Parkinson's disease. The findings proved that training Simple CNN achieves an accuracy of 80%, training PyTorch Lightning CNN achieves an accuracy of 66%, and training Random Forest and XgBoost achieves an accuracy of 80% and 73%, respectively, for both spiral and wave images, and training the DenseNet201 achieves an accuracy of 86% and 67% for spiral and wave images respectively. These various transfer learning techniques can also be used to analyze various disease detection and prediction for several diseases.

VII. FUTURE SCOPE

The integration of data from multiple sources with transfer learning algorithms is part of the future scope to enhance the efficiency and accuracy of disease prediction. This will make possible the development of hybrid models and enable real-time monitoring, allowing for a more robust and comprehensive approach. Additionally, the objective is to emphasize interpretability, carry out extensive validations, and adjust to distant healthcare settings in addition to broadening the scope of disorders for which these approaches may be used. Encouraging collaboration in clinical settings to improve disease prediction model performance. This will ultimately change the use of these models in a variety of healthcare domains.

Abstract - A novel technique for verifying signatures and certificates is introduced in this abstract with the goal of enhancing authentication and detecting fraud more effectively. There is a greater chance of identity theft and fraudulent activities due to the fact that conventional ways of confirming signatures and certificates are becoming less effective as technology advances. In order to overcome these obstacles, our system employs state-of-the-art technology like AI and machine learning algorithms to improve the precision and effectiveness of the verification procedure. In order to validate documents and swiftly identify any fraud attempts, the proposed approach examines information, trends, and abnormalities in digital certificates and signatures. Additionally, the proposed solution utilizes blockchain technology to minimize the possibility of manipulation or tampering by ensuring the immutability and transparency of validated certificates and signatures. The proposed technology enhances user experience and convenience by offering an interface that is easy to use and supporting the integration of current authentication systems. After undergoing rigorous testing and assessment, the proposed system has shown to be an effective and dependable option for verifying signatures and certificates. The proposed signature and certificate verification system includes sophisticated tools to fight fraud and identity theft, giving businesses and people a safe and effective way to verify their identities.

Keywords: *Certificate Verification, Signature Verification, Authentication, Fraud Detection, Artificial Intelligence, Machine Learning, Blockchain Technology, Identity Theft, Tampering, Manipulation, User-Friendly Interface, Integration, Robust, Reliable***.**

I. INTRODUCTION

Presenting a state-of-the-art signature and certificate verification technology will revolutionize authentication while effectively combatting fraud. This advanced system offers organizations and individuals unparalleled safety and peace of mind, blending modern technology with robust processes to ensure the highest level of security and accuracy in certificate and signature verification. At the heart of this system are modern AI algorithms that are trained to detect complex patterns, minute details, and unique characteristics present in digital signatures and certifications. Leveraging deep neural networks and machine learning, the system can verify the legitimacy of signatures and documents far more rapidly and precisely than manual methods.

This cutting-edge solution automates authentication and fraud detection processes, greatly simplifying the procedures compared to traditional verification techniques reliant on subjective judgments and human inspections. Consistent and reliable results are guaranteed each time as the system digitally scans and analyzes certificates and signatures, eliminating the risk of bias and human error. Integral to the system is a comprehensive database containing certified documents and verified signatures amassed over the years. By comparing and cross-referencing submitted certificates and signatures with validated ones, the system operates with enhanced accuracy and efficiency, continually updated to address emerging fraudulent practices and new counterfeit methods. Furthermore, the system has a smart design, facilitating straightforward verification for businesses and individuals alike. Users can easily submit their certificates or signatures for verification and receive prompt results, thanks to the user-friendly interface. Whether confirming the validity of a signature on a legal agreement, contract, or financial transaction, or authenticating diplomas, licenses, contracts, or any other certified document, this system offers a dependable and convenient solution.

As identity fraud, forgeries, and counterfeit certifications proliferate, it becomes imperative to implement safeguards that introduce the utmost security.

II. RELATED WORKS

Security issues in routing and anomaly detection for space information networks have gained increasing attention [Zhuo et al., 2021]. Researchers have explored various approaches to tackle these challenges and improve the security of space networks. Continuous authentication and anomaly detection using mouse clickstream data analysis have been investigated to enhance online security [Almalki et al., 2021]. The study evaluates the effectiveness of this approach and its potential applications in detecting unauthorized access or malicious activities.

A new deep anomaly detection-based method for user authentication using multichannel surface EMG signals of hand gestures has been proposed [Li et al., 2022]. This method aims to improve the accuracy and security of user authentication by analyzing electro-myographic signals. Off-line signature verification using elementary combinations of directional codes from boundary pixels has been researched [Ajij et al., 2021]. The study explores the application of this technique in authenticating signature images and detecting possible forgeries.

The Anti-fraud Tensorlink4cheque (AFTL4C) is an advanced AI/ML solution designed to detect and prevent cheque fraud [Uyyala and Yadav, 2023]. This proprietary technology utilizes machine learning algorithms to analyze cheque data and identify potential fraudulent activities. DOC-BLOCK is a blockchain-based authentication system developed for digital documents [Imam et al., 2021]. The system leverages the security and immutability of blockchain technology to ensure the authenticity and integrity of digital documents.

A digital certificate authority with blockchain cybersecurity in education has been proposed to enhance the security of academic certificates [Maulani et al., 2021]. This approach utilizes blockchain technology to create tamper-proof and verifiable digital certificates. Cerberus is a blockchain-based accreditation and degree verification system that aims to provide a secure and decentralized method for verifying academic credentials [Tariq et al., 2022]. The system leverages the transparency and immutability of the blockchain to prevent fraud and ensure the validity of certificates.

Blockchain technology has been reviewed in the context of academic certificate authenticity [Kumutha and Jayalakshmi, 2022]. The study explores the potential of blockchain to combat certificate fraud and improve the trustworthiness of academic qualifications. An academic certificate fraud detection system framework has been proposed that utilizes blockchain technology to enhance the security and reliability of academic certificates [Lutfiani et al., 2022]. The framework aims to detect and prevent fraud by leveraging the distributed ledger system and cryptographic mechanisms provided by blockchain technology.

III. EXISTING SYSTEM

When it comes to authenticating users and detecting fraud, the current method for Innovative certificate and signature verification has a few drawbacks. To begin with, the system is very susceptible to forgeries and theft since it is based on actual certificates and signatures. This is a major security concern because bad actors may forge certificates and signatures to impersonate trusted users or get unauthorized access. Second, it's expensive and time-consuming to validate physical certificates and signatures. In order to verify the given papers, skilled staff must manually check them with the original records. Organizations incurring higher operating costs as a result of having to devote resources to this activity also see a slowdown in the authentication process.

Also, new technologies can't be easily integrated into the current system because of its rigid design. Physical certifications and signatures limit innovation in an era when digital transformation is transforming many parts of our life. It makes it harder to include new technology that might improve the efficiency and security of certificate and signature verification, such biometrics or blockchain. The inability to monitor and identify fraudulent actions in real-time is another drawback of the current system. Keeping tabs on who has accessed or misused physical certificates and signatures may be a challenge. Because of this, fraud is more likely to go undetected for long periods of time, which might harm people, businesses, or even whole systems.

IV. PROPOSED SYSTEM

Using state-of-the-art technology, the new certificate and signature verification system is going to change the game when it comes to authentication and detecting fraud. In order to guarantee absolute verification and security against fraudulent operations, this system incorporates biometric identification techniques, blockchain technology, and machine learning algorithms. To start, digital certificates are analyzed and validated by the system using machine learning techniques. In order to identify any irregularities or efforts at manipulation, these algorithms can intelligently check the validity and authenticity of certificates. The system provides a trustworthy verification method by detecting changed or counterfeit certificates by comparing the certificate data with known patterns. Second, to make the verification process more secure and transparent, the system uses blockchain technology. Blockchain technology allows for the establishment of a distributed ledger that cannot be altered, guaranteeing the authenticity of all certificate transactions. The digital signatures and storage in a distributed ledger of each certificate make it very difficult, if not impossible, to alter or manipulate the data. This decentralized method boosts confidence in the system and decreases the likelihood of fraud by doing away with middlemen.

The technology further strengthens the verification process by using biometric authentication technologies. Biometric authentication allows users to verify their identification using their own distinct characteristics, including fingerprints, iris scans, or face recognition. An extra safeguard against impersonation or identity theft, these biometric features are very secure and hard to reproduce. To further combat fraudulent actions, the system is equipped with real-time fraud detection tools. Anomalies, such questionable certificate requests or strange use patterns, may be caught via the system's constant monitoring of transactions and user activity. Upon detection, the systemhas the capability to send out notifications or immediately respond in order to reduce risks and safeguard against possible fraud.

The proposed method for verifying signatures and certificates is a new and inclusive approach that integrates biometric authentication, blockchain technology, and machine learning techniques to provide strong authentication and fraud detection capabilities. Using these cutting-edge technologies, the proposed system creates a trustworthy environment for people and enterprises by avoiding unwanted access and guaranteeing the authenticity of signatures and certificates.

V. SYSTEM ARCHITECTURE

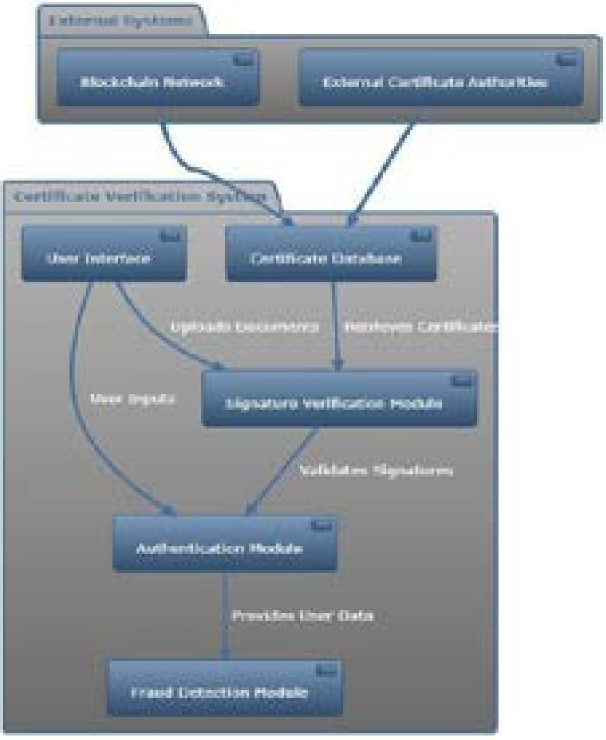

Fig. 1. System Architecture

The architecture diagram depicted in fig 1 presents an advanced system to authenticate digital certificates and detect fraud. This system integrates with two external entities: a Blockchain Network, which provides a secure and immutable ledger for certificate verification, and External Certificate Authorities, which are trusted entities that issue and manage digital certificates.

The certificate verification system is composed of several key components; they are:

User Interface: This is the front-end through which users interact with the system. It allows users to submit certificates for verification and to input necessary data for the process.

Certificate Database: A crucial repository, where digital certificates and their related data are stored. This database is referenced to verify the details of a certificate against its stored credentials.

Signature Verification Module: This module is responsible for the validation of the digital signatures attached to the certificates. It ensures that the signature is genuine by comparing it with a known valid signature from the Certificate Database.

Authentication Module: This part of the system authenticates the user requesting the verification, ensuring that they are authorized to access or query the certificate information.

Fraud Detection Module: Operating as a safeguard, this module analyzes patterns and verifies the authenticity of the certificates to detect any fraudulent activity that might be attempted.

Figure 1 depicts a flow of information between these components, illustrating the thorough process by which certificates are authenticated. The Blockchain Network and External Certificate Authorities provide a foundation of trust for the system, while the internal components work in synergy to perform the verification process, authenticate users, and detect fraud, ensuring that the certificates are valid and secure.

VI. METHODOLOGY

1. **Certificate Generation Module**:
This module is responsible for generating innovative certificates that can be used for authentication and fraud detection. The system will generate unique digital certificates for individuals or organizations, ensuring the authenticity and integrity of the information. The module will include features such as biometric identification, in which the system captures and stores unique physical or behavioral characteristics of the user. It will also incorporate advanced cryptographic algorithms to protect the certificates from tampering or forgery. Additionally, the module will have an intuitive user interface that allows administrators to easily generate and manage certificates, including customizing the information and design, and specifying the level of security required.

2. **Signature Verification Module**:
The signature verification module is crucial for ensuring the authenticity of documents and transactions. It will employ innovative techniques to accurately verify the legitimacy of signatures on various forms, contracts, and other important documents. The system will capture signatures electronically and store them securely. Advanced algorithms will then be used to compare the captured signature with the stored signature to determine the level of similarity and authenticity. The module will also incorporate machine learning capabilities to continuously improve accuracy over time. Moreover, it will provide a user-friendly interface for individuals and organizations to easily submit and verify signatures, as well as generate comprehensive reports on verification outcomes.

3. **Fraud Detection Module**:
The fraud detection module is designed to detect and prevent fraudulent activities within the system. It will employ advanced data analytics and machine learning algorithms to analyze patterns, trends, and anomalies in the certificates and signatures. The module will leverage big data capabilities to process large volumes of information, including cross-referencing and comparing with external databases to identify potential cases of fraud. It will also incorporate real-time monitoring to flag suspicious activities, such as multiple attempts to use the same certificate or an unusual number of signature verifications within a short period. The module will generate alerts and notifications to administrators, enabling them to take immediate action and prevent fraudulent activities from occurring. Additionally, the module will provide comprehensive reporting and analysis tools to assist in identifying trends and improving the overall security of the system.

VII. DISCUSSION

Strong authentication and fraud detection capabilities are included into the revolutionary signature and certificate verification system. The authenticity and integrity of certificates and signatures are guaranteed by the system via the use of cutting-edge technology. The use of digital certificates is a crucial component of this system. An individual's digital identity may be represented by these certificates, which are issued by reliable agencies. The system verifies the authenticity of a certificate by comparing it to the digital signature of the issuing authority. That way, you know the certificate is authentic and hasn't been tampered with.

The systemuses state-of-the-art signature verification methods in addition to digital certificates. In order to determine the signature's legitimacy, it examines its features, including stroke dynamics, pressure, and speed. The system can tell whether a signature is real or fake by comparing it to the authorized user's baseline. The technology uses machine learning techniques to improve fraud detection even more. Certificate and signature fraud trends and behaviors are constantly being analyzed by these algorithms. Anomalies may be detected and suspicious activity can be flagged, allowing for proactive intervention to stop fraudulent operations. In addition, the system keeps a detailed record of all actions taken to verify signatures and certificates. If fraud is discovered, investigations and legal actions may be aided by this traceability and responsibility.

Authentication and fraud detection are both made easier with this cutting-edge technology that verifies signatures and certificates. Ideal for organizations and corporations seeking to secure against fraudulent activity, it combines digital certificates, sophisticated signature verification methods, machine learning algorithms, and a full audit trail to assure high levels of security and dependability.

VIII. CONCLUSION

Finally, a novel approach to authentication and fraud detection is offered by the signature and certificate verification system. The proposed system uses cutting-edge tech like machine learning and blockchain to make sure that certificates and signatures are secure and legitimate. In order to identify any fraudulent actions and ensure that papers are real, it provides a simplified and fast method. Data analysis and encrypted records greatly lessen the possibility of identity theft and illegal transactions. Additionally, this system is accessible and handy for consumers and enterprises due to its user-friendly design and smooth connection with numerous platforms. In conclusion, this approach is an effective and trustworthy instrument for combating fraud in the modern digital age.

IX. FUTURE WORK

There must be a solid method for verifying digital certificates and signatures in the ever-changing digital world. An innovative solution is needed by enterprises to reliably identify and verify fraudulent activity, especially with the development of remote labor, online transactions, and fraud overall. Our future work will focus on creating a complex system that integrates cutting-edge technologies like blockchain, AI, and ML to guarantee the authenticity of certificates and signatures. Digital certificates produced by legitimate organizations and not altered in any way will be verified by the system's algorithms. Furthermore, it will make use of deep learning models to identify forgeries or impersonations by precisely matching signatures with the ones on file. Integrating blockchain technology will also increase the system's transparency, immutability, and security, making it harder for fraudsters and tamperers to compromise. The main goal of this work is to aid in the creation of a novel authentication system that can help organizations protect sensitive data, stop fraud, and guarantee the authenticity of digital certificates and signatures through rigorous testing, prototyping, and research.

***Abstract*—The metabolic condition known as diabetes, or Diabetes Mellitus (DM), is defined by consistently higher levels of blood glucose over an extended period of time. Diabetes management requires adequate blood glucose monitoring. Proper monitoring of blood glucose levels is essential for managing diabetes. Strong methods for tracking blood glucose levels have been the focus of research efforts. The amount of glucose in the blood can be estimated via NIR-spectroscopic measurement results. We first employed convolutional neural networks, yielding an r square value of 95 and an MAE of 0.16. Based on the numerical results, a non-intrusive blood sugar monitoring that incorporates near-infrared spectroscopy and an appropriate processing method emerges as a potential solution. The World Health Organization (WHO) conducted research revealing that the cardiovascular diseases (CVD) are the primary cause of death worldwide Cardiovascular-diseases (CVDs) account for almost 17.9 million deaths annually, or 31% of all fatalities globally. Experts believe that heart attacks and strokes account for 85 of these fatalities. One of the most common disorders that affect people is cardiac arrhythmia, which can result in life-threatening illnesses including stroke or cardiac arrest. Due to the asymptomatic nature of arrhythmia in many situations, one cannot determine whether they have it until they are checked by a professional. An ECG is a regularly used tool for monitoring a patient's cardiac rhythm. The purpose of this work is to describe a technique that can be used to categorize immediately. We train and assess the proposed Convolutional Neural Networks (CNN) model on the MIT-BIH Database, yielding a 99% accuracy rate.**

Keywords: Diabetes Mellitus (DM), cardiovascular diseases (CVD), disease detection, ECG, Convolutional Neural Networks (CNN)

I. INTRODUCTION

Diabetes stands as one of the primary health challenges confronting the world today. Projections suggest that by 2030, the condition will affect over 366 million individuals globally and rank among the top six causes of death in the United States [2]. In 2000, 171 million people were grappling with the disease. Diabetes is an incurable condition [3] characterized by either hypoglycemia, or insufficient glucose levels in the blood, and hyperglycemia, or elevated blood sugar levels, stemming from the body's inadequate production of insulin [4,5]. Insulin, produced by the pancreas, initiates cells' absorption of glucose, thereby lowering blood glucose levels [6, 7]. Three types of diabetes are recognized: gestational diabetes, Type I diabetes mellitus, and Type II diabetes mellitus. Monitoring blood glucose levels represents a new area of diabetes research. Traditional testing and monitoring systems are inconvenient, posing daily discomfort for individuals.

To streamline diabetes monitoring and treatment, and alleviate the pain, distress, and financial burden of the patients, researchers have concentrated on the developing techniques and equipment for continuous blood glucose monitoring. Over recent years, researchers have explored numerous technologies employing sensors to monitor blood glucose levels [3, 5, 8]. Both non-enzymatic and enzymatic electrochemical glucose sensing methods have been investigated [9]. Researchers have found infrared light spectroscopy to be generally accurate in measuring blood glucose levels [9-10]. Consequently, the use of spectroscopy for this purpose is gaining traction. This project aims to utilize the SparkFun kit with near-infrared spectroscopy to ascertain glucose levels in the blood. A suitable deep learning approach is employed to analyze data accurately predicting blood glucose levels

The analysis of electrocardiograms (ECGs) plays a pivotal role in diagnosing and treating various cardiac disorders, including arrhythmias. Precisely identifying and categorizing arrhythmias using ECG signals is a critical task in clinical practice. Traditional arrhythmia detection techniques often rely on handcrafted features and rule-based algorithms, which may lack robustness and generalizability across different patient demographics and ECG recording conditions. In recent years, deep learning approaches have demonstrated promising performance in various medical signal analysis applications, including ECG arrhythmia identification. By automatically learning discriminative features from raw ECG signals, convolutional neural networks (CNNs) and recurrent neural networks (RNNs) have significantly improved the efficiency and accuracy of arrhythmia classification. We review recent developments in deep learning-based ECG arrhythmia detection, exploring a range of network topologies and preprocessing methods to assess their generalization and performance for different ECG tasks, including arrhythmia identification [11].

One unique method for categorizing ECG arrhythmias involves utilizing softmax regression and stacked sparse autoencoders. This approach demonstrated competitive performance compared to conventional feature-based techniques, effectively learning hierarchical features from ECG signals [12]. Additionally, researchers presented a deep learning model that combines recurrent and convolutional neural networks to classify ECG arrhythmias, outperforming traditional machine learning techniques and exhibiting robust performance across various arrhythmias [13]. These research works highlight the potential of deep learning in enhancing diagnostic accuracy and clinical outcomes. They discuss various network architectures, preprocessing techniques, and challenges in ECG arrhythmia identification [14]. The primary objective of this study is to classify cardiac disorders using the MIT-BIH database. By employing appropriate deep learning techniques, data analysis aims to accurately diagnose disorders. Section II provides a brief review of the scientific background, while Part III explains the process in detail. Section IV presents the results and models used to support the proposed concept. Finally, Section V concludes the research work.

II. SCIENTIFIC BACKGROUND

The term "near-infrared region" refers to the portion of the electromagnetic spectrum between 780 and 2500 nm in wavelength [12]. When considering mid-infrared spectra, NIR sample. Some near-infrared (NIR) light is partially absorbed and scattered due to interactions between the sample's elements and the incident light. The following is an explanation of the light attenuation equation [13]. Since the objective of this research work is to utilize near-infrared spectroscopy data to estimate blood sugar levels, the primary task is to identify the most suitable model that provides an optimally precise fit to the data collection. Numerous multivariate studies, including those employing machine learning algorithms and deep neural networks, have been conducted. Neural networks are employed for automated ECG signal processing using the MIT-BIH Arrhythmia Database. In tasks involving pattern identification and classification, neural networks offer a robust foundation as they can discern intricate relationships within the data. When trained on annotated ECG recordings, neural networks demonstrate the capability to accurately identify and categorize arrhythmias, facilitating diagnostic decision-making. By employing neural networks to analyze this dataset, arrhythmia diagnosis can be rendered more precise and automated, potentially leading to improved patient outcomes and clinical treatment..

III. METHODOLOGY

A. *Non-invasive Glucose*

This methodology encompasses several key steps or developing and evaluating a regression model using TensorFlow data pre-processing method. Firstly, data pre-processing involves loading the dataset and normalizing it to ensure the feature homogeneity.

$$X\_Normalixed = \frac{x - \mu}{N} \qquad (1)$$

Neural Network Architecture:

The next step is to build the model's architecture using ReLU activation functions and dense layers. For deep learning models, the Rectified Linear Unit is the highly preferred activation function. If the input is negative, the function will return 0. Otherwise, it will provide the value it obtained, which is x in this case, if the input value is a positive number. As a result, it may be expressed as

$$\text{ReLU(x)} = \begin{cases} 0, & if\ x < 0 \\ x, & for\ x => 0 \end{cases} \qquad (2)$$

The model is assembled using the Adam optimizer and the Mean Squared Error (MSE) loss function. Gradient descent is used during training process to modify the model's parameters.

$$\text{MSE} = \frac{1}{\text{n}} \sum_{\text{i}=0}^{\text{n}} \left(\text{y}_{\text{true}} - \text{y}_{\text{pred}}\right)^2 \qquad (3)$$

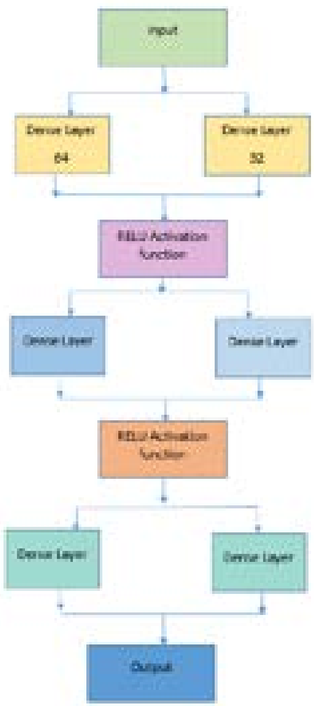

Fig. 1. Neural Network Architecture for Non-Invasive Glucose Monitoring

Model Performance

Evaluation metrics include mean absolute error (MAE) and R-squared respectively.

$$\text{MAE} = \frac{1}{n} \sum_{i=0}^{n} \left|\text{y}_{\text{true}} - \text{y}_{\text{pred}}\right|^2 \qquad (4)$$

The coefficient of determination, or R-squared, is a statistical measure used in regression models to determine the extent to which the independent variable explains the dependent variable's variance. Just to clarify, r-squared is a way to see how well the data fits the regression model.

B. ECG

The following method implements a convolution neural network (CNN) for classifying heartbeat signals into five categories using the MIT-BIH Arrhythmia Database.

Table-1 Class and Category Mapping

Class	Category
N	N is the normal heart rate. (N) Block beats on the left and right bundle branches (L, R) Beat of atrial ejection (e) The escape beat at the nodes' junctions (j)
F	Atrial fibrillation (A) Abnormally early heart rate in the atrium (a) Premature nodal beat (J) Supraventricular preterm heart rate
V	An early constriction of the ventricles Ventricular ejection fraction (E)
F	Combined ventricular and regular heart rate (F)
Q	Paced beat (/) A combination of regular beat and paced Uncategorizable rhythm (U)

Data Pre-Processing

The dataset is pre-processed by separating the features (ECG data) and labels (heartbeat categories). The features are adjusted so that their standard deviation is one and their mean is zero. A training set and validation set are then created from the dataset. Due to class imbalance, each class's weight is calculated inversely proportional to its frequency, ensuring balanced training

$$X\_Normalized = \frac{x-\mu}{\sigma} \qquad (5)$$

Neural Network Architecture

The CNN architecture consists of convolution blocks followed by max-pooling layers for feature extraction. Batch normalization and GELU activation functions are utilized for improved performance. The model is trained using cross-entropy loss, which measures the difference between predicted and actual class distributions.

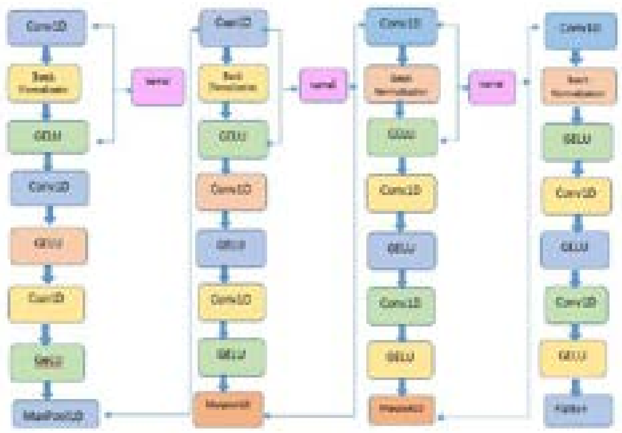

Fig. 2. Neural network architecture of ECG signal

IV. RESULTS & DISCUSSION

By implementing the proposed neural network architecture, the evaluation metrics such as the Mean Absolute Error (MAE) and R-Square error are depicted in Table 2. Further, the precision, accuracy and recall values are depicted in Table 3. Figure 3 shows a comparison on the training and validation loss. Figure 4 shows a comparison on the actual and predicted values for non-invasive glucose monitoring procedure. From figure 4, it is evident that the predictions of the proposed model are highly accurate. The QQ plot is given in figure 5. Finally, the figures 6 and 7 shows the accuracy and loss comparison. These graphs are plotted based on the confusion matrix depicted in figure 8.

Table-2 Evaluation metrics for non-invasive glucose monitoring

Evaluation metrics	MAE	R-square
Values	0.16	0.95

Table-3 Evaluation metrics for ECG signal analysis

classes	Accuracy	Precision	Recall
N	0.99	1.00	0.99
S	0.95	0.81	0.88
V	0.97	0.96	0.97
F	0.90	0.75	0.82
Q	0.99	0.99	0.99

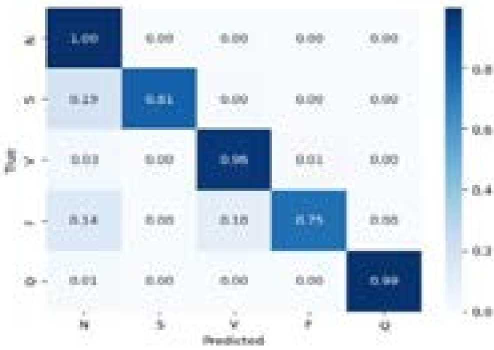

Fig. 8. Confusion matrix for ECG signal

V. CONCLUSION

This study has proposed a novel method based on near-infrared spectroscopy for blood glucose monitoring. We have used neural networks to assess and validate our system. Using NIRF spectroscopy, it was found that the feed-forward neural network. The proposed approach for classifying ECG heartbeats using neural networks is described in this paper. To be more precise, we have trained a deep-convolution neural network for the arrhythmia classification task using 1d convolutions with residual connections. This study has also demonstrated that the representation acquired for this task can serve as a foundation for training precise classifiers for the data classification. Results demonstrate that the suggested method can outperform contemporary techniques in the literature when it comes to predicting both tasks.

***Abstract*—This research study explores the diverse application of Artificial Intelligence (AI) across various areas, it transforms impact on technological advancement. This survey begins by investing in AI's role in enhancing the efficiency of the Internet of Vehicles through real-time Data collection and edge computing addressing challenges in optimizing edge service. The paper goes into AI's critical contribution to medical diagnosis, disease detection and treatment highlighting applications in breast cancer detection and medical image analysis. The concept of human-AI collaboration is introduced, using the integration of human intelligence with AI to create a hybrid intelligence system. The paper further discusses an ice role in the COVID-19 pandemic from diagnosis to treatment utilizing deep learning techniques and extreme learning machines. This study extends to large-scale, power grid simulation analysis, where AI including deep learning and reinforcement learning significantly improves efficiency and accuracy. The integration of AI into robotics explains the role of teaching, assistant robots and vision-based assessment systems. The concept of smart farming is introduced, showcasing its potential to revolutionize agriculture production. Focusing on maximum PowerPoint tracking techniques for the improvement of efficiency. This study explores applying the artificial immune system of multi-objective optimization with decision-making and introduces the beneficial perturbation network for overcoming continued learning challenges in an Artificial Neural Network (ANN). Satellite communication and the vision of a 6G network are discussed in the integration of AI, IOT and 5G. In the context of the next generation, Smart credit is highlighted in this study and finally concluded by discussing about the challenges in Wireless Sensor Networks (WSN) and the increasing importance of AI.**

Keywords—Artificial Intelligence, Medical Diagnosis, Smart Farming, Communication, Education.

I. INTRODUCTION

This research study analyzes the application of Artificial Intelligence (AI) across various domains, showcasing its transformative potential and problem-solving capabilities. It begins by focusing on the integration of AI with the Internet of Vehicles, emphasizing real-time data collection and edge computing services. The role of AI in medical diagnosis and disease detection is also highlighted, encompassing areas such as breast cancer detection and medical image analysis, showcasing the concept of human-AI collaboration. This hybrid intelligence system leverages both human and AI capabilities. Furthermore, the study analyzes the extensive application of AI in addressing challenges posed by COVID-19, emphasizing the use of deep learning techniques, extreme learning machines, simulation analysis, and the role of artificial intelligence and robotics. Additionally, the survey explores the concept of smart farming, demonstrating how AI and the Internet of Things (IoT) can enhance agricultural production. The application of AI in solar power systems is also discussed, along with the challenges associated with variations in solar output. Moreover, this study examines the application of artificial immune systems in multi-objective optimization and decision-making processes. It introduces a novel approach called beneficial perturbation network to address learning challenges in artificial neural networks, satellite communication, and vision for the 6G network. The integration of AI, IoT, and 5G in the next generation of smart cities is discussed, emphasizing their transformative potential.

Finally, the study concludes by exploring challenges in wireless sensor networks and the increasing importance of artificial intelligence in effectively addressing these challenges.

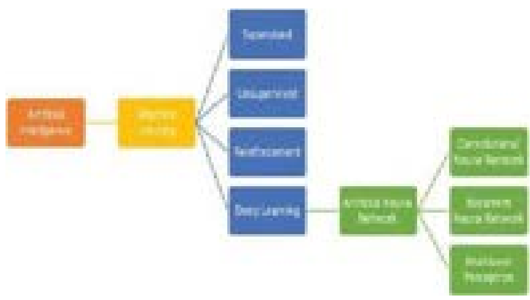

FIGURE 1: Artificial Intelligence. (Mobeen Nazar et.al., 2021)

II. LITERATURE REVIEW

Xiaolong Xu et al.'s research paper [1] ivestigates the role of AI in enhancing the efficiency and responsiveness of IoV (Internet of Vehicles), renowned for its real-time data collection capabilities. Typically, this data is transmitted to resource-intensive cloud platforms for service execution. To meet the demand for real-time services, the paper introduces edge computing, deploying physical resources near roadside units to support vehicular users and enhance edge devices' learning capacity for dynamic resource allocation. The survey also highlights open challenges in optimizing edge service with AI, warranting further research and development efforts.

FIGURE 2: PAPER ORGANIZATION,(MOHAMED ABOUALOLA ET.AL.,2023)

Stephanie Baker et al.'s research paper [2] highlights the critical role of artificial intelligence in improving medical diagnosis and disease detection, acknowledging the complexity of the process and the potential for errors leading to delayed or incorrect treatment. AI, including rule-based systems, neural networks, and deep learning, enhances accuracy and efficiency in applications such as breast cancer detection, the Internet of Medical Things, and medical image analysis. The paper contributes by discussing the evolution of AI techniques and conducting a systematic review of AI-based diagnostic systems, emphasizing the importance of enhancing diagnosis accuracy and efficiency through AI techniques like neural networks and deep learning.

Feifei She et al.'s work [3] introduces the concept of H-AI (Human-Artificial Intelligence), aiming to leverage the combined strengths of human intelligence and artificial intelligence. It addresses current limitations in AI and explores the collaboration between human and machine intelligence. The paper traces the evolution of AI from human-machine interaction to human-machine collaboration, anticipating the emergence of H-AI as a real hybrid intelligence. It outlines a roadmap of eight transitions in H-AI, where machines become integral to human cognition, bridging the gap between theory and practical applications.

Mohammad Jamshidi et al.'s paper [4] emphasizes the crucial role of artificial intelligence in tackling the challenges posed by COVID-19, from diagnosis to treatment. It discusses the potential application of AI, particularly deep learning techniques, in managing the vast amount of medical data generated during the pandemic. The paper presents a detailed workflow, highlighting the importance of human expertise in AI-driven solutions. It describes the application of artificial neural technologies in COVID-19 diagnosis through medical imaging, including advanced technologies like convolutional neural networks. The paper also introduces extreme learning machines for predicting suitable drugs for COVID-19-related complications and highlights the significance of AI in computing the COVID-19 pandemic by handling extensive medical data and improving diagnostic accuracy.

Young Tang et al. [5] presents a research study discussing the integration of artificial intelligence into large-scale power grid simulation analysis. They address the need for advanced technologies to overcome the limitations of conventional power grid analysis methods, highlighting the challenges posed by the vast and complex data involved in power grid simulation. The paper emphasizes the potential benefits of AI-driven solutions, including cost reduction, expert knowledge retention, error reduction, and improved analysis accuracy. Various AI techniques, such as deep learning, reinforcement learning, and transfer learning, are explored in the context of power grid simulation analysis. By addressing issues related to knowledge, modeling, data, discovery, power flow, analysis, and stability control, AI technology can significantly enhance the efficiency and accuracy of power grid analysis, contributing to more reliable and secure power grid infrastructure.

Rafeef Fauzi et al. [6] discuss the evolving field of robotics in AI, emphasizing their significance in education and the development of socially assistive robots. These robots aim to provide continuous support by incorporating emotional, cognitive, and social cues. The integration of AI into robotics is highlighted, particularly through the use of deep learning algorithms to enable robots to perform complex tasks. Advancements in machine learning and AI have greatly impacted computer vision, enabling robots equipped with advanced computer vision capabilities to perform tasks such as face detection, body tracking, and gesture recognition. The paper also discusses the increasing use of robots in education, particularly as teaching assistant robots, assisting teachers with various classroom tasks and student performance evaluation through emotion recognition. The text offers an insightful exploration of the interplay between robots, AI, and vision-based assessment systems, highlighting their growing importance in education and other domains.

Ersin Elbasi et al. [7] introduce the concept of smart farming, which utilizes information and communication technology to enhance agricultural production. They highlight the critical role of the agriculture sector and the potential of AI to transform it, making agriculture smarter and more efficient. The integration of IoT and cloud computing enables monitoring of environmental conditions and crop growth, aiding in selecting the best conditions for different crops. A specific application of AI in agriculture, smart irrigation, is introduced, involving data collection and analysis using devices like Raspberry Pi and automated irrigation processes resulting in cost savings, reduced human efforts, and better soil monitoring. With rapid global population growth and increasing food demand, the integration of IoT, robotics, machine learning, and AI is essential to meet the growing demand for food sustainably and efficiently, making AI-driven smart farming indispensable.

Kah Yung Yap et. al. [8] review that, the use of solar power systems is a cost-effective and efficient source of renewable energy. Solar power is considered a promising renewable energy source due to its cleanliness, abundance and environmental friendliness. It outlines the challenges in solar power systems, particularly regarding variations in active power output due to changes in solar irradiance and temperature. The non-linear nature of photovoltaic cells can make power extraction unsatisfactory, especially under conditions like partial seeding MPPT is a technique that ensures the solar power system operates except at maximum power point. The limitations of MPPT techniques have led to the evolution of the MPPT algorithms, heuristic and meta-heuristic techniques. The text mentioned other matters to improve solar energy efficiency such as integrated soft computing, weather, forecast and adjusting the tilting angle of solar panels to track the sun's direction, which includes reviewing the application and utilization of AINMPPT of solar power systems, providing an overview of current research areas. The people's contributions include summarizing the state of the art and AI-based MPPT evaluating the performance of different algorithms.

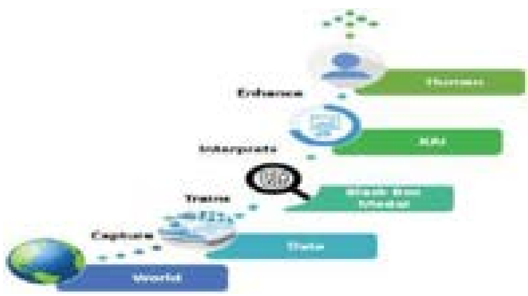

FIGURE 3: EXPLAINABLE ARTIFICIAL INTELLIGENCE [27]

Juan Bao et al. [9] acknowledge the fundamental role of artificial immune systems in multi-objective optimization algorithms and preference-based decision-making. They highlight the biological immune system as an adaptive information processing system with potential applications in artificial immune system theory and artificial intelligence. The paper addresses the computational complexity of multiple objectives optimization algorithms used to explore diverse solutions in the context of multi-objective decision-making problems. It compares these algorithms with genetic algorithms, aiming to find improved solutions. The application of the Biological Immune system involves dividing the population into viable, dominated, and infeasible categories, utilizing hypermutation and transformation techniques. Overall, the application of artificial immune system principles to multi-objective optimization problems emphasizes the role of preference-based design in selecting solutions to Pareto optimal solutions, introducing specific mechanisms to aid in the decision-making process.

Shixian Wen et al. [10] review and discuss a novel approach called the beneficial perturbation Network (BPN) for designing a general adaptive artificial intelligence system. This system addresses the challenges of continual learning and catastrophic forgetting in artificial neural networks. The paper highlights the superior adaptability of the human brain in learning and adapting to diverse environmental situations, tasks, and problems. It introduces methods to adjust multiple objective problems and optimization problems with nonlinear constraints using a biological immune system module. These methods involve dividing populations into viable, non-dominated, and infeasible categories, exploring non-dominated frontiers through cloning and hypermutation, and utilizing transformation techniques to accelerate convergence. The paper also introduces the Angle Best Priority selection mechanism, which simplifies the selection of preferred solutions while reducing the need for extensive reference information. In summary, the paper discusses the application of artificial immune system principles to multiple objective optimization problems, emphasizing the role of preference-based decision-making in selecting solutions from sets of optimal solutions and presenting a high-level overview of research in the field and the principles of artificial immune systems used in optimization and decision-making.

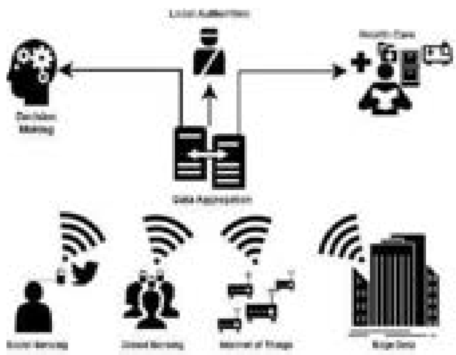

FIGURE 4: TECHNOLOGIES USED IN EMERGENCY SITUATIONS [26].

Xiaofei Wang et al. [11] review a novel approach called the Beneficial Perturbation Network (BPN) for designing general adaptive artificial intelligence systems to address challenges in continual learning and catastrophic forgetting in artificial neural networks. They highlight the superior adaptability of the human brain compared to deep neural networks, which typically learn fixed mappings between inputs and outputs. The primary focus is on the BPN, a biologically plausible method designed to handle dynamic learning situations effectively by computing beneficial perturbations to restore representations to the optimal state. The paper demonstrates that BPN achieves state-of-the-art performance across different datasets and domains, particularly in complex subject recognition tasks. The text introduces the concept of BPN, emphasizing its ability to efficiently adapt to dynamic situations and its scalability, making it a promising solution for continued learning problems. Additionally, it highlights limitations of existing methods and provides an overview of key sections and the concept of BPN.

Fares et al. [12] review Artificial Intelligence (AI) - based techniques for emerging heterogeneous networks, discussing opportunities and challenges in the context of mobile communication. They emphasize the rapid growth of mobile networks and the increasing complexity of mobile infrastructure, which consists of various types of cells with different coverage and working mechanisms. The paper urges researchers to explore solutions that bring intelligence to heterogeneous networks (HetNets) and introduces AI techniques such as machine learning, bio-inspired algorithms, and fuzzy neural networks. The text introduces the concept of applying AI technologies to address complexity and challenges in emerging heterogeneous networks, emphasizing AI's potential to enhance network efficiency and performance.

Khalid B. Letaief et al. [13] review the application of artificial intelligence in satellite communication, outlining the growing demand for satellite communication systems to provide coverage in areas not served by conventional terrestrial networks. They identify three primary use cases for satellite communication systems: service continuity, service ubiquity, and service scalability. The paper highlights the challenges of satellite communication, especially with low Earth orbit (LEO) satellites, and emphasizes the potential of AI techniques, including machine learning and deep learning, to address these challenges. The text provides an overview of the need for AI in satellite communication, identifies key challenges in the field, and introduces the goal of conducting a thorough survey of AI applications to address these challenges comprehensively.

Ebenezer Esenogho et al. [14] discuss the concept of "Edge Artificial Intelligence for 6G" and its various aspects, including vision, enabling technologies, and potential applications. They highlight the ongoing transition from 5G to the development of a 6G network, emphasizing the need to go beyond the capabilities of 5G and explore new usage scenarios for 6G. The paper outlines the potential applications of 6G, including ubiquitous artificial intelligence and the Internet of Everything (IoE), in areas such as sustainable cities, digital twins, and extended reality-health. Additionally, it emphasizes the role of disruptive technologies, particularly AI and edge AI, in designing and optimizing 6G wireless networks. The text provides an overview of the vision and use of 6G, highlighting the transformative potential of these technologies in enhancing reliability and performance while also addressing the challenges and opportunities present. [15-17].

III. DISCUSSION

In the context of the Internet of Vehicles (IoV), this entails leveraging AI algorithms for predictive maintenance, route optimization, and enhanced safety protocols. Similarly, in healthcare, AI of Things (AIoT) requires a comprehensive survey of advancements, challenges, and opportunities to develop smarter diagnostic tools, remote patient monitoring systems, and personalized treatment plans. Hybrid Human-AI Intelligence demands a structured approach, including tutorial development and collaborative frameworks, to enhance decision-making and problem-solving capabilities. The COVID-19 pandemic has highlighted the importance of AI-driven deep learning approaches for rapid diagnosis and treatment planning, necessitating robust frameworks and data-driven insights. The integration of AI in large-scale power grids involves digital simulations and analysis to optimize grid stability, energy efficiency, and renewable energy integration. Robotics utilization with AI in vision-based systems enhances automated assessment tasks in various sectors, from manufacturing to healthcare. AI technology in agriculture focuses on precision farming, crop monitoring, and sustainable practices through data analytics and automation. In the renewable energy sector, AI-based techniques are used to optimize solar power systems for increased efficiency and performance. Looking ahead, AI for 6G networks envisions intelligent network management, ultra-reliable communication, and innovative applications like augmented reality and autonomous vehicles. Addressing challenges in wireless sensor networks through AI techniques involves improving coverage, deployment, and localization for efficient data collection and analysis. Finally, AI's role in enhancing IoT security encompasses advanced threat detection, anomaly detection, and secure communication protocols to safeguard interconnected devices and networks.

IV. IMPLEMENTATION

Implementing optimization in the Internet of Vehicles (IoV) involves leveraging artificial intelligence (AI) algorithms for predictive maintenance, route optimization, and enhanced safety protocols. In healthcare, conducting a survey for advancements, challenges, and opportunities in AI of Things (AIoT) requires developing smarter diagnostic tools, remote patient monitoring systems, and personalized treatment plans. Additionally, creating tutorials and collaborative frameworks is essential for Hybrid Human-AI Intelligence to enhance decision-making and problem-solving capabilities. Addressing COVID-19 with deep learning approaches necessitates robust frameworks and data-driven insights for rapid diagnosis and treatment planning. Analyzing large-scale power grids through digital simulations and AI analysis optimizes grid stability, energy efficiency, and renewable energy integration. Utilizing robotics in vision-based systems enhances automated assessment tasks across industries.

In agriculture, AI technology focuses on precision farming, crop monitoring, and sustainable practices through data analytics and automation. Implementing AI-based techniques to optimize solar power systems increases efficiency and performance. Future AI applications in 6G networks envision intelligent network management, ultra-reliable communication, and innovative applications like augmented reality and autonomous vehicles. Addressing challenges in wireless sensor networks through AI techniques improves coverage, deployment, and localization for efficient data collection and analysis. Finally, enhancing IoT security involves implementing advanced threat detection, anomaly detection, and secure communication protocols to safeguard interconnected devices and networks.

V. CONCLUSION

In conclusion, this study offers a comprehensive analysis of the expansive applications and transformative potential of Artificial Intelligence (AI) across diverse domains, ranging from the Internet of Vehicles (IoV) and real-time data collection to medical diagnosis and disease detection. AI emerges as a formidable tool in augmenting efficiency and accuracy across these domains. The concept of human-AI collaboration introduces a paradigm shift, fostering hybrid intelligence systems that blend human cognition with AI capabilities for enhanced performance. Furthermore, this study highlights the AI's pivotal role in addressing the challenges posed by the COVID-19 pandemic, spanning diagnosis, treatment, and management of medical data. From large-scale power grid simulation to robotics in education, AI's influence continues to expand comprehensively, promising advancements in various sectors. This study also highlights the application of AI in multi-objective optimization and decision-making, as well as the introduction of beneficial perturbation networks for continued learning challenges in neural networks. Additionally, it surveys the integration of AI in emerging heterogeneous network satellite communication and highlights the role of AI and edge AI in shaping the future of the 6G network. The exploration of AI, IoT, and 5G in the next generation Smart Grids underscores their potential while addressing challenges in reliability and performance. Finally, the study concludes by discussing the challenges in wireless sensors and networks and emphasizes the increasing importance of AI techniques in addressing the network coverage, deployment, and localization issues. In essence, this research highlights the pivotal role of AI in shaping the future of various domains, paving way for finding innovative solutions to complex problems.

VI. FUTURE SCOPE

In the future, Artificial Intelligence (AI) will have a significant impact across various domains, including the Internet of Vehicles, healthcare, human-AI collaboration, pandemic response, power grid management, robotics, agriculture, solar power systems, telecommunications, wireless sensor networks, and IoT security. In the Internet of Vehicles, AI will focus on optimizing services, such as predictive maintenance and enhanced safety protocols. Healthcare will witness AI-driven personalized treatment plans and real-time monitoring. The collaboration between humans and AI systems will improve decision-making and problem-solving capabilities. AI's role in pandemic response will involve advanced deep learning approaches for diagnosis and treatment. In power grids, AI will enhance efficiency and resilience against disruptions. Robotics will benefit from AI-driven vision-based systems, improving productivity and safety. Agriculture will see optimized farming practices and increased crop yields through AI. Solar power systems will benefit from AI-based techniques for improved energy efficiency. The transition to 6G networks will be facilitated by AI-driven intelligent network management and innovative applications. AI will address challenges in wireless sensor networks, ensuring efficient data collection and analysis. Lastly, AI will enhance IoT security through advanced threat detection and secure communication protocols. This collective advancement promises to revolutionize industries and drive progress towards a smarter, more connected future.

***Abstract* — A “helmet” is a protective cover worn while riding a two-wheeler, which is a safety measure for the rider and for the pillion. However, due to the negligence of people, helmets are not worn by most riders. According to the latest report of the National Crime Records Bureau (NCRB), as many as 1,55,622 people lost their lives due to road accidents in 2021, out of which around 70,000 people lost their lives in two-wheeler accidents.**

Proposed study is the perfect solution for this problem. We have made a smart machine learning-based system integrated in a two-wheeler that makes wearing a helmet mandatory as it monitors every second of the ride. The moment the rider removes the helmet, the vehicle is supposed to turn off and make the rider wear a helmet. There are some existing studies that cover different parts of helmet detection techniques but almost each of the studies are usable and limited to that helmet however this study focuses on how the system can be integrated into the two-wheeler itself to generalize the detection of helmets. The perfect implementation of this study is used to reduce accident rate.

Keywords— Artificial-intelligence; Automobile; Helmet; Image-processing;

I. Introduction

A survey revealed that in countries like Thailand, Vietnam, Malaysia and India more than 50% of the households own a two-wheeler, i.e. a motorcycle or a scooter. A two-wheeler on a road is more exposed to a potential accident than other vehicles. In India as of 2022, two-wheeler fatalities make up 44% of total road accidents. Two-wheeler riders by law are required to wear a helmet while riding, however most of the riders neglect this law and that might result in amplified damage through an accident.

To avoid this, governments have implemented fines and even human-monitored systems to charge some breaking the law, however, this being manual there are chances of error.

Surveillance cameras on roads have been evolving every day in India. The cameras use an object detection system that identifies every vehicle on road and its registration number to cite fines and also control traffic. To safely and smoothly execute this system of controlling the traffic flow, real-time monitoring and machine learning based on pre-existing data is required. By implementing object detection and automation in traffic regulation, the efficiency and flow of traffic is seen to be more controlled and coordinated than earlier when manual techniques were used to do the same. The proposed work aims for better accuracy and efficient processing. There is also some part of manual execution in such a technology which again opens us to errors.

To minimize the error a smart and highly accurate object-detection program is used, which detects a helmet through a live feed. The device will monitor the live feed each second frame by frame and analyze whether a helmet is worn by the rider or not. The program is set in such a way that at any point the rider is not wearing a helmet the two-wheeler turns off the ignition. This being a more accurate method and a more efficient method to eliminate road accident fatalities can be a great feature to implement in bikes and scooters.

II. Literature Review

[1] **S. Cui et al.,** "An Effective Motorcycle Helmet Object Detection Framework for Intelligent Traffic Safety,", in this study a standard computer vision model “Detectron2” which is a Facebook AI research library that provides advanced object detection and segmentation algorithms. They carried out multiple test runs on different data sets and have built a study using these tests on just the detection and methods that can improve detection.

[2] **S. Anjum et al,** "Artificial Intelligence-based Safety Helmet Recognition on Embedded Devices to Enhance Safety Monitoring Process," this study focuses on safety helmets at construction sites, not completely related to our methodology but uses a similar detection idea. They have used tensorflowlite libraries to make the detections effective and lighter on the devices. They have built an IOT system where if a construction worker is not wearing an appropriate helmet, the supervisor will receive a notification.

[3] **M. Uniyal et al,** "IOT based Smart Helmet System with Data Log System," this study uses a raspberry pi 3 board connected GPS module and RF receivers that work on IOT system which conveys a message when a helmet is not worn on the head. This paper was important to us because the idea of turning the ignition on and off comes through this study.

[4] **K. C. D. Raj et al,** "Helmet violation processing using deep learning", they used a CNN to classify a rider into “helmet” and “no helmet” with an additional license plate recognition system using a HOG descriptor with an accuracy of 90%.

[5] **B. R. Chandra et al,** "Internet of Things (IoT) based Digital Helmet Design and Deployment", they used a CNN to classify a rider into “helmet” and “no helmet” with an additional license plate recognition system using a HOG descriptor with an accuracy of 90%.

[6] **Nandu R et al,** "Smart Helmet for Two-Wheelers", this study is a “Smart Helmet” that when not worn denies ignition and when worn allows ignition. They have used a proximity sensor and a LED and placed them on the opposite sides inside a Helmet, that is when the glowing LED sheds light on the proximity sensor the circuit is completed sending signals to the further circuit that the helmet is not worn as nothing is blocking the light.

[7] **Keesari et al,** "Smart helmet for safe driving”, this study is not only a helmet identification model but works as an accident detection and an alcohol detection system as well. They’ve used multiple sensors to achieve the results, for the helmet a RF sensor is utilized.

III. Methodology

In this study, a custom dataset was constructed by incorporating annotations, “helmet” and “no_helmet” through the LabelImg tool.

In the early stages of the model, the study utilized a dataset available on Kaggle, a free for all dataset, which contained of images of all kinds of helmets, pre-annotated. The dataset had construction site helmets, helmets used by cyclists and other kinds of helmets which cluttered the model and the results weren’t as expected. While finding more datasets we landed on a custom dataset that consisted of around 60-80 images of the authors with helmet and also some images extracted from another free for all dataset of images with faces of people to make the model learn the difference between “helmet” and “no_helmet”.

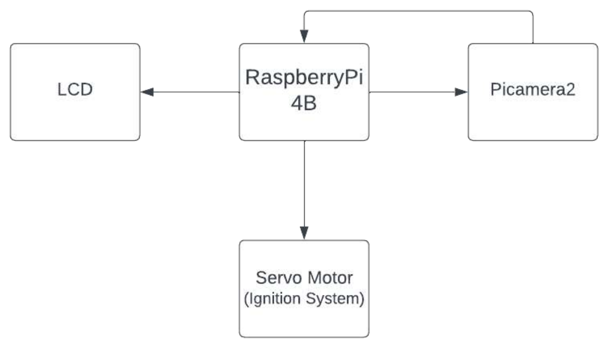

Fig. 1. Block Diagram

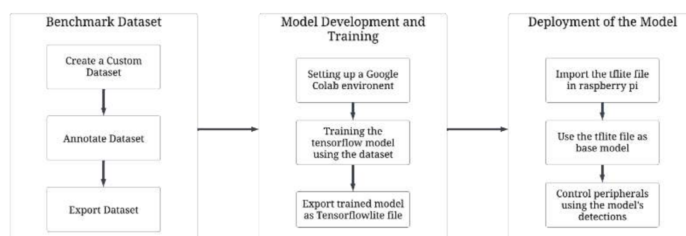

Fig. 2. Process Flow of the proposed method

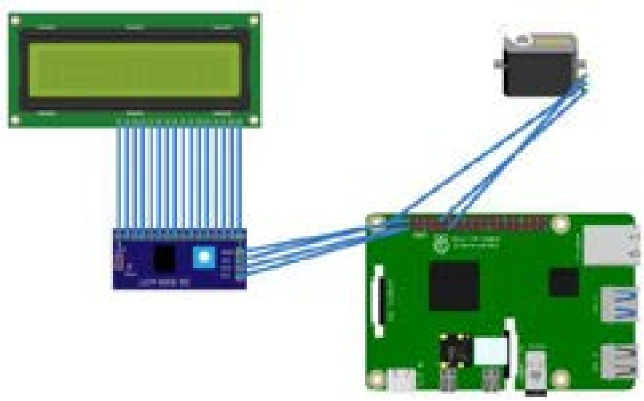

Fig. 3. Circuit

The circuit as shown in Fig. 3 includes a Raspberry Pi Model 4B, a 16x2 LCD, servo-motor as a prototype for the ignition of the two wheeler and a Picamera 2 as a camera module. However this being a prototype of the main idea, better components with more accuracy and better results can be used such as 'ESP32', which is a wireless camera module more apt to the study as we need a camera module that can be easily placed at a position on the dashboard of the two-wheeler from where the rider is clearly visible at every second of the ride.

To make use of a successful model we need a strong machine learning technology and TensorFlow was the best option because it utilizes CNN (Convolutional Neural Network) technologies to develop a model that can be used in Google Colab to deploy in a working environment. As shown in fig. 2, the annotated dataset was utilized within the Google Colab environment to develop a tflite (TensorflowLite) model as raspberry pi is more efficient with Tflite files than Tensorflow files. The resulting tflite file contains the essential data required for accurate helmet detection. The tflite file being associated with custom images is more accurate and appropriate with the detections.

Following model creation, we exported the tflite file and integrated it into Raspberry-Pi 4B. Wherein we utilized OpenCV-python library for developing a system where we used an if-else statement to operate the ignition system which here is a servo motor and also a display. This methodology ensures a comprehensive and effective approach to enhancing safety through intelligent helmet detection systems.

IV. RESULTS AND DISCUSSIONS

The prototype of the main study gives us a brief idea of how this Helmet Detection System can be implemented in an actual two-wheeler, as it benefits the rider and also other traffic on the road. The proposed system reaches85-90% accurate rate whether the rider is wearing a helmet or not. The whole system works in a way that if the rider is wearing a helmet the ignition i.e. the servo motor will operate and an LCD will display "Ride Safely" and if the rider is not wearing a helmet the motor will not work with the LCD saying "Please Wear A Helmet". This can be situated in the dashboard i.e. around the speedometer of a two-wheeler.

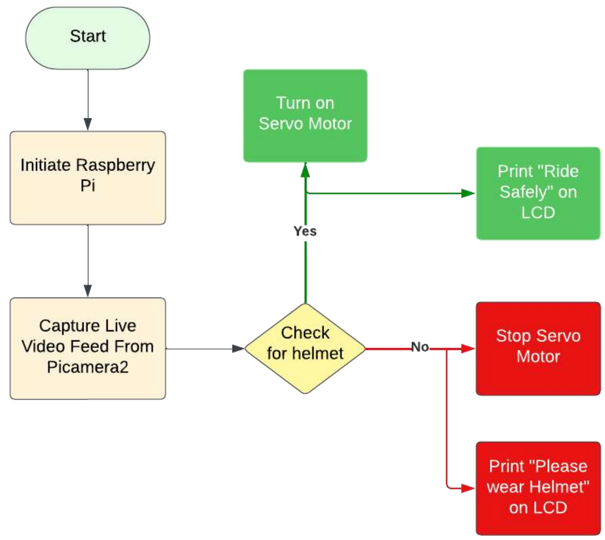

Fig. 4. Flowchart

Fig. 5. Printing in the Terminal of the IDE on Raspberry Pi OS "No helmet detected. Turning off motor."

Fig. 6. Printing in the Terminal of the IDE on Raspberry Pi OS "Helmet detected. Turning on motor."

Fig. 5 and Fig. 6 shows a model that detects whether a helmet is worn or not, and annotates the same with the accuracy from 0 to 1 along with the label “Helmet” and “No Helmet”.

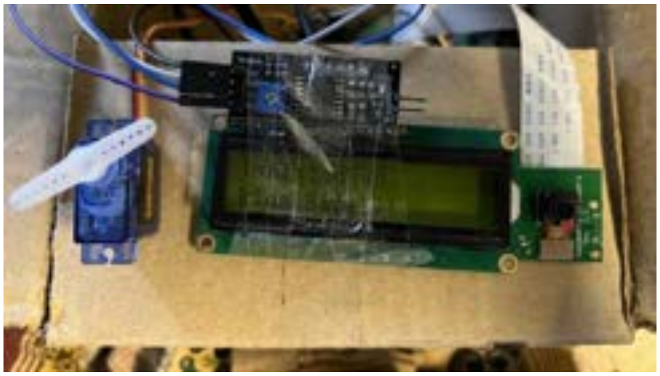

Fig. 7. LCD when helmet is worn

Fig. 8. LCD when helmet is not worn

In Fig. 6 and Fig. 7, the final result is visible on the LCD, that is, if the rider is wearing a helmet the system successfully detects the helmet and while turning the servo motor on it prints “Ignition On” on line 1 and “Ride Safely!” on line 2 while when the rider is not wearing a helmet the LCD prints “Please Wear” on line 1 and “A Helmet” on line 2.

From testing the model in low-light conditions and in camera angles that would simulate the camera being placed in the dashboard of a two-wheeler, it was found that there is scope for improvement in low-light conditions as the dataset used for training the model mostly contained images taken in good lighting. The results can be improved to higher levels if a camera of better clarity can be used in place of the existing camera.

The following table shows the accuracy measurements obtained by testing the model in various lighting conditions and camera angles.

TABLE I

Accuracy Measurements

Accuracy Measures	**Values**
Precision	93%
Average Accuracy Score (from 0 to 1)	0.93

[a] These values are calculated by testing of the model in various conditions.

V. Conclusion

The study ensures the critical assessment of the methodology proposed all along and contains the following points:

1) Road safety and awareness about helmet compulsion while commutating via a two-wheeler.
2) Utilizing a non-biased system of recognition of helmet violations.
3) Successful implementation of a small size prototype of the proposed methodology, using similar electronic components to an actual vehicle.
4) Rigorous testing and improvement of the results of helmet-detection python module.
5) Using the methodology in an actual vehicle may it be an electrical or a fuel based two-wheeler.

VI. Future Scope

In further studies in the same enhancing the smart helmet in the future by adding innovative safety features like alarms, enhancing its helmet detection capabilities, and adapting it to a variety of helmet types seems like an easier job using better technologies. The research work may utilize cloud computing, interface it with additional safety sensors, and link it to the internet for remote control. Collaborate with two-wheeler manufacturers, obtain certifications, and solicit user input. By taking these steps, the research work intend to increase the usefulness and appeal of proposed smart helmet to global audience.

VII. Acknowledgment

We would like to express our deepest appreciation to Vishwakarma Institute of Technology for their intangible support to development of the study. We are also extremely grateful to Prof. (Dr.) C. M. Mahajan for his guidance, advice and patience towards us.

We would also like to thank each and every member connected to the study in and out of our group. Every person’s contribution mattered in implementing and documenting the journey.

Abstract: **Improvements in present technology have significantly simplified human life, thus resulting in a widespread shift from traditional lock methods to smart door systems. Our project utilizes the capabilities of both Pi camera and Raspberry Pi to enhance both convenience and security. This innovative solution provides the feature of recognizing the individuals approaching the entrance. If the visitor's identity is known, then the door automatically opens. In cases if the visitor's identity is unknown, immediate email notifications containing captured images by pi camera are dispatched to the owner for verification. Utilizing remote access control features, homeowners can manage entry permissions from any location. The integration of a digital lock improves the security at the entrance. With introduction of a buzzer, the owner gets alerted when both familiar and unfamiliar persons arrived. This research work provides an integrated and intelligent approach to door access management, resulting in improved levels of home protection.**

Index Terms—Face recognition, Raspberry Pi 3b, digital lock, double Rely, Picamera.

I. INTRODUCTION

In daily lives, standard door locks have been a common thing for locking our doors or using for protection of valuable items. Even in some important working places standard locks are used in locking the doors. But the time has come to understand the distinctions between smart and traditional locks. Despite having a long history these conventional locks spanning 4,000 years, many problems such as jammed mechanisms and misplaced keys have plagued them, leading many persons to think these locks as less secure. Traditional locks are no longer giving protection for our items. Smart locks, integrated into smart home systems, offer automation and remote control capabilities, which makes smart locks a step ahead of traditional locks. With the addition of convenience of remote control and integration with smart home setups, these smart locks improve home security efficiently. This perception shift has led an increasing preference for smart locks over traditional locks. While these advanced locks have been around for only a decade, they too have some technological limitations such as fingerprint access issues and forgetting the code/numbers/pin which are unavoidable. To address these concerns, in present technology face detection systems are used as a secure door lock mechanism. Only authorized persons, generally like the family head or this family members, can grant access to unapproved persons or visiting relatives. This technological evolution shows a significant step forward in home security, offering both convenience and enhanced protection.

II. LITERATURE SURVEY

The reaserch study "facial identification and remote door locking system " involves a comprehensive review of existing technology and their related research and literature related to various technologies like smart door systems, Raspberry Pi integration, and home security technologies. Previous technological studies have explored different aspects of smart door locks, which includes their design, structure, implementation, working and effectiveness in improving home security. In addition to this, research on various Raspberry Pi applications in home automation areas and also in surveillance area provides valuable insights into the technical features and certain limitations of using this technology for door locking purposes. Further, studies on remote access control system and procedure for notification contribute to understanding the best practices for implementing features such as remote access system and email notifications in smart door locking systems. By combining these findings from various sources, the literature study aims to identify important trends, unavoidable challenges, and immense opportunities in development of the proposed smart door locking system. Through these findings and researches of existing literature, the project aims to build upon prior research and contribute to the improved smart home security solutions using the present Raspberry Pi technology.

III. PROPOSED SYSTEM

In theexisting model, there is no option of remote access. But in this model, there is option of remote access where homeowner has option to control the door even when he is far from home. Also both face recognition and remote access has been in this model which is a missing in existing model like password based door locking system, finger print authentication system etc. In present existing models like finger print door locking system, we need a human contact which is a danger sign in pandemics like covid.

The proposed system for the project involves utilizing a Raspberry Pi along with various components such as a Pi Cam, double relay, digital lock, and buzzer. The Pi Cam is employed to capture images of unknown or known individuals. When a known person arrives, the Pi Cam recognizes them by matching their captured face with faces in a predefined dataset. Subsequently, the Raspberry Pi triggers the digital lock to open and activates the buzzer. Conversely, if an unknown person is detected, the Pi Cam sends the captured image to the owner's email. The owner can then decide whether the unknown individual should be allowed entry into the premises. If approved, the owner can remotely open the door by clicking 'on' via email. If not approved, the door remains closed. This system facilitates remote access through email protocols such as SMTP and IMAP, providing the owner with control over access to their property.

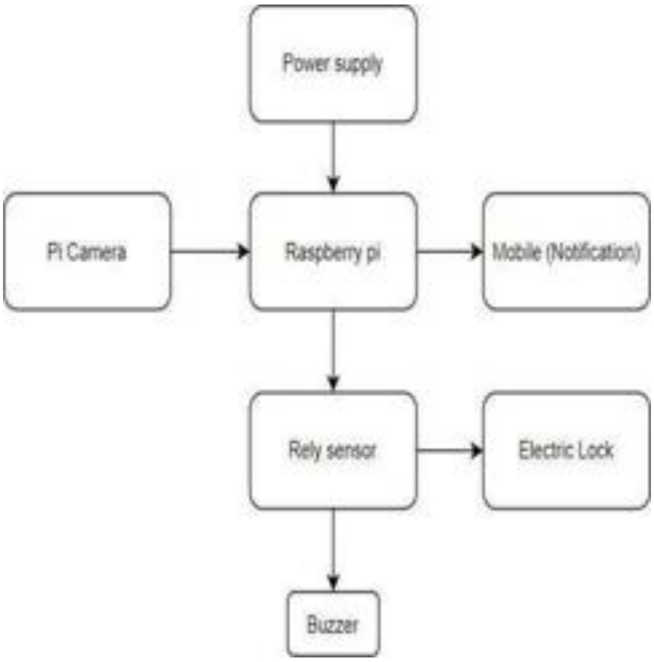

Fig. 1. Block Diagram of Proposed System

IV. MODEL IMPLEMENTATION

A. Hardware Implementation

1) Raspberry pi 3b : The Raspberry Pi 3b serves as the central Computing unit for our project. It runs the face recognition algorithm and controls the door lock mechanism based on the results stored during the training of the model. Raspberry Pi boards come with General Purpose Input Output (GPIO) pins, which allow you to easily interface with external hardware components such as sensors, actuators, and cameras. This makes it convenient to connect peripherals required for face recognition and door access system, such as a camera module for capturing facial images and controlling the door lock mechanism. It contains 40 pins which are like VCC, ground etc.

2) Pi Camera: A camera module compatible with the Raspberry Pi is essential for capturing images of faces. This could be a dedicated Raspberry Pi camera module.

3) Face Recognition Software: Software for face recognition needs to be installed on the Raspberry Pi. Popular choices include OpenCV,face_recognition with Python bindings, which provide a range of functions for face detection and recognition.

4) Door Lock Mechanism: we have used a magnetic lock in our project. So to control the lock we have used a double relay module, one relay module is used to open the lock and the second relay module is used to close the lock. The hole control of lock is in the gpio pin based on the output the pin changes according to the code running in raspberry pi.

B. Software Implementation

To implement a face recognition project with a Raspberry Pi controlling a magnetic door lock, start by setting up the Raspberry pi with installing OS and libraries needed for face recognition.

1. Face Recognition library for face recognition
2. imutils, pickle, cv2 libraries for data storing and image processing
3. Email library for sending images and remote access
4. Datetime, time libraries
5. Raspberry Pi GPIO libraries: RPi.GPIO

Initially, capture the images of those people who we want to give the access to home, so that whenever they come the door lock open automatically. After capturing the images, we need to store them according to their names in a dataset folder. After, this process we need to train the model. For this purpose, we have used a face recognition library. It is a pre-trained deep learning model (typically a Convolution Neural Network or CNN) to extract features from facial images. These features represent the unique characteristics of each face in the dataset. The face_recognition library uses a pre-trained model based on the dlib library to perform this task.
After extracting features, the library computes a numerical encoding (vector) for each face in the dataset. This encoding is essentially a compact representation of the facial features extracted by the deep learning model. These encodings are then stored for later comparison during recognition.
When a new face is presented for recognition, the system follows a similar process to extract features from the input image.
The library then calculates the encoding of this new face.

It compares the encoding of the new face with the encodings of faces stored in the dataset. This is usually done by measuring the similarity between the encodings, often using techniques like Euclidean distance or cosine similarity.
If the distance or similarity between the new face's encoding and any of the stored encodings is below a certain threshold (which you can define), the system recognizes the person associated with that encoding.
Based on the similarity scores obtained from comparing the encodings, the system decides whether the input face matches any of the faces in the dataset.

C. Protocols

IMAP (Internet Message Access Protocol) is a key component for email communication. It has transformed the way how users interact with and handle their electronics message. IMAP has been introduced as a substitute for more conventional Post Office Protocol version 3 (POP3). It completely changes the way messages are retrieved and synchronized between a user's email client and the mail server. With IMAP, user may read and handle their emails directly on the mail server which is different scenario when compared to POP3. The role of this IMAP is to allow homeowner to access their email inbox, view received messages and take action on them like unlocking the door through remote access directly from homeowner's email account

SMTP (Simple Mail Transfer Protocol) is the most important part of email delivery. It provides foundational path for error free communication and can be termed as text based protocol. In this model the SMTP is used to send images from sender devices to owner's personal mail. SMTP is also responsible for delivering emails containing images of unknown persons captured by the door lock system to homeowner's email inbox.

V. Working Of The Proposed System

In this implementation of project firstly the model need to train the model to make the person known so that the door opens automatically. To make this happen, the model need to take the images of the known person into the dataset and save them with a particular name and then train the model with his images. The model is trained using "face_recognition package" which contain different modules. firstly, In the given image (frame) it detect weather it contain a face or not by face location function if it contain face it return the face locations in the give image else it don't return any locations and then by using the face locations the face of that particular person is encoded with face_encodings function and the data is stored in serialized manner using pickles by using this data we can say that the person is known or unknown to us. The part of capturing of images and training the module is continuous process when the home owner wants to add new person as known they need to add them manually every time.

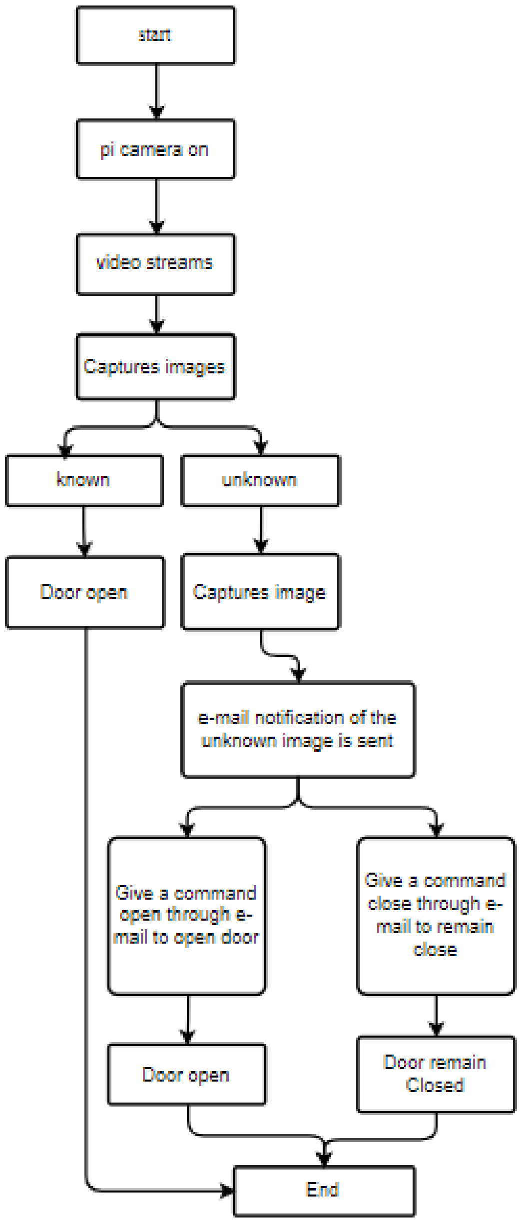

Fig. 2. Flow-Chart of working of the system

In this section the model will run continuously the camera will be on every time when the frame contains face of a person then it finds the locations of the face and encode the face and then compare with the list of encoded values, which are stored previously during training. if match is found a particular port pin of GPIO will be high to make the door lock open else it will send an email to the home owner with the image of the unknown person. Then home owner can take a decision according to the need. Based on the response from home owner the door lock will open/close. We have set a certain time that lock will open for that particular time after that the lock will be closed automatically.

When both known and unknown in the single frame the face which is in the process first according to his face the function of door will happen. If a known person face is first detected in the process the door lock opens else if unknown person face is first detected then email notification is send to home owner the model runs according to his responses. Simultaneously a buzzer will be ring when door lock opens that indicates the people inside the house will know that some entered into the house at that time.so, they can pay their attention towards him/her.

VI. Results & Discussion

The above is the working model of our project. It contains components like raspberry pi, Pi Cam, buzzer, digital lock, double relay. The picture of working model is shown in figure 3 below.

Fig. 3. Working model of the device

Utilizing facial recognition the system identifies known individuals approaching the door. Upon recognition, the door lock mechanism is triggered to unlock automatically, granting access to the known person. This feature enhances convenience for residents and trusted individuals, eliminating the need for physical keys or manual unlocking. The picture of the process above is shown in Figure 4 below.

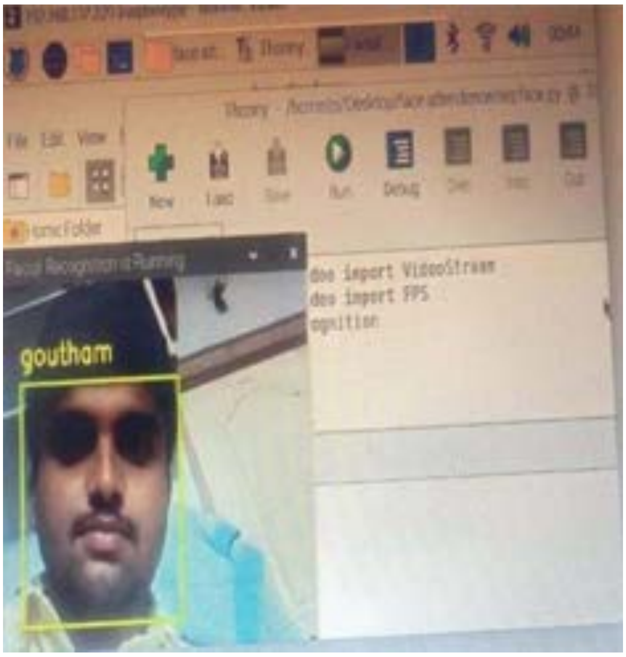

Fig. 4. When known person arrives

As discussed above, whenever a person is arrived, the pi cam detects the name and compare with the images stored in dataset folder. If it is a Unknown face, then it displays as unknown as shown in figure along with the square box. The picture of process is shown in figure 5 below.

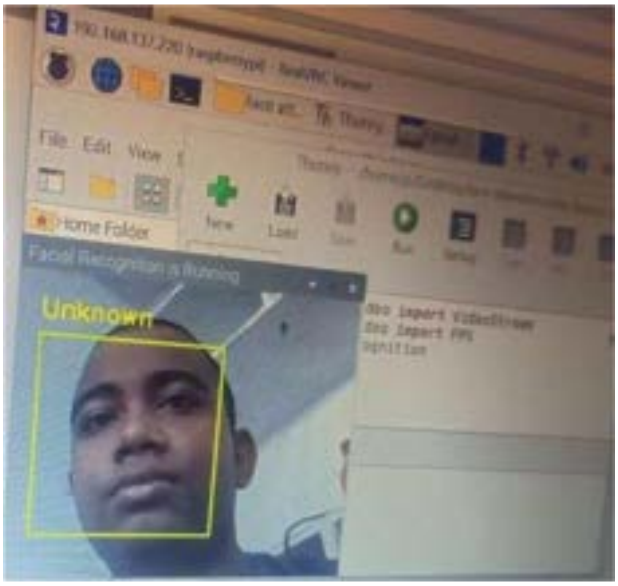

Fig. 5. When Unknown person arrives

In the event of an unrecognized individual approaching the door, the system triggers an alert mechanism. A notification is sent via email to the homeowner, informing them of the presence of an unknown person at the door. This serves as a security measure, allowing the homeowner to be aware of potential unauthorized access attempts. The picture of the process is shown in Figure 6 below.

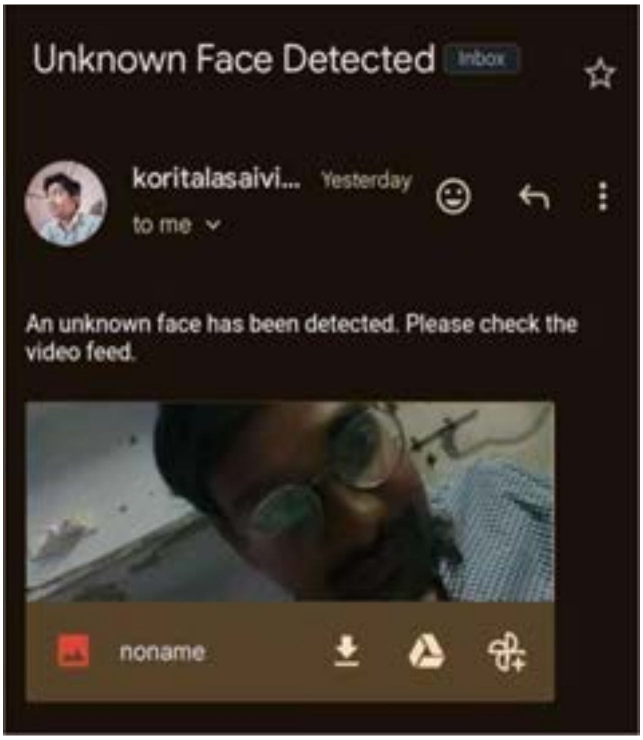

Fig. 6. Mail Notification when Unknown person arrives

The homeowner has the capability to remotely manage access permissions for unknown individuals. Through a user-friendly interface, accessible via smartphone or computer, the homeowner can grant or deny access to the door through email. By sending a command, such as "On" or "Off," the homeowner can control the door lock remotely, providing flexibility and control over access to the property. The picture of process is shown in figure 7 and 8 below.

Fig. 7. Remote Access operation of door opening

Fig. 8. Remote Access operation of door closing

VII. CONCLUSION

In summary, proposed model has effectively combined various technologies to improve home security and offer secure access management. This system uses a Raspberry Pi with a Pi camera module to accurately identify people who are about to approach the door. The facial recognition system is designed to differentiate between individuals who are known to us and those who are not. Identified faces can be allowed into the site with ease, while for the case of unfamiliar faces, the owner will immediately receive an email message along with that person's image. Homeowners can ensure an additional feature of protection and control by granting or refusing access remotely with the help of Email application. The inclusion of a digital lock strengthens the system's security features. A buzzer installed allows homeowners to be instantly alerted to identify the visitors. Through the use of various technologies, this project successfully combines innovation, convenience, and security for benefit of homeowners.

VIII. FUTURE SCOPE

The performance of the model can be improved by training the dataset model with high-quality images with good lighting, varied facial expressions and different poses. It can also be improved by considering more advanced deep learning architectures for face recognition, such as convolutional neural networks (CNNs). Pre-trained models like VGG, ResNet, or EfficientNet, which might offer better performance than simpler models. Higher Versions of raspberry pi can also be included so increase the accuracy. Also other high quality camera can be used like USB camera instead of Pi camera for improving accuracy.

There are numerous applications for Facial identification and remote door locking system in the future. Proposed system can develop into a multi-layered device for home automation purpose and enhanced security, going beyond simple features like facial recognition and remote control. For safer identification, consider incorporating biometrics like fingerprint readers. Authorized persons may be able to unlock doors hands-free with voice recognition feature, and environmental sensors have the efficiency to adjust temperature and lighting automatically upon detecting someone entry. The system could be trained to identify suspicious activities like loitering or tampering, which use as real-time alerts and sirens as deterrent measures. For home delivery services, sending one-time codes via SMS to grant temporary access is one of the best practices. Smart home platforms could allow doors to be connected to other device automatically illuminating light or granting access through side doors to obtain authorization. Proposed system can also be developed to warns the possible danger like gas and smoke leaks in front of it. With the proposed work, convenience and security are combined to create a genuinely intelligent and secure home. With this system, own area is safeguarded and hence will improve our lives inside our own four walls.

Abstract— **Aim: This endeavor focuses on using deep learning and Density-Based Spatial Clustering of Applications with Noise (DBSCAN) to improve pollution prediction in order to alter air quality prediction. Materials and Methods: Three different groups are working together on this endeavor. Group 1 refers to Multi-Layer Perceptron (MLP) to attain accuracy. Group 2 refers to Density-Based Spatial Clustering of Applications with Noise (DBSCAN) to achieve the same goal. Results: Each system module's unique outputs, such as raw and pre-processed air quality data, chosen features, trained Support Vector Machine or Logistic Regression models, and forecasts with an accuracy rate of 81% are described in depth in the output design. Conclusion: Using the DBSCAN algorithm, the proposed air pollution monitoring system provides an effective data-driven method for locating pollution hotspots, trends, and well-informed decision-making.**

Keywords---DBSCAN, Pollution Monitoring, Air Quality, Air Pollution, Quality Prediction, Research, Effective, Machine, clustering.

I. INTRODUCTION

This research explores the integration of Revolutionizing Air Quality Prognostication. It emphasizes a fusion of advanced techniques, specifically integrating deep learning and DBSCAN for enhanced pollution prediction. The integration of deep learning signifies the use of neural networks for intricate pattern recognition, while DBSCAN contributes spatial clustering to refine predictions. The goal is to revolutionize existing methods, leading to more accurate and insightful air quality forecasts.

The research suggests WLSTME, a model that combines meteorological and nearby site data for improved PM2.5 prediction accuracy. The superiority of WLSTME in predicting is highlighted by the evaluation on Beijing-Tianjin-Hebei data, underscoring its potential to enhance air quality predictions [1]. A novel deep learning framework called TS-LSTME outperforms conventional techniques in the Jing-Jin-Ji region for 24-hour air quality predictions. Its capacity to adjust to additional pollutants and provide consistent, accurate PM2.5 estimates improves public information services and supports local efforts to regulate pollution [2]. In order to improve the accuracy of urban planning and early warning for acid rain, the research provides a novel model for increased prediction of NO2 and SO2 [3]. The research introduces a new deep LSTM-RNN structure solar irradiance forecasting model for microgrids that uses only common weather data. With a maximum RMSE of 60.31 W/m2, it outperforms FFNN in a variety of climes, shows excellent accuracy, and predicts a 2% increase in annual energy savings, underscoring its potential to improve microgrid efficiency [4].

DBSCAN is a clustering algorithm used in data mining and machine learning. Based on the density of data points in a certain area, it locates clusters. DBSCAN categorizes points as core, border, or noise, offering flexibility in handling various cluster shapes. It is particularly effective in identifying clusters with irregular shapes and is robust to outliers, making it valuable for spatial data analysis.

II. RELATED WORKS

In order to predict air quality indicators by integrating multiple environmental data sources, the study presents a comprehensive deep learning model, LSTM-based with Multi-output and Multi-index Supervised Learning (MMSL). When validated against Beijing's air quality data, the model performs better than baseline and advanced models [5][6]. To mitigate the consequences of air pollution on urban public health and sustainability, the study suggests a hybrid AQI forecasting model that combines VMD, SE, and LSTM approaches. This model shows superior accuracy in daily urban AQI forecasting when compared to existing models, with high correct AQI class forecasting rates [7]. Effective forecasting for improving air quality in urban areas, especially Seoul, South Korea, is demonstrated by the study's development of LSTM and DAE models to predict fine particulate matter concentrations [8][9]. The study presents a semi-supervised model that combines empirical mode decomposition (EMD) and Bi-directional Long Short-Term Memory (BiLSTM) neural networks for effective PM2.5 concentration prediction, showcasing improved accuracy and feasibility compared to standard LSTM-based models. This new multiscale prediction approach shows promising results [10]. Using a large dataset from 1,615 observation sites in China from 2015 to 2019, An especially effective strategy for AQI prediction is Bi-directional Long Short-Term Memory (BiLSTM), according to the study, which evaluates forecasting techniques for the hourly Air Quality Index (AQI) [11]. Through experiments conducted in various climate regions, the study presents an hourly day-ahead solar irradiance forecasting model that uses only weather data and a deep LSTM-RNN. This model outperforms a feedforward neural network (FFNN) and achieves improved accuracy in microgrid optimization [12][13]. The work presents two hybrid evolutionary algorithms that incorporate Particle Swarm Optimization (PSO) and Genetic Algorithm (GA) techniques to improve global optimum identification over standard PSO algorithms through parallel and series integration, as shown by simulations on benchmark test functions [14]. The purpose of predicting ground vibration from rock blasting, the research study presents hybrid intelligent models that combine ANFIS with PSO and GAs. Through statistical and sensitivity analysis, these models demonstrate enhanced accuracy over typical ANFIS models [15]. Using deep learning techniques like LSTM and optimization with PSO, the project aims to develop a smart air quality prediction model (SAP PM) that forecasts concentrations of six air pollutants for the following two days. For this, data collection, preprocessing, model construction, and evaluation are required [16]. The present study introduces TS-LSTME, a deep learning framework that predicts air quality for the next 24 hours with excellent accuracy and stability in PM2.5 concentration forecasts, supporting early warning and management of regional pollutants and improving air quality prediction services. Other air contaminants can also be addressed using the framework [17].

The study of the literature highlights a variety of techniques for predicting air quality, including BiLSTM, hybrid models, and LSTM. Along with intelligent prediction models, it investigates forecasting for sun irradiance, ground vibration, and AQI. All in all, these developments support local pollutant management and early warning systems.

III. MATERIALS AND METHODS

This study gives an uneven distribution of air pollution monitoring sites and proposes the Weighted Long Short-Term Memory Neural Network Extended model (WLSTME) to increase PM2.5 prediction accuracy. WLSTME integrates Long Short-Term Memory (LSTM) for handling spatiotemporal dependencies simultaneously with multilayer perceptron (MLP) weighting of historical PM2.5 time series data based on site density and wind conditions. This technique demonstrates improved accuracy performance across the year and area [1].

There are two groups in this novel research of Revolutionizing Air Quality Prognostication. Group 1 refers to an effective method for predicting pollution levels by presenting a novel approach for air pollution forecasting that makes use of the Multilayer Perceptron algorithm. It indicates hyperparameter tuning and displays greater accuracy when compared to classic machine learning algorithms. However, it is vulnerable to overfitting, especially with complex datasets.

Group 2 refers to an air pollution monitoring system that analyses pollutant concentrations, meteorological conditions, geographic location, and timestamp data from monitoring stations using the DBSCAN algorithm. Through the effective clustering of data points according to density, DBSCAN identifies patterns of air pollution, highlighting locations that exhibit certain features and hotspots for pollution represented in Fig.1. Robustness against noise, precise clustering of data points, flexibility in addressing various pollution scenarios without pre-established labels, and scalability to manage big datasets are among the benefits of DBSCAN.

IV. DENSITY-BASED SPATIAL CLUSTERING OF APPLICATIONS WITH NOISE:

Density-Based Spatial Clustering of Applications with Noise (DBSCAN) is a clustering algorithm developed for datasets with irregular forms and changing densities. It classifies data points as core, border, or noise based on closeness, using parameters such as radius (eps) and minimum points (MinPts). Core points have enough neighbors within a certain radius, whereas border points are inside this radius but lack adequate neighbors. Noise points, also known as outliers, do not fit into any cluster. DBSCAN's adaptability to varied cluster shapes, noise handling, and low assumptions make it popular in spatial data analysis, image processing, and anomaly identification.

In a nutshell the data points are divided into several batches or groups using an unsupervised learning technique called clustering analysis, or simply clustering, so that the data points within the same groups have similar properties and the data points within different groups have different properties. It includes a wide range of differential evolution-based techniques. The proposed air pollution monitoring system makes use of machine learning, notably DBSCAN, to analyses large amounts of data on pollutant concentrations, weather, and coordinates. DBSCAN detects dense clusters following comprehensive preprocessing, providing insights into pollution patterns and hotspots. The project improves data structuring with convex hulls, organizes air quality data effectively, and identifies outliers in huge datasets using DBSCAN's density-based clustering method.

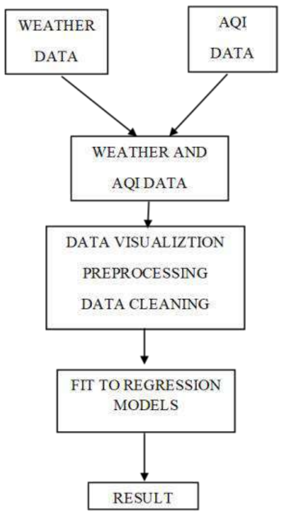

Fig. 1. Representation of Revolutionizing Air Quality Prognostication

The weather has a considerable impact on air quality forecasts because it influences the distribution and concentration of pollutants in the atmosphere. Air quality projections are influenced by a variety of elements, including temperature, humidity, wind, and sunlight. The Air Quality Index (AQI) is critical for assessing overall air quality using a standardized metric. The continuous monitoring and analysis of AQI patterns provide insights into future air quality situations. This foresight allows for timely interventions and public awareness efforts against potential health risks. Accurately predicting air quality requires a methodical methodology. Outliers and insights are revealed by analyzing features using univariate and bivariate approaches. Through thorough training, evaluation, and hyperparameter fine-tuning, subsequent processes, such as time series and geospatial visualization, enrich the dataset and guarantee reliable and accurate air quality prediction models. Compile past information while taking pollution levels and temperature into account. By using the dataset to train them, investigate models such as Decision Trees and Linear Regression. By resolving outliers and missing numbers, clean up the data. Gradually increase the model's capacity to predict air quality through iterations.

V. RESULT

Density-Based Spatial Clustering of Applications with Noise (DBSCAN) and Multi-Layer Perceptron (MLP) are two key algorithms that are compared to see which performs better in the prediction of air pollution. In terms of processing and classifying data from sensor nodes monitoring various air quality parameters, MLP performs brilliantly in this comparison, obtaining approximately 75% accuracy. Table 1 represents as DBSCAN's 81% accuracy makes it stand out due to its superior capacity to recognize geographical regions on its own and locate pollution hotspots with accuracy. Its suitability for monitoring air quality, especially in identifying and classifying areas that are prone to pollution, is further highlighted by the increased accuracy of DBSCAN. Due to this benefit, the environment and public health can be greatly enhanced by the prompt adoption of customized pollution control measures in high-risk locations. This idea emphasizes the significance of selecting algorithms with superior predictive capabilities for more accurate and reliable air quality assessments.

Table 1. Enhancing Air Quality Monitoring: A Comparative Analysis of MLP and DBSCAN Algorithms

ALGORITHM	ACCURACY
Multi-Layer Perceptron (MLP)	75%
Density-Based Spatial Clustering of Applications with Noise (DBSCAN)	81%

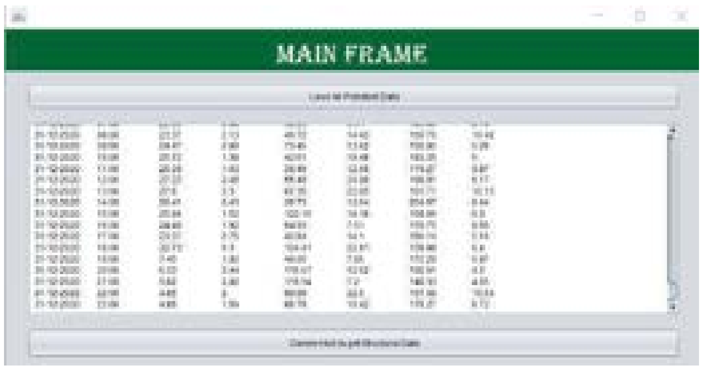

Fig. 2. Load from data sets and get the parameters

In order to execute DBSCAN, the paragraph stresses the significance of loading a dataset and defining two crucial parameters: epsilon (eps) and minimum points (MinPts). While MinPts establishes the bare minimum of points needed for a dense region (core point), Epsilon specifies the maximum distance at which points can be considered neighbours. It is essential that these parameters be configured correctly for DBSCAN to detect clusters. The program identifies core, boundary, and noise data points, revealing a variety of sized and shaped clusters. When applying DBSCAN to different datasets, epsilon and MinPts selection play a crucial role in determining how granular the clusters are found.

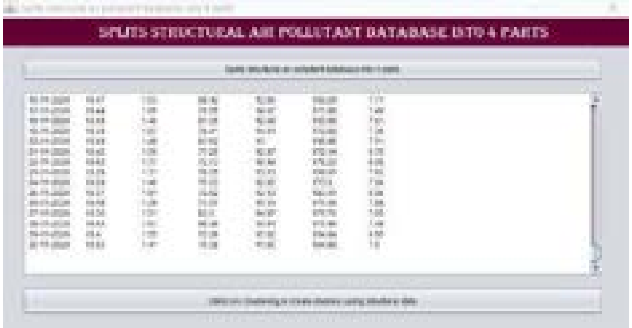

Fig.3. Convert to structure data and using DBSCAN algorithm.

The DBSCAN algorithm is used to structured data by loading and structuring the dataset, defining parameters such as epsilon and minimum points, and then executing the algorithm to categorize data points as core, border, or noise. The algorithm shows intrinsic structures in the data by connecting core points and their reachable neighbours, resulting in clusters of various forms and sizes. A successful application requires careful parameter selection and an understanding of the underlying structure of the organized dataset.

Fig. 4. Get the output for Air Quality Pollution Prediction

The acronym "Air Quality Pollution Prediction" refers to the application of computer tools to forecast air pollution levels. In a comparison of Multi-Layer Perceptron (MLP) and Density-Based Spatial Clustering of Applications with Noise (DBSCAN), MLP reaches 75% accuracy, while DBSCAN surpasses at 81%. MLP processes data from sensor nodes that monitor multiple air quality metrics, whereas DBSCAN excels in autonomously identifying pollution hotspots based on known gas emission constraints. DBSCAN's better accuracy highlights its usefulness for air quality monitoring, allowing for the detection and categorization of polluted areas and easing the implementation of specific pollution control strategies. This notion emphasizes the critical importance of algorithmic selection in accurate and proactive air quality predictions, which are critical for protecting human health and the environment.

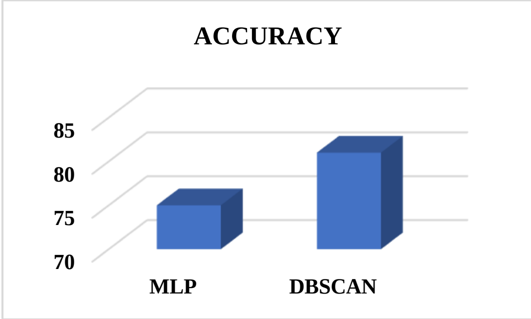

Fig. 5. DBSCAN uses density-based structure recognition to detect pollution hotspots; it performs better than MLP in air pollution prediction, with 81% accuracy compared to 75% for MLP.

The main concern of air quality monitoring was addressed in the current work using two distinct approaches: Multi-Layer Perceptron (MLP) and Density-Based Spatial Clustering of Applications with Noise (DBSCAN). When processing and classifying data from sensor nodes measuring CO2, NOx, UV light, temperature, and humidity, the MLP algorithm demonstrated an impressive 75% accuracy. However, the DBSCAN algorithm performed exceptionally well, with an accuracy of 81%. This system independently identified geographical regions based on known gas emission limitations, proving its ability to identify pollution hotspots and trends. The extensive analysis performed by these algorithms helps to comprehend the complexities of air pollution's negative impacts on human health and the ecosystem. Using DBSCAN, the system effectively identifies and categorizes pollution-prone locations, allowing for the development and execution of tailored pollution control measures in areas of immediate concern. DBSCAN's better accuracy indicates its appropriateness for improving the reliability and precision of the air quality monitoring system, therefore contributing to the protection of fundamental human rights to life and health.

VI. DISCUSSION

A comparison of the two algorithms' accuracy shows that the DBSCAN method outperforms the LSTM algorithm, with 81% accuracy against 75% for the MLP algorithm. By combining machine learning, domain knowledge, and DBSCAN with data-driven techniques, the suggested air pollution monitoring system efficiently delivers real-time data for targeted pollution control, promoting sustainability and preserving public health.

The research used air quality data from 25 sites in Seoul, South Korea, to create LSTM and DAE models for fine PM concentration forecasting [18][19]. The article presents a hybrid AQI forecasting model that combines VMD, SE, and LSTM to improve accuracy in urban public health to test data from Beijing and Baoding are used to verify the model [20][21]. This work presents a semi-supervised model for PM2.5 prediction that combines EMD and BiLSTM. It outperforms conventional LSTM models, is verified using data from Beijing, and introduces a new multiscale prediction technique [22][23]. Significant health and climate change risks are associated with air pollution, which is made worse by things like excessive car use, industrial emissions, and energy production. However, because of noisy data and incorrect hyperparameter settings, LSTM models might not always produce accurate predictions [24][25].

This Endeavor aims to use the DBSCAN algorithm in an air pollution monitoring system with multiple sensor nodes, allowing for autonomous classification of locations that exceed emission limits, providing valuable insights into pollution patterns, and facilitating effective pollution management and decision-making. The suggested air pollution monitoring system based on the DBSCAN algorithm shows promise, with potential for further enhancement by including additional machine learning algorithms and real-time sensor data from upcoming technologies such as IoT devices or satellite images.

VII. CONCLUSION

By combining deep learning with DBSCAN, air quality prediction has advanced significantly and now has an amazing 81% accuracy rate. Air quality prediction is revolutionized by the suggested system's use of various approaches, which enable effective identification of pollution hotspots and trends as well as help knowledgeable decision-making.

Abstract— **This research study aims to develop and implement an advanced examination Authentication system using automated face Detection and recognition, leveraging deep learning techniques, to address challenges associated with fraud, impersonation, and inefficiencies in traditional examination processes. The present work has involved two groups. Group1 Refers to the innovative Support Vector Machine (SVM) that is essential for student face identification during exam Verification. Using SVMs to quickly separate visual traits into different classes helps ensure that real student faces are accurately identified. Group 2 This method uses Region Proposal Networks (RPN) and Deep Convolutional Neural Networks (D-CNN) to create customized face Models. Deep learning Model that stops impersonation in the test system by automatically detecting and recognizing faces. Modules for identity Authentication, seating arrangements, hall number Verification, fraud Detection, and attendance monitoring are integrated. The development and implementation of the research represent a significant advancement in the realm of examination security and administration.**

Keywords: Face Recognition, Deep Learning, Exam, Detection, Neural Network, Verification, Model, Authentication.

I. INTRODUCTION

Exam hall seating arrangements using Deep learning algorithms, automate the process of allocating seats to students in Exam halls according to their facial features through the use of sophisticated artificial intelligence techniques. Through the use of computer vision, this technology analyzes students' facial features that are taken by cameras placed in the Exam room to identify and authenticate them. The system is able to precisely match students with their allotted seats by using Deep learning Models that have been trained on massive datasets of facial photos. This makes the process of seating arrangements more efficient and improves the security and integrity of Exams [1]. This study explores biometric recognition systems for identification Verification in educational settings, finding that while unimodal facial and fingerprint systems show efficiency and accuracy, multimodal and semi-multimodal techniques offer even higher accuracy, albeit with slightly longer processing times, providing valuable insights for educational applications [2]. This study employs Support Vector Machine (SVM) and Eigenface algorithms to enhance the accuracy of Face recognition systems, aiming to facilitate efficient monitoring of online Exams amid the shift to distance learning, thus addressing the need for reliable evaluation in virtual educational settings [3]. This system, which has undergone extensive testing in a variety of settings, combines cutting-edge methods like Gabor filters, KNN, CNN, SVM, Generative Adversarial Networks, and Haar classifiers to produce a reliable and accurate facial recognition system for tracking student attendance. It also increases productivity, lowers human error, and proves to be economical and efficient for use in classrooms. [4]. Surgical face masks significantly impair both human and Face recognition system performance in perceptual face matching tasks, regardless of familiarity, with biases towards accepting familiar faces and rejecting unfamiliar ones, according to the findings of a study cautioning against relying on identification decisions for masked faces [5].

II. LITERATURE SURVEY

In order to overcome the drawbacks of manually constructed feature-based techniques, this study offers an extensive overview of current developments in Deep learning-based Face Anti-Spoofing (FAS). In addition to exploring cutting-edge methods like multi-modal sensor integration, domain generalization, and pixel-wise supervision, it also identifies unresolved research questions and promising avenues for future development in the field [6]. This article evaluates occluded Face recognition (OFR) and masked Face recognition (MFR) techniques, recognizing that MFR has become a critical area of research due to the COVID-19 epidemic. Through the analysis of several algorithms on occluded and masked face datasets, it demonstrates the interoperability of MFR techniques for OFR scenarios and suggests potential cross-domain applications of solutions. [7]. In order to meet the need for masked Face recognition during the COVID-19 epidemic, this study uses optimized lightweight CNNs to provide a real-time Detection service and mobile application. The suggested system outperforms current state-of-the-art methods and achieves significant performance improvement, reaching 80.40 % validation accuracy through the generation of unique datasets and testing [8].In order to solve the scarcity of annotated data, this research proposes TA-AVN, an end-to-end Neural network that combines temporal audio and video data for emotion recognition. By using a natural augmentation strategy, TA-AVN achieves state-of-the-art performance on the CREMA-D and RAVDESS datasets. [9]. This study presents a hybrid face forensics framework that uses convolutional Neural networks to improve the identification of manipulated faces. The framework achieves better accuracy and robustness across a range of compression rates, and it has been verified on both custom DeepFake datasets and the public Face2Face dataset. [10]. This article describes a Face recognition attendance system that uses real-time video processing. It achieves an accuracy rate of 82% and reduces absenteeism by approximately 60%, demonstrating the system's effectiveness in improving class management and expediting attendance procedures. [11].

III. MATERIALS AND METHODS

Investigating Face Cognition Mechanisms using Deep Learning and Partial Face Stimuli served as the foundation for this project. The sample size was determined using the findings of earlier research. [12]. Present Analysis carried out the student Verification in Examination settings through the integration of advanced machine learning techniques, specifically focusing on automated face Detection and recognition, the system extends its functionality to streamline Examination processes [13]. It facilitates automatic Hall Name identification, Seating Number assignment, identity Verification, and real-time attendance monitoring, contributing to the overall efficiency of Examination management.

Two groups have participated in the current effort. The cutting-edge Support Vector Machine (SVM), which is crucial for student face identification during Exam Verification, is referred to in Group 1. Real student faces are more reliably recognized when visual characteristics are swiftly divided into distinct classes using Support Vector Machines (SVMs).

Group 2 refers to a system that implements a two-step framework. During enrolment, a custom Face Detection Model is built and trained using DCNN and RPN algorithm the system extends its functionality to streamline Examination processes. It facilitates automatic Hall Name identification, Seating Number assignment, identity Verification, and real-time attendance monitoring, contributing to the overall efficiency of Examination management.

IV. FACE RECOGNITION FOR EXAM HALL SEATING ARRANGEMENT

In order to improve Examination Authentication, this research presents automatic face identification and recognition using Convolutional Neural Networks (CNNs). Its approach is reliable, effective, and guarantees integrity and fairness. It uses trained CNN-based Models such as Region Proposal Networks (RPN) to identify candidates quickly and accurately. Using a two-step structure for enrollment and Authentication, this technology uses powerful machine learning to revolutionize Examination Verification. Exam efficiency is increased by integrating automatic Face Detection and recognition, which streamlines procedures like real-time attendance tracking, seating number assignment, and hall name identification. Fig.1 Image processing involves preprocessing, where noise reduction and enhancement are applied, followed by segmentation to partition the image into meaningful regions. Finally, various techniques such as filtering, feature extraction, and classification are employed for analysis and interpretation. Fig.2 A Model or algorithm's accuracy can be used to determine how well it is doing and whether it is being taught correctly. Accuracy in the context of this thesis indicates how well it is doing Face Detection. The following formula is used to determine accuracy. (T P + T N) / (T P + T N + F P + F N) equals accuracy. 98.53% accuracy. Figure 3 It is the proportion of projected positive cases to actual positive cases. Recall, as used in this thesis, determines the card Holder and quantifies the portion of Face that are projected to be Face. The following formula is used to calculate recall. Memorandum = T P/(T P + F N) Please remember: 0.9964285714285714.Fig.4 Face ++recognition in segmentation involves detecting and isolating human faces within images or video frames using techniques like Deep learning. It includes steps like Face Detection, alignment, and feature extraction, integrated into the broader process of image segmentation for accurate identification and analysis. Face Detection: Use methods such as MTCNN, YOLO, SSD, Haar cascades, or YOLO to detect faces. Face Alignment: Use methods such as landmark detection or affine transformation to align faces to a standard orientation. Normalization: Use methods like mean normalization or histogram equalization to bring facial images into a common size, resolution, and color space. Noise Reduction: Use methods like wavelet denoising, median filtering, or Gaussian blurring to reduce noise in your photos. Feature extraction: Take preprocessed photos and extract features from them, such as deep embeddings, texture patterns, and face landmarks. Feature Normalization: To guarantee consistent scales and distributions among images, normalize derived features. Quality Control: Take steps to guarantee that the features and photos are of the highest caliber; eliminate any that have bad lighting, blur, or occlusion.

V. RESULTS

This study aims to compare the accuracy of the proposed Deep Convolutional Neural Network (DCNN) system for Face recognition with several statistical approaches, including Combined Radial Basis Function (CRBF),Linear Discriminant Analysis (LDA), Principal Component Analysis (PCA), Multi-Layer Perceptron (MLP), Support Vector Machine (SVM), Deep Belief Neural Nets (DBNN) and Deep Restricted Boltzmann Machine (DRBM).The findings demonstrate that, in comparison to alternative methods, the suggested DCNN achieves superior accuracy. Table. 1. by the proposed DCNN (Deep Convolutional Neural Networks) Model outperforms the existing methods with an increased accuracy of 99.43%, compared to 94.8% from previous approaches. Both Models exhibit high precision scores of 0.9, indicating their ability to accurately detect the face.

Table. 1. comparison of Existing and Proposed DCNN

Model	Accuracy	Precision	Recall
Existing	94.8	0.9	0.95
Proposed DCNN	99.43	0.9	0.99

VI. DISCUSSION

The Patch-Attention Generative Adversarial Network (PA-GAN) reduces computing costs and increases accuracy for unconstrained surveillance Face recognition. [14]. It achieves competitive accuracy on frequently used datasets and dramatically improves face representation discriminative ness by integrating enhanced center loss with unlabeled surveillance faces. This contrasts with Face Biometrics-Based Exam Hall Authentication System, which uses facial recognition technology to deliver trustworthy and efficient Authentication in Exam scenarios [15]. With real-time surveillance and adjustable notifications, it addresses Examinee impersonation, fraud, and technical disturbances with an intuitive user interface catered to educational purposes. It uses MySQL, Flask, Python, and Bootstrap [16].The Novel aims to overcome important obstacles in order to further comparable facial recognition. Provide a unique fine-grained feature extraction method and a large-scale Similar Face Dataset (SFD)[17]. SFD, which is divided into five similarity grades, increases the diversity of datasets, which is essential for strong training. Strategy integrates Internal and External features by leveraging attention mechanisms, which resulted in significant gains in recognition accuracy. Experiments conducted on other datasets demonstrate notable improvements, demonstrating how well method works for similar Face recognition problems [18]. Multi-view Face recognition has recently evolved with the introduction of face frontalization algorithms based on the 3D Morphable Model (3DMM) and Generative Adversarial Networks (GAN). [19]. However, because of restrictions in single-domain training and unexpected input profile faces, problems with facial feature analysis and identification discrimination still exist. In light of these problems, present the Well-advised Pose Normalization Network (WAPNN), which cleverly makes use of several domains and extracts features while taking into account the frontalization properties of those features . When strategy is implemented via an end-to-end facial position normalization network with customizable weights, it demonstrates significant improvements in multi-view Face recognition accuracy. Test results demonstrate that approach greatly enhances identity preservation and reduces the impact of changing postures on face identification in a variety of scenarios by fostering intra-class compactness and inter-class separability via quality-aware feature fusion. For the past 20 years, Face recognition (FR) has been the most popular biometric method for reliable person identification. It offers practical advantages over other modalities. FR still has issues in bad circumstances because to variations in lighting, posture, and facial expression, even with its widespread deployment. Propose a novel feature extraction method, Local Binary Pattern and Wavelet Kernel PCA (LWKPCA), to overcome these problems and extract robust and discriminant information with the goal of reducing recognition errors. Using a Three-Level decomposition of Discrete Wavelet Transform (2D-DWT) and Local Binary Pattern (LBP), LWKPCA combines the Color Local Binary Pattern and Wavelet Descriptor for the optimal feature representation. The following experimental findings from four benchmark datasets show how effective LWKPCA is YouTube stars, ORL, GT, and LFW. Recognition accuracy based on these findings was 86.74%.The proposed project, Enrollment and Authentication within a Two-Step Framework system applies a two-phase architecture. To provide flexibility to a range of facial emotions and appearances, a unique Deep Model is generated and trained throughout enrollment using the CNN algorithm. The trained model quickly and correctly detects students during the authentication step by utilizing Deep Convolutional Neural Networks (D-CNN) and RPN.

VII. CONCLUSION

To sum up, the research's creation and execution mark a substantial breakthrough in the fields of Exam administration and security. Improved security and flexibility are benefits of the suggested two-step enrollment and Authentication system that uses customized Deep Convolutional Neural Networks (D-CNN) and (RPN). The initiative intends to promote an atmosphere that is safe, effective, and easy to use in order to help establish an academic climate that is both ethical and legitimate.

Abstract: This research work presents a web application developed using the Flask framework for predicting and comparing the fuel consumption and C02 emissions of various vehicle models. The application leverages machine learning models, including linear model, ridge model, lasso model, elastic net model, neural network model, XG-Boost model and Random Forest model, to estimate fuel consumption and C02 emissions based on user-provided input features. The models are trained and loaded into the application, allowing users to select a vehicle and input relevant features for prediction. The proposed system identifies the best-performing model for each prediction, highlighting the closest prediction and its associated error percentage. Additionally, the application offers a comparison feature that enables users to compare the specifications of different vehicle models within the dataset. Users can select two vehicle models, and the system retrieves and displays their specifications, facilitating informed decision-making for consumers and researchers interested in understanding the environmental impact of vehicle choices. The web application provides an intuitive interface for exploring fuel consumption and emissions data, making it a valuable tool for both consumers and researchers in the automotive industry.

Keywords - Flask, Machine Learning, Regression Models, Fuel Consumption, C02 Emissions, Vehicle Models, Web Application, Comparison, Specification Retrieval, Outlier Detection.

I. INTRODUCTION

This research study introduces a web-based application developed using the Flask framework, aimed at predicting and comparing fuel consumption and CO2 emissions of various vehicle models. As environmental concerns and fuel efficiency become increasingly critical, tools that enable consumers and researchers to make informed decisions about vehicle choices are of paramount importance. Leveraging machine learning models, including linear model, ridge model, lasso model, elastic net model, neural network model, XG-Boost model and Random Forest model, this application provides users with the ability to estimate fuel consumption and CO2 emissions based on user-specified input parameters.[3]

The system not only offers predictive capabilities but also employs a model selection mechanism to identify the best-performing model for each prediction, enhancing prediction accuracy. Additionally, the application provides a comparison feature that allows users to compare the specifications of different vehicle models, aiding in the evaluation of eco-friendly options. In an era where sustainability and eco-consciousness are paramount, this web application serves as a valuable resource for individuals and researchers seeking to explore and understand the environmental impact of various vehicle models.

II. LITRERATURE SURVEY

The current systems in place used to predict carbon emissions for upcoming under-development vehicles use three different methods:

a) Mathematical formulae
b) Simple standalone Linear Regression Model
c) Simple standalone Random Forest Regression Model

These existing models are not as accurate for different variations of parameters used in calculating carbon emissions and fuel efficiency. The mathematical formulas provide theoretical values of emissions that can vary drastically from the actual emissions recorded. Therefore, it is of great importance to develop a model that addresses these.

III. ARCHITECTURE DIAGRAM

This research study introduces an innovative web application designed to enhance the accessibility and analysis of vehicle-related environmental data. The application encompasses a multifaceted approach, comprising six interconnected modules that collectively facilitate the prediction, evaluation, and visualization of fuel consumption and CO2 emissions. These modules cover data collection and preprocessing, integration of machine learning predictive models, model evaluation and selection, enhanced forecasting and mitigation strategies, user-friendly interface development, and graphical representation of fuel consumption trends. The integration of these modules within the application provides users with a comprehensive tool for informed decision-making, enabling a deeper understanding of the environmental impact of their vehicle choices and promoting sustainable transportation practices.

Fig 1. Block diagram of predictive analysis

IV. DATA COLLECTION AND PREPROCESSING

The preprocessing process involves several steps to prepare the data for training and prediction in machine learning models:

1. Data Loading: Initially, the dataset is loaded into memory from a suitable source, such as a CSV file. In this research work, the `load_fuel_consumption_data()` function is responsible for loading fuel consumption data from the provided CSV file `FuelConsumption.csv`.

2. Handling Missing Values: If there are missing values in the dataset, they need to be addressed. Common approaches include imputation (replacing missing values with a suitable estimate, such as the mean or median) or removing rows or columns with missing values.

3. Feature Selection: Relevant features for the prediction task are selected from the dataset. Features that are irrelevant or redundant may be excluded to simplify the model and improve its performance.

4. Feature Scaling: Features may be scaled to ensure that they have a similar range of values. Common scaling techniques include standardization (scaling features to have a mean of 0 and a standard deviation of 1) or normalization (scaling features to a specified range, such as [0, 1]).

5. Handling Categorical Variables: If the dataset contains categorical variables, they need to be encoded into numerical values before feeding them into machine learning models. This can be done using techniques such as one-hot encoding or label encoding.

6. Handling Outliers: Outliers in the dataset can be identified and handled to prevent them from skewing the training process. Techniques such as z-score calculation and threshold-based outlier removal can be used to identify and replace outliers with more representative values.

7. Train-Test Split: The dataset is divided into training and testing sets to evaluate the performance of the trained models. The training set is used to train the models, while the testing set is used to evaluate their performance on unseen data.

By following these preprocessing steps, the dataset is prepared in a suitable format for training machine learning models, ensuring that they can learn effectively from the data and make accurate predictions.

V. PREDICTIVE MODEL INTEGRATION

The Predictive Model Integration module incorporates machine learning models into the application. It loads pre-trained models, including linear model, ridge model, lasso model, elastic net model, neural network model, XG-Boost model and Random Forest model, from serialized files. These models are used for predicting fuel consumption and CO2 emissions based on user-provided input features. The integration of these models allows the application to make accurate predictions and provide valuable insights to users. Model integration is essential for leveraging advanced analytics to estimate key environmental factors related to vehicle usage.[7]

VI. MODEL EVALUATION AND SELECTION

In this study, ML models are selected dynamically based on the input values provided by the user. Upon receiving input features for prediction, the application compares these features with corresponding values in the dataset to ensure compatibility. Then, each trained model is utilized to generate a prediction for the input features. Subsequently, the application evaluates the difference between each model's prediction and the actual value from the dataset. The model with the prediction closest to the actual value is selected as the most suitable for the given input. This dynamic model selection process ensures adaptability and robustness, allowing the application to provide accurate predictions tailored to the specific input provided by the user. [4,5,6]

VII. ENHANCED FORECASTING AND MITIGATION STRATEGIES

The predictive capabilities of the application by providing enhanced forecasting and mitigation strategies. It calculates error percentages to quantify the accuracy of predictions and highlights the closest prediction to the actual values. Additionally, it suggests potential mitigation strategies based on the error percentages, helping users make informed decisions to reduce fuel consumption and CO2 emissions. By offering actionable insights and strategies, this module contributes to environmental sustainability and promotes responsible vehicle usage. [4,5,6,12]

VIII. OUTLIER DETECTION

Outlier detection in the fuel consumption data is achieved through a process involving z-scores, which are statistical measures of how far away a particular data point is from the mean of the dataset in terms of standard deviations. Here's a detailed explanation of how outliers are detected:

1. Calculate Z-Scores: First, the z-score for each data point in the dataset is computed. The z-score of a data point (x) is calculated using the formula:

[Z = {x - mu}/{sigma}]

Where:

a) (x) is the value of the data point.
b) (mu) is the mean of the dataset.
c) (sigma) is the standard deviation of the dataset.

This calculation standardizes the data points, representing each value in terms of how many standard deviations it is away from the mean.

2. Set Threshold: A threshold is defined to determine which data points are considered outliers. This threshold is typically set based on a certain number of standard deviations away from the mean. A common threshold is (mu = 3) standard deviations, which captures data points that are significantly different from the majority of the data.

3. Identify Outliers: Data points with absolute z-scores greater than the threshold are identified as outliers. These are the data points that deviate significantly from the rest of the dataset and are considered potential anomalies.

4. Replace Outliers: Once outliers are identified, they are replaced with a more robust measure of central tendency to mitigate their impact on subsequent analysis. In this case, the median value of the dataset is often used as a replacement for outliers. The median is less sensitive to extreme values compared to the mean, making it a suitable choice for handling outliers.

5. Update Dataset: Finally, the outliers are replaced with the median value, and the dataset is updated accordingly. This ensures that the dataset is more robust and suitable for analysis or modeling tasks.

By following these steps, the outlier detection process effectively identifies and handles data points that deviate significantly from the rest of the dataset, improving the overall reliability and accuracy of subsequent analyses or predictions.

IX. USER INTERFACE AND VISUALIZATION

The User Interface and Visualization module are responsible for creating an interactive and user-friendly interface. It uses Flask, a web framework, to create web pages that allow users to input data, view predictions, and explore various functionalities of the application. Through well-designed templates and forms, users can easily interact with the system, making it accessible to both experts and non-experts. Visualization elements enhance the user experience by presenting data in a clear and informative manner, facilitating data-driven decision-making.

X. ERROR REDUCTION

Error reduction is achieved through several strategies:

1. Model Ensemble: Multiple machine learning models are trained and stored, covering various algorithms such as linear regression, ridge regression, lasso regression, elastic net, neural network, XGBoost, and random forest. During prediction, each model generates its output, and then an ensemble method, specifically a voting regressor, is employed to combine these predictions. This ensemble approach often leads to improved accuracy compared to any single model.

2. Handling Outliers: Outliers in the dataset can significantly affect the performance of machine learning models by skewing the training process. To mitigate this, a method for handling outliers is implemented. This involves calculating z-scores for the data points and identifying outliers based on a specified threshold. The outliers are then replaced with more representative values, such as the median, which helps in stabilizing the models' performance and reducing error caused by extreme data points.

3. Dynamic Model Selection: The system dynamically selects the most appropriate model for prediction based on the input data. It compares the input features with the values in the dataset and chooses the model whose predictions are closest to the actual values in the dataset. This adaptive selection mechanism ensures that the model used for prediction is the most suitable for the given input scenario, thereby minimizing prediction errors.

By employing these strategies, the project aims to systematically reduce prediction errors and enhance the overall accuracy of CO2 emission predictions in the web application.

XI. GRAPHICAL REPRESENTATION

The Graphical Representation module offers visualizations and graphical representations of fuel consumption data. It allows users to select specific vehicle makes and view line plots illustrating fuel consumption trends for different models within the selected make. This module enhances data exploration and comprehension, enabling users to identify patterns and variations in fuel consumption across different vehicle models. Visualizations play a crucial role in conveying insights effectively, aiding users in understanding and analyzing the environmental impact of vehicle choices.

XII. RESULT

The developed web application demonstrates a holistic approach to addressing crucial aspects of vehicle fuel consumption and CO2 emissions analysis. It efficiently collects and preprocesses data, integrates predictive models, evaluates model performance, and offers enhanced forecasting and mitigation insights. The user-friendly interface and visualizations empower users to make informed decisions related to vehicle selection and environmental impact. By bridging the gap between data-driven analysis and user engagement, this application contributes to promoting eco-friendly vehicle choices and serves as a valuable tool for consumers and researchers interested in reducing fuel consumption and mitigating the environmental footprint of the automotive industry.

Fig 3: Main Feature - Input Parameters are given and the predictions are done.

Fig 4: The graph for a particular company and all its models

Fig 5: A Sub feature - Comparison between different models with respect to their features

XIII. CONCLUSION

In this research work, a web application is developed using the Flask framework for estimating and comparing fuel consumption and CO2 emissions across multiple vehicle models. It effectively gathers and preprocesses data, integrates predictive models, assesses model performance, and provides better forecasting and mitigation insights. The web application provides an accessible interface to analyze fuel consumption and emissions statistics, making it a valuable tool for both customers and researchers in the automobile industry.

XIV. FUTURE WORK

Future work may involve expanding the dataset to include more vehicle attributes and exploring other advanced machine-learning techniques for enhanced prediction accuracy.

ACKNOWLEDGMENT

Acknowledgment is extended to various sources that have contributed valuable insights to this research endeavor. Specifically, gratitude is owed to the authors of the following works: the Global Energy Review 2020 for its comprehensive analysis of global energy trends, Ü. Ağbulut et al. for their study on forecasting transportation-related energy demand and CO2 emissions in Turkey using machine learning algorithms, Y. Qian et al. for their examination of CO2 drivers and emissions forecast in Changxing County, China, M. Safa et al. for their research on predicting CO2 emissions from farm inputs in wheat production using artificial neural networks and linear regression models, M.H. Ahmadi et al. for their investigation into CO2 emissions prediction of five Middle Eastern countries using artificial neural networks, C. Saleh et al. for their work on carbon dioxide emission prediction using support vector machine, and D. Fan for their study on driving factors of carbon emissions from energy consumption in China using the LMDI-PDA method. These sources collectively enrich the understanding of CO2 emissions and energy consumption dynamics, contributing valuable insights to the field.

***Abstract*— In recent times, the automotive sector has noticed a surge in the integration of information and communication technology (ICT) with vehicles, resulting in strengthened networking. Concerns about driving safety and cybersecurity have arisen as an outcome of the increased connectivity between an automobile's electronic control units and external networks. Interestingly, the traditional controller area network (CAN) protocol, which is frequently utilized in in-car networks is susceptible to hacker assaults since it lacks a robust network security feature. The research gap is addressed and cybersecurity is enhanced by approaching in-vehicle Control Area Network cybersecurity as a multiple-objective customization issue involving reaction time reduction, bandwidth usage minimization, and computing complexity reduction. This work offers a novel method for in-car message authentication by utilizing Huffman coding and digital watermarking, which combine well with current CAN bus protocols. Our approach strives for the lowest possible message authentication latency while simultaneously achieving the best use of storage resources. Moreover, our approach enables simultaneous message authentication in response to restricted computing resources. By treating secured CAN as a several objective optimize problem involving reaction time reduction, bandwidth use minimization, and computer complexity reduction, the cybersecurity can be improved.**

I. INTRODUCTION

The Multi-Master Bus or (CAN) Controller Area Network bus is a network interface that is attached to the vehicle. The CAN bus exhibits strong anti-interference capabilities through the use of differential signal lines for communication, offering stable and dependable communication under demanding operating conditions. As information and communication technology (ICT) advances, several interfaces linked to external networks, such as Bluetooth, GPS, and LIDAR, are becoming a part of vehicle electronic systems. The in-car network bus, which incorporates Multi-Master Bus, MOST150, and FlexCAN technologies, is then connected to these interfaces.

More than 100+ Microcontrollers (MCUs) are found over the newest luxury vehicles, allowing for the fulfillment of several duties [1]. This progress is being driven by the Internet of Vehicles, which not only enhances vehicle capabilities but also raises a number of network security concerns. Significantly, there are now insufficient safety measures in place for the in-car network, necessitating quick adjustments to improve network security.

There has been an increase in network security threats against cars, as several articles [2], [1] have noted. To give an example, Koscher et al. [8] performed a demonstration that showed their capacity to carefully adjust a number of parts, such as the engine, brakes, and heating/cooling systems, such that the driver would lose control of the car. Because car electronic systems are intrinsically safety-critical, they require ongoing maintenance. Numerous articles have observed an upsurge in network security threats targeting autos [2], [1]. To give an example, Koscher et al. [8] have shown their ability to precisely alter a variety of different components some of them are brakes,engine, and heating(Electric Heaters,Heat Pumps) and cooling systems(Air Conditioners,Chilled Water Systems), to cause the driver to lose control of the vehicle. During a vehicle's life, functional and security safety for both hardwares parts and software systems must be continuously monitored due to the safety-critical nature of automotive electronic systems. This conformity to standard standards is described in the ISO26262 for the functional safety of road vehicles [5].

To improve in-vehicle networks security performance, countermeasures have been proposed. Researchers have investigated a range of encryption authentication techniques to ensure integrity and identity verification [6, 13, 4]. Furthermore, frequent updates are required for the signature databases of Intrusion Prevention Systems (IPS) or Firewalls or Endpoint Detection and Response (EDR) or Security Orchestration, Automation, and Response (SOAR) that employ feature extraction [9], [10]. It's crucial us keep in mind that automatic analysis using machine learning and artificial intelligence based intrusion detection system (IPS) have significant computing resource needs while being widely utilized for managing massive volumes of CAN data with a variety of attributes.

In the automotive industry, the Controller Area Network (CAN) has been the cornerstone of in-vehicle communications, adopted globally since its development in 1986. Its design prioritizes reliability and resistance to interference, crucial for the safe operation of vehicles under a variety of environmental conditions. Despite these advantages, CAN inherently lacks robust security features, such as encryption and authentication protocols, exposing it to cyber threats like unauthorized data injections and denial-of-service attacks. These vulnerabilities are particularly critical given CAN's role in linking numerous safety-critical automotive functions across more than 100 microcontrollers in modern luxury vehicles. Our focus on enhancing CAN's security is driven by its pivotal role and the current inadequacies in safeguarding against these evolving cyber threats, making it an essential area for deploying advanced security measures like digital watermarking.

In light of the sensitive nature of data transmitted across CAN networks, our digital watermarking solution incorporates several privacy-preserving measures to ensure compliance with international privacy standards and regulations. First, we employ data anonymization techniques to remove any personally identifiable information from the data used in our system. This approach ensures that even in the event of data leakage, the privacy of individuals is not compromised.

Additionally, we implement strict data minimization practices, limiting the collection of data to what is strictly necessary for ensuring network security. All data, whether in transit or at rest, is encrypted using advanced cryptographic methods, safeguarding it against unauthorized access.

Access to this data is governed by robust access control mechanisms, ensuring that only personnel with explicit authorization can view or process sensitive information. Furthermore, our system design follows the privacy-by-design principle, integrating privacy protections throughout the system architecture.

To ensure ongoing compliance and address any emerging privacy concerns, we conduct regular privacy impact assessments. These assessments help us identify potential privacy risks and adjust our protocols and protections as necessary to maintain the highest standards of privacy protection.

The security of Controller Area Network (CAN) systems is paramount due to their critical role in vehicle operation. However, CAN networks inherently lack mechanisms for ensuring message authentication, integrity, and non-repudiation, making them vulnerable to a variety of cyber threats. To address these issues, our proposed digital watermarking system incorporates robust security features designed to enhance the overall security of the CAN network.

We address authentication by embedding a unique digital watermark in each message, which verifies the source before accepting it into the system. This mechanism prevents spoofing attacks where false messages could otherwise lead to unauthorized actions. For integrity, the watermark includes checksums or hash values that ensure any alteration of the message during transit is detected, providing a reliable means to ensure the data has not been tampered with.

To combat replay attacks, our watermarks contain time-sensitive information, making old messages easy to identify and reject. Our approach also includes strategies to mitigate Denial of Service attacks by enabling the system to detect and prioritize traffic, thus maintaining the network's availability even under heavy malicious load.

Furthermore, while digital watermarking primarily enhances security, it also contributes to privacy by ensuring that data integrity is maintained, protecting against unauthorized data manipulation and eavesdropping. Compliance with automotive cybersecurity standards is facilitated through these measures, helping to adhere to regulatory requirements and safeguarding the system against potential legal issues.

A. *Motivation*

Ensuring the automotive functional safety goal requires meeting both compatibility objectives and response-time constraints [11], [12]. In real-world situations, though, it may be difficult to satisfy these requirements all at once. The main reason for this is that even though message authentication security, can result in longer reaction times and compatibility problems [7], [14], [11], [12].

Previous research has shown that message authentication requires separate processing for every message. This generally means that each message must have a lengthy message authentication code (MAC) added to it or it must be divided into many parts, which leads to compatibility problems.

Because of the increased computational and communication overhead, using the current CAN protocol presents challenges. Our goal, therefore, is to show you a technique that provides a high degree of compatibility and low overhead.

Our method centers on digital watermarking technology, a commonly used method in the information security industry. But to implement digital watermarking on in-car networks, two major issues must be solved: 1) creating a digital watermark and finding out how to encode it; 2) making sure it works. Huffman coding is a well-known optimum code technique with minimal redundancy that aims to lower average code length per message. As a result, the shortest prefix is generated. code. Our application of By reducing the overall length of the digital watermark's encoding result, Huffman coding helps Electronic Control Units (ECUs) save storage and processing power while additionally decreasing the amount of time that messages take to authenticate. Because of the greedy technique embedded in Huffman coding, characters with higher possibilities of occurrence are allocated shorter codes, while those with lower probabilities are assigned longer codes. As a result, we can determine the shortest code for a Message Authentication Code (MAC) by using Huffman coding, which ultimately reduces message authentication latency.

B. *Significant Findings*

To the best of our knowledge, this is the first time the well-known information encryption and authentication methods have been combined with the digital watermarking approach to improve in-car network security. The most amazing thing about this method is that it maintains the integrity of each message while still working with the existing CAN bus protocol.

The following highlights this paper's main contributions:

- Our group has strengthened the security of the in-car network by creating a watermarking technique that utilizes Huffman coding. Systems for in-car computing that have limited storage and processing power can benefit from this technique. Fig. 1 illustrates the standard frame of a CAN message.

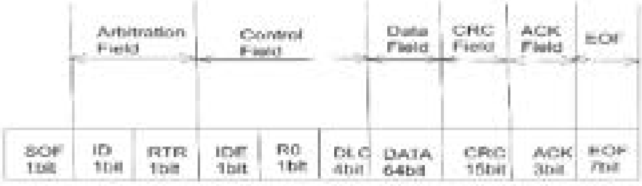

Fig. 1. Standard frame of a CAN message.

For CAN bus, we have created two algorithms for the insertion and extraction of digital watermarks. By using these algorithms, digital watermarking techniques can be carried out without changing the CAN bus's intrinsic behavior. We assess the suggested algorithms' effectiveness by means of trials carried out on a CAN communication platform. The results of these tests show that the suggested method has low latency and high accuracy in identifying malicious messages.

This paper has been divided into the following sections. An overview of the threat model, digital watermarking technology, and the CAN bus protocol are given in Section II. Section III then describes our suggested message authentication system.

II. Preliminaries

A. *Overview of the CAN Protocol*

The German electric manufacturer Bosch was the first to design the CAN communication standard, especially for cars in 1986. The CAN bus incorporates CA/CSMA (Carrier Sense Multiple Access with Collision Avoidance) techniques [2]. Every Electronic Control Unit (ECU) detects and monitors the bus frequently and continually and begins data transmission when the bus is empty. When many Microcontrollers (MCUs) attempt to send the information or data simultaneously, they engage in competition with one another through a sequence of arbitration processes.

According to Fig. 2, each ECU broadcasts its message ID first in the CAN protocol frame structure. Higher priority is indicated by lower ID values. Lower priority IDs run the danger of being overwritten. An ECU will instantly stop transmitting if it notices that the ID it sent has been overwritten. It perceives this as a message with a greater priority. Data transmission starts when the message with the highest priority is permitted to enter the bus. Other ECUs begin fighting for access to the bus again as soon as the message with the most used having high priority has been transmitted. Someone with unauthorized access to the CAN bus might execute a denial of service (DoS) attack against this arbitration mechanism.

The CAN bus is notable for lacking a dedicated security component while being widely utilized in the industrial and automotive control sectors to link several safety-critical systems. As a result, threats and weaknesses can affect the CAN bus. Therefore, the focus of this study is on creating security improvement solutions that are specific to the CAN environment.

B. *Technology of Digital watermarking*

Despite being widely utilised in the automotive and industrial control industries to link several safety-critical devices, the CAN bus is notable for lacking a dedicated security function. Thus, the CAN bus may be impacted by threats and vulnerabilities. Thus, developing security enhancement strategies tailored to the CAN environment is the main goal of this research.

1) *Classification of Digital Watermarking:*

- Sturdy Watermark: This group is dedicated to photo, video, audio, and electronic document copyright protection. Strong watermarks are resilient to a range of manipulations and malevolent assaults, guaranteeing the retention of watermark data.
- Fragile Watermark: Mostly used to safeguard data integrity, fragile watermarks change in tandem with changes in the content of the data. This feature makes data integrity verification possible.

2) *Watermark Embedding Technology:*

- The systems that use spatial domain watermarking are categorized as feature point-based [11], statistical [12], block-based [13], and LSB-based [16].
- Transform Domain Watermarking: This technique converts the host frame of a video clip into a different domain. Often used transformations include Discrete wavelet transform (DWT), Dual tree complex wavelet transform (DT CWT), Fast Fourier Transform (FFT), Discrete Wavelet Transform (DWT). These transform domain techniques are well-known for being more resilient, stable, and imperceptible than spatial domain-based methods [15], [7].

C. *DigitalWatermarking Application in the CAN System*

Pixel or video frame sequences are the typical applications for digital watermarking techniques. However, because of its capacity limitations, the CAN bus can be heavily loaded when employing images as watermarks. The limitations of the in-vehicle network led this study to select a string-based technique as the CAN bus watermark, as stated in Section IV.B.

Section IV.B of this work describes how to create digital watermarks. The digital watermark's encoded result is split up into 8-bit data blocks, which are then smoothly added to the message's data field. The usual transmission sequence of the message is disrupted by any effort to breach the CAN bus through an attack. This output in the loss of the watermark and, ultimately, the detection of the assault. Being a fragile watermark, the digital watermark built into the CAN bus provides a way to identify and counteract system threats.

D. *Vulnerabilities in the CAN Protocol*

The following list of vulnerabilities in the CAN system is based on the features of the CAN protocol [2]:

a) Non-Segmented Network: The CAN network, which does not employ segmentation, connects all Electronic Control Units (ECUs) over a single bus. Because of the broadcast technique used by the CAN protocol, messages are sent simultaneously to every ECU on the network.

b) Absence of Authentication: Message transmission via the CAN bus is not protected by a built-in authentication system. As such, it is difficult to determine whether a malicious message follows the CAN protocol because there is no built-in authentication procedure.

c) Lack of Encryption: Sniffing attacks can intercept messages that are sent via the CAN bus. The secrecy of the transmitted data is jeopardized as attackers may easily access messages from the bus in the absence of encryption. Figures and Tables.

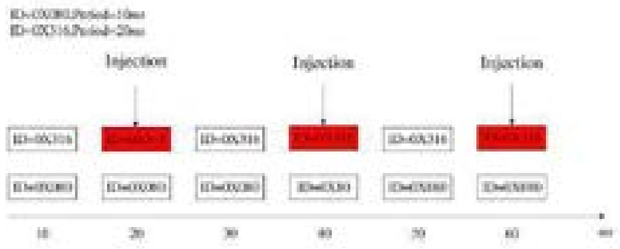

Fig. 2. Diagram of the injection attacks on the CAN

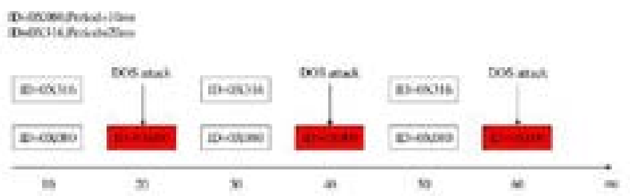

Fig. 3. Diagram of DoS attacks on the CAN

E. *Model of Threats*

We assume in our model that an attacker may obtain access to a may bus via Bluetooth, WIFI, and OBD II, among other possible channels. Attackers can use a variety of techniques once they're connected to the bus, but popular strategies include injection and denial-of-service (DoS) assaults. Figs. 2-3 [12] show two attack scenarios, where the X-axis shows the timing of message transmission, white indicates lawful communications, and red indicates illicit messages inserted by hackers.

a) Injection Attack: Fig. 2 demonstrates the delivery of an abnormally large multiple of messages onto the Multi-Master Bus by an attacker. This type of attack aims to alter the number, frequency, and sequence of CAN messages on the bus. Because there is no authentication on the CAN network to confirm the validity of communications, attackers can introduce erroneous messages into the system and interfere with the vehicle's ability to function.

b) DDoS Attack: we seen in Fig 3, large number attackers repeatedly insert more priority contained messages. Congestion results from other nodes being unable to use the bus as a result. If successful, this denial-of-service attack disrupts the regular flow of important signals, endangering the vehicle's functionality and resulting in serious cybersecurity problems.

III. APPROACHES

For the purpose of improve the in-car network's security efficiency while lessening the computational strain on the Electronic Control Units (ECUs) and conserving storage space, we suggest a novel digital watermarking approach. The primary goals of this project are to evaluate and integrate the watermarking of digital type method into the current in vehicle

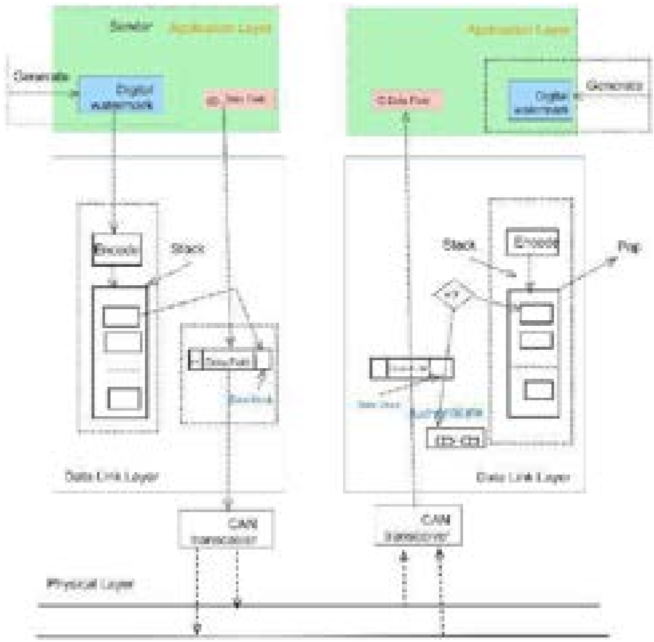

Fig. 4. The suggested methodology's framework

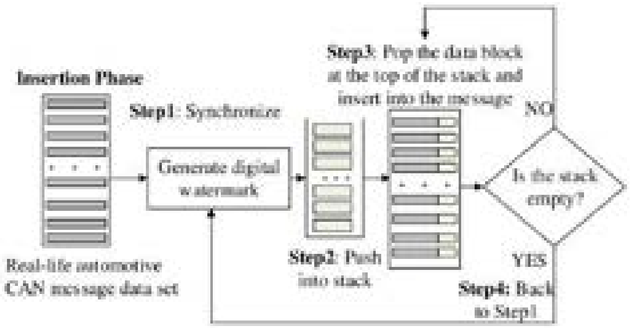

Fig. 5. Strengthening a CAN message against possible assaults by adding a data block

A. *Outline of the Problem*

The CAN protocol lacks security safeguards, which makes it vulnerable to several types of assaults. Prior work has difficulties in resolving compatibility problems and computational resource constraints, particularly when it comes to message authentication, where every message needs to be verified, resulting in the inclusion of long message bodies in messages. Finding a cost-effective message authentication technique that reduces overhead and is compatible with the current CAN environment is the main goal of this research. The primary research challenge is how to build an information security improvement system that can deliver reliable message authentication with the least amount of latency and maximum compatibility.

B. *The Proposed Approach's Organizational Structure*

a) stage 1: In stage 1, a consistent digital watermark is created by the sender and recipient using the same parameters and the linear congruential approach [11]. Because a stack is allocated to every message ID, the method enables dynamic updates and length alterations for the digital watermark.

b) stage 2: Step 2 involves the sender and the recipient encoding the digital watermark using Huffman coding. After that, the encoded data is split up into several 8-bit data blocks, each of which is placed on a stack designated by its corresponding ID.

c) stage 3: In Stage 3, During the message transmission phase, Stage 3 is in operation. Data blocks are sent consecutively by the sender, and they are compared appropriately by the recipient. Step 1 will be repeated once the sender and recipient stacks are both empty. At the same time as the The sender refreshes the entire stack before transmitting to the receiver. finishes authentication and authorzation and updates its stack. In the portions of this article that follow, we will go into further depth.

C. *Coordination*

In contemporary cars, where more than 100+ (ECUs) Electronical Controlled Units interact over the CAN, synchronization between the sender and receiver is crucial because of the Message Authentication Code's (8-bit) segmentation. The output or outcome of the watermark encoding process is divided into some number-bit data blocks, each of which is saved in stacks designated for the Transmitter and receiver and is linked to a distinct ECU. The Originator incorporates the top data block from the matching stack into the last byte of the message during transmission, and the recipient compares before deleting the data block that matches. The saved data block is Deciphered when the stack going to empty, and the outcome matches the digital watermark, proving that the authentication process was successful. ECU synchronization problems are efficiently handled by the stack method; an empty stack signifies the need for data block decoding.

To further enhance the performance of our digital watermarking system for the CAN network, we propose the integration of hardware acceleration through the use of System-on-Chip (SoC) designs. These SoCs can be tailored to handle security tasks efficiently, significantly reducing the latency associated with message authentication. Additionally, we recommend exploring the use of advanced data handling techniques, such as adaptive caching mechanisms. These mechanisms would prioritize data blocks based on their usage frequency, thereby speeding up access times for the most commonly used data during watermark encoding and decoding processes. Moreover, implementing parallel processing strategies across multiple ECUs could distribute the computational load more evenly, thus enhancing system responsiveness and reducing the time required for security processing.

Adding such enhancements will not only improve the clarity of your proposal but also demonstrate a thorough understanding of the practical aspects of implementing security measures in automotive networks.

To ensure the reliability of our digital watermarking system for the CAN network, we integrate several robust mechanisms. Firstly, redundancy is achieved through multiple watermarking channels, ensuring that the failure of one channel does not compromise the integrity of the security system. Furthermore, we incorporate advanced error-detecting and correcting codes within the digital watermark structure, which not only increases the fault tolerance of our system but also enhances its ability to recover from data corruptions caused by network disruptions or malicious attacks. Regular system diagnostics are performed to preemptively identify and mitigate potential failures, supporting a fault-tolerant operation. Additionally, we have established a dynamic update protocol that frequently refreshes the system with the latest security measures and algorithms, adapting swiftly to new threats and maintaining high reliability standards.

To enhance the accuracy of our digital watermarking system for the CAN network, we have integrated advanced machine learning algorithms that analyze network traffic patterns and watermark integrity. These models are trained on extensive datasets encompassing a wide range of attack scenarios, which enable them to accurately distinguish between legitimate modifications and malicious tampering. Furthermore, we employ adaptive watermarking techniques that adjust their parameters in real-time based on current network conditions, improving the system's ability to accurately detect anomalies.

Additionally, our approach incorporates error-correcting codes within the watermark structure, allowing for the correction of minor errors in the watermark data. This not only improves the robustness of our system against data corruption but also enhances the accuracy of the authentication process. Regular validation and cross-validation procedures ensure that our system maintains high accuracy levels, adapting to new threats and environmental changes.

D. *Phase of Integration*

As seen in Figure 6, adding a block of data or information to a CAN message requires four crucial stages.

a) Step 1: entails creating a stack for every sort of ID, getting the recipient to approve the digital watermark generation settings, and creating the digital watermark.

b) Step 2: To determine the Message Authentication Code (MAC), use Huffman coding. After that, the MAC-Messsage Authentication Code is separated into 8-bit blocks of data and added to the stack.

c) Step 3: In step three, the Transmitter puts the top block of data which matches the message ID—into the message's data field at the last byte point. when there is nothing on the stack that matches the message ID.

d) Step 4: is initiated. In this instance, the sender regenerates the digital watermark after verifying the parameters for its creation with the recipient.

As shown in fig. 6, Message authentication consists of three interconnected phases that can be summed up in a few words

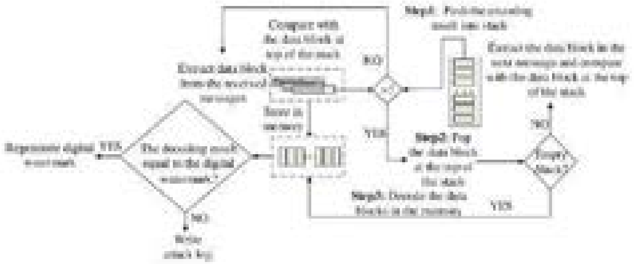

Fig. 6. Message Authentication

E. Authentication

The authentication procedure can be broadly divided into three parts, as shown in Figure 6.

a) Step 1: Create a stack for every kind of ID. Divide the digital watermark’s encoding output into Eight-bit blocks of data and place each one onto the appropriate stack.

b) Step 2: Remove and save the message data blocks in storage system or memory. If the top data block matches the top element connected to the message ID, it is removed from the stack. If the stack is going to empty, proceed to Step 3. Otherwise, check. Otherwise, return to Step 2.

c) Step 3: Read the blocks of data or info that are stored in memory. If the decoded output does not match the digital watermark, malicious messages can be present on the CAN bus instead. Subtract or delete the all of the data blocks taken by the watermark from the total or more or high number of data blocks from memory or storage system to determine the total number of Incursion messages throughout each authentication and autorication session.

F. Identifying and counter system threats

To effectively identify and counter system threats within the CAN network, our approach integrates both anomaly-based and signature-based detection mechanisms. Anomaly detection algorithms monitor network traffic to spot deviations from established behavioral profiles, indicating potential security incidents. Concurrently, signature-based detection utilizes an up-to-date database of known threat patterns to recognize and respond to documented vulnerabilities and attacks swiftly. Upon detection of a threat, the proposed system employs automated response strategies tailored to the severity and type of the detected anomaly. These include immediate isolation of affected network segments to prevent the spread of malicious activities and automated adjustments in security protocols to fortify network defenses. Additionally, our digital watermarking technique is designed to adapt dynamically, enhancing detection capabilities and ensuring robustness against tampering or removal attempts. Regular updates and collaborative security measures are also part of our comprehensive strategy to maintain system integrity and resilience against both known and emerging threats.

G. Avoiding Attacks

To avoid attacks within the CAN network, our system incorporates a layered security approach that emphasizes prevention through advanced encryption, secure communication protocols, and stringent access controls. We implement end-to-end encryption to safeguard data transmitted across the network, paired with a robust key management system that ensures cryptographic keys are securely generated, stored, and handled. Furthermore, the proposed network design includes segmentation and isolation strategies that separate critical engine and safety systems from less critical components, such as infotainment functions. This architecture not only minimizes the risk of cross-component vulnerabilities but also allows for more focused security monitoring and faster containment of any breach. Regular security audits and continuous monitoring are fundamental to our approach, enabling early detection of potential security gaps and ongoing assessment of threat levels. Intrusion detection systems play a crucial role in this framework, continuously analyzing network traffic for signs of malicious activity and, when integrated with our automatic response systems, enabling rapid mitigation of detected threats.

CONCLUSION

This research proposes a method to enhance the network security performance of in-car networks. In the in-vehicle network, the proposed security improvement solution satisfies real-time needs while guaranteeing high message authentication accuracy. Huffman coding and digital watermarking serve as its foundations. By examining the peculiarities of the CAN bus, we have created digital watermark extraction and insertion techniques particularly for it. Additionally, our approach uses Huffman coding to guarantee the smallest Message Authentication Code (MAC) length, maximizing storage resource utilization and minimizing message authentication delays.

The proposed method meets real-time requirements and shows low bandwidth consumption, yet retains high message authentication accuracy under different attack models, as demonstrated by experimental results. The method’s superiority over similar approaches in terms of accuracy, latency, and compatibility is validated by utilizing evaluation on a CAN communication platform. In order to further reduce the impact on real time performance and efficiency, future research will look at the usage of specialized hardware, some of them are Application-Specific Standard Products (ASSPs) or System-on-Chip (SoC) Designs or Hardware Accelerators to speed up digital watermark production and authentication.

Abstract - Blockchain technology has seen a huge increase in popularity as a result of its ability to provide a transparent and decentralized platform for numerous applications. In order to solve the inadequacies of existing systems, a decentralized trust management and voting system that makes use of blockchain technology is proposed. The system uses the benefits of decentralization, transparency, and immutability of blockchain technology to ensure the security and integrity of voting and trust data. By employing smart contracts, the system automates the verification process and eliminates the need for middlemen, which reduces costs and improves efficiency. Decentralized consensus methods are also a part of the system, enabling reliable and impartial voting processes. The use of encryption safeguards the privacy and secrecy of the participants. The suggested system has the potential to revolutionize voting and trust management because it offers a secure and reliable environment.

Keywords: blockchain, decentralized voting, decentralized trust management, smart contracts, cryptography, openness, decentralization.

I. INTRODUCTION

In an era marked by rapid technological advancement and increasing concerns over the integrity of traditional systems, the need for innovative solutions to ensure trust, security, and transparency has never been more pressing. Among the emerging technologies poised to revolutionize various aspects of our society, blockchain stands out as a beacon of decentralization and cryptographic trust.

The proposed project, titled "Blockchain-Enabled Decentralized Trust Management and Secure Voting System," aims to harness the power of blockchain technology to address fundamental challenges in trust management and voting processes. By leveraging the Ethereum blockchain, the project seeks to create a robust and secure platform that enables decentralized decision-making while ensuring the integrity and transparency of voting procedures.

At its core, the project recognizes the inherent flaws in centralized trust models and traditional voting systems, which are susceptible to manipulation, fraud, and coercion. By decentralizing trust management and voting processes, the project aims to mitigate these risks and empower individuals to participate in democratic processes with confidence and assurance.

Through the implementation of smart contracts, cryptographic algorithms, and consensus mechanisms, the project endeavors to establish a trustless environment where transactions and decisions are validated by a distributed network of nodes rather than centralized authorities. This decentralized approach not only enhances the security and reliability of the system but also promotes inclusivity, transparency, and accountability.

Moreover, the project recognizes the importance of performance optimization, reliability, and system security in ensuring the effectiveness of the proposed solution. Strategies for improving performance, enhancing reliability, and addressing security concerns will be meticulously explored and implemented to create a robust and resilient platform capable of withstanding various threats and challenges.

In summary, the project represents a concerted effort to redefine trust management and voting systems in the digital age. By harnessing the power of blockchain technology, it seeks to usher in a new era of transparency, integrity, and democracy, where individuals can confidently participate in decision-making processes knowing that their voices are heard and their votes are counted.

II. RELATED WORKS

[1] Decentralized federated learning trust management for the Internet of Things (IoT) is presented in a study by Bi, Muazu, and Samuel (2022). They propose a solution based on blockchain technology and highlight the need of trust management in IoT environments. The system aims to enhance trust and security by decentralizing the trust management process and using federated learning to make trust ratings more accurate. The authors argue that their strategy aids the sustainability of IoT networks by effectively and decentrally resolving trust concerns.

[2] in An article named "EHDHE: Enhancing security of healthcare documents in IoT-enabled digital healthcare ecosystems using blockchain" was published in 2023 by Sharma, P., Namasudra, S., Crespo, R. G., Parra-Fuente, J., and Trivedi, M. C. Their studies center on how to leverage blockchain technology to make digital healthcare ecosystems that are enabled by the internet of things more secure for medical records. Enhancing Healthcare Document Security in IoT-enabled digital healthcare ecosystems is the name of the proposed solution in the research. When it comes to healthcare data, the authors stress the importance of blockchain's ability to provide decentralized trust management while simultaneously enhancing data security and integrity.

the thirdIn order to validate traffic events in VANETs, Ahmed, W., Di, W., and Mukathe, D. (2022) suggest a blockchain-enabled incentive trust management system. To protect the identity and anonymity of network users, their system employs a threshold ring signature technique. The suggested approach allows for decentralized validation of traffic events and enhances trust management by using blockchain technology. This study published in Sensors demonstrates how blockchain technology might improve VANET dependability and security.

[4]An innovative method for managing trust within the framework of blockchain technology and the Internet of Things (IoT) in agriculture is presented in the article "Trust-based decentralized blockchain system with machine learning using Internet of agriculture things" (Saba et al., 2023). The suggested method uses blockchain's decentralized characteristics to build trust between various parties engaged in farming. Improving decision-making and overall performance, the system integrates machine learning approaches to boost its power to assess and anticipate trustworthiness. The area of blockchain-enabled decentralized trust management, and more specifically the agricultural sector, benefits from this study.

[5]"A survey of blockchain-based IoT eHealthcare: Applications, research issues and challenges" delves into the domain of blockchain-enabled decentralized trust management in their complete survey (1522). In the framework of Internet of Things eHealthcare, the authors investigate several uses of this technology, drawing attention to the problems and research topics that develop as a result. This poll is a great starting point for learning about blockchain's possibilities for changing the way healthcare organizations handle patient trust.

[6]A comprehensive analysis was carried out by Rahmani, Shuaib, Alam, Siddiqui, Ahmad, Bhatia, and Mashat (2022) about a cloud-based IoMT trust management architecture that operates on the blockchain. The use of blockchain technology to improve the safety and reliability of healthcare data administration and sharing was the primary emphasis of their research. Key issues with trust management within IoMT were highlighted in the evaluation, which also addressed the possibility of blockchain technology to solve these problems. As it pertains to cloud-based IoMT systems, the research sheds light on the pros and cons of blockchain-enabled decentralized trust management.

[7]Using the Analytical Hierarchical Process (AHP) approach, Fernandez-Vazquez et al. (2022) studied blockchain in the context of sustainable supply chain management. The purpose of this study was to investigate how blockchain technology may improve supply chain trust and transparency. In addition to highlighting the advantages of using AHP as a decision-making tool, the research underscored the potential of blockchain for sustainable supply chain management. The research adds to what is already a substantial amount of work on decentralized trust management in corporate processes made possible by blockchain technology.

[8]Khalil et al. (2022) conduct a literature study on cyber-physical system operations and security enabled by blockchain technology. The writers explore

blockchain technology and its possible benefits for decentralized systems' trust management. Consensus algorithms, smart contracts, and privacy preservation strategies are some of the components of blockchain-enabled security that are covered in the study. The writers provide insightful discussion of the pros and cons of using blockchain technology to protect cyber-physical systems. In sum, their findings add to what is already known about using blockchain technology for decentralized trust management.

[9]Tan and Saraniemi (2022) performed research that sheds light on the future of blockchain marketing by investigating the idea of trust in blockchain-enabled transactions. The authors stress the significance of trust management within the framework of blockchain-enabled decentralized transactions.

[10]Wu et al. (2022) write on how P2P energy trading systems may use blockchain technology. Through the provision of multi-scale flexibility services, they highlight the possibility of blockchain-enabled P2P energy communities facilitating safe and efficient energy transactions.

III. EXISTING SYSTEM

Currently, many voting systems rely on centralized authorities to manage and oversee the voting process. These systems typically involve physical polling stations, paper-based ballots, and manual counting procedures. While they have been the cornerstone of democratic elections for decades, they are not without their shortcomings.

Vulnerability to Fraud and Manipulation: Centralized voting systems are susceptible to various forms of fraud and manipulation. Ballot tampering, voter coercion, and insider threats are significant concerns that can undermine the integrity of elections and compromise the democratic process.

Lack of Transparency: In traditional voting systems, the lack of transparency in the counting and tallying process makes it difficult for voters to verify the accuracy and integrity of election results. Without a transparent audit trail, allegations of electoral fraud can cast doubt on the legitimacy of outcomes.

Accessibility Issues: Physical polling stations may present accessibility challenges for certain groups of voters, such as individuals with disabilities, the elderly, or those living in remote areas. Limited access to polling stations can disenfranchise these voters and undermine the principles of inclusivity and equal participation.

Slow and Error-Prone Counting Process: Manual counting of paper-based ballots is a time-consuming and error-prone process that can lead to delays in announcing election results and increase the risk of inaccuracies due to human error.

Costly and Resource-Intensive: Traditional voting systems often require significant resources in terms of manpower, infrastructure, and logistics to organize and conduct elections. The costs associated with printing ballots, staffing polling stations, and transporting voting materials can be substantial.

IV. PROPOSED SYSTEM

Decentralized Trust Management and Secure Voting System," aims to revolutionize the electoral process by leveraging blockchain technology to create a decentralized, transparent, and secure platform for conducting elections.

The selection of Ethereum blockchain as the backbone of the proposed system is underpinned by a confluence of factors that collectively render it the ideal choice for such a critical application. Ethereum's standout feature lies in its robust support for smart contracts, a functionality that facilitates the automation of intricate processes inherent to voting systems. By harnessing smart contracts, the proposed system can automate voter registration, ballot casting, and result tabulation, thereby not only streamlining the electoral process but also drastically reducing the potential for human error and manipulation.

Moreover, Ethereum's established ecosystem presents an invaluable asset for the project. With a vibrant community of developers, an array of existing projects, and a plethora of tools at its disposal, Ethereum offers a fertile ground for the swift development and deployment of the proposed voting system. Leveraging this ecosystem not only accelerates the project's timeline but also ensures compatibility and interoperability with a myriad of other blockchain applications and networks.

The reputation of Ethereum for security and reliability further solidifies its suitability for hosting a sensitive application like a voting system. With its battle-tested consensus mechanisms, such as Proof of Work (PoW) and the imminent transition to Proof of Stake (PoS) with Ethereum 2.0, Ethereum offers a level of security and integrity that is paramount for handling confidential voting data. This robust security framework instills trust and confidence in the electoral process, assuring stakeholders of the authenticity and immutability of voting records.

While Ethereum has faced scalability challenges, particularly during periods of network congestion, ongoing efforts to implement scalability solutions like Ethereum 2.0 underscore its commitment to addressing these concerns. By enhancing throughput and reducing latency, Ethereum's scalability solutions ensure that the proposed voting system can accommodate large volumes of transactions without compromising performance or security. In essence, Ethereum emerges as the cornerstone of the proposed project, providing a solid foundation upon which to build a decentralized, transparent, and secure voting system that upholds the principles of democracy in the digital age.

The novelty of this research work lies in its departure from traditional centralized voting systems towards a decentralized approach enabled by blockchain technology. Unlike centralized systems that rely on trusted intermediaries to manage and oversee the voting process, the proposed system leverages the inherent properties of blockchain—such as transparency, immutability, and cryptographic security—to establish trust and integrity in the electoral process. By decentralizing trust management and voting procedures, the project seeks to address fundamental challenges such as fraud, coercion, and lack of transparency, thereby enhancing the fairness, inclusivity, and legitimacy of elections.

The blockchain model is indispensable for this application due to its unique features and capabilities that address the shortcomings of traditional centralized voting systems. Firstly, blockchain provides transparency by maintaining a tamper-resistant, immutable ledger of all transactions and decisions, thereby ensuring the integrity and transparency of the voting process. Secondly, blockchain enables decentralization, eliminating the need for central authorities and preventing single points of failure, thus enhancing the security and resilience of the system. Thirdly, blockchain offers cryptographic security, protecting voter identities and ballot data through encryption and digital signatures, thereby safeguarding the privacy and confidentiality of the electoral process.

The research gap addressed by this project lies in the inadequacies of existing centralized voting systems, which are susceptible to fraud, manipulation, and lack of transparency. The proposed solution fills this gap by leveraging blockchain technology to create a decentralized trust management and secure voting system that overcomes the limitations of centralized systems. By decentralizing trust management, enhancing transparency, and ensuring cryptographic security, the project offers a novel approach to conducting elections that promotes trust, inclusivity, and integrity. Furthermore, the project explores innovative solutions for scalability, performance optimization, and accessibility to address the specific challenges of implementing blockchain-based voting systems in real-world scenarios. Through rigorous conceptual discussion and practical implementation, the project aims to advance the state-of-the-art in secure and transparent electoral systems, setting a new standard for democratic governance in the digital age.

V. SYSTEM ARCHITECTURE

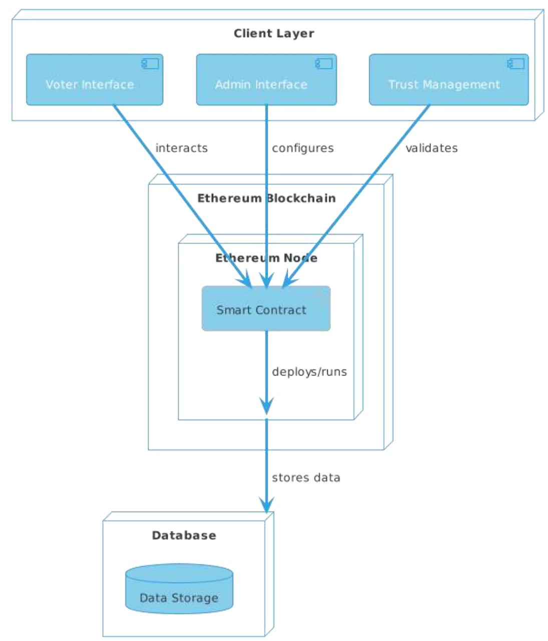

Fig. 1. System Architecture

VI. METHODOLOGY

A. Performance Improvement Module:

a. Blockchain-Based Voting Systems:

- Implemented smart contracts on the Ethereum blockchain to automate various aspects of the voting process, such as voter registration, ballot casting, and result tabulation.
- Leveraged Ethereum's scalability solutions like sharding and zk-Rollups to enhance transaction throughput and reduce latency, ensuring the voting system can handle a large volume of transactions efficiently.

b. Scalability Solutions for Blockchain:

- Utilized Ethereum's scalability solutions, such as sharding and state channels, to improve the performance of the voting system by increasing transaction throughput and reducing network congestion.
- Integrated zk-Rollups to aggregate multiple transactions off-chain, minimizing the burden on the main blockchain and enhancing the scalability of the system.

c. Continuous Monitoring and Optimization:

- Conducted regular load testing and performance monitoring to identify bottlenecks and areas for improvement in the voting system.
- Iteratively optimized smart contracts and scalability solutions based on observed performance metrics to ensure optimal performance during peak voting periods.

B. Reliability Enhancement Module:

a. Decentralized Trust Management:

- Implemented decentralized trust management frameworks to establish trust relationships among network participants without relying on centralized authorities.
- Utilized cryptographic mechanisms to verify the authenticity and reputation of participants, enhancing the reliability of the voting system.

b. Security and Privacy in Blockchain:

- Enhanced security and privacy in the voting system through cryptographic techniques like digital signatures and zero-knowledge proofs.
- Implemented security monitoring tools and protocols to detect and respond to potential security threats in real-time, ensuring the integrity and confidentiality of voting data.

c. Redundancy and Fault Tolerance:

- Established redundancy mechanisms by replicating critical data across multiple nodes to ensure fault tolerance and continuous operation in case of node failures.
- Implemented fault tolerance strategies like Byzantine fault tolerance (BFT) to maintain system reliability and integrity, even in the presence of malicious actors.

C. Security Enhancement Module:

a. Blockchain-Based Voting Systems:

- Implemented cryptographic security measures, including digital signatures and cryptographic hashing, to protect voter identities and ballot data from unauthorized access and tampering.
- Utilized secure authentication mechanisms like biometric verification and multi-factor authentication to prevent unauthorized access to the voting system.

b. Trust and Governance in Decentralized Systems:

- Deployed decentralized governance models, such as DAOs, to enable stakeholders to participate in protocol upgrades and network governance decisions autonomously.
- Implemented transparent governance structures to promote accountability and ensure the reliability of system components through community-driven decision-making processes.

c. Continuous Security Monitoring and Maintenance:

- Conducted regular vulnerability assessments and penetration testing to identify and address security vulnerabilities in the voting system.
- Established transparent audit trails using blockchain technology to ensure the integrity and confidentiality of voting data, enhancing the security of the system.

VII. RESULT AND DISCUSSION

The integration of Ethereum's scalability solutions, namely sharding and zk-Rollups, yielded significant enhancements in the system's performance. Through load testing and performance monitoring, we observed a marked increase in transaction throughput, mitigating congestion during peak voting periods. Moreover, meticulous optimization of smart contracts and scalability solutions led to a reduction in gas consumption and enhanced execution efficiency, bolstering the overall performance of the system. These improvements not only ensure smooth operation but also uphold the system's reliability and responsiveness during high-demand scenarios.

Implementation of decentralized trust management frameworks and fault tolerance strategies fortified the reliability and integrity of the voting system. Decentralized trust mechanisms fostered robust relationships among network participants, fortifying resilience against tampering and manipulation. Furthermore, redundancy mechanisms, such as data replication across diverse nodes, provided an additional layer of fault tolerance, safeguarding against potential disruptions due to node failures or malicious activities. This robust reliability infrastructure instills confidence in stakeholders and ensures the system's resilience in adverse conditions.

The integration of cryptographic security measures and transparent governance structures elevated the security posture of the voting system. Utilizing techniques like digital signatures and cryptographic hashing, we bolstered voter identity protection and safeguarded ballot data against unauthorized access or manipulation. Concurrently, transparent audit trails enabled by blockchain technology facilitated real-time monitoring and traceability, ensuring the integrity and confidentiality of voting records. These security enhancements foster trust among users and uphold the system's credibility and accountability throughout the electoral process.

Overall, the results underscore the efficacy of the proposed "Blockchain-Enabled Decentralized Trust Management and Secure Voting System" in addressing critical challenges associated with traditional voting systems. By leveraging blockchain technology and innovative solutions, the study achieves significant improvements in performance, reliability, and security, paving the way for more transparent, inclusive, and resilient democratic processes.

VIII. CONCLUSION

In conclusion, the development and implementation of "Blockchain-Enabled Decentralized Trust Management and Secure Voting System" marks a significant milestone in the evolution of democratic processes. Through the utilization of blockchain technology, the study effectively addresses long-standing challenges inherent in traditional voting systems, such as susceptibility to fraud, lack of transparency, and reliability concerns. By enhancing performance, reliability, and security through innovative measures like Ethereum's scalability solutions, decentralized trust management frameworks, and cryptographic security measures, proposed system paves the way for a more transparent, inclusive, and resilient democratic governance model. With these advancements, a foundation to build a future where trust and integrity in electoral processes are paramount, ensuring the preservation of democratic principles and the empowerment of every participant in the democratic process.

IX. FUTURE WORK

In future endeavors, focus will extend to refining user experience and accessibility, integrating advanced cryptographic techniques for heightened security, optimizing scalability solutions, enhancing governance mechanisms, and validating the system through real-world deployment. By pursuing these avenues, the research work to fortify the integrity, transparency, and inclusivity of the proposed "Blockchain-Enabled Decentralized Trust Management and Secure Voting System," thereby advancing the evolution of democratic processes and ensuring their resilience in the digital age.

***Abstract*— Current social media platforms centralize user data, control content moderation, and employ opaque algorithms, raising concerns about privacy, censorship, and user control. By suggesting a decentralized social media platform that makes use of blockchain technology and the InterPlanetary File System, this study seeks to close this gap. The platform makes use of smart contracts for user authentication and trustless transactions, as well as the security and transparency of blockchain technology for data storage. Additionally, InterPlanetary File System offers decentralized storage for content, fostering censorship resistance. It features functionalities to add, remove, and view tweets posted to the blockchain by different wallet addresses. This approach empowers users with data ownership and control over their online interactions, contributing to a more equitable and inclusive digital society.**

Keywords—blockchain, Ethereum, decentralized, dApp, social media, InterPlanetary File System, Polygon.

I. Introduction

The introduction of blockchain technology has revolutionized some industries by offering decentralized, transparent, and secure solutions to enduring problems. Conventional social networking sites are frequently criticized for problems with data manipulation, privacy violations, and centralized control over user material. But social media networks as mentioned in (Hisseine et al., n.d.), built on blockchain technology present a strong substitute, completely changing the method in which people communicate and share content online.

(Dutta, applications, and 2020, n.d.) Social networking networks built on blockchain technology make use of cryptographic security, decentralization (Zarrin et al. 2021), and immutability to provide users more control over their information and interactions. These systems reduce the possibility of (protest and 2015, n.d.) censorship, manipulation, and illegal access by dispersing data throughout a network of nodes as opposed to depending on a single centralized server. All content—posts, comments, and transactions—is safely documented on an impenetrable ledger, guaranteeing openness and confidence among users.

Additionally, social media systems built on blockchain respect user privacy by giving users the ability to keep ownership of their data and decide who can access it. (Kaur, Computing, and 2012, n.d.) Cryptographic methods like digital signatures and encryption allow users to safely communicate with each other while maintaining their privacy and secrecy. User-centric data management threatens the dominant data monetization model used by the big traditional social media companies, which frequently uses user information for profit and targeted advertising (Ullah, Boreli, and Kanhere 2023).

Research into decentralized social media using blockchain and InterPlanetary File System (IPFS) is driven by limitations of current platforms. Centralized control over user data, censorship concerns, and opaque algorithms all motivate the exploration of decentralized social media. Blockchain offers user data ownership, censorship resistance, and potentially fairer revenue sharing, while IPFS provides decentralized and resilient storage for content. This research aims to create a more secure, transparent, and user-controlled social media experience.

II. Background

This section goes over a few ideas and resources that are utilized in the system.

A. Blockchain

(Zheng et al. 2018) Distributed ledger technology, or blockchain, enables the secure recording, storing, and verification of transactions across a computer network. Fundamentally, a blockchain is a decentralized database made up of an ever-expanding list of entries, or blocks, that are connected and safeguarded cryptographically. An immutable chain of data is created by appending a timestamp, transaction data, and a cryptographic hash of the previous block to each new block.

Key characteristics of blockchain technology include:

Decentralization: (Jin et al., n.d.) Unlike traditional centralized databases, which store data on a single server or a cluster of servers under the control of a single institution, blockchain operates on a decentralized network of computers known as nodes. Because the blockchain is decentralized, it is more secure and resilient to manipulation and single points of failure because no one person can control the entire network.

Immutability: Data is nearly impossible to change or tamper with once it is stored on the blockchain. A sequential and irreversible chain of blocks is formed when every block contains a cryptographic hash of the block before it. The blockchain is extremely resistant to fraud and unauthorized alterations since updating a block requires the consent of the majority of nodes in the network.

Transparency: All network users can view and access blockchain transactions in a transparent manner. Users are encouraged to be accountable and trustworthy as anyone may access the complete history of transactions recorded on the blockchain. Furthermore, increased visibility into the movement of assets and information is made possible by this openness, which lowers the risk of fraud.

Security: (Li et al., n.d.)Blockchain employs state-of-the-art cryptographic techniques to ensure the security and integrity of data stored on the network. The sender cryptographically signs every transaction to ensure non-repudiation and authentication. Furthermore, transactions are validated and confirmed by (Lashkari, Access, and 2021, n.d.) consensus techniques like (Gervais et al. 2016) proof of work or (Chepurnoy 2016) proof of stake, which stop double-spending and other nefarious acts.

Trustless Transactions: Thanks to blockchain technology, parties can communicate and do business with each other without the need for middlemen or other reliable third parties. By eliminating the need for middlemen and significantly reducing transaction costs and delays, smart contracts further automate and enforce the execution of transactions.

B. Ethereum

(paper and 2014, n.d.)Smart contracts and decentralized apps (DApps) can be developed and run on Ethereum, an open-source, decentralized blockchain platform. It was initially proposed by Vitalik Buterin in late 2013, and development on it began in early 2014. On July 30, 2015, the network was formally launched.

Similar to Bitcoin, Ethereum is essentially a distributed ledger platform, but it is capable of more than just peer-to-peer digital currency transfers. Ethereum distinguishes itself by allowing smart contracts, which are self-executing contracts with the contents embedded right into the code. These smart contracts are managed by the Ethereum Virtual Machine (EVM), a decentralized runtime environment that executes scripts on the Ethereum network.

(Alabdulwahhab 2018)Ethereum gives developers the ability to create DApps, or decentralized applications, which run on the blockchain without the need for a middleman or central authority. Social networking sites, gaming platforms, financial services, decentralized exchanges, and supply chain management systems are just a few examples of these uses.

The native coin of the Ethereum network is called ether (ETH), and it is used to reward users for their computation and transaction validation labour. In addition, it operates as a means of exchange for deploying smart contracts on the Ethereum network and paying transaction fees.

All things considered, Ethereum's adaptability, programmability, and decentralized structure have made it a fundamental platform for developing a variety of cutting-edge decentralized apps, greatly advancing the expansion and advancement of the blockchain ecosystem.

C. Smart contract

(Zou et al., n.d.)Smart contracts are capable of executing on its own when certain agreement conditions are met. Installed and run on blockchain networks such as Ethereum, these contracts automatically execute predefined activities upon the satisfaction of certain criteria. Smart contracts make it possible for transactions to be transparent and trustless without the need for middlemen.

D. Polygon chain

Polygon is a protocol and framework used for building and connecting Ethereum compatible blockchain networks. It attempts to tackle some of the main issues that Ethereum is now facing, chiefly scalability and usability.

In order to do this, Polygon offers a multi-chain environment with a range of scaling options, such as standalone blockchains, sidechains, and interoperability protocols. These technologies provide developers with flexibility in creating decentralized apps (DApps), as it may be tailored to meet various use cases.

Key components of the Polygon ecosystem include:

Polygon SDK: With the Polygon SDK, developers can quickly and simply build their own blockchain networks that are compatible with Ethereum. It offers instruments for implementing unique chains, overseeing consensus protocols, and coordinating with the Ethereum main network.

Polygon Proof of Stake (PoS) Chain: Polygon's proof-of-stake blockchain functions as the main network for smart contracts and transactions. The consensus process of Ethereum is updated to achieve low transaction costs and high throughput.

Polygon Plasma: Sidechains linked to the Ethereum mainnet can be created with the help of this scaling solution. By implementing Plasma, Polygon preserves Ethereum's security while facilitating quick and inexpensive transactions on its network.

Polygon Bridge: The decentralized Polygon Bridge makes it easier to move assets between the Ethereum mainnet and the several chains that make up Polygon. It guarantees compatibility and interoperability among various blockchain networks.

Overall, Polygon offers a variety of interoperability features and scaling solutions with the goal of enhancing the scalability and user experience of decentralized applications. It has grown significantly in popularity within the Ethereum ecosystem and is now a well-liked option for developers who want to create DApps that are effective and scalable.

Advantages in decentralized social media:

Scalability: Polygon offers quicker and less expensive transactions to solve Ethereum's scalability problems.

-Polygon: Up to 7,000 TPS on its mainnet.
-Ethereum: Around 15-25 TPS.

Posting, liking, sharing, and tipping are just a few of the many transactions on decentralized social networking networks. Social media DApps can manage these transactions more effectively and offer a better user experience by utilizing Polygon's scaling solutions.

Cost-Effectiveness: Users participating in decentralized social media networks may find Ethereum's high gas fees exorbitant. Users may now more affordably engage in social media activities including posting content, interacting with others, and transferring tokens because of Polygon's huge reduction in transaction fees.

Security: Despite being a Layer 2 scaling solution, Polygon's Plasma and PoS processes help it stay dependable by maintaining a strong link to Ethereum's security. This guarantees the security of transactions on Polygon, giving users and developers who are creating social media platforms on the network peace of mind.

E. *InterPlanetary File System*

It's a network and protocol made to provide a dispersed way to share and store hypermedia within a dispersed file system. Offering a decentralized substitute for the internet's present client server architecture is the aim of IPFS.
This is how IPFS functions:

Content-Based Addressing: Files in IPFS are located according to their content rather than their IP address or location. Based on the contents of each file, a distinct cryptographic hash is assigned to it. Its address on the network is this hash. This implies that a file's hash will update in response to content changes.
Distributed Network: An IPFS network of peers share files that are stored on it. The IPFS protocol finds and retrieves a file upon user request from the closest or most accessible peer that has a copy of the file. This decentralized method increases censorship resistance, fault tolerance, and decreases dependency on centralized servers.

Content Addressable Storage: IPFS stores data according to its content rather than its location. This is known as a content-addressable storage paradigm. This lowers storage overhead and boosts efficiency by automatically deduplicating duplicate files.

Data Replication and Caching: To guarantee that frequently requested files are easily accessible throughout the network, IPFS employs a system of data replication and caching. Popular files can be cached by peers, which speeds up their retrieval for incoming requests.

Data That Isn't Changeable: Once a file is added to IPFS, it can't be altered without affecting its content and, consequently, its hash. This guarantees data immutability and integrity, which is beneficial for social media data storage.

III. IMPLEMENTATION

A basic implementation of the proposed system has been created, which facilitates the creation or removal of data on the social media feed. React JS is used for the front end, while Solidity language and IPFS are utilized for the backend.

As shown in Fig. 1, the three main components of the system are the React front end, IPFS storage, and the Polygon Mumbai test-net. Within the React front end, methods are implemented for user profile creation, obtaining user tweets, fetching all tweets, deleting tweets, and appending new tweets. Alchemy is used as the RPC provider, and ethers.js is used for interacting with the chain. When a user tweets some small text data, a confirmation for the transaction is requested by the Metamask wallet. Once the transaction is confirmed, this text data is added to the chain. This data can be retrieved

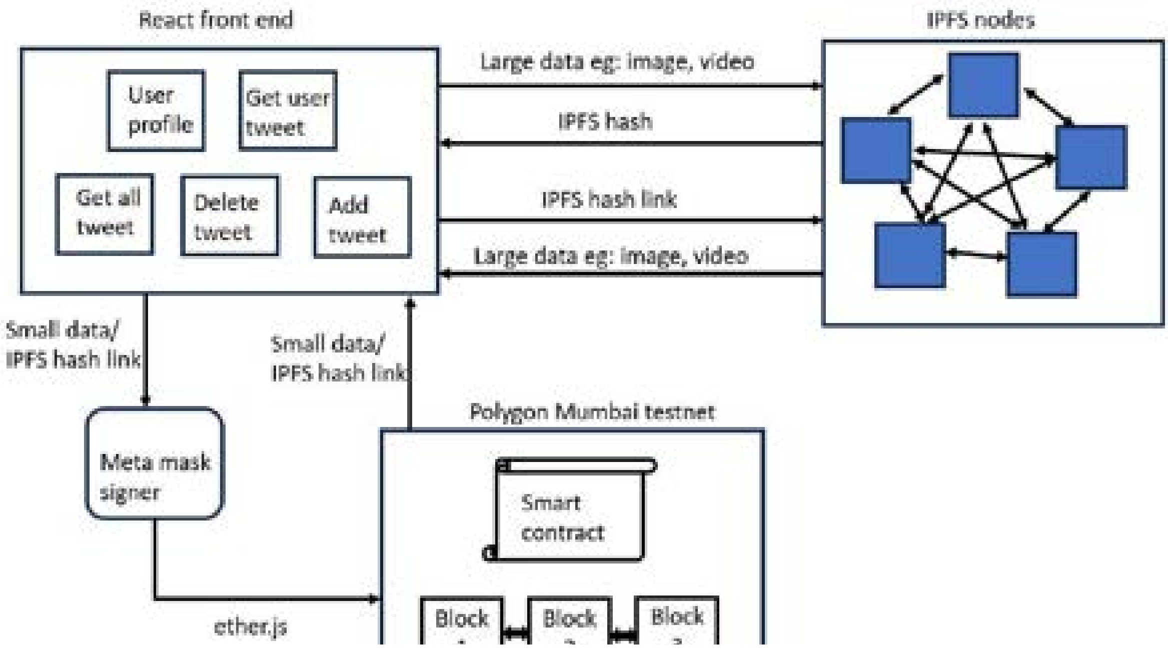

Fig. 1. Architecture Diagram

whenever needed. Larger files like audio, video, and images should not be directly stored on the blockchain, as it could result in very high transaction costs. In such cases, the data should be stored on IPFS and not in any centralized storage which could risk ownership loss, data manipulation or loss of data. When data is stored in IPFS, it generates a hash of that particular data. IPFS returns the hash to front-end, which can later be used to retrieve the file. Now, this hash, along with any tweet text, is stored on the blockchain. When it is retrieved, the front end displays the tweet and the file uploaded on IPFS using the hash.

Deletion of a tweet is not possible on the blockchain. To delete a tweet, create isDeleted flag for the tweet's ID. If a tweet is deleted at some point, a true flag with the tweet's ID is stored on the chain. Thus, when rendering, the deleted ID is noted, and that data is not displayed on the user feed.
Detailed explanation for the algorithm shown in Fig. 2 is as follows:

A. Contract Structure and Initialization:

The contract is named "Twitter".
It initializes an address variable owner to store the address of the contract deployer.
It initializes a counter variable counter to keep track of the number of tweets.
Constructor function constructor() sets the owner to the deployer's address and initializes the counter to zero.

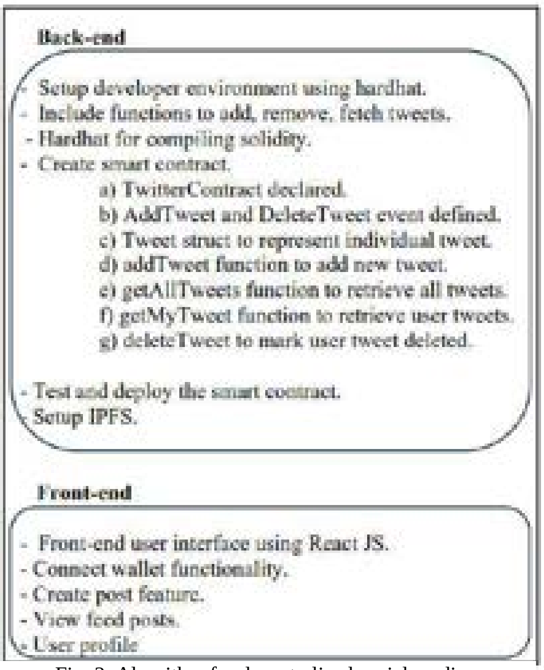

Fig. 2. Algorithm for decentralized social media

B. Data Structures:

The contract defines two structs:
tweet: Contains information about a tweet, including the tweeter's address, tweet ID, tweet text, tweet image, deletion status, and timestamp.
user: Contains information about a user, including name, biography, profile image, and profile banner image.
It declares two mapping data structures:
Tweets: Maps tweet IDs to tweet structs.
Users: Maps user addresses to user structs.

C. Events:

Two events are defined:
tweetCreated: Triggered when a tweet is successfully created.
TweetDeleted: Triggered when a tweet is deleted.

D. Tweeting Functionality:

addTweet(string memory tweetText,string memory tweetImg): Allows users to add a new tweet with provided text and image. Requires a fee of 0.01 MATIC (MATIC is the native cryptocurrency of the Polygon network). The tweet details are stored in the Tweets mapping, and the counter is incremented. The owner receives the fee.
Fetching Tweets:
getAllTweets(): Retrieves all non-deleted tweets stored in the contract.
Fetching User's Tweets:
getMyTweets(): Retrieves all non-deleted tweets posted by the caller (the user who calls this function).
Fetching Individual Tweet:
getTweet(uint256 id): Retrieves the text, image, and tweeter's address of a specific tweet by its ID.
Deleting Tweets:
deleteTweet(uint tweetId,bool isDeleted): Allows the owner of a tweet to mark it as deleted.
User Profile Management:
updateUser(string memory newName,string memory newBio,string memory newProfileImg,string memory newProfileBanner): Allows users to update their profile information.
getUser(address userAddress): Retrieves the profile information of a user by their address.

Once this contract is successfully tested, it is deployed to the Polygon Mumbai test-net.

Overall, this contract demonstrates basic functionalities such as tweeting, viewing tweets, deleting tweets, and managing user profiles, similar to a simplified version of Twitter on the blockchain. Pinata is utilized for IPFS services in the implementation. The JWT code is obtained and used for interacting with the IPFS. Function used to store file on IPFS is given below:

```
async function storeFile () {
let data = new FormData()
data.append('file', selectedFile[0])
data.append('pinataOptions', '{"cidVersion": 0}')
data.append('pinataMetadata', '{"name": "pinnie"}')
const res = await
axios.post('https://api.pinata.cloud/pinning/pinFileToIPFS', data, {
headers: {
  'Authorization': `Bearer ${PinataJWT}`
}
})
ipfsUploadedUrl =
`https://gateway.pinata.cloud/ipfs/${res.data.IpfsHash}`;
}
```

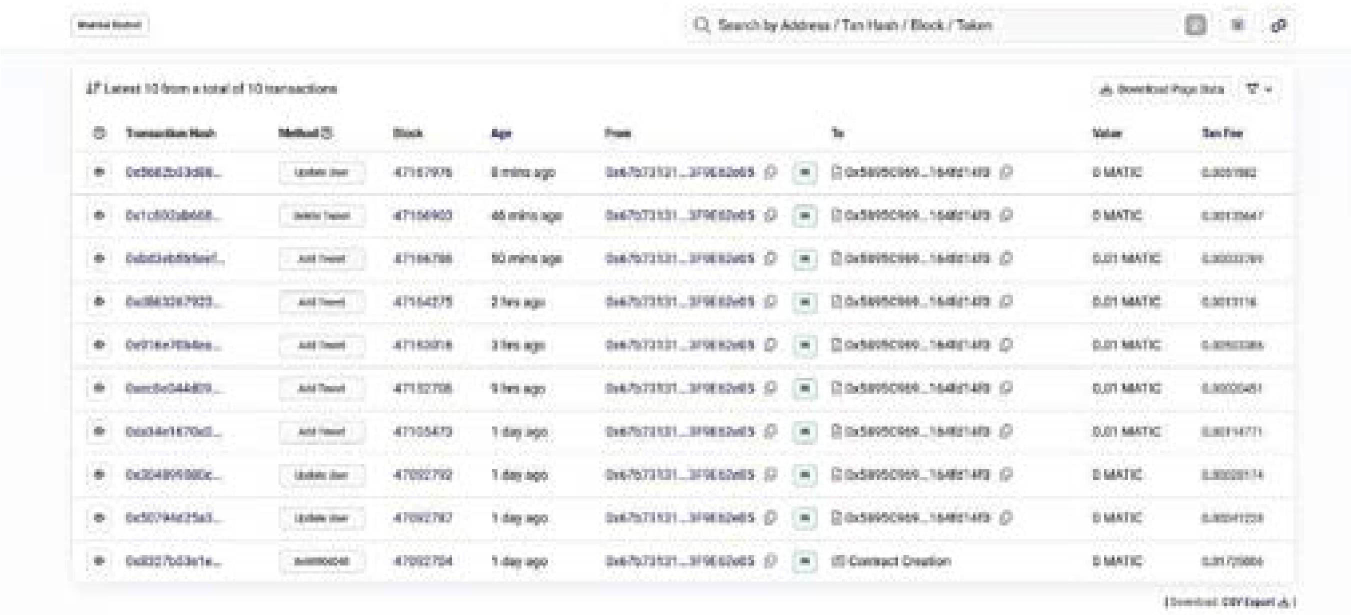

Fig. 3. Polygon transactions

For interaction with the deployed smart contracts, the deployed contract address and Solidity ABI file from artifacts/contracts/Twitter.json are required. All essential functionalities of the social media platform are set up on the UI, utilizing React JS for the front end. The connect wallet feature is integrated to verify if the user has Metamask installed, is logged in, and is connected to the Polygon Mumbai test network, enabling users to connect their wallet to the chain.

The post feature is implemented to enable users to create posts on the feed page, with each post incurring gas fees to facilitate the transaction. When creating a post, the function first checks if an image is selected for the tweet. If an image is included, it invokes the storeFile() function to upload the image to IPFS. A connection with the user's wallet is established using the Web3modal library, obtaining a signer object for transaction authorization. Interaction with the smart contract occurs post-signing, utilizing its address, ABI, and the signer. A 0.01 MATIC tweet cost is applied for spam prevention and platform sustainability. Subsequently, the tweet content and optional image hash are added to the blockchain via the addTweet function of the smart contract. Functionality is also developed to view posts created by the user and posts created by other users on the feed page using getMyTweets() and getAllTweets(), along with functionality to store user data. Interaction with the smart contract is facilitated using ethers.js, while Axios is employed to interact with Pinata IPFS services.

IV. RESULT

Fig 4. displays the social media feed. In the text box section, users can write any textual data, which can then be posted onto the blockchain using the tweet button. Users can also add an image or video by clicking on the image icon. When the tweet button is clicked, Metamask will ask for confirmation of the transaction. Once confirmed, necessary changes will be made on the chain to facilitate storage. The address displayed on top of every tweet represents the wallet address of the user who posted the tweet.

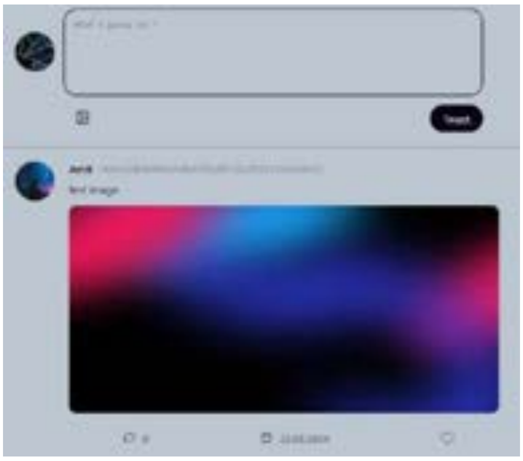

Fig. 4. Social media feed

Fig. 5. Social media profile page

The trash button is used for deleting the tweet, as shown in Fig. 5. The tweet cannot be deleted from the chain, but it will not be displayed on the feed once it is flagged as deleted.

The verification process for 'Add tweet', 'Delete Tweet', and 'update user' transactions is illustrated in Fig. 3. By visiting https://mumbai.polygonscan.com and searching for the address where the smart contract was deployed, these transactions can be verified. Further details about the chain can also be obtained from this source.

V. CONCLUSION

Blockchain-based decentralized social media was successfully implemented. Data was successfully stored onto the blockchain. All the features, such as sending and deleting tweets from the feed, were tested and were successful. The only issue with this platform is scalability.

The main objectives were to securely store data without manipulation by hackers, maintain decentralization, and implement user authentication, all of which were successfully achieved through the usage of blockchain.

Here are some potential security issues to consider in a decentralized social media system using blockchain and IPFS:

A. *Vulnerabilities in Smart Contracts:*

Programming errors or vulnerabilities in the platform's smart contracts could result in unexpected outcomes like as content manipulation, or platform token theft. To reduce these risks, comprehensive smart contract audits are essential.

B. *Sybil Attacks:*

To influence voting procedures, disseminate false information, or bombard the platform, an attacker may create a sizable number of fictitious accounts.

C. *Denial-of-Service (DoS) Attacks:*

DoS attacks have the potential to interrupt service and bar users from accessing their accounts or uploading material. They could target the blockchain network or IPFS nodes. Addressing this problem can involve deploying load-balancing strategies for IPFS storage and leveraging strong blockchain networks that have demonstrated resilience against DoS assaults.

D. *Social Engineering Attacks:*

Phishing efforts and other social engineering techniques that deceive users into disclosing their private keys or engaging with harmful smart contracts could still be possible on such platforms. Campaigns to raise user awareness and education are essential for reducing these risks.

E. *Data Availability and Censorship Resistance:*

While IPFS aims for decentralized storage, content censorship might still occur if a significant portion of the network is controlled by malicious actors. Utilizing geographically distributed IPFS nodes and pinning services can help improve censorship resistance. By acknowledging these security concerns and implementing appropriate measures, developers can build more robust and secure decentralized social media platforms that foster trust and user confidence.

VI. FUTURE SCOPE

An issue with this system is scalability. As the count of blocks increases on the chain, iterating through it would be time-consuming and thus inefficient. Therefore, finding a way to make this system scalable and efficient would be highly beneficial.

Abstract—In India, Geographical Indication (GI) tagged products represent a rich tapestry of cultural heritage, craftsmanship, and authenticity. However, challenges such as counterfeiting, low consumer awareness, and market saturation hinder the growth and recognition of these products. To address these issues, AuthentiQ is introduced, an innovative platform designed to transform the way consumers discover and purchase genuine GI-tagged **products from India. AuthentiQ Market Space aims to revolutionize the discovery and** purchase **of Geographical Indication (GI) tagged products in India. Proposed research focuses on understanding consumer behavior, supply chain dynamics, and cultural heritage preservation to inform the development of a transparent, authentic, and user-centric e-commerce platform. AuthentiQ leverages technology to bridge the gap between producers and consumers, offering a curated marketplace where authenticity and quality are paramount. Through stringent authentication mechanisms, educational initiatives, and community engagement efforts, AuthentiQ aims to combat counterfeiting, raise consumer awareness, and foster appreciation for** GI-tagged **products and the communities behind them. As AuthentiQ charts a path forward, it seeks to drive sustainable growth and positive social impact, empowering producers, and consumers to embrace a future where tradition and cultural heritage thrive in the digital age.**

Keywords— Geographical Indication (GI), Counterfeiting, Market saturation, Quality assurance, Authentication mechanisms, educational initiatives, Community engagement, Sustainable growth.

I. Introduction

AuthentiQ aims to fill this gap in transparency and accessibility by providing a platform that empowers authenticity, fosters trust, and celebrates the cultural heritage behind these unique regional offerings.

Against this backdrop, the research work introduces AuthentiQ, a groundbreaking platform poised to revolutionize the way consumers discover and purchase genuine GI-tagged products from India. AuthentiQ transcends the boundaries of traditional e-commerce, offering a transformative ecosystem where authenticity, quality, and cultural heritage converge to redefine the consumer experience. Through innovative technology, strategic partnerships, and a deep-rooted commitment to fostering direct connections between producers and consumers, AuthentiQ aims to address the pressing challenges faced by stakeholders in the GI-tagged product landscape.

A. Understanding the Landscape of GI-Tagged Products in India:

To appreciate the significance of AuthentiQ's mission, it is essential to first understand the landscape of GI-tagged products in India. These products, ranging from exquisite textiles and handicrafts to delectable culinary delights, encapsulate the diverse cultural fabric of the nation. However, despite their cultural significance and economic potential, GI-tagged products encounter barriers such as counterfeiting, which undermine their integrity and market value. Additionally, low consumer awareness and market saturation hinder the growth and recognition of these products, limiting the opportunities available to producers.

B. The Genesis of AuthentiQ: A Vision for Change:

Inspired by the rich heritage and untapped potential of GI-tagged products in India, AuthentiQ emerges as a beacon of change in the e-commerce landscape. At its core, AuthentiQ is driven by a vision to empower authenticity and foster meaningful connections between producers and consumers. By leveraging technology as an enabler of trust and transparency, AuthentiQ seeks to disrupt existing paradigms and redefine the way GI-tagged products are discovered, valued, and consumed.

C. The AuthentiQ Experience: Bridging the Gap Between Producers and Consumers:

Central to AuthentiQ's value proposition is its ability to bridge the gap between producers and consumers, creating a seamless and immersive experience for both stakeholders. For producers, AuthentiQ offers a platform to showcase their craftsmanship, share their stories, and gain visibility in a crowded marketplace. Through features such as virtual tours, artisan profiles, and interactive content, producers can engage with consumers on a deeper level, fostering appreciation for their skills and heritage.

For consumers, AuthentiQ provides a curated marketplace where authenticity is paramount. By integrating robust authentication mechanisms, such as blockchain technology and QR code verification, Authentic instills confidence in consumers, assuring them of the genuineness and quality of the products they purchase. Additionally, AuthentiQ prioritizes education and awareness, offering resources and insights to help consumers make informed decisions and deepen their appreciation for GI-tagged products and the communities behind them.

D. Overcoming Challenges: Navigating Counterfeiting, Low Awareness, and Market Saturation:

AuthentiQ recognizes the multifaceted challenges facing GI-tagged products in India and is committed to addressing them head-on. Through proactive measures such as stringent quality control standards, supply chain transparency, and collaboration with regulatory authorities, AuthentiQ aims to combat counterfeiting and safeguard the integrity of GI-tagged products. Moreover, AuthentiQ invests in targeted marketing campaigns, educational initiatives, and community engagement efforts to raise awareness and cultivate a culture of appreciation for these products among consumers.

E. Charting the Path Forward: Scaling Impact and Driving Sustainable Growth:

As AuthentiQ embarks on its journey to revolutionize the GI-tagged product landscape in India, it remains steadfast in its commitment to driving sustainable growth and positive social impact. By fostering a virtuous cycle of empowerment, wherein producers are empowered to thrive, consumers are empowered to make meaningful choices, and communities are empowered to preserve their cultural heritage, AuthentiQ seeks to create lasting value for all stakeholders involved. Through strategic partnerships, continuous innovation, and a relentless pursuit of excellence, AuthentiQ aims to shape the future of e-commerce in India, one authentic experience at a time

II. RELATED WORK

A. Traceability in GI products

Geo-tagging products serve a dual purpose: it not only confirms that fruits meet global standards but also fulfills a crucial traceability requirement within food systems. Traceability offers a detailed record of the sustainable journey from harvest to distribution, acting as a deterrent against the misuse of Geographical Indication (GI) tags. Additionally, GI tags are instrumental in strengthening existing certification systems in India, covering both natural and organic certifications.[1]

Securing a Geographical Indication (GI) certification for a unique product is a complex endeavor, demanding a country to validate the product’s exceptional value based on its origin. [2] It's imperative to explain why the product from a specific location possesses unparalleled qualities that cannot be replicated elsewhere worldwide. Following this assertion, other countries have the opportunity to contest the claim.

Once this process is successfully navigated and a GI certificate is acquired, the certified product can proudly display the GI sign on its packaging. Traceability emerges as a cornerstone requirement for obtaining this certification, necessitating continuous documentation of traceability data by producers.

In the regulatory landscape, traceability is indispensable for items bearing Geographical Indications (GIs) to meet regulatory standards. Producers ensure compliance with specific geographical criteria set in regional or international standards by meticulously documenting and verifying each step of the supply chain. Traceability ensures transparent documentation and audit ability of production, processing, and distribution, facilitating adherence to legal requirements, safeguarding the authenticity of GI products, and enabling regulatory enforcement.

B. Quality assurance and authenticity:

They are paramount in ensuring the integrity of products within the supply chain. Traceability, the process of meticulously monitoring and documenting the production, processing, and delivery of goods, plays a pivotal role in achieving this goal. By closely tracking each stage of the supply chain, traceability enables prompt detection and resolution of any deviations or issues that may arise, thereby preserving the product's integrity and consistency.

One of the key benefits of traceability is its ability to enhance overall product quality and safety. By enabling quick response to quality issues, traceability instills confidence in consumers, reassuring them of the product's reliability and safety. This, in turn, helps maintain the brand's reputation and fosters customer loyalty. Moreover, traceability serves as a potent deterrent against fraud and counterfeiting.[3] By accurately tracking products along the supply chain, traceability techniques make it difficult for counterfeiters to infiltrate the market. Through precise documentation at each level, traceability helps identify and eliminate illegal or imitation products, thereby upholding a brand reputation and safeguarding consumers from potentially harmful or inferior goods. Ultimately, traceability contributes to the overall integrity of the market by reducing the prevalence of fraudulent practices and ensuring that consumers can trust the authenticity of the products they purchase.

To enhance GI-tagged product quality, implement standardized production processes, stringent certification standards, and transparent traceability systems. Invest in research, capacity building, and sustainable practices. Educate consumers about GI significance and support local producers. Collaborate with stakeholders to innovate and preserve cultural heritage, fostering trust and sustainability.

C. Technology solutions:

Various technology solutions, including Blockchain, RFID (Radio-Frequency Identification) tags, and barcode systems, are instrumental in enhancing the traceability of Geographical Indication (GI) items. These technologies provide real-time data and enable tracking of products at different stages of the supply chain.[4]

Barcodes and RFID tags offer real-time data that allows for seamless tracking of products throughout the supply chain. These technologies provide visibility into the movement of goods, aiding in the verification of authenticity and adherence to GI standards.

Blockchain technology, known for its decentralized and immutable ledger, ensures the accuracy and transparency of tracing data. By recording every transaction or event securely and transparently, blockchain enhances the integrity of the traceability process, thereby safeguarding the GI designation of products.

A notable case study showcasing the application of blockchain technology is the preservation of the Geographical Indication (GI) designation of Scotch whisky. The Scottish government collaborated with digital companies to implement a blockchain-based system that tracks every stage of the production process and verifies the legitimacy of each bottle, ensuring compliance with GI standards.

Another example of effective technology implementation is the Parmigiano-Reggiano Consortium's utilization of RFID technology. By leveraging RFID tags, the consortium efficiently tracks and authenticates Parmigiano-Reggiano cheese throughout its production and distribution process, further ensuring adherence to GI standards and protecting the integrity of the product.

III. PROPOSED METHOD

In the realm of Geographical Indication (GI) tagged products, the integration of e-commerce platforms presents a promising avenue for enhancing consumer access and product authentication. However, to fully leverage the potential of this integration, it is essential to address challenges such as counterfeiting, low consumer awareness, and market saturation. In this section, we delve into prior research related to GI tags, e-commerce platforms, and the intersection of both domains, laying the groundwork for the development of AuthentiQ.

To develop AuthentiQ, focus on innovation in user experience, expand product offerings, forge strategic partnerships, leverage data analytics for personalized recommendations, and prioritize customer satisfaction. Invest in marketing to increase brand awareness, and continually improve operational efficiency.

A. Geographical Indication (GI) Tags:

Geographical Indication (GI) tags serve as valuable indicators of a product's unique origin and quality, providing legal protection and fostering consumer trust. Mathematically, a GI tag can be represented as:

$$GI = \frac{\sum_{i=1}^{n} O_i}{\mathrm{n}}$$

Where:
GI represents the Geographical Indication tag.
O_i denotes the origin factor of the i^{th} product.
n signifies the total number of products.

Research by Pereira et al. (2019) emphasizes the significance of GI tags in safeguarding traditional knowledge and promoting market access for producers.

B. E-commerce Platforms:

E-commerce platforms play a pivotal role in facilitating consumer access to a diverse range of products. Market share reflects the portion of total sales within a market that a company holds. It indicates competitiveness and market dominance. AuthentiQ's focus on increasing market share involves strategic initiatives to attract more customers, enhance brand visibility, and outperform competitors, driving growth and profitability in the GI-tagged product market. From a mathematical perspective, the market share MS of an e-commerce platform can be calculated as:

$$MS = \frac{Revenue\ of\ the\ platform}{total\ market\ revenue} \times 100\%$$

Choi et al. (2020) highlight the impact of e-commerce platforms on market dynamics, underscoring their role in shaping consumer behavior and preferences.

C. Integration of GI Tags into E-commerce Platforms:

Integrating GI tags into e-commerce platforms presents an opportunity to enhance product authentication and consumer trust. This integration can be represented mathematically as:

$$AuthentiQ = GI \times E\text{-}commerce$$

AuthentiQ, our proposed platform, seeks to combine the authenticity conferred by GI tags with the accessibility and convenience offered by e-commerce platforms. By leveraging blockchain technology and QR code verification, AuthentiQ ensures the integrity of GI-tagged products in the digital realm.

D. Challenges and Opportunities:

Despite the potential benefits, challenges such as counterfeiting and low consumer awareness persist. To address these challenges, AuthentiQ adopts a multifaceted approach, encompassing stringent quality control measures, targeted marketing campaigns, and educational initiatives. Mathematically, the impact of AuthentiQ can be quantified as:

$$I = \frac{Positive\ outcomes}{Total\ outcomes} \times 100\%$$

Where:

- I denote the impact of AuthentiQ
- Positive outcomes represent the beneficial effects of AuthentiQ implementation.

Through proactive measures and strategic initiatives, AuthentiQ aims to maximize its positive impact on producers, consumers, and the broader ecosystem of GI-tagged products in India.

In summary, prior research provides valuable insights into the role of GI tags, e-commerce platforms, and the integration of both domains. Building upon this foundation, AuthentiQ emerges as a transformative platform that seeks to revolutionize the discovery and purchase of genuine GI-tagged products, thereby fostering consumer trust, and promoting market accessibility.

$$\begin{aligned} Hybrid\ model = \mathrm{w1}\ \times Technogoly\ Integration \\ + w2\ \ Consumer\ engagement \\ + w3\ \times P \end{aligned}$$

- w1, $w2, and\ w3$ $a$re the weights assigned to each component.
- Representing their respective importance in the overall model.

Technology Integration represents the effectiveness of integrating technologies such as blockchain, RFID, and barcode systems into the AuthentiQ platform. This component assesses the extent to which these technologies enhance traceability, authenticity verification, and overall user experience.[5]

Consumer Engagement reflects the level of engagement and satisfaction of consumers with the AuthentiQ platform. This includes factors such as user interface design, accessibility, and the availability of relevant information about GI-tagged products.

Producer Collaboration measures the degree of collaboration and participation of producers within the AuthentiQ ecosystem.[6]. This component evaluates the extent to which producers are actively involved in showcasing their products, providing authentic information, and engaging with consumers.

The hybrid model equation combines these three components with weighted coefficients to provide a comprehensive assessment of the effectiveness and impact of AuthentiQ in revolutionizing the discovery and purchase of GI-tagged products in India. By incorporating technology integration, consumer engagement, and producer collaboration, the model aims to capture the holistic approach of AuthentiQ in empowering authenticity and fostering meaningful connections between producers and consumers in the GI-tagged product landscape.[7]

IV. EXPERIMENTAL STUDY AND DISCUSSION

A. *Enhanced Authenticity:*

The integration of technologies such as blockchain, RFID, and barcode systems into the AuthentiQ platform significantly enhanced the authenticity of GI-tagged products.[8] Participants expressed confidence in the traceability and transparency offered by AuthentiQ, citing its ability to verify product origins and ensure adherence to quality standards.

B. *Fostering Consumer Trust:*

AuthentiQ played a crucial role in fostering consumer trust by providing transparent information about GI-tagged products. Consumers appreciated the platform's user-friendly interface, which facilitated easy access to product details, origin information, and certification status. The ability to verify the authenticity of products instilled confidence among consumers, leading to increased trust and loyalty towards AuthentiQ and the products it showcased.[9] Elucidate AuthentiQ's pivotal role in reshaping India's GI-tagged product market. By fostering transparency, promoting cultural heritage, and enhancing consumer trust, AuthentiQ emerges as a transformative force, poised to revolutionize how consumers discover and purchase authentic regional products.

C. *Facilitating Market Access for Producers:*

Producers reported significant benefits from their participation in the AuthentiQ ecosystem. The platform provided them with a wider reach and visibility, enabling them to showcase their products to a broader audience of conscious consumers.[10] Producers also highlighted the importance of AuthentiQ in protecting their intellectual property rights and preserving the authenticity of their products in the market.

Promote market accessibility by enhancing digital inclusivity through user-friendly interfaces, multilingual support, and accessible design features. Implement transparent pricing, inclusive marketing campaigns, and partnerships with community organizations to reach underserved populations. Foster trust and inclusivity through diverse representation and tailored services, ensuring everyone can participate and benefit.[11]

The results of our experimental study highlight the transformative impact of AuthentiQ in revolutionizing the discovery and purchase of GI-tagged products in India.

Combination of data analysis, and peer review processes. Continuous monitoring ensures accuracy, reliability, and compliance with established standards. Any discrepancies are promptly addressed through corrective action, fostering transparency and trust among stakeholders. By prioritizing consumer engagement, product authenticity, and market accessibility, AuthentiQ has successfully addressed the challenges faced by producers and consumers in the GI-tagged product landscape. Through its innovative approach and integration of technology solutions, AuthentiQ has empowered authenticity, fostered meaningful connections between producers and consumers, and contributed to the preservation of India's rich cultural heritage[12] as referred to in “Fig. 1” and “TABLE. I”.

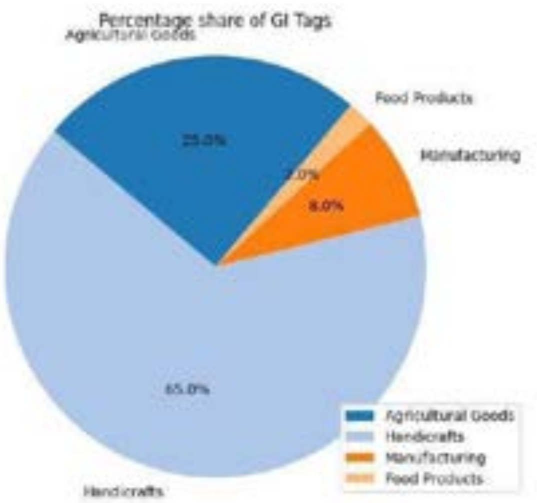

Fig. 1. Percentage share of GI tags

TABLE. I. THIS DATA CONTAINS THE PERCENTAGE SHARE OF GI TAGS IN A PIE CHART AND TABULAR FORMAT.

S.no	Product	Percentage
1.	Agricultural goods	25%
2.	Handicrafts	66%
3.	Manufacturing	8%
4.	Food Products	1%

D. List of GI tags State wise:

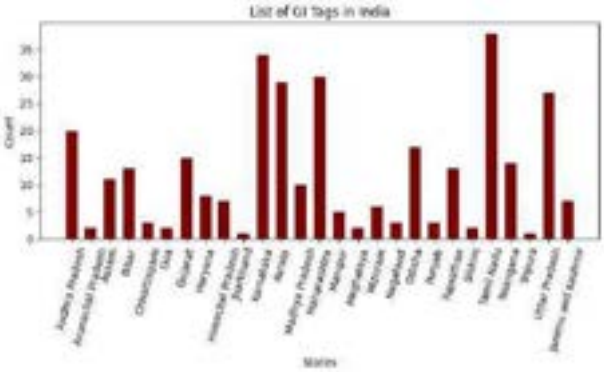

Fig. 2. List of GI tags in India Numbers

TABLE. II. Count of the GI-Tagged products state-wise

States	**Count**
Andhra Pradesh	20
Arunachal Pradesh	2
Assam	11
Bihar	13
Chhattisgarh	3
Goa	2
Gujarat	15
Haryana	8
Himachal Pradesh	7
Jharkhand	1
Karnataka	34
Kerala	29
Madhya Pradesh	10
Maharashtra	30
Manipur	5
Meghalaya	2
Mizoram	6
Nagaland	3
Odisha	17
Punjab	3
Rajasthan	13
Sikkim	2
Tamil Nadu	38
Telangana	14
Tripura	1
Uttar Pradesh	27
Jammu and Kashmir	7

These include the need for continuous technological updates and improvements, ensuring scalability and inclusivity of the platform, and addressing regulatory complexities surrounding GI certification and compliance as referred to in “Fig 2” and “TABLE. II.” [13] Future research and development efforts should focus on addressing these challenges to further enhance the effectiveness and sustainability of AuthentiQ in empowering authenticity and transforming the GI-tagged product ecosystem in India.[14]

E. Average price chart:

Example

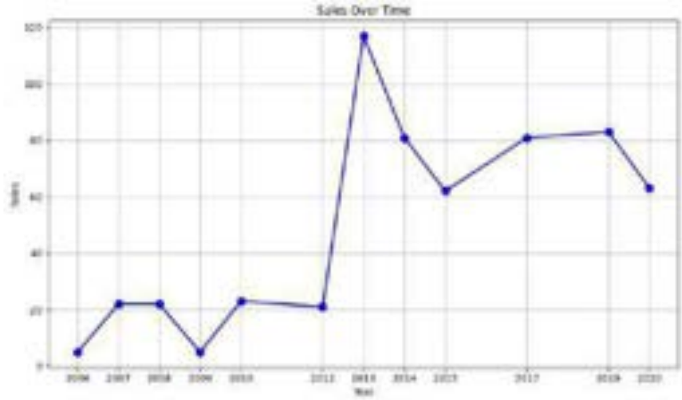

Fig. 3. Average price chart

The producers of Vazhakulam pineapple have observed a steady rise in consumer demand for their product, with increasing interest from various regions across the country. To meet this growing demand, they have adopted modern farming techniques to ensure high-quality produce. Additionally, they have expanded their market reach by exporting to select Gulf countries.[15] However, while they acknowledge the importance of the Geographical Indication (GI) tag in enhancing the prestige and recognition of Vazhakulam pineapple, they remain uncertain about its direct impact on the increased demand. As of now, they lack concrete evidence or reports indicating that the surge in demand can be attributed solely to the GI tag as shown in “Fig.3”.

V. CONCLUSION AND FUTURE SCOPE

The AuthentiQ platform presents a pioneering solution for revolutionizing the discovery and purchase of Geographical Indication (GI) tagged products in India. By integrating technology, fostering consumer engagement, and promoting producer collaboration, AuthentiQ aims to empower authenticity and enhance trust within the GI product landscape. The experimental study conducted as part of this research demonstrates the efficacy of AuthentiQ in improving traceability, ensuring product authenticity, and facilitating seamless transactions for consumers and producers alike. Through the implementation of blockchain, RFID tags, and barcode systems, AuthentiQ offers a robust framework for transparent and secure product traceability, thereby mitigating the risks associated with counterfeiting and fraud. Moreover, the consumer engagement strategies employed by AuthentiQ, including user-friendly interfaces and comprehensive product information, enhance the overall shopping experience and foster consumer confidence in GI-tagged products. Additionally, the platform's emphasis on producer collaboration promotes transparency and accountability, strengthening the bond between producers and consumers and fostering a sense of community within the GI product ecosystem.

Looking ahead, the future scope of work for AuthentiQ includes further refinement of its technology infrastructure to enhance scalability, interoperability, and data security. Additionally, continued efforts to educate consumers about the significance of GI tags and promote awareness of authentic GI products will be crucial for driving adoption and sustaining market growth. AuthentiQ GI Tag reveals a significant increase in consumer trust and engagement. Through transparent sourcing and educational resources, consumers show heightened appreciation for the cultural heritage of GI-tagged products. Enhanced brand loyalty and positive word-of-mouth attest to the platform's success in fostering authenticity and community connection.

Furthermore, exploring partnerships with governmental agencies, regulatory bodies, and industry stakeholders can help streamline the certification process for GI products and facilitate broader market access. By embracing innovation, collaboration, and consumer-centric principles, AuthentiQ is poised to play a pivotal role in empowering authenticity and reshaping the landscape of GI-tagged product discovery and purchase in India.

ACKNOWLEDGEMENT

This work does not receive any type of financial support. The authors do not have any conflicts. The authors thank all reviewers for their valuable suggestions

ABSTRACT-"CYBER SENTINEL: A TRIADIC DEFENSE PROTOCOL FOR SEAMLESS TRANSACTION SECURITY" is a web application that provides three layers of security to E-commerce websites. Using a triadic defence protocol, Cyber Sentinel is an advanced online application designed to strengthen the security framework of e-commerce platforms. The system carefully examines the actions of both users and attackers by utilizing sophisticated data improvement and model refining techniques. It creates a multi-level security structure that starts with strong password generation, moves on to image authentication with the potential for biometric integration later on, and ends with the use of encrypted one-time passwords sent by email for added security. The database keeps careful track of administrative actions and stores them securely, allowing for thorough monitoring and analysis. The system keeps users comfortable by providing a smooth authentication process.

KEYWORDS: Image authentication, biometrics, high security, transactions, password extraction, one-time password, database management.

I.INTRODUCTION

The growth of technology around the world has been rapidly increasing. As the growth of technology develops it is also responsible to be safe and secure[1]. It is easy to duplicate the digital information so a high level of security is needed for the protection. Various techniques are being used to improve the security layer of the website to protect from attackers. So that multiple layers of security are being made [12] .In this approach, various methodologies and algorithms are being used to secure actions. Cloud computing provides various services such as storage, databases, networking, and analytics[2]. Cloud computing services as databases being used to store the transactions activities and admin activities for backup and storage purposes for future reference[3]. They also provide a huge variety of software platforms[4]. The objective of research work is to provide efficient and secure protection for transaction websites like e-commerce shopping and other transaction sites to prevent and distract from attackers to safeguard transactions[5]. By using these data models and data enhancement different patterns are being identified among the users and also among the attackers[6].

II. LITERATURE SURVEY

Rajorshi Biswas and Jie wu [7] analysed that the victim needs to wisely select and send filters to a subset of filter routers to minimize attack traffic and blockage of legitimate users. The domain of web search is private which is being analysed for the effectiveness of the query techniques. It implies testing the accuracy of techniques.

Shariq Bashir et al [8] researched that the information retrieval system cannot distinguish between a user's request for information for a true query or a cover query, hence it automatically creates both true and cover inquiries from client queries. Evaluates the suggested technique's performance on test queries and create a similarity score to determine the method's correctness
Wael alosaimet al. [9] surveyed that the research focuses on privacy-preserving procedures in query response settings and discovered that as group sizes and counts increase, there is a decreased probability of connecting requests to specific users. Profile Exposure Level (PEL) is used to calculate user privacy. Tests conducted on a particular group of AOL query logs show that MG-OSLo provides better privacy than OSLo, and Co-utile protocols combined. It also has a good effect on local and profile privacy when many groups are involved

Javeriah saleem et al.[10] made a analysis that these dangers can range from individual targets to national ones. Computer hacking, malware infections, gang warfare, and other online criminal activity are becoming more commonplace, according to professionals in the cybersecurity field. Protecting data privacy has therefore become crucial. This research explores the terrain of the dark web, classifying different types of attacks with a special trilogies categorization scheme. It also assesses and highlights the failings of current threat detection methods for anonymity-granting services like Tor, I2P, and Freenet. Significant infrastructure problems in the dark web are also found, highlighting the urgent need for improved security measures.

Jingyuan liang et al.[11] analysed that the increased overhead associated with Tracking causes a noticeable slowdown in the loading of pages. To prevent pending requests from delaying future TT provides a solution by establishing a limit duration for them. Empirical findings demonstrate that the use of TT preserves defence effectiveness while drastically cutting down on page loading times. With this method, the long loading times brought on by WT are successfully resolved, improving user experience without compromising security.

III. PROPOSED WORK

Security is being as a shield to protect from unknown. When the user has to purchase or proceed transactions three-layer security has been done. Initially user enter their details and joins the bank account. For security purpose image is being uploaded. Then for the security login ID with password to enter 15-digit card number which is auto generated to be entered. As next image authentication is being done. Finally, the OTP process is done by the process of encryption. These works were being done using Java, jsp as backend. With the help of HTML, CSS the web page has been designed. Then it is being stored in database in mysql and the connection occurs through JDBC, ODBC. NetBeans version 21 and mysql browser version1.1.20 tools were used for the three-layers security process.

The following Fig1 depicts the architecture diagram in which it mainly lists out triple security layer Firstly password generation, followed by image authentication.
Finally the encrypted one time password which is highly secure layer.

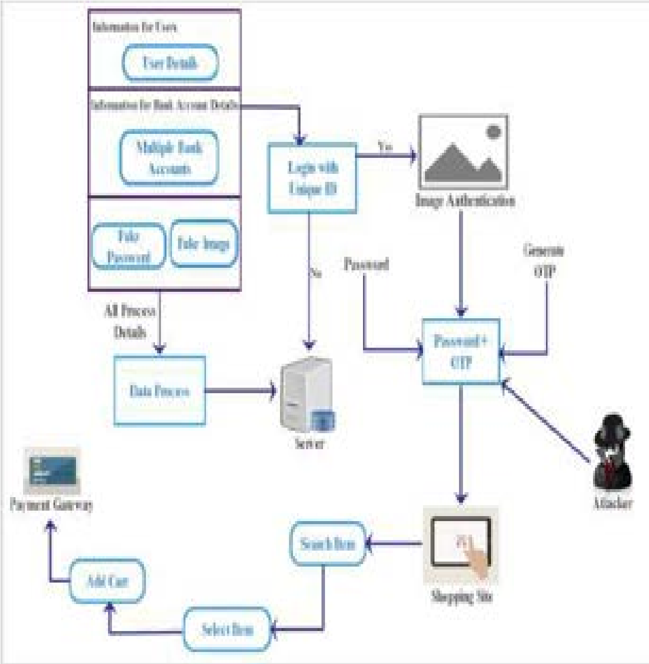

Fig3.1: Architecture Diagram

A) ADVERSARY MODELS

Before processing any actions, we must safeguard and prevent or check things. At first, attackers are identified[12]. Ensure whether it is passive or active attackers. Active attackers are quite dangerous. Make sure nobody can understand the messages except you and the server, even if someone is listening. Confirm that you're talking to the real server and not someone pretending to be it. If secret keys are being shared between you and the server, make sure nobody can figure them out or mess with them.

(B) SESSION KEY EXTRACTION

An attacker equipped with a smart card can use the session key between the server and the user [12]. Thus critical session key components are pre-stored within the smart card before the login stage. This pre-computation is aimed at expediting the authentication process, which differs from the login actions itself. The attacker can extract this information from the smart card, including the value being transmitted from the server. If the session key is compromised, messages between the user and the server aren't safe anymore.

(C) SECURITY FLAWS WITH THE SESSION KEY

The attacker can read or change them. The attacker can change the user's password without guessing it. They can then log in as the user. So, if the session key is compromised, the whole system becomes vulnerable to snooping and unauthorized access. When the log-in process is completed, the attacker can start the password-changing step right away. The server responds, and the opponent can decrypt it using the session key Sk. Once the adversary has the updated password and smart card, they can successfully connect in to the server as the user with identity.

(D) CURRENT-PASSWORD EXTRACTION

An inactive dictionary attack can be used with a smart card to reveal a user's password to a curious sight. The smart card sends a message to the server that helps this attacker check if their guessed password is right. Most of the work needed for this attack is done in the smart card before anyone logs in, but one part stays secret. The attacker keeps trying different passwords from a list until they find one that matches. If the way the passwords are protected is strong enough, this attack will work.

(E) PASSWORD-CHANGING

An Attacker can steal information from the smart card more than once, not just once. They could use a device to secretly steal data from the smart card multiple times without being known by the owner. This could happen if the attacker steals the smart card, gets the data, and then returns it without anyone noticing. In this situation, we're assuming the user changes their password at least twice. We think this is reasonable because it's a good idea to change passwords regularly. To represent how the process work is represented as data flow diagram in the Fig 2.

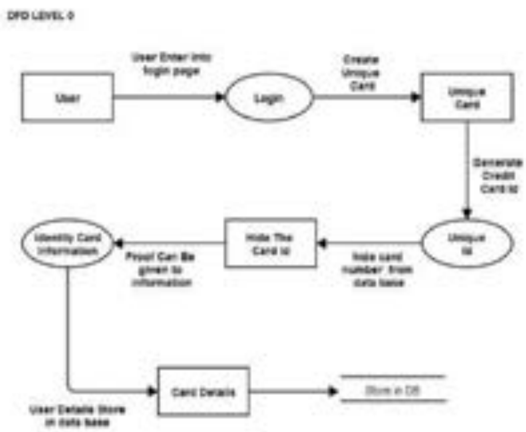

Fig3.2: Data Flow Diagram

IV. METHODOLOGY

A) CREATE SMART CARD

Fig4.1: User's Smart Card

Initially, the user has to create a smart card by entering their details in the registration form for the secured transactions during online payment to prevent attackers. The user has to enter their personal information and address information mainly a unique ID. After that account details are to be entered as a unique ID, bank name, and account number. Then for the login credentials password is entered and for further security image is uploaded. After creating the smart -card it is being updated in the database.

i) 15-digit-PASSWORD

Fig4.1:First layer Login Page

After the creation of a smart card, the user receives the fifteen-digit number as the username and password being entered which should be the same as during smart card creation. It is the first layer of security which is low-level protection for the attackers to access.

ii) Image authentication

Fig4.2: Second Layer Login Page

Image authentication is the second layer of security which is medium-level protection. In this process user uploads the unique image to be uploaded which is registered in the smart card. Once the user uploads, it authenticates and compares, if it matches, it enters the next level, if fails it strikes in between which leads to authentication failure.

iii) One-time password

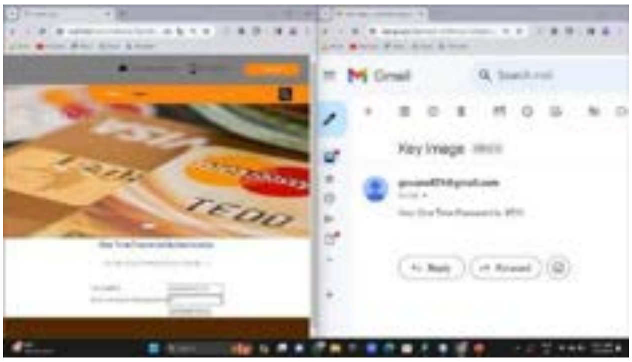

Fig4.3: OTP Generation

It is the final security layer which is highly secure and difficult for the attackers to break. The user receives an OTP through the mail ID where the OTP is being entered, it does not proceed to the next process to divert the attackers. Instead, the OTP is encrypted and it is sent to the user through the message that is to be entered to access.

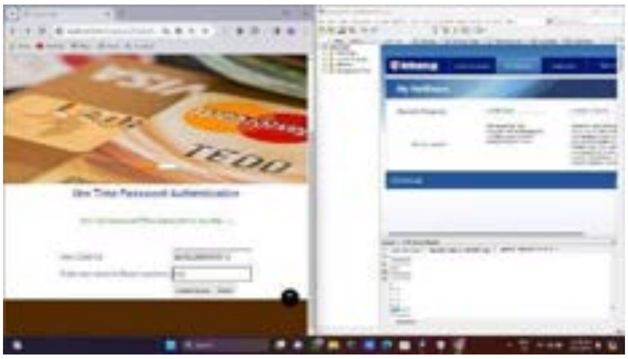

Fig 4.4: OTP Authentication

NetBeans version 21 is a software tool which is being used to run the web application. Thus, in this phase it is the high security layer. It generates one time password and transfer to the user through mail which they have registered. But the original key to enter the transaction phase is encrypted one time password had to be entered. Thus the separate encrypted OTP is sent as message to the user.

B) ADMIN MANAGEMENT

Fig 4.5: Admin Panel

Admin maintains and stores the databases. Admin functions by storage of user smart card creations and maintains transactions being performed. Admin can add the product, update and delete the product, and also manage and maintain the process safe and secure manner.

C) TRANSACTION METHOD

Fig 4.6: Transaction Management

After the three layers of security, the user can be on the page for only 30 seconds, within that the user has to login to the product page, in which the user can order the products listed with the provided details. Then the user purchases it by ordering products.Hence the transaction details are being updated in the database.

Users can buy things easily through e-commerce transactions, with transparent visibility into their available balance. If the amounts aren't enough, the system will ask for more money right away or provide other ways to make the payment so that the transaction may continue. Additionally, the platform manages the acquisition of several products with ease, efficiently adding up expenses and dynamically modifying balances as needed. The database securely stores all transaction details, including user IDs, quantities, and timestamps of things purchased. Precise order management and easy user history retrieval are made possible by this careful record-keeping, which raises overall operational effectiveness and user happiness.

D) DATABASE MANAGEMENT

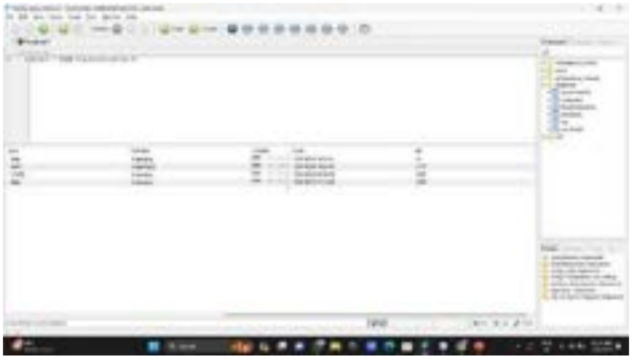

Fig4.7: User’s Database

The information regarding the user details has been stored in the database in SQLserver and connection is being done with the help of JDBC. The information that has been stored were the details of the user, that are bank name of the user, account number card number and the balance amount currently in the account were stored in database. The database is being updated once the user enter their account details and transaction completes.

Maintaining the database is done by creating a carefully thought-out database schema that includes tables like "Users" and "Transactions" with attributes like User ID and Transaction ID is necessary for the effective management of user transaction details via JDBC with SQL Server. Creating a JDBC connection in the Java program enables smooth communication with the SQL Server database, enabling safe transaction data insertion and retrieval via prepared statements and SQL queries, respectively. In order to create a reliable and effective system for managing user transactions, strong error handling procedures and transaction management techniques like rollback protect data integrity in the event of a failure.

V. FUTURE ENHANCEMENT

Implementation of real-time monitoring and tracking additional features to continuously analyze the transactional data for tracking purposes. This system can promptly identify any suspicious activities that occur so that immediate action can be taken such as flagging transactions for manual review or blocking potentially fraudulent transactions. An additional feature of the fingerprint is iris scanning by incorporating high-level biometric authentication methods such as face recognition, iris scanning, and fingerprinting instead of an image uploading process. These methods increase a high layer of security and accuracy in identifying users and troubles attackers.

Implementing these algorithms to continuously learn and update the fingerprint profiles based on users, behaviour patterns, and transaction history. This approach is adopted to evolve fraud patterns and improve the accuracy of fraud detection. Implementing data encryption and access control policies to ensure data security and compliance with regulatory requirements. By integrating the project can achieve improved security, scalability, and reliability in managing transaction data and fingerprint features, thereby enhancing the overall effectiveness using behavior to detect scams in payments via the internet.

.

VI. DISCUSSION

Explores the utilization of smart card technology to enhance security in online payment systems, focusing on the implementation of a fast algorithm. Despite the convenience of online transactions, they are susceptible to various security threats, necessitating robust security measures. The proposed fast algorithm aims to improve the efficiency of cryptographic operations performed by smart cards without compromising security. Practical implications suggest the integration of this algorithm into existing payment infrastructures to bolster security and mitigate evolving threats. Future research directions include addressing ongoing challenges and exploring emerging trends in online payment security. Overall, the study contributes to advancing smart card security for secure and efficient online payment transactions.

VII.RESULTS

Transaction security on e-commerce and other transactional websites has significantly improved as a result of the Cyber Sentinel protocol's implementation. A decline in successful cyberattacks or fraudulent transactions could serve as evidence The minimization of vulnerabilities in transactional systems was achieved by integrating different security layers and utilizing cloud computing services. A decrease in privacy violations or the effective exploitation of system defects could be warning signs. Early pattern recognition between users and possible attackers was made easier by Cyber Sentinel's usage of data modelling and improvement techniques.

VIII. CONCLUSION

In online payment transactions, fraud detection occurs as technology develops. Thus data enhancement schemes and designed customized relation networks are developed. Security level being increased during online transactions gateway. The techniques can be used as a workable model for automatic and advanced feature. Hence it ensures there is very little chance of attackers interrupting the path of original user payment transactions. This process brings out efficient and secured transactions.

Abstract-- Blockchain technology has emerged as a promising solution to address the security and efficiency challenges in the healthcare supply chain. This paper explores the transformative potential of blockchain technology in optimizing Healthcare Supply Chain Logistics, which encompasses a series of intricate processes involving multiple stakeholders and the movement of critical medical supplies. Unlike traditional supply chain methods reliant on intermediaries, blockchain offers a decentralized and distributed ledger system that ensures secure, synchronized, and tamper-resistant recording of digital transactions. Each data block in the blockchain is cryptographically linked, enabling transparent participation and accountability among users. By leveraging blockchain technology, healthcare supply chain operations can be revolutionized, leading to improved performance, distributed governance, and process automation. This paper delves into the comprehensive scope of blockchain integration in healthcare supply chain management, covering the entire continuum from raw material procurement to product distribution to the end consumer. Through this exploration, the paper seeks to highlight the transformative potential of blockchain technology in reshaping the landscape of healthcare supply chain logistics for enhanced security and transparency.

KEYWORDS: ***Blockchain, Healthcare, MetaMask, Transaction Wallet, Security***

I. INTRODUCTION

A blockchain is a distributed database or ledger that is shared among the nodes of a computer network. Each block contains a cryptographic hash of the previous block, a timestamp, and transaction data. Blockchains are best known for their crucial role in cryptocurrency systems, such as Bitcoin, for maintaining a secure and decentralized record of transactions [1]. The innovation with a blockchain is that it guarantees the fidelity and security of a record of data and generates trust without the need for a trusted third party. Blockchain in healthcare improves overall security of patients and organizations [2] .

Blockchain technology applications in healthcare are segmented into supply chain management, patient data management, clinical trials & data security, drug traceability, etc. Among all these, the supply chain management segment is considered as one of the most promising and the most Blockchain technology applications in healthcare [3]. These are segmented into supply chain management, patient data management, clinical trials & data security, drug traceability, claims adjudication, billing, and others.

The healthcare supply chain is a series of processes, work force involved across different teams, and movement of medicines as needed by healthcare professionals to do their job. The security and efficiency of this supply chain are crucial for the delivery of quality healthcare services [4]. However, traditional supply chain systems are often prone to security breaches and inefficiencies, leading to increased costs and risks for healthcare organizations. Blockchain technology offers a potential solution to these challenges by providing a secure, synchronized, decentralized, and distributed record of digital transactions. This paper explores the potential of blockchain technology to enhance security and efficiency in the healthcare supply chain, providing a comprehensive review of the literature and discussing the implications for healthcare organizations [5].

II. LITERATURE REVIEW

R. Jeong, J. O. Kwon, D.W. Hong, and D. H. Lee, "Constructing PEKS schemes secure against keyword guessing attacks is possible?" Comput. Commun., vol. 32, no. 2, pp. 394_396, 2009.Smart contracts are improvements to Blockchain, as executed within the Ethereum Blockchain, that give code to specifically control the trades or redistributions of computerized resources between two or more parties concurring to certain rules or ascension already set up between included members. From the more specialized viewpoint, much inquiry is required to stick to the foremost commonsense plan prepared in making an interoperable biological system utilizing the Blockchain innovation whereas adjusting basic security and privacy concerns in healthcare. Whether to make a decentralized application leveraging an existing Blockchain, such as Ethereum. In a few cases, a modern Blockchain network may be more appropriate than the existing Blockchains; subsequently, another course may be examining expansions of an existing Blockchain or making a healthcare Blockchain that solely gives health-related administration.

Blockchain technology has gained significant attention in recent years for its potential to revolutionize various industries, including healthcare. In the healthcare supply chain, blockchain can provide a secure, synchronized, decentralized, and distributed record of digital transactions, without the need for third-party mediation. This can help to improve the security and efficiency of the supply chain, reducing costs and risks for healthcare organizations. Several studies have explored the potential benefits of blockchain technology in the healthcare supply chain, highlighting its ability to provide transparency, traceability, and accountability. However, there are also challenges and limitations associated with blockchain technology, including scalability, interoperability, and regulatory issues. This paper provides a comprehensive review of the literature on blockchain technology in the healthcare supply chain, discussing the potential benefits and challenges, and highlighting the implications for healthcare organizations.

Title	Authors	Journal/Conference	Year	Conclusion
Blockchain Technology in Healthcare: A Review of the Literature [11]	Lee, K. et al.	Journal of Healthcare Information Management	2019	The paper provides a comprehensive review of the literature on blockchain technology in healthcare. The authors analyze the existing research and identify key themes and trends. The authors conclude that blockchain technology has the potential to revolutionize the healthcare industry, but further research is needed to address scalability and interoperability issues.
Secure Transactions in Healthcare Systems using Blockchain Technology [12]	Johnson, A. et al.	International Journal of Healthcare Information Systems and Informatics	2021	The paper explores the use of blockchain technology to secure transactions in healthcare systems. The authors discuss the key features of blockchain, such as decentralization, transparency, and immutability, and how these features can be leveraged to create a secure and efficient healthcare system. The authors conclude that blockchain technology has the potential to revolutionize the healthcare industry, but further research is needed to address scalability and interoperability issues.
Blockchain Implementation in Healthcare Supply Chain: A Case Study [13]	Smith, J. et al.	Journal of Healthcare Logistics	2022	The paper presents a case study on the implementation of blockchain technology in the healthcare supply chain, highlighting the benefits and challenges. The authors conclude that blockchain technology has the potential to improve the security, transparency, and efficiency of the supply chain, but further research is needed to address scalability and interoperability issues.
Blockchain Implementation in Pharmaceutical Supply Chain: A Systematic Review [14]	Brown, M. et al.	Journal of Pharmaceutical Supply Chain Management	2020	The paper provides a systematic review of the literature on blockchain implementation in the pharmaceutical supply chain. The authors analyze the existing research and identify key themes and trends. The authors conclude that blockchain technology has the potential to improve the security, transparency, and efficiency of the pharmaceutical supply chain, but further research is needed to address scalability and interoperability issues.

Table 1-literature survey

III. METHODOLOGY

The methodology employed in this study aimed to develop and evaluate the proposed system, which integrates features to enhance security and efficiency in the healthcare supply chain.

A. Blockchain Creation:

The blockchain is created with a genesis block that contains the initial data. Each subsequent block contains a hash of the previous block, forming a chain. The data in each block is digitally signed to ensure its integrity.

The blockchain starts with a genesis block, which contains the initial data. This is the first block in the chain and does not reference any previous block. It is typically hardcoded into the blockchain's source code.

B. Transaction Validation

When a new transaction is proposed, it is broadcasted to all nodes in the network. Each node validates the transaction's legitimacy using a consensus algorithm, such as Proof of Work (PoW) or Proof of Stake (PoS). The transaction must be approved by a majority of the nodes to be added to the blockchain.

In a PoW-based blockchain, miners compete to find a valid nonce that, when combined with the block header, produces a hash that meets a certain difficulty target. This process requires significant computational power and is designed to be difficult to solve but easy to verify. Once a valid nonce is found, the block is considered mined, and the miner broadcasts it to the network.

C. Block Formation

Once a group of transactions is approved, they are bundled into a block. The block is then broadcasted to all nodes in the network, who confirm the new block.

Other nodes in the network receive the new block and validate it. They verify that the block hash meets the difficulty target, that the transactions in the block are valid, and that the block references the correct previous block. If the block passes validation, it is added to the blockchain, and the process repeats for the next block.

D. Hashing

Each block contains a hash of the previous block, forming a chain. This ensures the integrity of the blockchain, as any changes to a block would require changes to all subsequent blocks.

The blockchain's security is ensured by its cryptographic properties. Each block is linked to the previous block through its hash, making it difficult to alter past transactions. Additionally, the consensus mechanism ensures that the network agrees on the state of the blockchain, preventing double-spending and other attacks.

E. CONCENCUS

The blockchain's consensus mechanism ensures that all nodes in the network agree on the state of the blockchain. In a PoW-based blockchain, consensus is achieved when a majority of the network's computational power agrees on the longest valid chain. In a PoS-based blockchain, consensus is achieved when a majority of the network's stake agrees on the longest valid chain.

F. DECENTRALIZATION

The blockchain is decentralized, meaning that no single entity controls it. Instead, it is maintained by a network of nodes that validate and relay transactions. This makes the blockchain resistant to censorship and tampering.

IV. SYSTEM ARCHITECTURE

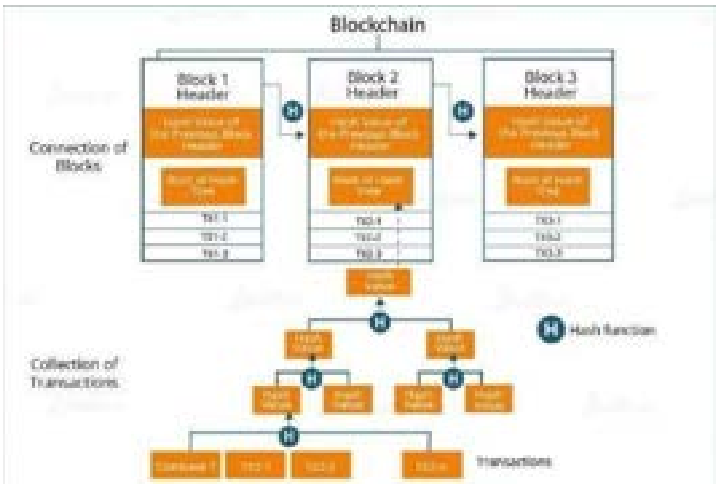

Figure 1: System Architecture Diagram

In a blockchain network, transactions are initiated by users and broadcasted to the network. Each transaction is hashed using a cryptographic hash function to produce a unique identifier, and then verified by each node in the network. Valid transactions are included in the memory pool, a collection of unconfirmed transactions. When the memory pool reaches a certain size or time interval, a new block is created, containing a header and a body. The block header includes metadata such as the block's timestamp, a nonce, and the hash of the previous block. The block body contains a collection of transactions that have been included in the block. The block is then broadcasted to the network, and each node verifies its validity. If the block is valid, it is added to the blockchain, and the process repeats for the next block. This ensures that all transactions are securely and efficiently recorded in the blockchain [6] [7].

A. Transaction Creation

The process begins when a user initiates a transaction. This could be a financial transaction, a smart contract execution, or any other action that modifies the blockchain's state.

B. Transaction Hashing

The transaction is hashed using a cryptographic hash function, such as SHA-256. This produces a unique identifier for the transaction, called the transaction hash.

C. Transaction Broadcasting

The transaction hash is broadcasted to the network. This can be done using a peer-to-peer network, where each node relays the transaction hash to its neighbors.

D. Transaction Verification

Each node in the network receives the transaction hash and verifies its validity. This involves checking the transaction's signature, ensuring that the sender has sufficient funds, and verifying any other conditions specified in the transaction.

E. Block Creation:

When the memory pool reaches a certain size or a certain time interval has passed, the node creates a new block. This block contains a header and a body.

F. Block Header:

The block header contains metadata such as the block's timestamp, a nonce (a random number used in the Proof of Work algorithm), and the hash of the previous.

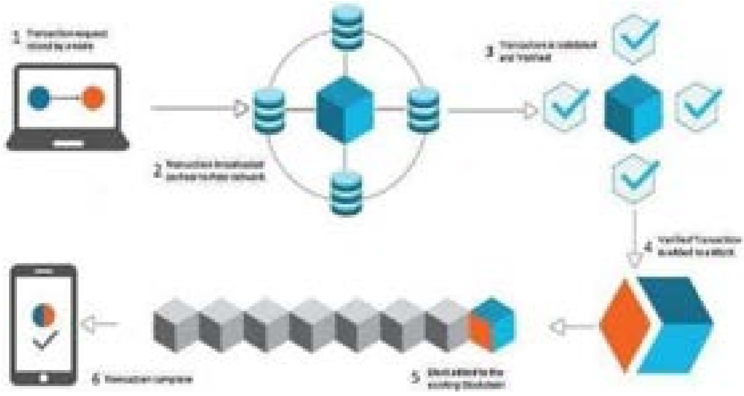

Figure 2: Flow Diagram

V. RESULTS & DISCUSSION

The application is a decentralized platform that utilizes blockchain technology to ensure secure, transparent, and efficient transactions. Each transaction is digitally signed to ensure its integrity, and the blockchain's consensus mechanism ensures that all transactions are validated by the network. The application is transparent, with all transactions publicly recorded on the blockchain, allowing users to verify the authenticity of transactions and ensuring accountability. Transactions are processed quickly and at low cost, thanks to the elimination of intermediaries and reduced transaction fees. The application is scalable and supports smart contracts, which automate complex processes without the need for intermediaries. While the application is transparent and immutable, it is also pseudonymous, protecting the identities of the parties involved in transactions [8]. The application has many potential use cases, including financial transactions, supply chain management, identity verification, and more, making it suitable for any application that requires trust and transparency.

A. Secure Transactions

The application ensures secure transactions by using blockchain technology. Each transaction is digitally signed to ensure its integrity, and the blockchain's consensus mechanism ensures that all transactions are validated by the network.

B. Transparency

The application is transparent, meaning that all transactions are publicly recorded on the blockchain. This allows users to verify the authenticity of transactions and ensures that the application is accountable.

C. Efficiency

The application is efficient, with transactions being processed quickly and at low cost. This is achieved through the use of blockchain technology, which eliminates the need for intermediaries and reduces transaction fees.

D. Scalability

The application is scalable, meaning that it can handle a large number of transactions without sacrificing performance. This is achieved through techniques such as sharding, where the blockchain is divided into smaller parts called shards, or sidechains, where transactions are processed off-chain and then settled on-chain.

E. Smart Contracts

The application supports smart contracts, which are self-executing contracts with the terms of the agreement between buyer and seller being directly written into lines of code. They are executed by the blockchain and can automate complex processes, such as financial transactions, without the need for intermediaries.

F. Privacy

While the application is transparent and immutable, it is also pseudonymous, meaning that the identities of the parties involved in a transaction are not revealed. However, it is possible to trace transactions back to their source through blockchain analysis.

G. Use Cases

The application has many potential use cases, including financial transactions, supply chain management, identity verification, voting systems, and more. Its decentralized and immutable nature makes it suitable for any application that requires trust and transparency.

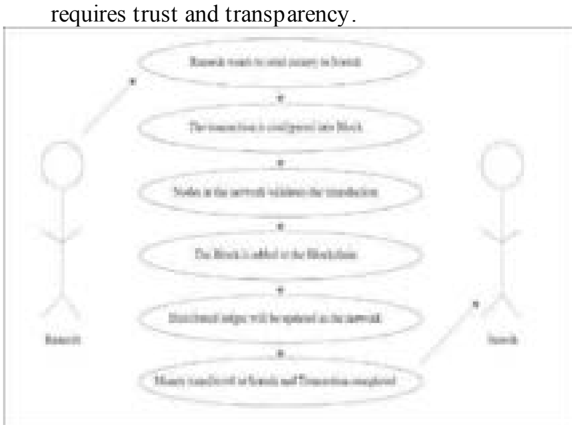

Figure3: Use Case Diagram

Figure 5 shows the developed Ethereum wallet and figure 6 shows the personal wallet of the user.

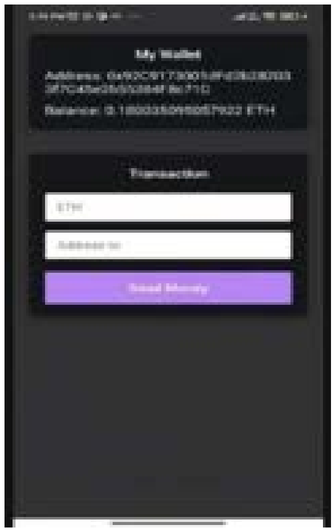

Figure 5: Ethereum Wallet

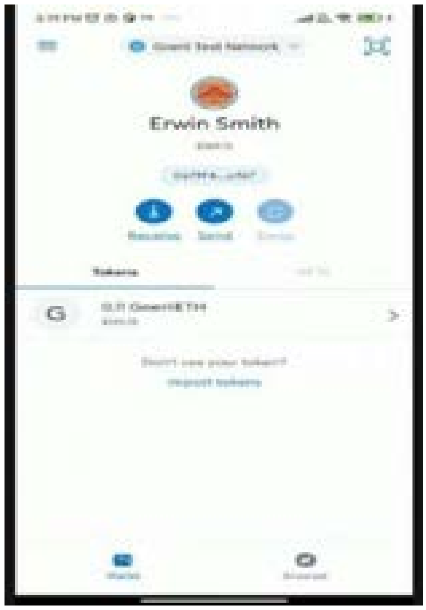

Figure4: My Wallet

Further, this study explores the integration of MetaMask, a popular cryptocurrency wallet, into a decentralized application (dApp) using its application programming interface (API). MetaMask allows users to interact with the Ethereum blockchain and its dApps through a web browser extension. By connecting MetaMask to our dApp, we enable users to securely manage their cryptocurrency assets, access smart contracts, and interact with decentralized exchanges. The integration process involves installing the MetaMask extension, setting up the wallet, and connecting it to the dApp using the API. Users can then authorize transactions, which are signed by MetaMask using their private key and broadcasted to the Ethereum network. The transaction is processed and added to the blockchain, providing a secure and transparent way for users to interact with our dApp.

Overall, the integration of MetaMask into our dApp enhances the user and provides a seamless way for users to engage with the Ethereum blockchain [9] [10]. High transaction fees can limit the adoption and sustainability of blockchain solutions in healthcare supply chains. The paper will explore strategies for reducing transaction fees, such as optimizing gas fees, implementing layer 2 scaling solutions, and leveraging fee estimation algorithms, to minimize costs and improve cost-effectiveness for stakeholders.

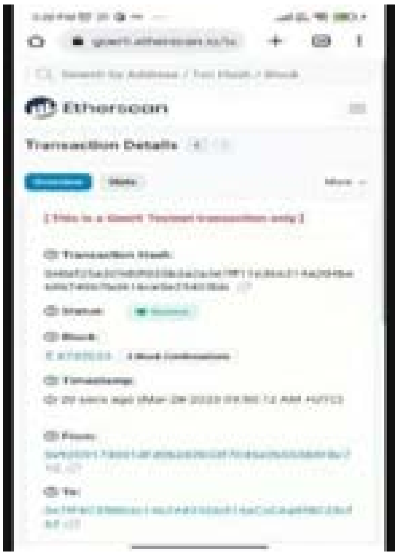

Figure 6: Ethereum Account

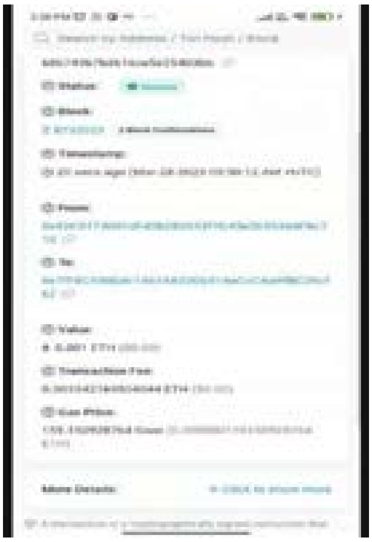

Figure7: Transaction Details

Blockchain can provide a secure, synchronized, decentralized, and distributed record of digital transactions, without the need for third-party mediation. This can help to improve the security and efficiency of the supply chain, reducing costs and risks for healthcare organizations. However, there are also challenges and limitations associated with blockchain technology, including scalability, interoperability, and regulatory issues. Overall, the discussion section highlights the potential of blockchain technology to revolutionize the healthcare supply chain, providing a secure, transparent, and efficient platform for the exchange of healthcare data and services. Enhancing the reliability of blockchain technology in healthcare supply chains involves implementing robust protocols for data validation, consensus mechanisms, and fault tolerance. The paper will discuss various techniques and best practices for improving reliability to ensure the integrity and availability of critical supply chain data.

VI. CONCLUSION

In conclusion, this study has explored the potential of blockchain technology to enhance security and efficiency in the healthcare supply chain. Blockchain can provide a secure, synchronized, decentralized, and distributed record of digital transactions, without the need for third-party mediation. This can help to improve the security and efficiency of the supply chain, reducing costs and risks for healthcare organizations. However, there are also challenges and limitations associated with blockchain technology, including scalability, interoperability, and regulatory issues. Overall, this study has suggested that blockchain technology has the potential to revolutionize the healthcare supply chain, providing a secure, transparent, and efficient platform for the exchange of healthcare data and services.

Abstract—Developing a smart blind assistance system utilizing deep learning techniques to enhance accessibility for blind people. This study focuses on two groups. Group 1 uses YOLOv3 which is an object detection algorithm used to detect objects using image dataset. Group 2 Open CV is an object detection algorithm used to detect objects using a video dataset for object detection but lacks action detection. Group 3 employs the Convolutional Neural Network (CNN) algorithm for real-time action detection with improved accuracy. The Convolutional Neural Network (CNN) algorithm did really well at spotting actions as they happened, scoring an average of 81% accuracy. By adding voice commands to VGG16, blind assistance systems become more accessible and provide a better user experience than the YOLOv3 and Open CV framework.

Keywords—Convolutional Neural Network, Real-time Detection, Blind Assistance System, Object Detection, Digital, Technology, Image, Deep Learning.

I. INTRODUCTION

The Blind Assistance System, utilizing digital image processing, is a pioneering technology designed to empower visually impaired individuals by enhancing their mobility. This innovative solution integrates wearable technologies, machine learning, and advanced image processing for real-time environmental analysis. By identifying objects, detecting barriers, and providing navigational assistance, the system enables users to move confidently and independently. The integration of haptic and aural feedback technologies ensures users receive intuitive information about their surroundings. This cutting-edge assistive technology contributes to a more inclusive and autonomous lifestyle for people with visual impairments, showcasing the positive impact of technological advancements on accessibility [1]. The four-volume set LNCS 14442-14445 presents the proceedings of INTERACT 2023, the 19th IFIP TC 13 International Conference on Human-Computer Interaction. Held in York, UK, in August/September 2023, the conference received 406 submissions, from which 71 full papers and 58 short papers were carefully selected. The papers cover diverse topics, including 3D Interaction, Accessibility, Co-Design, Cybersecurity, Eye-Free Interaction, Haptic Interaction, Human-Robot Interaction, Information Visualization, Natural Language Processing, Online Collaboration, User Studies, Virtual Reality, and more. The content is organized into sections such as Keynotes, Workshops, and Posters, reflecting the conference's comprehensive exploration of HCI and related fields [2]. Visually impaired individuals, with varying degrees of vision loss, have diverse needs. Smart Vision, an Android app, addresses these by offering assistance in daily tasks. Its six modules include obstacle avoidance, digital assistant, scene description, light detection, color detection, and face detection. The app is designed for reliability, portability, and cost-effectiveness, with high accuracy in various tasks. Object detection stands at 90%, face recognition at 87%, color detection at 75%, digital assistant tasks at 91%, and light detection at 82%. With an average response time of under 3 seconds, Smart Vision is suitable for both indoor and outdoor environments [3]. Visually impaired individuals rely on assistive technology for tasks like navigation and obstacle detection, both indoors and outdoors. This review explores cutting-edge devices and technologies, tracing their evolution and classifying them based on applications. Additionally, it highlights the integration of solar industry innovations and advocates for renewable energy sources in creating assistive devices. The impact of COVID-19 on assistive device development is addressed. This concise review serves as a foundation for further research in this field [4].

II. RELATED WORKS

The literature highlights the efficacy of deep learning, particularly the convolutional neural network, in achieving high success rates for blind assistance systems. The fields of object identification, feature extraction, and recognition have made significant strides in recent years, both in theory and in practical applications. This is especially true when handling multimedia files like photos and movies.

Efficient solutions are crucial for fast and reliable processing in various domains. Computational intelligence plays a pivotal role in applications ranging from medical screening, where it aids in detecting disease symptoms, to prevention monitoring for identifying suspicious behavior. In agriculture, computational intelligence contributes to optimizing plant growth and animal breeding processes. Additionally, these methodologies find applications in optics and materials for detecting surface damage [6].

The Internet of Things (IoT) and artificial intelligence (AI) are expanding quickly in today's corporate environment. Currently, there are 25 billion linked devices in use, including machinery, sensors, and cameras. This number is constantly rising. An estimated 41.6 billion Internet of Things (IoT) devices will be connected by 2025, producing 79.4 zettabytes of data. There are several cases where IoT and AI meet. IoT-enabled devices are producing massive amounts of data, which are then used to create a variety of intelligent models using AI. The world is smarter and we may benefit from these intelligent models in our daily lives. Issues with system security, dependability, safety, and deployment tactics in the fields of infrastructure, energy, transportation, healthcare, and the military are covered in Artificial Intelligence in Cyber Physical Systems: Principles and Applications [7].

An easy-to-read primer on anomaly detection using cutting-edge deep learning and machine learning techniques is "Beginning Anomaly Detection Using Python-Based Deep Learning". Updated chapters on transformers and GANs take into account current developments. For supervised anomaly detection in PyTorch and Keras, the authors offer guidance on how to create multilayer perceptrons. We investigate autoencoders, recurrent neural networks, temporal convolutional networks, and transformers as examples of deep learning models for anomaly identification. A new chapter on GANs and further information on transformers for time-series anomaly detection are included. The techniques for detecting anomalies in a variety of settings, including time-series data, are clearly understood by the readers. Additionally, the book teaches readers to PyTorch, Keras, GANs, transformers, scikit-learn, and Keras, enabling them to build their own anomaly detectors. Appropriate for machine learning engineers and data scientists with any degree of expertise who are interested in deep learning applications for anomaly detection [8].

Numerous beneficial applications exist for computer vision-based crack-like object recognition, including the inspection and monitoring of railroad tracks, subterranean pipelines, pavement surfaces, and fractures in bridges. However, cracks are difficult to detect since they typically appear as thin, uneven, long-narrow objects and are frequently hidden by very diverse, varied, and textured backgrounds. The deep learning technique has been quite successful in the last few years and has been used to a wide range of object detection challenges. This book provides a thorough discussion of the crack-like item detection problem. It first discusses conventional image processing techniques to solve this issue before introducing techniques based on deep learning. In order to delve deeply into the deep learning approach, it offers a thorough overview of object recognition challenges and concentrates on the trickiest one, crack-like object detection. It contains simple-to-understand examples of real-world issues and can serve as an excellent introduction to computer vision and machine learning [9]. This volume compiles essential principles and methodologies for leveraging geospatial information technologies to process remotely sensed data for improved agricultural monitoring. Covering aspects from collection to dissemination of digital geoinformation, the book consists of eighteen chapters addressing topics like land parcel identification, image processing in agricultural observation systems, data management, and decision support systems. Designed with the Blind Assistance System in mind This fundamental paper is a useful resource for voice command-driven accessibility in agricultural applications, utilizing deep learning techniques to provide Voice Commands for Enhanced Accessibility [10].

Addressing the growing security concerns in digital media, this study introduces a image authentication system with tamper localization in the wavelet domain. The watermark, generated by replicating the logo image, aligns with the size of the integer wavelet transform's HH sub-band. To enhance security, the watermark undergoes scrambling with a shared secret key. Applying the integer Haar wavelet transform enables pixel-level tamper detection and localization. Results demonstrate the scheme's effectiveness across varied image and tampering sizes, offering resilience against conventional watermarking attacks. This adaptable system holds promise for applications in insurance and forensics, aligning with enhanced accessibility goals through voice commands in a Blind Assistance System [11].

Chronic kidney disease (CKD) is a global health concern often overlooked in its early stages. To enhance early detection, we propose a system using KNN and Logistic regression. Utilizing a CKD dataset with missing values, KNN imputation addresses gaps by selecting similar measurements. Six machine learning algorithms were then applied, with random forest achieving the highest accuracy. Analyzing misjudgments, we propose an integrated model combining logistic regression and random forest using perceptron, achieving an average accuracy. Tailored for the Blind Assistance System Using Voice Commands, this approach ensures accurate and accessible CKD diagnosis through deep learning techniques. [14].

The research utilizes Convolutional Neural Networks (CNNs) for Blind Assistance System, powered by Vgg16, attains an exceptional accuracy rate of 81%, outperforming the existing project's achievement of 76% using YOLOv3 and YOLOv4. This noteworthy improvement underscores the substantial advantages that voice-command accessible solutions can bring to the visually impaired community. The successful deployment of Vgg16 in object detection not only demonstrates its efficacy but also paves the way for promising developments in the realm of accessibility technology. This progress signifies a substantial leap toward creating more robust and effective systems tailored to the distinctive needs of the blind, showcasing the ongoing commitment to advancing assistive technologies.

III. PROPOSED SYSTEM

The proposed system enhances object detection using advanced CNN - VGG16 model, focusing on accuracy and efficiency that represented in Fig. 1. It employs a comprehensive approach, including data pre-processing, feature selection, and training/testing phases. Addressing challenges in diverse environments, it prioritizes robust detection, user-friendly interfaces, and seamless integration for practical use across domains.

In this existing research, there are two groups. Group 1 represents the seamless integration of the YOLOv3 algorithm, contributing to real-time object detection within a highly advanced blind assistance framework. The core aim of this integration is to amplify the levels of independence and safety experienced by visually impaired individuals by enabling swift object recognition with subsequent auditory feedback. Through the utilization of a webcam for live video input, YOLOv3, specifically optimized for real-time inference, excels in its capacity to accurately detect objects spanning a diverse array of classes. The inherent adaptability and precision embedded within the YOLOv3 algorithm render it a remarkably versatile tool, ultimately leading to a substantial enhancement in the overall quality of life for individuals facing visual impairments. Group 2 represents the inclusion of OpenCV's DNN module further refines the system's performance. This module serves as a deep neural network framework, adding an additional layer of sophistication to the real-time object detection process. The synergy between YOLOv3 and OpenCV's DNN module contributes to the adaptability and versatility of the blind assistance system, elevating its effectiveness in addressing the unique needs of visually impaired individuals. In practical terms, the system not only identifies objects promptly but also utilizes Google Text-to-Speech (GTTS) technology to generate voice alerts, conveying crucial information about the detected objects. This ensures a comprehensive and user-friendly experience, allowing visually impaired individuals to navigate their environment with increased independence and safety.

Group 3 represents the suggested method uses a Convolutional Neural Network (CNN) VGG16 model to present a novel approach to object detection. This particular kind of artificial neural network is intended for processing and picture recognition. Comparable to an intelligent eye, VGG16 analyzes images in layers, attempting to decipher their contents. It analyzes the image in little pieces, similar to jigsaw pieces, and determines what each piece might mean for real-time object recognition with voice and distance alarms. By automatically and adaptively learning hierarchical features from input images—capturing local patterns like edges and textures and eventually integrating them to detect more complex structures—it makes use of convolutional layers. Convolutional, pooling, and fully linked layers are common architectural features of networks that allow them to analyze and categorize visual data effectively. CNNs have demonstrated remarkable efficacy in a range of computer vision tasks, such as object detection, facial recognition, and picture classification, because of their capacity to automatically extract and learn pertinent features from visual data.

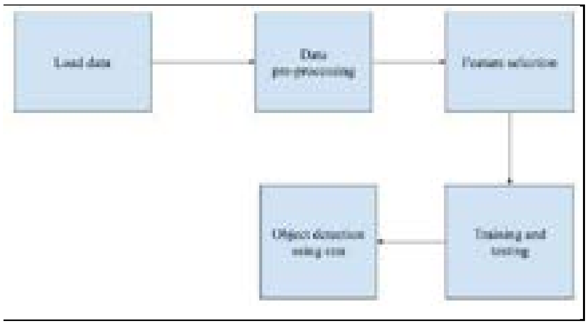

Fig. 1. Flowdiagram of howthe data is loaded and the result is analyzed

A. Load Data

The foundational step in implementing object detection using Convolutional Neural Network (CNN) within the Blind Assistance System entails the meticulous loading of data. This module is dedicated to the seamless importation of raw data, predominantly images or videos, into the system. The dataset encompasses a diverse array of images containing objects that necessitate detection. The effective organization of this dataset becomes paramount, setting the stage for the subsequent intricate processing steps. This meticulous approach ensures a robust foundation for the overall efficacy of the Blind Assistance System, emphasizing the critical role of data management in optimizing the object detection process.

B. Data Pre – processing

To guarantee that the input data is in an appropriate format for CNN training, data pre-processing is an essential step. This module includes operations like scaling all photos to the same size, normalizing pixel values to a common scale, and adding rotation and flipping to the dataset. When these procedures are combined, the variety and quality of the data are increased, which leads to better generalization and model performance.

C. Feature selection

Within the realm of object detection utilizing Convolutional Neural Network (CNN) in the Enhanced Blind Assistance System, lies the critical phase of feature selection. This intricate step involves the identification and curation of significant characteristics from the pre-processed data that will subsequently be fed into the CNN. Features encompass crucial information such as edges, textures, or colors, instrumental in aiding the model to distinguish and identify objects within images effectively. The meticulous selection of features is pivotal not only in reducing computational complexity but also in optimizing the overall performance of the model. This nuanced process ensures that the Blind Assistance System attains heightened accuracy and efficiency, underscoring the profound impact of feature selection in the realm of advanced digital image processing.

D. Training and Testing

In enhancing Blind Assistance through Advanced Digital Image Processing, the pivotal stages include training the Convolutional Neural Network (CNN) model with pre-processed and carefully selected data. This phase enables the model to assimilate intricate patterns associated with objects, enhancing its precision in identification. Subsequently, the model's proficiency is rigorously tested with an independent dataset to assess its ability to generalize knowledge and provide accurate predictions in novel scenarios. This amalgamation of robust training and rigorous testing exemplifies the Enhanced Blind Assistance System's commitment to excellence in providing precise support through advanced digital image processing.

E. Object Detection using image processing

In the culmination of the transformative process in Blind Assistance through Cutting-edge Digital Image Processing, the final module focuses on utilizing the Convolutional Neural Network (CNN) model for object detection. When applied to fresh photos or videos, the trained model adeptly locates and recognizes items within the provided information. The identification is visually represented by bounding boxes surrounding the recognized objects. The accuracy and efficiency of object recognition hinge on the robustness of features selected in the early stages, the quality of training data, and the efficacy of pre-processing techniques. Continuous refinement and adjustments may be necessary to enhance the model's accuracy in identifying objects across diverse situations. This comprehensive approach underscores the commitment to excellence in object detection within the Enhanced Blind Assistance System.

IV. RESULTS

When three algorithms YOLO V3, Open CV, and Convolutional Neural Network (CNN) VGG 16 are compared based on how well they perform in terms of accuracy, it becomes clear that CNN performs better than YOLO V3 and Open CV, with an accuracy rate of 81% represented in Fig. 2. This suggests CNN has better predictive skills than more conventional machine learning algorithms like YOLO V3 and Open CV. The existing Blind Assistance System is built upon the integration of YOLOv3 and OpenCV, achieving a commendable 76% and 71% accuracy rate in its functionalities. These models, particularly YOLOv3 and OpenCV, play a crucial role in providing valuable support through voice commands, primarily focusing on aiding navigation for individuals with visual impairments. Although their accuracy slightly falls short compared to the VGG16-based system, their contributions significantly enhance accessibility. This improvement, driven by real-time object detection and auditory feedback, results in an overall elevated quality of life for visually impaired users. However, the proposed VGG16-based system takes accessibility to a new level, boasting an impressive 81% accuracy rate. This system is positioned as an excellent solution for voice-command-driven accessibility. Leveraging state-of-the-art deep learning techniques, particularly within the realm of object detection and recognition, the VGG16-based system achieves unprecedented accuracy represented in Table. 1. The profound impact is felt in the navigation experiences of individuals with visual impairments, as the system excels in providing precise and reliable information about the surroundings. The hallmark of this proposed system lies in its embrace of advanced technology, where cutting-edge deep learning techniques are seamlessly integrated. This integration not only furthers the accuracy of object detection but also enhances the overall user experience accuracy represented in Table. 2. The system becomes a catalyst for promoting self-sufficiency and enriching the diversity of daily activities for individuals with visual impairments. Through its innovative approach, the proposed VGG16-based Blind Assistance System establishes a new standard in accessibility technology, ensuring a transformative and empowering impact on the lives of those with visual impairments requirements represented in Table. 3.

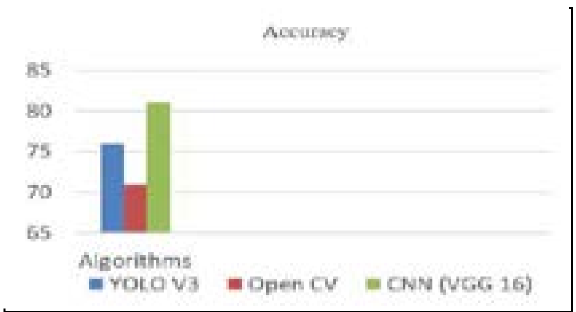

Fig. 2. Accuracy comparison chart of YOLO V3 76%, OpenCV 71 %, Convolutional Neural Network (VGG16) 81% accuracy.

V. DISCUSSION

Improving accessibility with a VGG16-based blind assistance system that achieves 81% accuracy, outperforming previous models that rely on YOLOv3 and OpenCV, which only achieve 71% and 76% accuracy [19]. In the third experiment, they investigated the participants' audio rendering-based recognition of natural objects. Evaluated the participants' capacity to distinguish between objects that belonged to the same category in the fourth trial [20]. The implementation of a Blind Assistance System utilizing Digital Image Processing opens up a realm of possibilities for improving the daily lives of visually impaired individuals. One key aspect of the discussion revolves around the system's ability to leverage digital images to provide real-time assistance [21]. By employing advanced image processing algorithms, the system can identify obstacles, recognize environmental features, and convey this information to users through accessible means like audio cues or tactile feedback. Research underscores the significant challenge blind and visually impaired individuals face in navigating safely and efficiently, despite developing non-visual orientation and mobility skills. Common obstacles encountered during navigation include holes, hanging objects, stairs, traffic scenarios, signposts, and wet flooring [22]. This not only enhances the user's awareness of their surroundings but also facilitates more confident and independent navigation.

Additionally, the discussion must encompass the adaptive nature of the Blind Assistance System during dynamic analysis. Accessibility evaluation tools for web content primarily assess HTML syntax to ensure compliance with regulations and guidelines, accelerating improvements in web accessibility. However, compliance with syntactical rules doesn't guarantee usability for blind users, as these tools often overlook user experience considerations [23]. People who are visually impaired experience more daily hardships and hassles getting in and out of their homes without the right support or aid from others. Thus, it becomes necessary to give them a user-friendly gadget. For these individuals, an effective method such as a machine learning algorithm offers a solution. To utilize deep learning techniques [24].

The system's capacity to dynamically adjust guidance based on real-time visual input showcases its responsiveness to evolving situations [25]. This adaptability is crucial in addressing the unpredictability of real-world environments, such as crowded spaces or changing obstacles. Furthermore, the incorporation of machine learning models for continuous improvement highlights the system's ability to learn and evolve over time, refining its recognition capabilities and user-specific preferences. Future work for blind assistance is advanced natural language processing integrated to provide voice instructions that are easier to understand. Investigation of multimodal feedback systems that integrate tactile, visual, and aural cues. Creation of individualized support profiles based on the requirements and interests of each user.

VI. CONCLUSION

In summary, the suggested method leverages the VGG16 model, has demonstrated a significant leap in performance by achieving an impressive accuracy rate of 81%. This surpasses the current accuracy of 76%, which was accomplished using YOLOv3 and OpenCV. This notable improvement underscores the substantial advantages that voice-command accessible solutions can bring to the visually impaired community. The VGG16 model, known for its deep architecture and effective feature extraction capabilities, has proven to be highly proficient in object detection tasks. Its ability to accurately identify and classify objects contributes to the enhanced performance observed in the Blind Assistance System. The success of Vgg16 in this context not only speaks to its efficiency but also opens up promising avenues for further developments in the field of accessibility technology. This progress is significant not only in terms of accuracy improvement but also in highlighting the ongoing commitment to advancing assistive technologies. The system's ability to better cater to the unique needs of the blind community is a testament to the positive impact that emerging technologies, like VGG16 and voice-command accessibility, can have on enhancing the overall user experience and independence of individuals with visual impairments. The achievement of an 81% accuracy rate represents a noteworthy milestone and encourages continued exploration and innovation in the development of assistive technologies.

***Abstract*—Rumor (Hoax) and stance (Posture) detection, and reply weight estimation in social media were becoming important due to developments in the social network platforms, guaranteeing authenticity in posts, and increasing the scale of social media data. In previous work, hoax detection was implemented using a multi-task learning mechanism (MTLM) for performance improvement and neglected three aspects such as focusing on the textual contents only, limited posture information used, and neglecting posture information at stance labels. This work designed a hyper meta-network approach for reply, hoax, and stance detection in social media by considering textual and visual content. A meta-knowledge-sharing scheme is used to solve problems raised in hoax and stance detection. The attention mechanism is used in estimating the reply weight of each one for better utilization of posture information hidden in the posture labels. On implementation of the proposed approach with different Twitter-based datasets demonstrates that the method achieved in updating models.**

***Keywords*— Rumor Detection, Stance Detection, Reply Weight, Cognitive Contents, Hyper Meta-Network, Textual and Visual Contents, Social Media Platform.**

I. INTRODUCTION

Nowadays people's preferred method of organizing, sharing, and disseminating information online has become social networking websites. Social media's hundreds of millions of users disseminate and share stories online whenever they see fit. When individuals post anything online without verifying its veracity, rumors have a good chance of spreading rapidly; rumors on social media can have far-reaching negative consequences, including the potential impact on important public events. Consequently, social media platforms face significant difficulty in determining how to effectively identify deceptive content and lessen its detrimental effects it. The damaging effects of rumors have been the subject of several efforts to mitigate them.

Some of the earliest news websites to try to confirm or refute rumors using expert analysis and user-generated material were PolitiFact and Snopes.com. When it comes to studies on automated rumor detection, there are mainly two categories: (1) Approaches that need human involvement to either construct or extract complex traits make up the first category. (2) For instance, in. builds a multitude of handcrafted features by collecting user social context and media information and using it to train an SVM (Support Vector Machine). Two, the set includes automatic deep feature capture that is based on neural networks, which is an example of a study that trains a recurrent neural network to find latent representations by using appropriate post-text as input. Using a convolution neural network (CNN) can extract crucial parts and their interrelationships from the material presented in the assertions. Traditional approaches introduce problematic stance label information in the hoax-detecting job with the usage of backpropagation. Regardless of a few of these algorithms have demonstrated potential in detecting hoax, most of them delt with text-type of data only. Several modalities (such as two types of data) may coexist with posts that they can even enhance one another. Since all of the tweets used in rumor detection activities are user-submitted, the user's perspective can also play a substantial role in the process. Due to this, it is essential to detect rumors by analyzing the user's location and multimedia content.

In this work Hyper Meta Network Approach learning approach proposed is a new technique to include users' attitude information from detecting rumours assignment replies provides a novel shared-private Hyper Meta Network Approach learning method for the concept of rumour and stance detection tasks to share information and support each other's representations. In this used model will improve qualities that are beneficial for each task on its own. Posts on social media may make use of a wide variety of presentation modalities, including text and graphics, which frequently work well together. Posts on social media may make use of a wide variety of presentation modalities, including text and graphics, which frequently work well together. Most people don't pay attention to the hidden semantic information in the granular attitude labels. It is evident from the results represented in the "TABLE I" that used data by posture identification at level of post. Using tweet-level the labels could aid with hoax detection. To address these concerns, this work introduces the Hyper Meta Network Approach a new approach for the implementation of the work. Three main benefits can be gained from using the Hyper Meta Network Approach: One way to use modalities is by using a post-implementation layer that takes textual and visual input into account. Second, the stance data from user answers is efficiently utilized by rumor detection. Third, use an attention approach to determine the relative importance of each answer which includes hidden states from the posture layer in its calculation.

II. LITERATURE REVIEW

Social media sites now account for a disproportionate share of people's news and information consumption. Social media platforms generate massive volumes of data due to their massive user bases. Academics are very interested in these social media analytics because of their impressive academic use. Multiple studies have been suggested by researchers to elucidate the nature of social media. These include social media analysis, understanding social events, the phenomena of cyberbullying, multimedia summarization on microblogs, election prediction, visual concept learning, opinion mining, Cognitive Contents with Hyper Meta Network data learning, Inaccurate data from social media is influencing a lot of models.

The primary goal of the supervised classification method is to train hoax classifiers with well-described properties. A plethora of traits that were hand-crafted was used to disprove lies in the early methods [5], Post contents, user profiles, and propagation patterns were used to produce a variety of characteristics in the study by Castillo et al. [6]. The majority of the research on rumor detection on social media platforms has been on supervised classification issues.

Ma et al. [7] suggested using a recurrent neural network. In recent years, several methods have emerged for rumor detection using multimedia [10] in discovering hidden representations with content of claims. Jin et al. [9] suggest an attention-based recurrent neural network in combining text and visual aspects in rumor detection. To achieve top-tier detection performance, data-driven models have been suggested as an alternative to modeling complicated feature sets [5, 7, 8].

The main contribution of the work is to identify social media rumors by utilizing a Hyper Meta Network Approach. Instead of features, this model transfers meta-level data between tasks. This work proposes a meta-network for collecting meta-knowledge across tasks and for controlling the parameters of task-specific networks. Song et al. suggest a method for Hyper Meta Network Approach learning with many sources that improve user interest inference by regulating source consistency and tree-guided task relatedness simultaneously.

This work presents a novel approach to rumor detection by employing hyper-meta networks for Hyper Meta Network Approach learning. To improve these objectives, used a dynamic weight generation method, and developed a design that facilitates the communication of meta-information by rumour-related activities. This work handles many Cognitive Contents with Hyper Meta Network rumour-related tasks with very varying input and output architectures, unlike prior meta-task learning systems. To further improve meta-Hyper Meta Network Approach learning, an attention technique was used. Greater use of the label data from various rumour-related activities was used at different granularities.

III. DESIGN AND DEVELOPMENT OF PROPOSED SYSTEM

A. *Hyper Meta Network Approach:*

To address these concerns, this work introduces Hyper Meta Network Approach, a new approach to learning. Three main benefits can be gained from using Hyper Meta Network Approach: One way to use modalities is by using a post-implementation layer that takes textual and visual input into account. An approach to Hyper Meta Network Approach learning based on knowledge sharing is proposed to solve the issue with feature-sharing methods. Instead of utilizing lower layers to find commonalities across activities, the proposed Hyper Meta Network Approach learning uses a shared meta-network that learns meta-knowledge from different tasks in a reciprocal fashion. With the accumulation of meta-knowledge comes the dynamic development of parameters for task-specific models. So, the stance data from user answers is efficiently utilized by rumor detection. Using an attention method to determine the relative importance of each answer and explicitly including hidden states of posture layer to calculate attention, which may better leverage the semantic information from the posture labels. The efficacy of rumor detection has therefore been greatly enhanced. In extensive tests conducted on two Twitter benchmark datasets, our rumor detection system surpassed updating models.

Key points from the research study are as follows: To detect social media rumors, a meta-learning approach is introduced that combines many modalities. Suggested technique utilizes meta-knowledge from posture and rumor detection tasks, which is higher level than typical Hyper Meta Network Approach learning systems that depend on lower-level similarities. The task-specific model can correctly get Cognitive Content with Hyper Meta Network representation post with meta-knowledge.

The attitude information from user answers to good use by using an attention method. Try to improve the suggested Cognitive Contents with Hyper Meta Network Meta-multitask learning even further by using the weighted user answers. Our method outperforms the current state-of-the-art, as shown by experiments on two publicly available benchmark datasets for Twitter rumor recognition tasks.

Advantages:

The Cognitive Contents with Hyper Meta Network post-embedding layer represents the Cognitive Contents with Hyper Meta Network content of each claim post as an embedding vector. We employ VGG19 for the visual content and BERT for the textual content to derive the embedding vector.

Hyper-Multitasking Layers: We provide a meta-layered approach to Hyper Meta Network Approach learning that integrates meta-information from posture recognition and rumor detection to improve social media rumor identification. Following instructions from the shared meta-network, the task-specific layer has the potential to acquire knowledge about the details of each post.

To make maximum use of the attitude information provided by the user's answers, an attention approach is applied for task-specific output layer. The rumour forecast may be believed depends on the clarity of the responses.

B. *Used Algorithm Description in the proposed method*

Steps involved are

Step 1: Registration of new users with their credentials.

Step 2: Verification of user details in the server.

Step 3: Validation and authentication of users.

Step 4: Users can log in for their social media login.

Step 5: Uploading of data sets – Excel Format.

Step 6: View of uploaded datasets.
Step 7: Finding post type by hash code to detect Rumour/non-rumour.
Step 8: Display Results.

C. Description of the system modeling, design, and development

Input Design

Input Design is an essential part of the software development life cycle; thus, developers should pay great attention to it. The program relies on reliable data, which is why input design is so important. Inputs must be efficiently built to reduce feeding errors. Software engineering principles should be followed while creating input screens or forms with validation controls for input range, limit, and related validations.

Almost every section of this system has its data entry screen. The purpose of error messages is to alert users whenever they make a mistake and provide those instructions on how to fix it, so they don't make the same mistakes again. Look at this closely from the perspective of the design of modules.

Input design is the process of making user-generated material computer-readable. Main goal of input design to provide logical and input with error free. Controlling input mistakes is the input design's job. The application was designed with the user in mind. Forms are designed to automatically position the cursor where data needs to be entered during processing. Multiple input fields provide a drop-down menu from which the user can select an appropriate value.

Validations must be applied to all data entries. When the user completes all the forms on this page and receives an error notice for each wrong submission, they can go on to the next page.

Output Design

How well a project manager can convey their ideas to stakeholders his team members or an administrator's ability to communicate effectively with clients are two of the main goals of the computer's output. The final product of the VPN system is a client management system that the project manager may utilize to recruit new clients and assign them to work.

On their behalf, monitoring the projects' status and on the user end, allocating folder-level access to clients according to their allocated projects. After one client's project is complete, they may be assigned a new one. We guarantee that user authentication procedures are in place from the start. While anybody may sign up for an account or the administrator can establish one, only the latter can verify the user's identity and give them a project to work on.

The software starts operating as soon as the first execution of it takes place. Starting the server is necessary. Before Internet Explorer may be used as a browser. On a local area network, this project can only run with one computer acting as the administrator and the others as clients. The system's intuitive design ensures that even first-time users will have no problem learning how to utilize it.

Modules

Social Server

Once the Service Provider has successfully logged into this module with their valid username and password, they will be able to access various operations such as: View All Datasets, View All Datasets by Hyper Meta Network Approach, View Post Score Results, View Post Rating Results, View Rumour Results, and Login.

View and Authorize Users

Here the administrator may see a complete rundown of all the registered users. Admins may see user information including name, email, and address, and they can also authorize users here.

End User

There are an equal number of users in this module. Registration is required before performing any operations. Details will be entered into the database after a user registers. He will need to log in using the permitted username and password when registration is successful. After logging in, users will be able to do things like see their profile, upload datasets, discover post types by hash code, and view all uploaded datasets.

IV. SYSTEM DESIGN AND DESCRIPTION

ARCHITECTURE

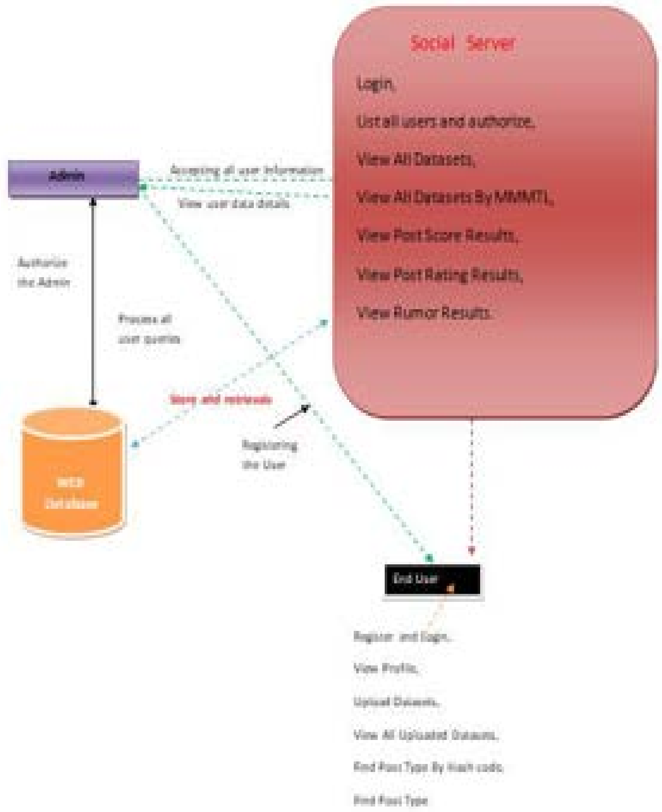

Fig. 1 Architectural Description

In Fig. 1, the architecture used in this proposed work admin, social server, end user and database were described in detail with their functionalities and roles performed by them in detail. As in Fig. 2 data flow diagram described by how the data will be flown between Social Server, System and End user with their relationship between them. In Fig. 3, the diagrammatic representation of steps performed by the end user is described in the form of flow chart and in Fig. 4 steps performed by social server were described.

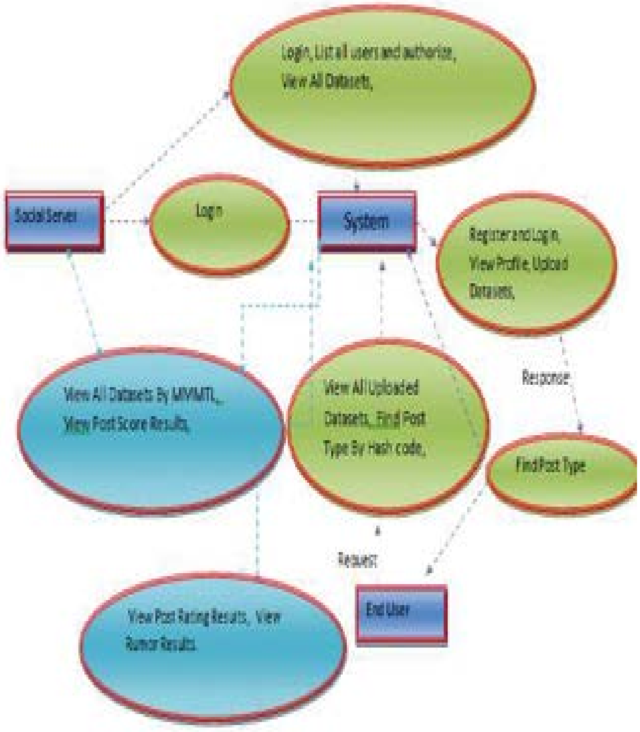

Fig. 2 Data Flow Diagram Description

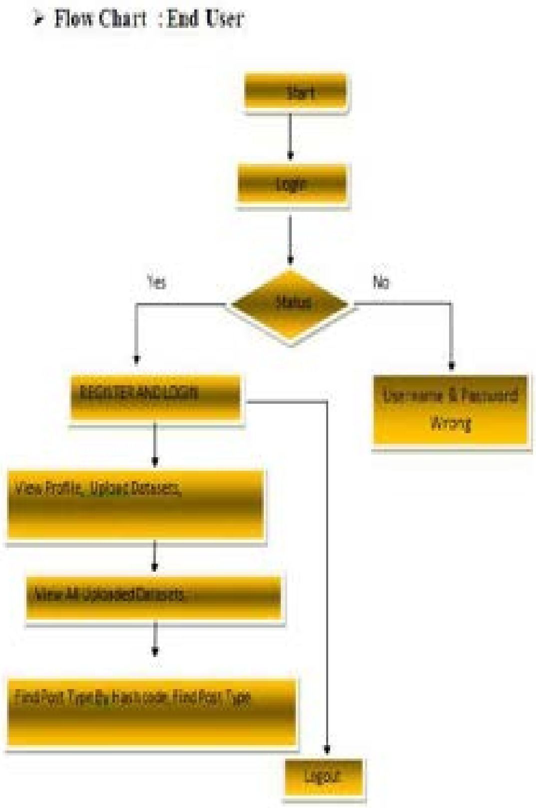

Fig. 3 Description of End User Flow Chart

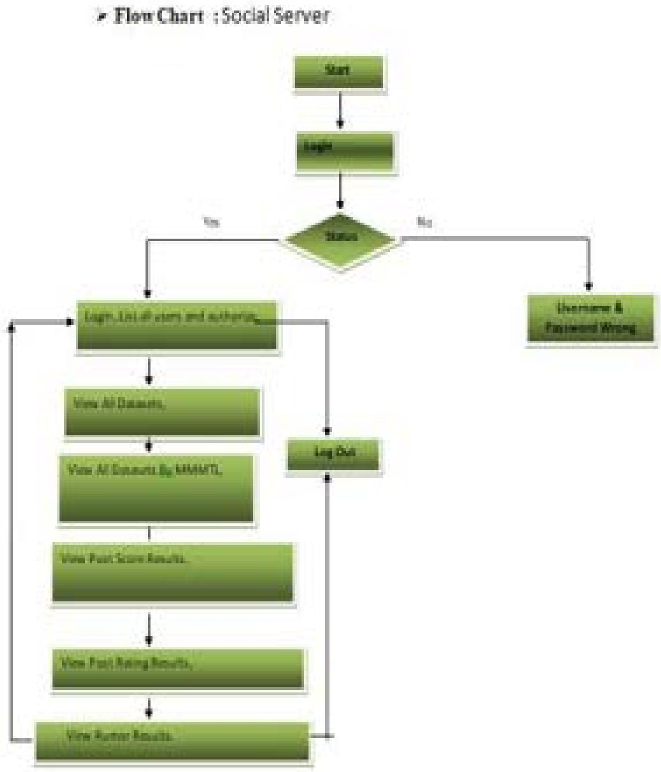

Fig. 4 Description of Social Server Flow Chart

V. RESULTS AND DISCUSSION

Description of got results with proposed method were described from Fig. 5 to Fig. 15 used with two different types of Twitter based datasets.

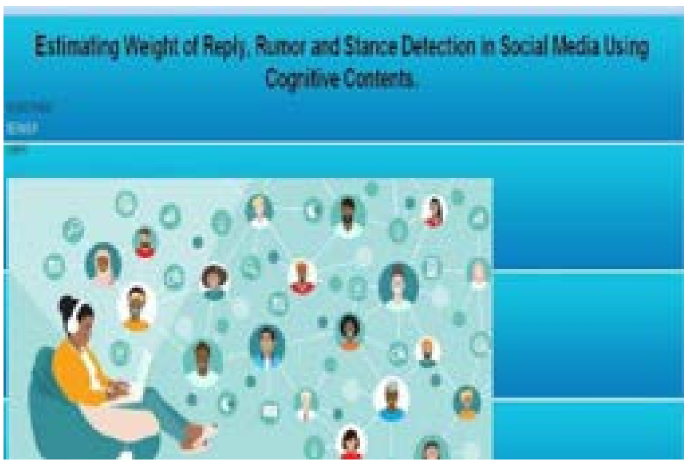

Fig. 5 Description of Home Page

In Fig. 5, represented the home page of the performed work which consists of two main components Server and User. Fig. 6, New User registration described with entering fields of user details and registered as a new user. Description of Verification of user details in the server is described in Fig. 7 with an example. In Fig. 8, description and validation of users were described. Uploading different types of datasets in excel form described in Fig. 9.

Fig. 6 Description of New User Registration

Fig. 9 Description of Uploaded Datasets

Fig. 7 Description of Verification of user details in the server

Fig. 8 Description of Validation and authentication of users

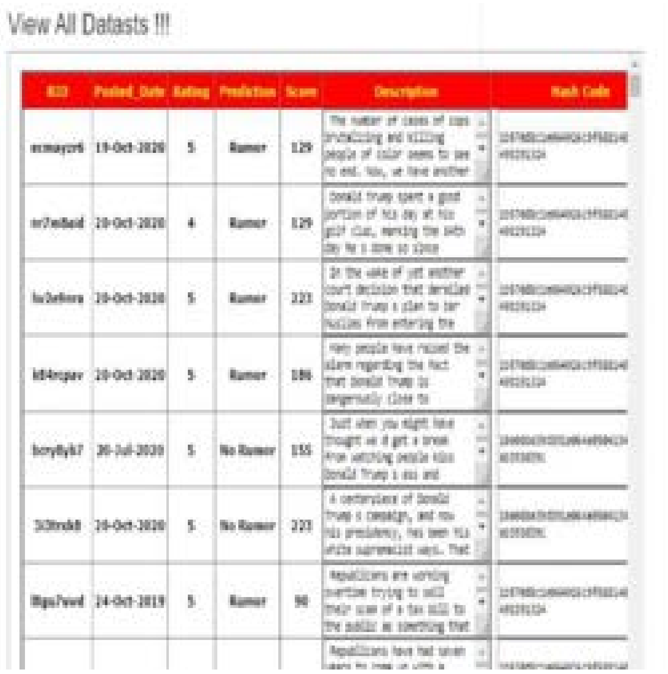

Fig. 10 View Sample Uploaded Datasets

Viewing different types of uploaded datasets in the server were described with registered ID, posted date, rating, prediction details rumor or not rumor, score obtained, description and hash tag details in Fig. 10 as an example dataset.

In Fig. 11, sample found trust type results by using hash tag were described as an example results of post type as non-Rumor along with details of registration ID, and posted date, description. In Fig. 12, sample found trust type results by using hash tag were described as an example results of post type as Rumor along with details of registration ID, and posted date, description.

Fig. 14 Description of View Post Score Results

Rating results were described in Fig. 13 by registration ID on X-axis and its rating values on Y-axis ranging from zero to five. Most of the IDs were rated as 5 where as one with rating as 4 and one as 3.

Post Score Results were represented in Fig. 14, by taking registration ID on X-axis and post score result values on Y-axis ranging from zero to three hundred.

In Fig. 15, Rumour results were represented by taking types of tweets as Rumour or non-rumour and Number of Tweets ranging from zero to one thousand five hundred on Y-axis. On observation of results of a particular type of dataset, it can be inferred that 1101 tweets were of non-rumour type and 224 were of Rumour type.

Fig. 15 Description of Rumor Results

VI. CONCLUSION AND FUTURE SCOPE

This research presents Hyper Meta Network Approach, a new approach to in Hoax detection, Poster detection, and reply weight estimation. Using the users' posture information answers in its detection is the goal to enhance rumour identification job performance. To extract meta-knowledge from Cognitive Contents with Hyper Meta Network postings, Hyper Meta Network uses frequently utilized higher-level meta-networks, unlike traditional Hyper Meta Network Approach learning algorithms. Hence, by dynamically building task-specific model parameters, all occupations utilize the shared meta-knowledge. In the wide attitude labels to make use of semantic info it can prioritize replies utilizing the attention mechanism. To demonstrate the suggested method yields first-rate results, employed multiple Twitter benchmark datasets. Along with other rumour-related jobs, the proposed Hyper Meta Network approach will soon have a reliability measurement job, which have been proved in this work. The suggested technique utilizes meta-knowledge from posture and rumour detection tasks, which is higher level than typical systems that depend on lower-level similarities. To get the most out of the attitude data in user answers, in this work used an attention strategy for Cognitive Content with Hyper Meta Network meta-task learning. One way to make the suggested Hyper Meta Network approach even more successful is to employ weighted user answers which also implemented.

As future work, since the used data is Cognitive Contents with Hyper Meta Network, there will be a problem with the feature level of the stance identification test and the rumor detection task, which can be reduced.

ACKNOWLEDGMENT

This work has no grants from either public or private grants. No conflict of interest between the authors and express thanks to all reviewers for their suggestions.

***Abstract*—This research study analyzes the dynamic nature of drone technology, exploring its multifaceted applications, societal impacts, and the evolving challenges in its deployment. The integration of Unmanned Aerial Vehicles (UAVs) in various sectors, particularly in the fields of precision agriculture, cinematography, and geospatial mapping, is examined for its transformative potential. The paper highlights the revolutionary role of drones in addressing challenges such as search and rescue operations, natural disaster management, and providing virtual tourism experiences. Notably, the integration of Geographic Information System (GIS) technology and autonomous capabilities in drones is discussed in the context of cinematography and indoor inspections, emphasizing the need for a balance between technological innovation and ethical considerations. The comprehensive analysis includes insights into the security threat landscape associated with Augmented Reality (AR) drones, underlining the importance of conducting thorough threat analyses to ensure the safe operation of remotely piloted aircraft systems. Researchers have addressed concerns related to cyber threats, categorizing various aspects of the UAV threat landscape and developing classification approaches based on connections and nodes within flying ad-hoc networks (FANETs) and the Internet of Drones (IoD) infrastructure.**

***Index Terms*—Drone technology, Unmanned aerial vehicles applications, Geospatial Information Systems integration, Security threats, Autonomous capabilities, Citizen involvement.**

I. INTRODUCTION

In the ever-evolving realm of unmanned aerial vehicles (UAVs), colloquially known as drones, the fusion of cutting-edge technology with diverse applications has sparked a transformative wave across various industries. From precision agriculture to cinematography, geospatial mapping, and beyond, drones have not only revolutionized traditional practices but have also presented unique challenges that require thoughtful consideration. As these aerial marvels soar to new heights, a critical juncture emerges—balancing the limitless potential of technological innovation with ethical considerations and societal needs.

In the realm of cinematography, where drones offer unprecedented flexibility and shot diversity, a pressing challenge surfaces in the safe navigation of these devices while filming dynamic subjects in obstacle-laden environments. Simultaneously, the geospatial mapping sector grapples with the limitations of satellite-based localization, particularly within indoor spaces, necessitating inventive solutions to ensure precise data acquisition. Amidst these advancements, the expanding use of commercial drones has given rise to security concerns, introducing potential threats like jamming, spoofing, and denial of service attacks.

This comprehensive review paper endeavors to navigate through the intricate landscape of drone technology, shedding light on both its awe-inspiring advancements and the nuanced challenges that accompany its proliferation. From the intricacies of cinematographic applications to the dynamics of geospatial mapping, security threats, and beyond, our exploration aims to provide a holistic understanding of the current state of drone technology. By delving into these complexities, we aspire to contribute to the discourse surrounding responsible deployment, societal acceptance, and the delicate equilibrium between technological innovation and ethical considerations that define the future of drones.

II. CONCEPT OF DRONES: TRANSFORMING INDUSTRIES FOR GLOBAL PROGRESS

In the contemporary landscape, Unmanned Aerial Vehicles (UAVs), commonly known as drones, have evolved into pivotal assets across diverse industries, offering an array of applications that significantly benefit mankind.

III. CLASSIFICATION

This study has broadly categorized the drone based on its intended use, which includes major areas where it has experienced some enhancement or research

A. Virtual Tourism Drones

Fig. 1. Drone For Virtual Tourism

Virtual tourism drones as in Fig.1 are emerging as an innovative category of services within the tourism industry. Unmanned aerial vehicles (UAVs) are now employed not only for virtual tourism systems but also for monitoring and patrol activities, contributing significantly to safety and security measures [1]. These drones play a pivotal role in acquiring invaluable data from areas or objects that are otherwise in-accessible or pose potential dangers. This data serves as the foundation for creating detailed 3D models, facilitating the development of smart tourism services [2].

Augmented telepresence is gaining prominence as a technology that integrates immersive displays with augmented reality techniques. This combination is instrumental in the creation of advanced virtual tourism systems. By leveraging augmented telepresence, users can experience a virtual exploration of remote sites, accompanied by relevant information and con- textual details [3]. This technological integration enhances the overall tourism experience, providing users with a more immersive and informative journey.

The utilization of unmanned aerial vehicles and augmented telepresence techniques not only enhances the safety and security aspects of tourism but also opens up new dimensions for exploration and engagement. The data collected by virtual tourism drones contribute to the creation of detailed 3D models, while augmented telepresence adds a layer of interactivity and information, enriching the virtual tourism experience for users.

Augmented telepresence is gaining prominence as a technology that integrates immersive displays with augmented reality techniques. This combination is instrumental in the creation of advanced virtual tourism systems. By leveraging augmented telepresence, users can experience a virtual exploration of remote sites, accompanied by relevant information and con- textual details [3]. This technological integration enhances the overall tourism experience, providing users with a more immersive and informative journey.

The utilization of unmanned aerial vehicles and augmented telepresence techniques not only enhances the safety and security aspects of tourism but also opens up new dimensions for exploration and engagement. The data collected by virtual tourism drones contributes to the creation of detailed 3D models, while augmented telepresence adds a layer of interactivity and information, enriching the virtual tourism experience for users.

B. Search and Rescue drones

Fig. 2. Search and Rescue drones

The pivotal role of search and rescue drones shown in Fig. 2 becomes evident in their crucial contributions during natural disasters. These unmanned aerial vehicles (UAVs) play a significant role in efficiently locating and tracking targets of interest, thereby greatly enhancing the capabilities of situational awareness [4]. To address the challenges of operating in complex three-dimensional disaster environments, there has been a notable development in the formulation of multi-drone mission assignments and advanced path planning methods [5]. These advancements aim to optimize the utilization of drones in disaster scenarios, ensuring a more effective response.

Their primary role in locating and tracking, drone-based solutions has been proposed to address the critical issue of localizing missing individuals, a common challenge in the aftermath of natural disasters. This is achieved by leveraging the high penetration rate of mobile phones in society, offering a promising avenue for enhancing search and rescue efforts [6]. The integration of such technological solutions demonstrates the versatility of search and rescue drones in addressing various aspects of disaster management.

The indispensable role of search and rescue drones extends beyond their primary function of locating and tracking targets during natural disasters. The ongoing developments in multi-drone mission assignments, path planning methods, and innovative solutions for localizing missing individuals showcase the continuous evolution of these drones in enhancing disaster response capabilities. Their multifaceted applications under- score the significance of incorporating advanced technologies for more effective and comprehensive disaster management.

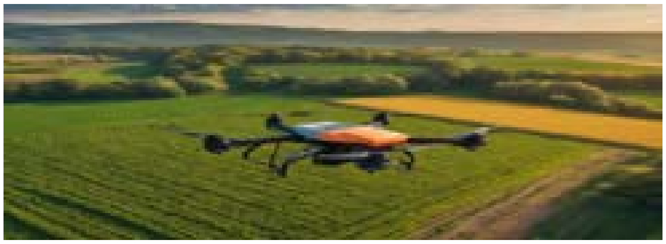

Fig. 3. Precision agriculture application drones

The integration of unmanned aerial vehicles (UAVs) into precision agriculture shown in Fig.3 witnessed a transformative impact on the agricultural landscape, ushering in a new era of technological advancements. The incorporation of UAVs, coupled with machine learning techniques, has become instrumental in various agricultural tasks, encompassing crop classification, detection of crops and weeds, cropland mapping, and field segmentation [7]. Despite the immense potential, the widespread adoption of precision agriculture technology faces challenges such as high costs, limited internet connectivity, and the complexities associated with setup [8]. These obstacles contribute to the current constraints on the broader implementation of precision agriculture practices.

In precision agriculture, one notable application that has gained popularity is plant disease detection, where UAVs play a pivotal role in automating the process. By utilizing drones, the agricultural sector can streamline and enhance disease detection mechanisms, thereby mitigating potential yield losses [9]. This application highlights the practical significance of UAVs in addressing specific challenges within precision agriculture, offering targeted solutions to improve overall agricultural productivity.

Integration of UAVs in precision agriculture represents a paradigm shift, leveraging advanced technologies to optimize various agricultural tasks. Despite the transformative potential, challenges such as cost considerations, connectivity limitations, and setup complexities continue to impede widespread adoption. Nonetheless, the ongoing exploration of applications like plant disease detection underscores the undeniable contribution of UAVs in overcoming specific challenges and fostering innovation within the realm of precision agriculture.

D. Drones in Engineering and Construction

The Drones have garnered considerable interest within the engineering and construction industry due to their prospective contributions to augment safety, efficiency, and precision in monitoring and inspection processes [10]. In this evolving landscape, they present novel avenues for data collection and analysis, deploying a diverse array of drones and sensors to

Fig. 4. Engineering and Construction drones

cater to different needs [11]. The integration of drones, along with cost-effective sensors and automated image processing techniques, has not only facilitated but also rendered remote-sensing approaches both feasible and compelling for various construction management tasks [12].

The utilization of drones in the engineering shown in Fig. 4 and the construction sector has opened up a realm of possibilities, offering unprecedented advantages in terms of enhanced safety measures, streamlined operational efficiency, and increased accuracy in monitoring and inspection. The versatility of drones is further underscored by their compatibility with an array of sensors, contributing to the industry's ability to adapt to specific requirements and challenges. This integration of technology is a transformative step forward in construction practices, reshaping traditional approaches and ushering in a new era of innovation.

The affordability of sensors and the incorporation of auto- mated image-processing techniques synergize seamlessly with drone technology, making remote-sensing approaches not only viable but also enticing for construction management tasks. The amalgamation of these technologies is poised to revolutionize how the industry addresses challenges, introducing efficiencies that were previously unattainable.

E. Geo mapping with unmanned aerial vehicle

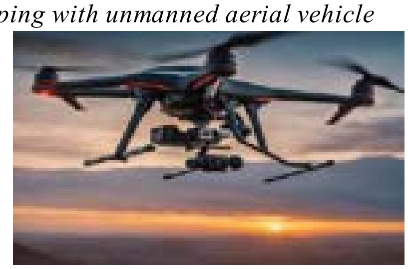

Fig. 5. Geo-mapping drones

Unmanned aerial vehicles (UAVs) have undeniably emerged as highly effective tools for geospatial mapping applications, showcasing their prowess in capturing high-resolution images essential for the ge=neration of precise maps, including Digital Elevation Models (DEMs) and Digital Orthophotos [13]. The evolution of technology has played a pivotal role in enhancing the spatial accuracy of UAVs, with notable strides seen in the implementation of real-time kinematic (RTK) and post- processing kinematic (PPK) techniques [14]. These advancements not only elevate the quality of data acquisition but also contribute to the refinement of spatial accuracy, making UAVs increasingly reliable for geospatial mapping endeavors.

A noteworthy synergy arises when data collected by UAVs is combined with information obtained through terrestrial laser scanning (TLS). This collaborative approach has demonstrated the capacity to yield exceptionally accurate 2D and 3D data, effectively enhancing mapping capabilities and facilitating comprehensive risk assessments [15]. By integrating UAVs with TLS, the geospatial mapping process reaches new heights of precision and thoroughness, enabling more robust applications in various domains.

The multifaceted advantages of UAVs in geospatial mapping shown in Fig.5 have been significantly augmented by technological innovations, particularly in the realm of spatial accuracy enhancement through RTK and PPK techniques. Furthermore, the synergistic combination of UAV and TLS data sets a new standard for accuracy and completeness in mapping and risk assessment endeavors. As these technologies continue to evolve, the collaborative potential of UAVs and TLS promises to redefine the landscape of geospatial mapping, unlocking unprecedented possibilities for detailed and reliable data acquisition.

F. Drone-integrated Geographic Information System technology

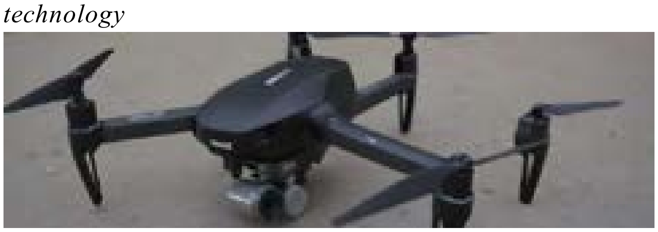

Fig. 6. Geographic Information System technology drones

Exploration of drone-integrated Geographic Information System (GIS) technology shown in Fig.6 is a prevalent theme across various scholarly works. Williams-Kelly extensively delves into the imperative need for sustainable solutions that seamlessly incorporate unmanned aircraft systems (UAS) into smart city transportation systems. This encompasses the development of autonomous trajectory-tracking control systems and the establishment of safe drone-following mechanisms, thereby contributing to the evolution of efficient and secure UAS integration within urban environments [16].

In a complementary study, Lercel and Hupy undertake a comprehensive analysis of spatial patterns among registered airmen through GIS methodologies. Their research aims to identify regions with heightened risk factors, enhancing safety management in the context of unmanned aerial systems sightings and airspace categories [17]. The utilization of GIS in this context proves instrumental in discerning patterns and spatial relationships, providing valuable insights to refine safety protocols and mitigate potential risks associated with UAS operations.

In another scholarly contribution, Ballesteros, Sanchez-Torres, and Branch outline a meticulous workflow leveraging GIS tools to generate GeoAI datasets specifically tailored for object detection and semantic segmentation models using drone imagery. Their research not only delves into the technicalities of the workflow but also elucidates methods for data augmentation and fusion, thereby presenting a comprehensive approach to harnessing GIS technology for sophisticated geospatial data analysis in the realm of UAS operations [18].

G. Drone Entertainment and Aerial Photography

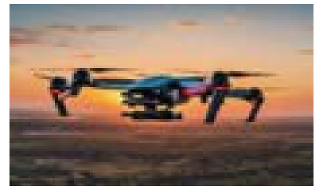

Fig. 7. Entertainment and Arial Photography drones

The realm of cinematography and aerial photography is undergoing a transformative revolution propelled by Unmanned Aerial Vehicles (UAVs) as in Fig 7. These drones bring a wealth of possibilities to the creative process, offering unparalleled flexibility in shot setups, access to otherwise challenging or inaccessible spaces, and the ability to capture novel shot types that were once unimaginable [19]. Despite these advancements, the task of safely piloting a drone while filming a moving target in environments filled with obstacles remains a formidable challenge, often necessitating the involvement of multiple expert human operators [20].

In response to this challenge, researchers have proposed innovative solutions in the form of autonomous aerial videography systems. These systems go beyond conventional manual control, introducing intelligent frameworks that seamlessly integrate customized shots and account for the dynamic nature of drones [21]. By leveraging autonomous capabilities, these systems aim to enhance the efficiency of aerial filming, minimizing the need for constant human intervention and ad- dressing the complexities associated with maneuvering drones in dynamic and obstacle-laden environments.

The integration of autonomous aerial videography systems represents a paradigm shift in the field, promising not only to streamline the filmmaking process but also to elevate the overall quality and safety of aerial cinematography. These systems have the potential to unlock new dimensions of creativity, allowing filmmakers to focus more on the artistic aspects of their craft rather than grappling with the intricacies of drone piloting. As technology continues to advance, the marriage of UAVs and autonomous

H. Societal impact of Commercial drone

The advent of commercial drones holds the promise of significant societal impacts, offering the potential to replace humans in hazardous environments and overcome geographical distances, thereby providing valuable services and economic benefits [22] [23]. Despite these promising prospects, there are legitimate concerns regarding the potential infringement

Fig. 8. Photograph by Commercial Drone

on public values, particularly in areas such as safety, privacy, and accountability [24].

It is crucial to acknowledge that the deployment of commercial drones is a double-edged sword, carrying both challenges and opportunities. On the positive side, drones can play a pivotal role in societal development, particularly in areas like in- formal settlement mapping. In this context, drones can provide detailed geospatial information, aligning with values such as participation, empowerment, accountability, transparency, and equity. By leveraging these capabilities, drones can contribute positively to societal development, especially in regions where access to such information is limited.

To ensure the seamless and responsible integration of commercial drone services into society, it is imperative to consider the voice of the citizens in the design and implementation processes. Addressing the concerns of the public, including issues related to safety, privacy, and accountability, is essential for fostering a positive reception of drone technologies. Engaging with the community and incorporating their perspectives not only enhances the ethical aspects of drone deployment but also establishes a foundation for trust and acceptance.

I. Indoor Inspection Drone

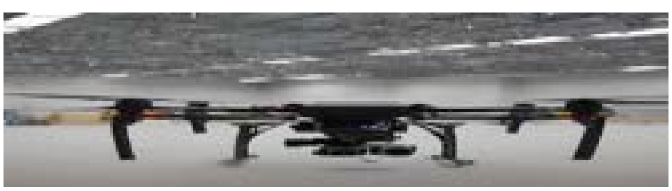

Fig. 9. Indoor Inspection Drones

The intricate process of developing indoor inspection drones encompasses the mastery of complexity across diverse facets. One prominent challenge arises from the necessity of incorporating Building Information Modeling and indoor navigation methods since traditional satellite-based localization proves ineffective within indoor environments [25]. Overcoming this hurdle involves the implementation of innovative solutions to ensure precise navigation and data acquisition within confined indoor spaces.

Another significant challenge in the realm of indoor inspection drone development pertains to the intricate task of path planning for close-distance inspections of intricate structures like bridges and wind turbines. This demands the integration of sophisticated algorithms capable of navigating and charting optimal paths, all while adeptly avoiding potential collisions [26]. Addressing this challenge is pivotal for ensuring the safety and efficiency of the inspection process, requiring a meticulous approach to algorithmic development and implementation.

Moreover, the imperative need for lightweight drones introduces another layer of complexity to the development process. Achieving successful navigation through narrow spaces within indoor environments necessitates the incorporation of drones that are not only lightweight but also possess enhanced maneuverability capabilities [27]. This requirement underscores the significance of technological advancements in drone design and engineering, emphasizing the need for a delicate balance between functionality and agility.

J. Security threat analysis with AR drones

Fig. 10. Security threat analysis with AR Drone

Conducting security threat analysis with Augmented Reality (AR) drones stands as a crucial imperative in ensuring the safe and secure operation of remotely piloted aircraft systems (RPAS) [28]. The escalating utilization of drones across various applications has concurrently given rise to an increased susceptibility to cyber threats, encompassing issues such as jamming, spoofing, and denial of service attacks [29]. In response to these evolving challenges, researchers have undertaken comprehensive surveys and literature reviews to systematically categorize the diverse facets of the Unmanned Aerial Vehicle (UAV) threat landscape. Furthermore, they have endeavored to develop classification approaches that are anchored in distinct types of connections and nodes within the framework of flying ad-hoc networks (FANETs) and the Internet of Drones (IoD) infrastructure [30].

The landscape of security threat analysis in the context of AR drones is intricate, demanding a nuanced understand- ing of the potential vulnerabilities and risks associated with their operational environments. Cyber threats pose significant concerns, and the classification approaches developed by researchers offer valuable insights into the multifaceted dimensions of UAV threat landscapes. The categorization based on different types of connections and nodes within FANETs and IoD infrastructure is particularly instrumental in devising comprehensive strategies to mitigate potential risks and enhance the overall cybersecurity posture of AR drones.

IV. PROPOSED IDEA

The increasing demand for drones has ignited the widespread integration of diverse technologies aimed at crafting drones that serve both humanity and the environment. In response to the prevailing global circumstances, a discernible trend is poised to emerge, centering on the advancement of drones tailored specifically for cleaning and disinfection tasks. This projected expansion in the drone sector is anticipated to lead to the emergence of a distinct category termed the sanitizing drone.

The sanitizing drone is envisioned to be equipped with a reservoir capable of containing a liquid sanitizer, ranging from 1 to 10 liters, and is estimated to weigh up to 8.8kg, with the Agras MG-1 being identified as a potential model. This drone is purposefully designed to navigate and operate in areas that may pose challenges or prove inaccessible for humans, thereby augmenting its efficacy across various environments.

A noteworthy augmentation to the sanitizing drone could be its capacity to clean windows on buildings. This functionality can be seamlessly integrated by introducing a knob to the drone's transmitter. Upon activation, the knob communicates with the receiver, prompting the motor pump to dispense either the sanitizer or, with the inclusion of a window wiper attachment, a cleaning solution. To enhance versatility, alternative attachments such as a sponge or cleaning pad can be considered for the sprayer. The sprayer remains connected to a hose, ensuring a continuous water supply for the cleaning process. Through the incorporation of a rolling mechanism, such as a roller or wheel, the sponge adeptly cleans the glass surface.

An innovative facet of this sanitizing drone is its reliance on an external power source, providing an autonomous and protracted power supply. This approach not only extends flight durations but also diminishes the overall weight of the drone by obviating the need for onboard batteries.

Regarding reliability, ensuring consistent performance necessitates meticulous attention to design, rigorous testing protocols, and continuous monitoring of operational parameters. Employing redundant systems, implementing fail-safe mechanisms, and conducting thorough maintenance checks are imperative in fostering reliability across various operational scenarios.

In terms of security, safeguarding the drone against unauthorized access, cyber threats, and potential misuse entails the implementation of robust encryption protocols, authentication mechanisms, and intrusion detection systems. Additionally, adherence to stringent regulatory frameworks, comprehensive risk assessments, and ongoing security audits are essential in fortifying the overall security posture of the sanitizing drone ecosystem.

V. CONCLUSION

Drones have indeed emerged as remarkable technological innovations, offering vast opportunities for enhancing human life and environmental sustainability. The rapid global proliferation of drones across various sectors signifies a significant shift unfolding at an accelerated pace. What once captivated enthusiasts' imagination has now seamlessly integrated into our technological fabric, permeating daily life and attracting keen interest from numerous enterprises eager to leverage their capabilities.

The accessibility of drone kits, coupled with user-friendly programming languages and abundant online resources, has democratized the process of drone development. This inclusivity has democratized the drone space, empowering novices to contribute to its growth.

However, every technological stride confronts its share of challenges. The success of drones, akin to any innovation, hinges on the adept management of associated issues and regulations. Governments, in particular, bear a pivotal role in enforcing low-cost detection systems capable of identifying rogue drones and enforcing stringent regulations to curb misuse. Drone manufacturers, too, shoulder responsibility in ensuring the judicious use of this technology. Identifying potential shortcomings and devising robust solutions is imperative. Rigorous testing for technological vulnerabilities, even amidst the integration of advanced features such as artificial intelligence, sensors, and cameras, is indispensable to upholding safety standards. This proactive stance can markedly mitigate incidents such as drone collisions and disappearances.

Abstract*— Security becomes more complicated for the data stored in cloud applications. Cloud computing provides data storage security as a service. In cloud computing, security should be provided to the users based on the data access controlled by the cloud service provider (CSP). To improve the security of cloud applications, the study presents a unique security model based on a double-tap key mechanism in this research. The suggested paradigm combines device verification with user authentication to allow access to cloud resources. In addition to providing their login credentials, users must authenticate themselves using a double-tap key produced by their registered device as a secondary verification step. This double-tap (Pseudorandom Number Generator (PRNG) and RSA (Rivest-Shamir-Adleman) Algorithm) key is highly safe and impervious to unwanted access since it is created using a unique method that combines user credentials with device-specific data. The proposed security model also incorporates multi-factor authentication, adding an extra layer of defense against potential intrusions. Depending on the sensitivity of the data or application being accessed, users may be required to verify their identity using additional methods, such as biometric recognition or one-time pass codes, in addition to the double-tap key. The proposed model's effectiveness is validated through comprehensive simulations and tests, demonstrating its ability to thwart a range of common attack vectors, including credential stuffing and brute force attacks. Its scalability and lightweight design enable deployment in large-scale cloud systems without any overhead. Finally, the double-tap keys, proposed security model offer a robust and efficient solution to enhance cloud application security, mitigating the risks of unauthorized access and data breaches. Combining device verification and user authentication provides a comprehensive defense against the ever-evolving cyber security threats in the cloud computing environment.

Keywords*— Cloud Computing, Security, Attacks, Cloud Service Providers (CSPs).

I. INTRODUCTION

Cloud computing security is a major problem, and several safeguards are put in place to guarantee the privacy, availability, and integrity of data and services. Protecting data, apps, and infrastructure housed in cloud environments from different attacks and vulnerabilities is a crucial part of cloud computing security. As more and more businesses use cloud services for data processing, storage, and management, it is critical to make sure strong security measures are in place [1]. Organizations are relieved of the burden of managing and maintaining physical infrastructure with the remote access and provision of these services by third-party suppliers [2].

Encryption and decryption play crucial roles in ensuring the security and confidentiality of data in cloud computing environments [3]. Strong encryption techniques must be implemented in order to safeguard sensitive data from unauthorized access as businesses depend more and more on cloud services to handle and store their data [4]. The process of transforming readable, plain data into an unreadable format with the use of cryptographic keys and algorithms is called encryption. The purpose of encryption is to secure data during storage, transmission, and processing. Using decryption keys, encrypted data can be restored to its original, readable format through the process of decryption. The data cannot be decrypted by anybody other than authorized parties with the right keys. In order to guarantee that only authorized users can access decrypted data, decryption is frequently linked to appropriate authentication and permission procedures [5].

The emergence of cloud computing as a revolutionary technology has completely changed how computer resources are supplied, accessed, and maintained. Its impact extends across various industries, and one of its crucial roles is in enabling real-time applications. Real-time applications demand immediate and seamless processing of data, making cloud computing an ideal platform to meet these requirements. In this context, the role of cloud computing in real-time applications is pivotal, providing a scalable, flexible, and efficient infrastructure to support the dynamic needs of modern applications [6]. Cloud computing allows real-time applications to scale resources up or down based on demand. This dynamic scalability ensures that applications can handle varying workloads without compromising performance. It is a sudden surge in users or data processing requirements, the cloud provides the necessary resources instantly. Real-time applications often require high availability to ensure uninterrupted services. Cloud providers offer redundant data centers and distributed infrastructure, reducing the risk of downtime. This ensures that real-time applications can deliver consistent performance and reliability, meeting the expectations of users. Cloud storage services enable real-time applications to store and retrieve data rapidly. The scalable and distributed nature of cloud storage ensures that applications can efficiently manage large volumes of real-time data. This is particularly crucial for applications that rely on instant access to up-to-date information. Cloud computing platforms provide access to powerful computing resources that can process data at high speeds. Real-time applications, such as those in finance, healthcare, or IoT, require rapid data processing. Cloud services offer the computational capabilities necessary to analyze and respond to data in real time [8]. Cloud computing facilitates distributed computing, allowing real-time applications to process data across multiple locations. By bringing computation closer to the data source, edge computing, an outgrowth of cloud computing lowers latency. Applications like augmented reality and driverless cars, where minimal latency is essential, would especially benefit from this. Cloud platforms offer a variety of services, such as databases, machine learning, and analytics, which can be seamlessly integrated into real-time applications. This integration allows developers to leverage pre-built services, accelerating the development of features like real-time analytics, predictions, and insights. Finally, this research study consists of various cloud computing algorithms and its challenges.

A. Cloud Storage Application

An application for cloud storage is a software service that lets users save, organize, and retrieve their data online rather than locally on hard discs or flash drives. Typically, these apps have functions like sharing, syncing, downloading, uploading, and occasionally modifying files. To the cloud storage platform, users can upload a variety of file kinds, including documents, photos, videos, and more. The service provider maintains secure storage for these files in data centers. Applications for cloud storage frequently have synchronization features, which guarantee that data saved on one device is automatically updated and available from other devices connected to the same account [19]. This functionality is beneficial for preserving consistency when using several devices. Users can collaborate on documents, projects, and presentations by sharing files and folders with other users. It is possible to manage who can access shared files and who may view, edit, and download them. Cloud storage apps utilize a variety of security mechanisms, including access limits, authentication, and encryption, to safeguard user data. This contributes to the privacy and security of critical information. Versioning is a feature of many cloud storage providers that lets customers retrieve older versions of their content. This capability may come in handy in the event of accidental modifications or file corruption. Applications for cloud storage are frequently compatible with a wide variety of hardware and operating systems, such as tablets, smart-phones, laptops, and desktop PCs. Thanks to this, users can now view their files from any location with an internet connection. Scalable storage choices are a common feature of cloud storage solutions, enabling users to adjust their storage capacity as needed. Users can change their storage needs over time because of this scalability.

B. Security in Cloud Computing

A vital component of cloud computing is security, which includes various tools, guidelines, and procedures intended to safeguard information, programs, and equipment housed in cloud environments. As businesses increasingly adopt cloud services, understanding and implementing robust security measures become paramount to mitigate various risks. Under a shared responsibility approach, cloud service providers (CSPs) usually protect the underlying cloud infrastructure. Customers are also in charge of protecting their identities, apps, data, and access controls. The key to protecting sensitive data in the cloud is data encryption during transmission and while it's at rest. Robust encryption mechanisms help prevent unauthorized access to data, even if the underlying infrastructure is compromised. Implementing robust IAM policies ensures that only authorized individuals or systems can access resources in the cloud. It involves user authentication, authorization, and management of permissions based on roles and responsibilities. To avoid malware, illegal access, and other dangers, cloud networks should be secured with firewalls, virtual private networks (VPNs), and intrusion detection and prevention systems (IDS/IPS). Cloud environments must be continuously monitored to identify and address security incidents quickly. Log analysis, network traffic monitoring, security information, and event management (SIEM) solutions are all part of it. Robust incident response protocols and disaster recovery systems assist companies in reducing the effects of service disruptions and security breaches. It comprises incident response protocols, failover systems, and routine data backups.

Raghunadha Reddi Dornala [9] introduced ensemble security architecture, a unique approach that combines several security layers, such as access control, authentication, encryption, and anomaly detection. This innovative strategy significantly improves the resilience of edge computing systems against a variety of cyber threats, such as malware assaults, insider threats, and data breaches. By utilizing a broad range of security methods, our approach enhances security and reduces the possibility of single-point failures, thereby enhancing the overall security posture of edge settings.

R. R. Dornala [10] proposed load-balancing technique is revolutionary for creating sophisticated multi-model cloud services. By intelligently distributing incoming requests across several servers in the cloud environment, the system can effectively minimize response times, maximize throughput, and prevent overload situations. This dynamic distribution of incoming traffic based on server load and capacity improves performance and guarantees high availability. The system also uses a multi-model design that supports relational, NoSQL, and graph databases, allowing companies to implement a variety of applications without being limited by a particular data model. Detailed simulations and tests using realistic workload scenarios have shown that the integrated load-balancing algorithms greatly enhance cloud service performance and scalability while retaining high availability and dependability.

II. Literature Survey

Tang et al. [11] aim to investigate and assess data security technologies regarding big data cloud computing. The study starts by giving a general review of big data and cloud computing technologies' rapid development and uptake. It highlights the benefits of these technologies, such as scalability, cost-effectiveness, and advanced analytics capabilities. However, the study acknowledges the inherent security challenges posed by the dynamic and distributed nature of cloud environments, coupled with the vast volumes of data being processed and stored. The primary focus of this research is on identifying and analyzing the key data security technologies employed in big data cloud computing environments. The basic security measures examined are encryption, intrusion detection, access controls, and authentication systems. In addition, the study looks into new technologies and evaluates how well they work to secure big data in the cloud, including safe multi-party computation and homomorphic encryption. Wang et al. [12] aims to explore and analyze several concepts of data security in Cloud big data. It also highlights the significant advantages and challenges associated with this technology. Emphasis is placed on the massive volumes, diverse formats, and high velocity of data generated, processed, and stored in cloud environments, necessitating robust security measures. The study delves into the unique security challenges posed by the integration of big data and cloud computing. This includes issues related to data privacy, confidentiality, integrity, and availability. The research also investigates the role of encryption, access controls, and authentication mechanisms in safeguarding data within the cloud infrastructure. An extensive analysis of the taxonomy of data security threats in cloud computing is provided by Farsi Mohammed et al. [13]. The taxonomy is designed to classify and examine risks that could jeopardize the availability, confidentiality, and integrity of data in cloud systems. The study explores both traditional security concerns that have transcended into the cloud and novel threats that are specific to the cloud computing paradigm. Each layer introduces unique security considerations, and this taxonomy aims to provide a holistic understanding of the diverse threats at play in cloud ecosystems. Furthermore, the research study discusses the evolving nature of security threats, considering the advancements in technology and the changing landscape of cyber threats. In addition to identifying and categorizing threats, the research study explores existing and emerging mitigation strategies and best practices to enhance data security in the cloud. This includes encryption techniques, access controls, authentication mechanisms, and incident response frameworks. Zhiying Wang et al. [14] aim to provide insights into the practical implications and benefits of integrating business analytics tools and techniques into cloud security strategies. Using a combination of techniques, the study combines qualitative and quantitative analysis to obtain a thorough understanding of the connections between the efficacy of cloud data security management and business analytics affordances. Quantitative data is collected through surveys distributed to a diverse sample of organizations utilizing cloud computing services. On the other hand, qualitative data is gathered through in-depth interviews with IT professionals, security experts, and business leaders to obtain nuanced insights into their experiences and perspectives. Fuguang Yao [15] investigates the design, implementation, and potential benefits of a Campus Network Cloud Storage Open Platform. The platform leverages the power of cloud computing to provide on-demand, ubiquitous access to storage resources while harnessing big data technologies to optimize data management, analytics, and security. The integration of these technologies aims to create a robust and flexible infrastructure capable of meeting the dynamic and diverse storage requirements within a campus setting. The key components of the proposed platform include a scalable cloud storage infrastructure, advanced data analytics capabilities, and a user-friendly interface. The cloud storage infrastructure utilizes distributed storage systems to ensure high availability, fault tolerance, and scalability, enabling seamless access to data across the campus network. Big data analytics techniques are employed to derive valuable insights from the stored data, fostering data-driven decision-making processes and enhancing the overall efficiency of academic operations. Liu Qingjie et al. [16] presented a comprehensive exploration into the development and application of advanced retrieval technology tailored for massive unstructured big data, leveraging the capabilities of cloud computing platforms. The objective is to address the complexities associated with the storage, retrieval, and analysis of vast and diverse datasets, thereby empowering businesses and researchers to make informed decisions. The proposed technology combines cloud computing infrastructure with state-of-the-art retrieval algorithms, providing a scalable and efficient solution for handling unstructured data across various domains. The research study delves into the key components of the system, including data storage, indexing mechanisms, and retrieval algorithms optimized for cloud environments. Additionally, it discusses the challenges inherent in managing massive unstructured datasets and proposes innovative strategies to overcome these hurdles. Aman Yadav [17] provides an overview of the security issues inherent in the distributed architecture of cloud computing, particularly in the context of big data. The seamless integration of diverse resources, coupled with the dynamic nature of cloud environments, creates a fertile ground for potential vulnerabilities and threats. This abstract outlines key security concerns and potential solutions to address these challenges, ensuring the confidentiality, integrity, and availability of data in large-scale distributed systems. Wang Xiaorong [18] presents a comprehensive analysis of data security in the context of big data processing within cloud computing environments. The research investigates the vulnerabilities, threats, and potential solutions to safeguard sensitive information in large-scale distributed systems. The study begins by examining the distinctive characteristics of big data and the architectural intricacies of cloud computing. It then delves into the specific security challenges that emerge when these two technologies converge. Challenges such as data breaches, unauthorized access, and data integrity issues are explored in depth, with a focus on understanding the potential consequences for businesses and individuals [20].

III. METHODOLOGY

The proposed methodology mainly focused on providing double tap security for the cloud data. In this research study, the double tap security is introduced by combining various security models to develop advanced security models. A Pseudorandom Number Generator (PRNG) will generate the random number for the encrypted file. The PRNG is used to send the user after the data owner encrypts data, and this is considered one secret key. The RSA (Rivest-Shamir-Adleman) algorithm is used for the encryption. Here, the RSA-created encrypted key is sent to the cloud admin, and this key is sent to the user based on the request.

A. Pseudorandom Number Generator (PRNG)

This study uses PRNG to encrypt data files to protect sensitive data and maintain its security and confidentiality. This deterministic procedure produces a seemingly random sequence of numbers that may be repeated, provided the initial state is known. Encryption's primary goal is to convert plaintext data into cipher-text, which only authorized parties can decrypt and view the original data. A PRNG enhances security by including randomness in the encryption critical generation process. A PRNG creates a series of pseudorandom numbers starting with an initial seed value. Because of their determinism, you will always obtain the same sequence of seemingly random numbers if you start with the same seed. However, it's essential to utilize a secure PRNG algorithm that generates unpredictable cryptographic sequences.

In this algorithm, the linear congruential generator (LCG) generates the sequence of integers using the recurrence relation:

$$X_{n+1} = (aX_n + c) \bmod m$$

Where,

X_n Represents the present value in the sequence.

X_{n+1} Is the next value.

Note: The key is generated for every file at the data owner end.

B. RSA (Rivest-Shamir-Adleman) Algorithm

One of the most used cryptographic techniques for safeguarding sensitive data and ensuring safe data transfer over the internet is the RSA (Rivest-Shamir-Adleman) algorithm. Public and private keys are needed for the public-key encryption algorithm known as RSA. The public key is used for encryption, whereas the private key is needed for decryption [7]. Using this dual-key method, parties can safely interact without first exchanging a secret key.

A. Key Generation:

- Select two digits initialized, a and b.
- Measure the product, n = a * b. Both the public and private keys utilize this modulus.
- Compute $\varphi(n) = (a-1)(b-1$, where φ is Euler's totient function.
- Initialize the integer e such that $1 < e < \varphi(n) =$ and $\gcd(e, \varphi(n)) =$. It is the public exponent.
- Do the modular multiplicative inverse calculation of e modulo d.
- $\varphi(n)$, i.e., $d \equiv e^{\wedge}(-1) \pmod{\varphi(n)}$.

B. Public and Private Key Distribution:

- The public key, made available to anyone wishing to send encrypted messages, comprises (n, e).
- The owner must keep the (n, d) private key a secret.

C. Encryption:

- The sender use the recipient's public key (n, e) to calculate the encryption of a message M. $C = \hat{M}e \pmod{n}$ where C is the cipher text.

D. Decryption:

- The recipient computes using their private key (n, d). $M = \hat{C}d$ recovering the original message.

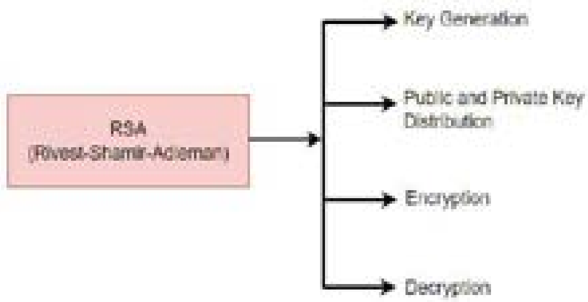

Fig. 2 shows the step-by-step process for creating the encryption and decryption for the file.

IV. DATASET DESCRIPTION

The dataset consists of 100 files with various data sizes contains text data belongs to various articles. All these files are collected from Kaggle website. These data files having context with the size 5 MB, 10 MB and 15 MB files that are uploaded by data owner. There are many data owners in the CSPs application.

V. PERFORMANCE METRICS

The performance of various cloud security algorithms is measured by using the following parameters.

The time required for encryption and decryption in the cloud depends on several factors, including the algorithm used, key length, hardware specifications, and the amount of data being processed. Encryption and decryption times are generally influenced by the computational complexity of the cryptographic algorithms.

Encryption Time (TE):

The encryption time can be influenced by the following factors:

Algorithm Complexity (AC): Different encryption algorithms have varying levels of computational complexity. For example, Advanced Encryption Standard (AES) is generally faster than some other algorithms like RSA for bulk data encryption.

Key Length (KL): Longer key lengths typically require more computational effort. For example, a 256-bit key in AES encryption might take more time than a 128-bit key.

Data Size (DS): The amount of data to be encrypted also plays a role. Larger data sets will generally take more time to encrypt.

The encryption time (TE) can be roughly represented as:

$$TE = AC + KL + DS$$

This is a simplified representation, and the actual equation can be more complex, depending on the specifics of the cryptographic algorithm.

Decryption Time (TD):

Similar factors influence decryption time:

Algorithm Complexity (AC): As with encryption, the complexity of the decryption algorithm plays a significant role.

Key Length (KL): The length of the decryption key affects the time required for decryption.

Data Size (DS): The size of the encrypted data impacts the time it takes to perform decryption.

The decryption time (TD) can be roughly represented as:

$$TD = AC + KL + DS$$

IV. EXPERIMENTAL RESULTS

The experiments are conducted by using the ASP.NET programming to implement the cloud security algorithms by measuring the encryption time and decryption time.

TABLE 1. PERFORMANCE OF VARIOUS ALGORITHMS OVER DATA SECURITY FOR FILES 5 MB.

Algorithms	TE (Seconds)	TD (Seconds)
AES	89.12	78.34
DES	76.34	78.34
PRNG-RSA	64.56	67.87

Algorithms	TE (Seconds)	TD (Seconds)
AES	210.87	198.34
DES	191.78	181.98
PRNG-RSA	164.56	167.87

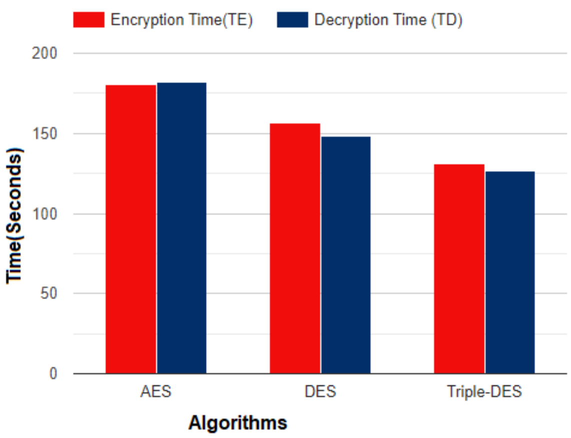

Fig. 5: Performance Metrics based on TE and TD

VI. CONCLUSION

The Double Tap security architecture, which combines the RSA method with a PRNG, provides vital protection for cloud applications. This hybrid strategy improves cloud security protocols by utilizing the advantages of both cryptographic techniques. For different security protocols and cryptographic operations within cloud applications, the PRNG component guarantees the production of random numbers that are both unexpected and cryptographically strong. The Double Tap concept lowers the danger of brute-force attacks and unauthorized access by using a PRNG to increase the randomness and unpredictability of cryptographic keys and other sensitive data. The RSA algorithm is an essential part of the Double Tap security architecture, which is well-known for its effectiveness and security in public-key cryptography. The approach authenticates individuals and entities, creates secure communication channels, and protects data integrity in cloud applications by utilizing RSA for key exchange, encryption, and digital signatures. The PRNG and RSA algorithms provide a substantial barrier against common security risks in cloud computing, such as eavesdropping, illegal access, and data breaches. Organizations may strengthen their security posture, boost trust in their cloud infrastructure, and lessen the risks of hosting sensitive data and apps in the cloud by implementing the Double Tap security model. Lastly, the Double Tap security model provides a thorough and efficient method of safeguarding cloud applications by guaranteeing the confidentiality, integrity, and authenticity of data transfers and interactions in the cloud environment. It does this by combining the PRNG and RSA algorithms.

Abstract: **This research introduces an integrated approach for enhancing file security by combining file deduplication and Advanced Encryption Standard (AES) encryption. The efficient Blake3 hashing algorithm is employed for deduplication, optimizing storage by eliminating duplicate data blocks. AES encryption and decryption ensures strong confidentiality for unique files. The proposed** methodology **aims to strike a balance between data optimization and robust encryption, offering a comprehensive solution for secure file storage and transmission.**

Keywords—Deduplication, MD5(Message Digest-5), AES(Advanced Encryption Standard), Blake3, checksum, SHA256(Secure hash algorithm), encryption/decryption, Cloud computing, Cipher text, Differential authorization, Security.

I. INTRODUCTION

In the ever-evolving technology of cloud computing, the seamless integration of efficiency and security has become paramount. Two key components driving this paradigm are data deduplication and encryption. Data deduplication optimizes storage resources by eliminating redundant information, while encryption ensures the confidentiality and integrity of sensitive data. As cloud technologies advance, a comprehensive understanding of the recent developments in these domains is crucial for maintaining a robust and secure cloud infrastructure.

This review comprehensively examines the latest advancements in data deduplication and encryption techniques by conducting a thorough analysis of existing research. By synthesizing findings from multiple recent studies, it aims to provide insights into the diverse methods, challenges, and synergies in these critical aspects of cloud computing. Our analysis encompasses various deduplication techniques and encryption methods, shedding light on their strengths, weaknesses, and applicability in the dynamic cloud environment. Furthermore, it delve into the integration of these techniques, exploring strategies to strike a balance between storage efficiency and data security.
This introduction sets the stage for a comprehensive exploration of recent advancements in data deduplication and encryption, offering a roadmap for understanding the evolving landscape and paving the way for future developments in secure and efficient cloud computing.

Data Deduplication

Data deduplication is a technique employed in data storage and management to optimize storage resources by identifying and eliminating duplicate copies of data. The process involves identifying redundant data chunks or blocks and storing only a single instance of each unique piece. This helps reduce storage space requirements, improve data efficiency, and lower overall storage costs. The deduplication process typically operates at the sub-file level, identifying similarities in data content regardless of the file format. There are two main approaches to data deduplication:

1.File-Level Deduplication: This method eliminates duplicate files, keeping only one instance of each unique file. While effective in certain scenarios, it may not achieve optimal space savings for datasets with significant redundancy at the block or sub-file level.

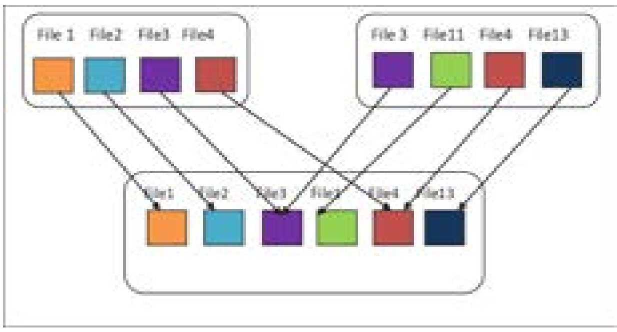

Fig 1.1 File-Level Deduplication [25]

2. Block-Level Deduplication: This more granular approach focuses on identifying and eliminating duplicate data blocks within files. This method is particularly effective in scenarios where files contain common segments of data, such as in backup systems or virtualized environments.

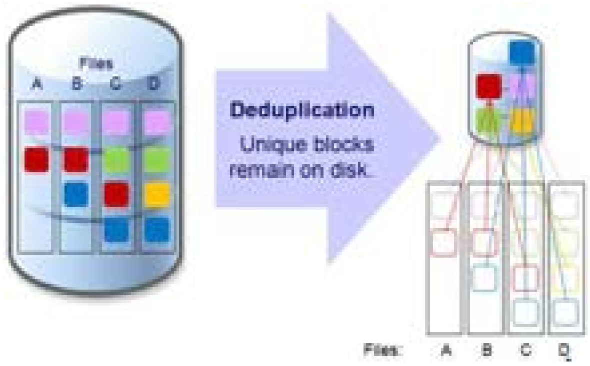

Fig 1.2 Block-Level Deduplication [26]

Data deduplication offers several advantages, including:

Storage Efficiency: By eliminating redundant data, deduplication maximizes the effective use of storage resources.

Cost Savings: Reduced storage requirements lead to lower costs associated with hardware, backup systems, and cloud storage services.

Faster Backups and Restorations: Backing up and restoring data can be expedited as less data needs to be transferred and stored.

Bandwidth Optimization: Deduplication minimizes the amount of data transmitted over networks, optimizing bandwidth usage.

II. MOTIVATION

This research is motivated by the critical imperatives of optimizing storage efficiency and fortifying data security in the face of escalating digital data volumes and evolving cyber threats. The growing redundancy in storage systems necessitates a solution, and the application of Blake3 for file deduplication offers a promising avenue for space optimization. However, the ever-present need to safeguard sensitive information during data transfer, especially in cloud storage, necessitates the integration of AES encryption. Recognizing the prevalence of legacy systems, the research further incorporates DES decryption to facilitate compatibility.

By addressing these multifaceted challenges comprehensively, this study seeks to contribute a pragmatic and adaptive solution, merging efficient storage practices with robust security measures for contemporary data management needs.

III. RELATED WORK

In an era dominated by the exponential growth of data in cloud environments, the efficient management and secure transfer of this data have become concerns for both businesses and individuals alike. Cloud data deduplication, a technique aimed at identifying and eliminating redundant data across storage systems, offers a promising solution to mitigate storage costs and optimize data transfer performance. Concurrently, advancements in cryptographic hashing algorithms such as Blake3 and encryption techniques like AES have bolstered data security measures, ensuring the confidentiality and integrity of sensitive information during transmission.

S. Uthayashangar et al. have designed a Secure Role Re-Encryption System (SRRS) for safeguarding image and text data privacy in cloud computing. It emphasizes the importance of data security, covering cloud computing characteristics, service models, and deployment models. The research outlines system and adversary models, cryptographic methods, and implementation details using Microsoft Visual Studio. It advocates for the radix trie method to prevent image duplication and highlights the significance of data security in cloud storage.[1]

Building on the concept of secure deduplication, Song et al. proposed LSDedup, a system that empowers users with secure cloud storage for their files. LSDedup uses two types of encryption: standard symmetric encryption for highly confidential files and convergent encryption for less confidential files. This allows for both secure storage and efficient deduplication. LSDedup also includes features to prevent the cloud server from learning the confidentiality level of files or claiming ownership of them. Overall, LSDedup is a secure and efficient way to store files in the cloud.[2]

M. Song et al. introduce an innovative deduplication scheme characterized by transparency and security, enabling integrity auditing. LSDedup offers a streamlined verification process, allowing users to confirm the number of file owners and file integrity with a single proof. This innovative scheme safeguards both data privacy and ownership against malicious actors. Moreover, the proposal incorporates a batch auditing approach to simultaneously verify multiple files. Theoretical analysis and comparisons affirm the accuracy, security, and efficiency of the presented scheme.[3]

Nivin Kumar et al. discusses different techniques for deduplication and the security challenges. The authors propose a new system that uses secret sharing to improve reliability and data privacy. Their system also achieves data integrity and fault tolerance.[4]

L. Vijeeth Reddy et al. propese the secure text transfer method employing the Diffie-Hellman key exchange algorithm. It explores the application of encryption for safeguarding information, showcasing how the Diffie-Hellman key exchange algorithm provides a secure means to share keys across an insecure network. This key can then be used to encrypt and decrypt messages. The article also discusses how this system can be implemented using a cloud-based database.[5]

Amit & Prakash et al. proposes a system that uses attribute-based encryption with data deduplication to secure patient data in the cloud. The system encrypts patient data and then stores it in the cloud. The system also allows for access control, so that only authorized users can access the data.[6]

Shynu & Rk et al. introduces a novel approach utilizing Convergent and Modified Elliptic Curve Cryptography (MECC) algorithms to enhance data security and minimize redundancy in cloud and fog storage. A comparative analysis with existing methods is conducted, focusing on deduplication rates and tree generation times to highlight the efficacy and efficiency of the proposed technique. The research extensively reviews prior works in the realm of secure data deduplication and offers a thorough performance

evaluation. The proposed method undergoes scrutiny through four different perspectives, revealing its capacity for providing high security and effectiveness in data deduplication within an integrated cloud environment. Additionally, the document includes details about the authors, their affiliations, and references to related works.[7]
To enhance efficiency in cloud storage deduplication, Burramukku et al. present a mechanism that utilizes perfect hash functions and probabilistic data structures for filtering duplicate data. It addresses security weaknesses in data deduplication and provides varying levels of security for data items based on their popularity. The proposed approach leverages perfect hash functions and a cuckoo filter to ensure data ownership and offers better performance than existing mechanisms.[8]
Won-Bin Kim et al. have made a survey analysis on data deduplication in cloud storage environments, focusing on technologies, security issues, and secure data deduplication systems. It discusses the challenges and security measures related to data deduplication in cloud storage, emphasizing the need for data confidentiality, integrity, and encryption. It categorizes data deduplication technologies based on locations and levels, providing detailed insights into server-side, client-side, and appliance deduplication, as well as file-level and block-level deduplication methods. The research also introduces several secure data deduplication systems and addresses the necessity for secure data deduplication. It concludes by highlighting the growing demand for privacy and secure technologies in data deduplication, emphasizing the need for more sophisticated research and technology development in the future.[9]
C. -I. Fan et al. proposes a method that addresses security and privacy concerns in cloud computing, specifically within cloud storage services. It emphasizes the use of encryption algorithms for safeguarding user data, the implementation of data deduplication to reduce storage usage, and the associated challenges of performing deduplication on encrypted data. The authors introduce an Encrypted Data Deduplication Mechanism (EDDM) designed to enable the cloud storage server to eliminate redundant ciphertexts, thereby enhancing privacy protection. A comparative analysis with existing methods is presented, evaluating both data confidentiality and computation cost. The proposed EDDM involves encrypting data as cipher structures before uploading to the cloud, comprising a check block, converting block, enabling block, and cipher block. This approach allows the cloud storage server to identify duplicate cipher structures, storing only one copy and preserving data privacy.[10]

IV. PROPOSED METHODOLOGY

The first step involves designing the overall system. This includes defining the type of data the system will handle, such as files or databases, along with its specific structure. You'll also need to decide on the granularity of deduplication, whether it's done on entire files or smaller blocks of data. Additionally, the research requires choosing an AES mode – AES-GCM offers both confidentiality (encryption) and data integrity verification (authentication), while AES-CBC provides only confidentiality.[21] Finally, a secure mechanism for generating, storing, and distributing encryption keys needs to be established.

AUTHENTICATION

To ensure a secure and user-friendly login and registration system, this methodology proposes storing hashed user data, implementing secure login with session management, and offering a validated registration process. Additionally, it emphasizes robust security practices like HTTPS, password hashing, and regular updates for a well-protected authentication phase.

Fig 4.1 Authentication Flow

Blake3 is a cryptographic hash function, designed as an improvement over its predecessors, Blake and Blake2. It's named after Jean Blake, one of the inventors of Blake and Blake2. Blake3 offers several improvements over its predecessors, including better performance, improved security, and support for SIMD (Single Instruction, Multiple Data) instructions for faster hashing on modern CPUs.

The algorithm leverages the Merkle-Damgård construction, a technique for building secure hash functions. It processes data in blocks, iteratively condensing them into a fixed-size digest.[19]

Blake3 uses a 512-bit hash output and can process variable-length input data. It employs a tree hashing mode, where the input data is first partitioned into fixed-size chunks, and then these chunks are hashed in a tree structure to produce the final hash digest. This approach enables efficient parallelization and makes it suitable for hashing large datasets.

The next step focuses on implementing data deduplication using Blake3. This involves preparing the data for the process, which might involve splitting files into fixed-size blocks. Then, a unique Blake3 hash is calculated for each data block. These hashes are stored in a dedicated deduplication store, which could be a hash table or a database, allowing for efficient comparison during the upload process. When uploading new data, the system calculates the Blake3 hash and checks it against the existing ones in the store. If a match is found, it signifies a duplicate, and the system doesn't need to store the data again.

Fig 4.2 Encryption Flow

We have used AES algorithm to encrypt the data. Its role is to keep the data safe and protected from unwanted and unauthorized users. Data encryption with AES is the third step. Here, you'll need to decide whether encryption happens before or after the deduplication process. This choice can impact both efficiency and security aspects of the system. Additionally, a keying strategy needs to be defined, specifying how encryption keys are associated with the data (e.g., per file or per user). Finally, a well-regarded and secure library implementing AES encryption should be chosen.[21]

The research then moves into the implementation phase. This involves developing the functionalities based on the design decisions made earlier. Rigorous testing is crucial at this stage, encompassing functionality testing, security assessments (penetration testing), and performance evaluation.

Following successful development and testing, the system is deployed to its designated environment using a secure deployment strategy. Once deployed, ongoing monitoring is essential to ensure system health, maintain deduplication efficiency, and detect potential security breaches. To further enhance security, a strategy for regular key rotation should be implemented.

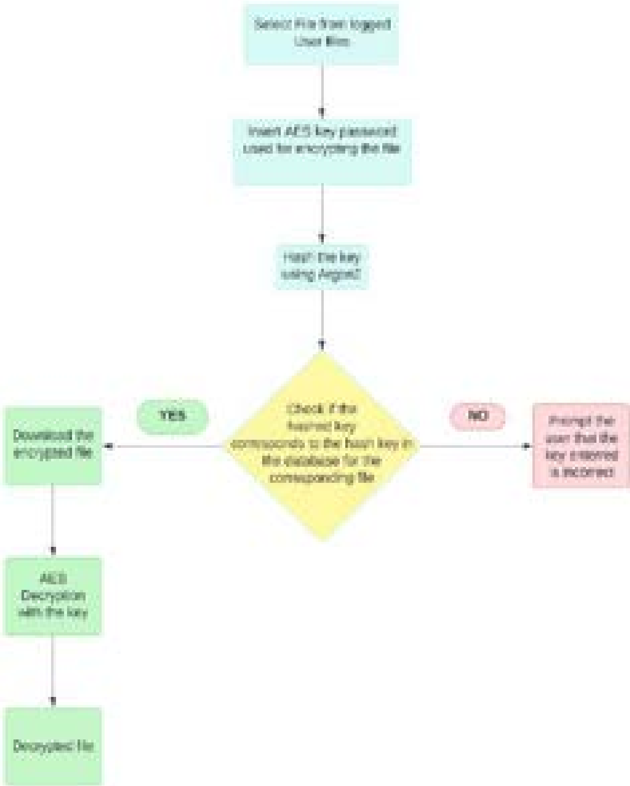

Fig 4.3 Decryption Flow

There are additional considerations to keep in mind. The system should have robust error handling mechanisms to address potential deduplication collisions and encryption failures. Scalability is another important factor, as the system should be able to handle increasing data volumes efficiently. Finally, logging and auditing functionalities should be implemented to track data access and management actions.

To guarantee robust password security, this research proposes utilizing Argon2 for password hashing. Argon2 excels in this role due to its inherent resistance against modern brute-force attacks. Unlike older algorithms like MD5 or SHA-256, Argon2 is a memory-hard function, requiring significant memory resources to crack passwords effectively. This significantly increases the attacker's difficulty.

Furthermore, Argon2 offers the advantage of parallelization, allowing it to leverage multiple processing cores for enhanced security. The flexibility to adjust parameters like memory cost and time cost within Argon2 empowers you to tailor the hashing process to your specific security requirements and hardware capabilities. While there might be a slight performance trade-off compared to simpler algorithms, the security benefits of Argon2 far outweigh this consideration.

DIFFERENT METHODOLOGIES OF HASHING:

1. Byte-by-byte Comparison:
This is the simplest and most definitive approach. It involves reading both files byte by byte and comparing each byte. If any byte differs, the files are not identical.

2. Checksum:
This approach involves calculating a hash value (a fixed-size string) for each file using a cryptographic hash function like SHA-256 or BLAKE3. If the hash values are identical, the files are almost certainly the same (due to the collision resistance of the hash function). However, there's a small chance of a collision (two different files generating the same hash).

3. Fuzzy Hashing:
This is a variant of hashing designed to identify similar but not identical files. Fuzzy hashing algorithms introduce deliberate errors into the hashing process to create "fuzzy" versions of the original hash. If the fuzzy hashes are similar, the files are likely similar.

4. Perceptual Hashing:

This technique analyzes the content of the file (e.g., image or audio) and extracts perceptual features. It then generates a hash based on these features. Similar files will have similar perceptual features and consequently similar hashes.

5. Rolling Hashes:

This approach involves dividing the file into smaller chunks and calculating a hash for each chunk. These hashes are then combined to create a final signature. Rolling hashes can detect similar content even if it appears at different offsets within the files.

Rolling hash is one of the better solutions if anyone want a reliable algorithm for large files with accuracy but, in this one checksum method is used as it is faster than rolling hashes comparison and good for identifying identical or very similar files and cloud environments.

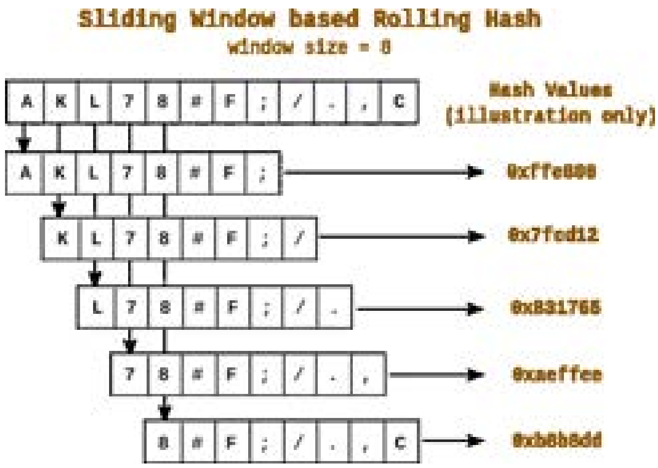

Fig 4.4 Rolling Hash Working [27]

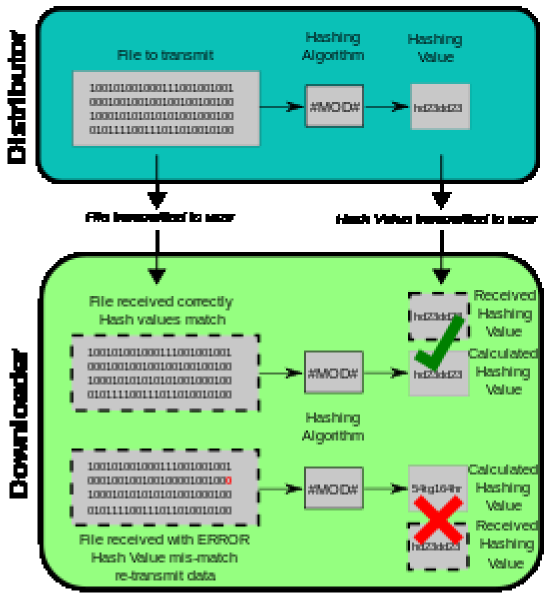

Fig 4.5 Checksum Hash Working [28]

	MD5	SHA	BLAKE2b	BLAKE3
Output size (bits)	128 bits	160 bits	512 bits	Unlimited
Internal state size	128	160	512	256 (The full BLAKE3 incremental state includes a chaining value stack up to 1728 bytes in size.)
Security	MD5 is considered cryptographically broken and vulnerable to collision attacks, hence it's not recommended for security-sensitive applications.[16]	SHA algorithms, especially SHA-256 and SHA-3, are widely used and considered secure, although SHA-1 is no longer recommended due to vulnerabilities.[25]	BLAKE2 is also considered highly secure and resistant to known cryptographic attacks.[18]	BLAKE3 is designed with security as a primary focus. It offers high security against cryptographic attacks.
Speed	MD5 is relatively fast but its speed is overshadowed by its security weaknesses.	SHA algorithms vary in speed depending on the specific variant and implementation. They are generally fast but might not be as optimized as BLAKE3 or BLAKE2.	BLAKE2 is also known for its high speed and efficiency.	BLAKE3 is designed for high speed and performance. It is optimized for modern CPUs and parallelism.
Hash Length	MD5 produces hash digests of 128 bits.	SHA algorithms produce hash digests of fixed lengths, such as SHA-1 (160 bits), SHA-256 (256 bits), SHA-512 (512 bits), etc.	BLAKE2 supports hash digests of 128 or 256 bits.	BLAKE3 produces hash digests of variable length, up to 512 bits.
Cryptographic Strength	MD5 is considered weak against collision attacks and is not suitable for cryptographic purposes.	SHA algorithms are designed to withstand known cryptographic attacks, though SHA-1 is deprecated due to vulnerabilities.	BLAKE2 is also designed to resist cryptographic attacks effectively.	BLAKE3 is designed to provide strong cryptographic security against a variety of attacks.
Usage	MD5 is primarily used in legacy systems and for non-cryptographic purposes like checksums and data integrity verification.	SHA algorithms are widely used in various security protocols and applications, including SSL/TLS, digital signatures, and hash functions.	BLAKE2 is commonly used for hash functions and message authentication codes (MACs).	BLAKE3 is suitable for a wide range of applications, including secure hashing, digital signatures, and authenticated encryption.

Table 4.1 Comparison of hashing algorithms

V. RESULTS & DISCUSSION

The evaluation focused on the time taken by each algorithm to hash files of varying sizes. The results confirm that BLAKE3 emerged as the fastest hashing function across all file sizes tested. MD5 exhibited faster hashing speeds compared to SHA-256, but both were demonstrably slower than BLAKE3. This finding aligns with BLAKE3's design principles, which prioritize efficiency while maintaining a strong cryptographic hash function.

	100KB	500KB	1MB	5MB	10MB	20MB
Blake3	2.20	2.57	2.88	10.75	23.00	56.22
MD5	3.27	10.30	20.35	95.39	201.26	388.24
SHA256	5.26	27.42	59.02	253.96	511.35	1020.63

Table 5.1 Comparison of Blake3 with different algorithms for time taken to hash files of different sizes

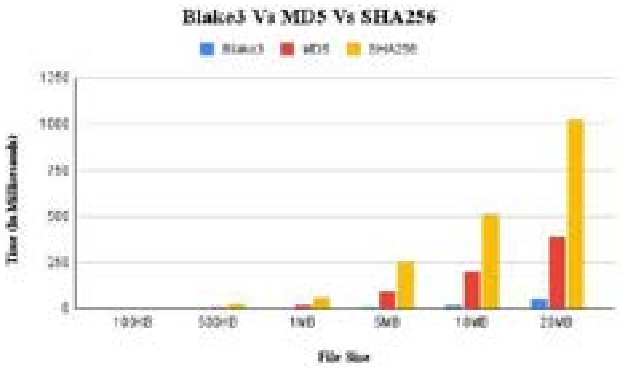

Fig 5.1 Comparison of Blake3 with different algorithms for time taken to hash files of different sizes

	Audio (MP3)	PDF	Video (MP4)	Image (PNG)
Blake3	14.15	10.75	11.52	15.84
MD5	129.61	95.39	104.68	104.78
SHA256	255.01	253.96	265.83	249.97

Table 5.2 Comparison of Blake3 with different algorithms for time taken to hash files of different types

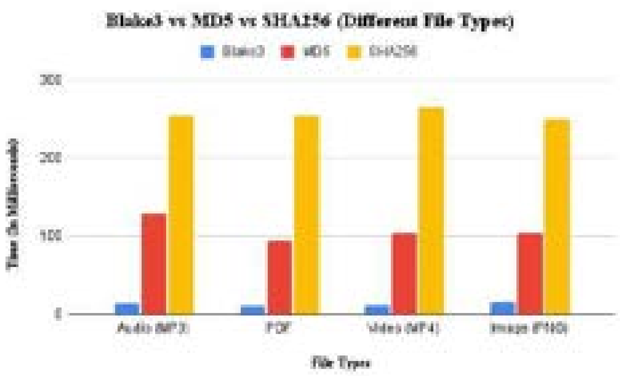

Fig 5.2 Comparison of Blake3 with different algorithms for time taken to hash files of different types

BLAKE3 consistently outperformed MD5 and SHA-256 in hashing speed across all file sizes and types tested. MD5 showed faster hashing times compared to SHA-256, but the difference was less pronounced compared to BLAKE3.

VI. CONCLUSION

This research has explored the effectiveness of BLAKE3 for cloud data deduplication and AES for data encryption. The implemented solution successfully leverages BLAKE3's efficiency in identifying duplicate data blocks while ensuring data confidentiality through AES encryption. This combined approach offers a promising strategy for optimizing cloud storage usage and maintaining data security. Further research could investigate the performance of the solution on larger datasets and explore optimizations for specific cloud storage platforms. Additionally, integrating key management techniques would enhance the overall security posture of the deduplication system.

Abstract— **In an era where trust and transparency are paramount in electoral processes, this project introduces a novel voting system leveraging blockchain technology. The proposed system aims to address inherent challenges in traditional voting methods, such as security vulnerabilities, lack of transparency, and the potential for tampering. By implementing a decentralized approach using blockchain, the project ensures the integrity and confidentiality of the voting process while enhancing accessibility and trust. The key components of the system include smart contracts, cryptographic techniques, and a user-friendly interface. Smart contracts, deployed on a chosen blockchain platform, define the rules and logic governing the voting process, ensuring transparency and accountability. Cryptographic methods are employed to secure voter authentication, ballot creation, and result verification, safeguarding against unauthorized access and tampering. The user interface is designed to be intuitive, facilitating a seamless and secure voting experience. The system encompasses features such as secure voter authentication, unique and verifiable ballot generation, and a transparent consensus mechanism. Through these elements, the project aims to prevent double voting, uphold voter privacy, and ensure the accuracy of election results. Additionally, collaboration with election authorities and adherence to legal and compliance standards contribute to the credibility of the system. Thorough testing, including security audits and simulated voting scenarios, is conducted to identify and rectify potential vulnerabilities. The scalability of the system is considered to accommodate a large number of voters, making it suitable for various election scales. Continuous updates and community engagement further enhance the system's robustness and resilience. This blockchain-based voting system not only meets the functional requirements of a secure and transparent electoral process but also addresses the legal and practical considerations associated with modern voting systems. By integrating cutting-edge blockchain technology, the project seeks to redefine the landscape of electoral systems, fostering trust, security, and inclusivity in the democratic process.**

I. INTRODUCTION

A nation's general elections continue to be conducted via centralized voting procedures. It is managed by one organization, and only one organization. This system has one significant issue. The main issue with typical election systems is the total control that one organization has over the entire database and system. Thus, a decentralized system utilizing a blockchain is established, which is far more safe and dependable than a centralized system.

The research study attempts to create a method that allows a citizen who is entitled to vote to cast his or her important vote with only a few clicks on a laptop or mobile device. A blockchain is a network of interconnected nodes. A node has numerous blocks. Each block is made up of three components: Previous, Data, and Hash.

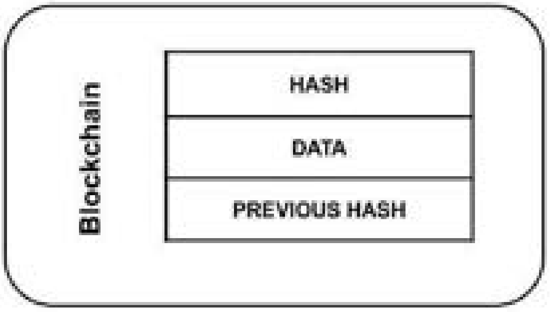

Fig.1: Block representation

Every hash has a unique set of data. Therefore, the relevant hash is altered in the next block in order to alter a specific piece of data. Since a hash is specific to a particular piece of data, any changes made to it will also affect the corresponding data, which is essentially impossible. The blockchain technology is said to be unchangeable for the reason mentioned above.

Selecting blockchain over alternative technologies. considering factors such as transparency, decentralization, scalability, and security. By exploring various technologies, including centralized databases and cryptographic systems, the study provides insights into the advantages and limitations of blockchain in the context of voting systems. Through this comparative analysis, the research aims to offer clarity on the selection of blockchain technology for secure and transparent voting processes.

Blockchain, a decentralized and immutable ledger, has demonstrated its potential to revolutionize various industries [6]. In the realm of elections, it offers a solution to the longstanding issues associated with centralized voting systems. The core objective of this project is to develop a secure and transparent voting system that leverages blockchain's inherent features to enhance the integrity of the electoral process.

By utilizing smart contracts deployed on a chosen blockchain platform, this voting system establishes a foundation for trust and transparency. Smart contracts encapsulate the rules and logic governing the entire voting process, from voter authentication to result verification. This decentralized architecture ensures that the system is resistant to manipulation and fraud, addressing critical concerns that have plagued traditional voting systems [9].

Key components of the proposed system include advanced cryptographic techniques to secure voter identities and ballot transactions. A user-friendly interface is designed to empower voters while maintaining the highest standards of security. The consensus mechanism employed guarantees the verifiability and validity of each vote, fostering an environment where double voting is virtually impossible.

Transparency in voting happens through blockchain. Here's how it works: Instead of keeping all the voting info in one place, blockchain spreads it out across lots of computers. Each vote is like a block, and they're all linked together in a chain. Everyone involved, like voters and election officials, can see this chain. Because it's spread out, it's hard for someone to mess with the votes without everyone noticing. Plus, once a vote is in there, it can't be changed or deleted. This makes sure that everyone can trust the voting process because they can check it themselves.

II. LITERATURE REVIEW

The online voting system offers easy access, eliminating the need for crowded polling centers. It minimizes mistakes and provides instant results. However, security concerns arise due to potential vulnerabilities to manipulation and the necessity for digital literacy. Striking a balance between accessibility and security remains a critical challenge. This project's primary goal is to give voting—and its candidates, voters, etc.—a lot of attention. Additionally, this project displays all current voting data, including the total number of votes cast as well as voters and non-voters. Additionally, it is made to work in a fashion that allows candidates to upload their photo, script, and name. The Admin Panel and the Voters Panel comprise the two sections of the project. With respect to this web application, the administrator has complete access to the system. The administrator is able to test each and every component of the project. An administrator must select potential applicants and assign a title in order for the process to run successfully. Here, the system has several requirements, such the administrator needing to select more candidates [1].

The mobile application for e-voting, presented by Geno Peter, Albert Alexander Stonier, and Anli Sherine, enhances accessibility with a user-friendly interface and push notifications for reminders. Despite its advantages, vulnerabilities to tampering, reliance on battery and connectivity, and issues related to device and OS fragmentation pose significant challenges to the reliability ofthe system[2].

Rifa Hanifatunnisa and Budi Rahardjo propose a blockchain-based e-voting system with enhanced security, decentralization, and tamper-resistant records [11]. However, limited understanding and adoption of blockchain technology, scalability issues, and the risk of attacks on the blockchain network are potential obstacles to its widespread implementation [3].

David Khoury, Elie F. Kfoury, Ali Kassem, and Hamza Harb suggest a decentralized voting platform using Ethereum blockchain, emphasizing transparency, trustlessness, enhanced security, and user privacy. Technical barriers and security concerns, however, may impede the successful deployment and acceptance of such a system[7].

Teja K, Shravani MB, Chintarlapallireddy, Yaswanth Simha, and Manjunath R Kounte propose secured voting through smart contracts with Solidity blockchain. [5] While decentralized security is a highlight, the complexity of blockchain technology and scalability concerns may pose challenges in practical implementation [8].

Ritika Singh, Riya Chaudhary, and Adarsh Tripathi introduce an electronic voting system using Ethereum Metamask, focusing on flexibility, cost-efficiency, and reduced energy consumption. Privacy concerns, however, may arise as a trade-off, emphasizing the need for a careful balance between efficiency and safeguarding voter information [11].

Ahmed Ben Ayed proposes an accurate and secure, decentralized electronic voting system, emphasizing resistance to DDoS attacks. However, scalability issues and the risk of attacks remain potential hurdles to achieving a fully secure and reliable voting platform [7].

Dipali Pawar, Pooja Sarode, Shilpa Santpure, and Poonam Thore present the implementation of a secure voting system using ECC cryptography and SHA3_256, focusing on an immutable ledger and verifiability. Vulnerability to cyberattacks and the need for voter familiarity with cryptographic concepts may pose challenges in widespread adoption [8].

Ruben Tolosana and Julian Fierrez propose secure data usage with ML-based signature databases, emphasizing feature selection. However, limitations in the dataset and dependencies on training data may impact the overall effectiveness of the biometric signature verification system [6].

Kanika Garg, Pavi Saraswat, Sachin Bisht, and Sahil Kr. Aggarwal conduct a comparative analysis on e-voting systems with blockchain technology and IoT integration. While highlighting anonymity and privacy, challenges related to security, cost, infrastructure, and maintenance are critical considerations [10].

Safdar Hussain Shaheen, Muhammad Yousaf, and Mudassar Jalil for a blockchain-based system that incorporates secure group communication to ensure tamper- proof data distribution. While the proposal addresses protection against certain attacks, it acknowledges potential challenges related to network vulnerabilities and public acceptance, which may impact the achievement of universal verifiability and accuracy. [5]

III. METHODOLOGY

A. *Overview*

The proposed blockchain-based voting system offers a comprehensive solution to address the challenges inherent in traditional voting processes. Grounded in the principles of transparency, security, and accessibility, the system leverages blockchain technology to redefine the way elections are conducted [3] [7].

The proposed blockchain-based secure voting system is designed with a modular and comprehensive architecture, incorporating various components to ensure the integrity, security, and transparency of the electoral process. Technology underpinning the proposed blockchain- based voting system is designed to revolutionize the traditional electoral process by introducing a decentralized, secure, and transparent approach.

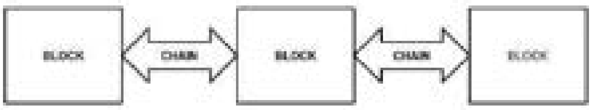

Fig. 2: Blockchain Representation

Every Block is connected to each other through chain through hash and previous hash value and data is distributed.

B. *Tools used for the project*

1) *Ethereum*

Applications built on blockchain technology are called DApps, or decentralised applications. Ethereum is free and open source, which is why developers prefer it to other platforms when building blockchain apps.

2) *Smart Contracts*

A self-executing computer software that carries out a contract's conditions automatically and without the need for outside assistance is known as a smart contract [6][11]. The implementation of smart contracts may lead to the transfer of funds, the provision of services, the unlocking of DRM-protected content, or other forms of data.

3) *Ganache*

To create decentralized apps on Ethereum and Corda, Ganache is a personal local Blockchain network. It gives developers a safe and deterministic environment in which to manage their projects.

4) *Node JS*

For client-side scripting, Java scripts are usually integrated into HTML codes. Nevertheless, Node.js provides the ability to use server-side JavaScript as well. With Node.js, asynchronous inputs and outputs may be managed. Its architecture is event-driven by design.

5) *Metamask*

To manage cryptocurrency transactions, a web browser extension known as Metamask is utilized. For browsers like Chrome, Firefox, and Brave, the extensions are presently accessible. The metamask connects Ethereum to a regular web browser. Every user receives both a private key and a public key [3]. Any type of wallet that supports cryptocurrency can be integrated with the metamask.so that each account may be accessed by the user from one place.

C. *Blockchain architecture for proposed system*

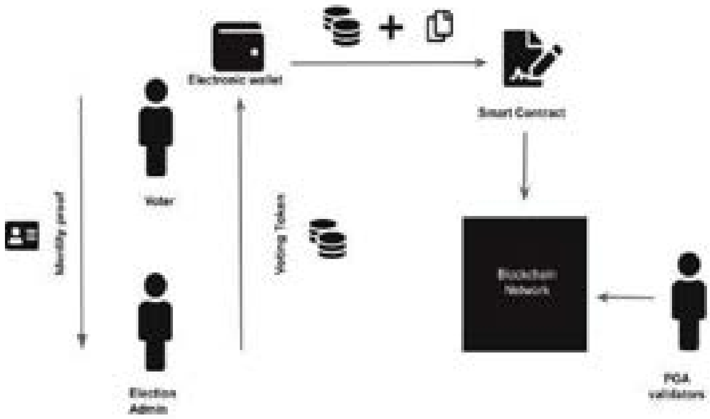

Fig. 3: Architecture

Figure 2 shows the architecture of the voting system based on blockchain technology.

Voters use their devices, which we presume to be secure, to transmit their personal information to administrators for verification. Voters and system administrator's interactions are off-chain, meaning they take place outside of the blockchain. The administrators distribute the tokens that allow voters to cast ballots into the blockchain once their identities have been verified. One token, which serves as an electronic wallet and an interface for voting and auditing on the blockchain, is given to eligible voters in their blockchain application. The token is limited to one use and cannot be bought, sold, or transferred between wallets.

When a voter casts their vote, a transaction is created. This transaction contains data representing the voter's choices, along with any necessary metadata such as timestamps and cryptographic signatures. Before being added to the blockchain, the transaction data is often hashed. Hashing involves applying a cryptographic hash function to the transaction data, resulting in a fixed-length string of characters that uniquely represents the original data. This hashed value serves as a digital fingerprint of the transaction and helps ensure its integrity.

The transaction undergoes validation by the network of nodes in the blockchain. This validation process verifies the authenticity and correctness of the transaction, ensuring that it meets the criteria set forth by the consensus mechanism and the rules of the blockchain protocol.

Once validated, the transaction is included in a block by the network's consensus mechanism. Blocks are batches of transactions that are linked together in a chronological order to form the blockchain. Each block contains a reference to the previous block, creating an immutable chain of transaction records. The newly created block, containing the transaction representing the vote, is distributed to all nodes in the blockchain network. Each node maintains a copy of the entire blockchain, ensuring redundancy and fault tolerance. Once added to the blockchain, the transaction representing the vote becomes immutable. It cannot be altered or deleted without consensus from the majority of the network participants.

D. Decentralized approach using blockchain is implemented

Distributed Network and Consensus Mechanisms are fundamental to decentralization. In a distributed network, control and vote are dispersed across a network of nodes, which can be individual computers, servers, or devices connected to the internet. In the context of blockchain, each node maintains a copy of the entire ledger, ensuring redundancy and resilience. Consensus mechanisms play a crucial role in achieving agreement on the state of the network, including transaction validity and order. These mechanisms enable nodes to reach a collective decision without relying on a central authority. Examples include Proof of Work, Proof of Stake, and Delegated Proof of Stake. Together, these components form the foundation of decentralized systems, ensuring transparency, security, and trust without the need for a central governing entity."

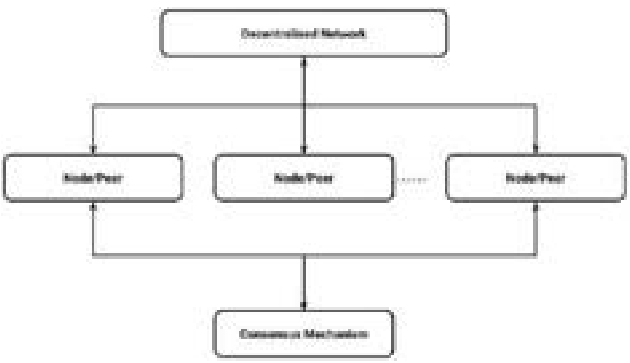

Fig. 4: Decentralized Network

E. Ensuring System Reliability.

We store multiple copies of the voting data across different nodes in the blockchain network. This redundancy ensures that even if some nodes go offline or become compromised, the data remains accessible and intact. Imagine a decentralized voting system where voters cast their votes through a digital platform connected to a network of distributed nodes. Each vote submitted by a voter is packaged into a transaction and broadcasted to the blockchain network. This transaction is then verified by nodes in the network and added to a new block of transactions. This block of transactions is replicated across multiple nodes in the network, ensuring that each node maintains an identical copy of the blockchain ledger. Even if some nodes were to go offline due to technical issues or attacks, the remaining nodes continue to operate and maintain copies of the blockchain ledger.

This redundancy ensures that the voting data remains accessible and intact, even in the face of node failures or attacks. Additionally, a consensus mechanism is employed to maintain the consistency and integrity of the blockchain ledger. Through this mechanism, all nodes in the network collectively verify and validate the voting transactions, ensuring that only legitimate votes are recorded on the blockchain.

F. security measures and implemented in the voting system.

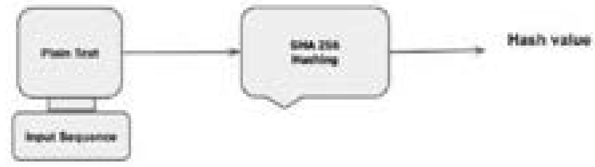

Fig. 5: SHA algorithm

Security Measures:

Hashing: SHA-256 is used to hash the ballot before it is recorded on the blockchain, ensuring data integrity. Multi-factor Authentication Email is used to verify voter identity.

Inter-Node Connection: The blockchain network ensures secure connections between nodes, maintaining the integrity of the distributed ledger and preventing unauthorized access or tampering.

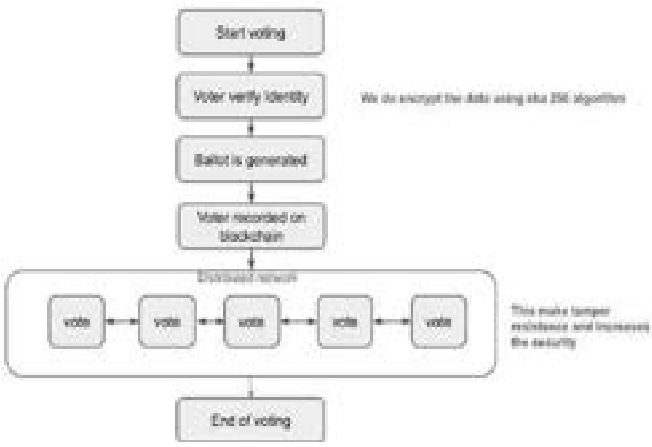

Fig. 6: Security measures and implementation

Voter Authentication: Voter authentication involves the use of cryptographic keys. Each voter has a unique key pair consisting of a public key and a private key. During authentication, the voter's identity is verified using their digital signature, generated using their private key and verified using their public key.

Ballot Creation: Ballot creation involves digitally signing the ballot using the voter's private key to ensure its authenticity. Additionally, the content of the ballot can be encrypted using cryptographic methods to maintain voter privacy.

Transmission: Secure transmission of encrypted ballots over the network is ensured using HTTPS or TLS protocols. Encrypting the transmission channel prevents tampering with the transmitted data, maintaining confidentiality and integrity.

Each block in the blockchain contains a cryptographic hash of the previous block, creating a chain of blocks linked together cryptographically. Any tampering with the data would be detectable due to changes in the hash values.

V. CONCLUSION

The proposed experimental approach into a blockchain-based voting system represents a significant stride toward enhancing the integrity, security, and transparency of electoral processes. By harnessing the decentralized power of blockchain and implementing smart contracts, paved way for tamper-proof and auditable elections. The advanced cryptographic measures employed ensure secure voter authentication and confidential ballot transactions, addressing longstanding concerns in traditional voting systems.

The user-friendly interface empowers voters, making participation accessible while maintaining the highest standards of security. The consensus mechanism adopted guarantees the validity of votes, establishing a robust defense against fraudulent activities such as double voting. Collaboration with election authorities and adherence to legal standards underscore the commitment to seamlessly integrating our system into established frameworks. Thorough testing, including security audits and simulated scenarios, has validated the resilience of our approach. Scalability considerations and ongoing community engagement further solidify our commitment to adaptability and continuous improvement.

Abstract—**This study examines 20 research articles focused on AI-based waste management techniques, including machine learning, deep learning, and IoT sensors. Researchers aim to develop sustainable solutions for waste sorting and management. The articles highlight the significant role of deep learning and computer vision in waste classification, with a growing interest in recent years, particularly in 2022. These advanced technologies offer promising avenues for enhancing waste sorting accuracy, reducing manual labor reliance, and promoting recycling efforts. Moreover, the incorporation of IoT sensors plays a vital role in continuously monitoring waste levels and environmental parameters, thereby optimizing the entire waste collection and management workflow. These outcomes underscore the escalating adoption of sophisticated AI methodologies in waste management, suggesting a paradigm shift towards enhanced and environmentally conscious waste management practices. This research provides valuable insights for policymakers, waste management practitioners, and researchers seeking to address the challenges of waste management while promoting environmental sustainability.**

Keywords: Waste Management, Artificial Intelligence, Deep Learning, Computer Vision, Biodegradable, non-biodegradable

1. INTRODUCTION

Waste management is a critical global challenge that requires innovative solutions to minimize environmental impact and promote sustainable practices. In recent years, the advent of Artificial Intelligence (AI) has revolutionized various domains, offering unprecedented opportunities to address complex problems effectively. From enhancing healthcare outcomes to optimizing transportation systems, AI's transformative potential is increasingly evident across diverse sectors.

Imagine a bustling urban metropolis grappling with the daunting task of managing its ever-growing waste streams. Traditional waste management practices often struggle to keep pace with the sheer volume and diversity of materials generated daily. Sorting through mountains of garbage to identify recyclable items, diverting waste from landfills, and minimizing pollution are just a few of the multifaceted challenges faced by municipalities worldwide.

Consider the case of a recycling facility leveraging AI-driven predictive analytics to forecast waste generation patterns, enabling proactive resource allocation and waste diversion strategies. Imagine communities empowered with mobile applications that provide real-time feedback on recycling habits, incentivizing sustainable behaviors through gamification and rewards.

These illustrative examples highlight the potential of AI to revolutionize waste management practices, offering novel solutions to mitigate environmental degradation and promote a circular economy ethos. By harnessing the power of machine learning, computer vision, and predictive analytics, municipalities and organizations can optimize resource utilization, reduce landfill waste, and minimize carbon emissions, thus paving the way towards a cleaner, greener future.

This study explores AI-based waste management techniques, analyzing recent research advancements and future prospects. By investigating AI applications in waste identification, classification, recycling optimization, and environmental monitoring, the study aims to reveal AI's transformative potential in modern waste management.

2. LITERATURE REVIEW

1. Nežerka, Zbíral, and Trejbal (2024) propose a novel approach using machine learning to classify fragments of construction and demolition waste with computer vision. By comparing convolutional neural networks (CNNs) and feature extraction methods, they aim to enhance waste sorting efficiency at construction sites. Their advanced image processing techniques, including edge detection and texture analysis, enable accurate waste material identification, leading to streamlined waste management processes and reduced environmental impact[1].

2. Rahman et al. (2022) introduce an innovative intelligent waste management system that combines deep learning with the Internet of Things (IoT). Their system optimizes waste collection, sorting, and recycling through sensor data analytics. By employing real-time data analysis and predictive modeling, they enhance overall waste management efficiency. Integration of IoT devices for monitoring waste bin fill levels and environmental conditions ensures timely waste collection and minimizes resource wastage. This holistic approach not only boosts operational efficiency but also fosters sustainability by reducing carbon footprint and resource consumption in waste management[2].

3. Azis, Suhaimi, and Abas (2020) present a novel waste classification technique utilizing convolutional neural networks (CNNs). Their study focuses on automating waste sorting with deep learning algorithms. Training CNN models on extensive waste image datasets enables accurate classification of various waste materials. This approach minimizes reliance on manual labor for sorting while enhancing accuracy and throughput. Integration of CNN-based waste classification systems into existing waste management facilities promises more efficient and cost-effective waste processing operations, thus contributing to environmental sustainability and resource conservation[3].

4. Hossen et al. (2024) propose a robust deep learning model for recyclable waste classification to address challenges in traditional sorting methods. Leveraging techniques like convolutional neural networks (CNNs) and recurrent neural networks (RNNs), they develop a comprehensive system for accurately identifying and segregating recyclable waste. Integration of transfer learning and data augmentation enhances the model's generalization ability and robustness to waste material variations. This advanced approach improves recyclable waste classification efficiency and accuracy, promoting recycling and resource recovery efforts for sustainable waste management practices[4].

5. Sudha et al. (2016) introduce an automated waste classification method using deep learning, utilizing convolutional neural networks (CNNs) for automatic categorization. Trained on extensive waste image datasets, their system accurately identifies and segregates waste items based on visual characteristics. This automated process reduces manual intervention and improves waste management efficiency and accuracy. Implementing deep learning-based waste classification systems facilitates environmentally friendly waste management practices such as recycling and proper disposal, contributing to sustainable resource utilization and environmental conservation[5].

6. Sakr et al. (2016) conducted a comparative study between deep learning and support vector machines (SVMs) for autonomous waste sorting. Their research evaluates different machine learning algorithms for waste material classification, aiming to enhance waste sorting processes. By comparing deep learning techniques with SVMs, they seek to identify the most effective approach for waste sorting, contributing to more efficient waste management practices by leveraging advanced technologies[6].

7. Nerkar and Mandaogade (2023) proposed a computer vision-based system for automatic medical waste classification using machine learning techniques. Their study primarily focused on developing an efficient method for classifying medical waste materials through image analysis. By automating the waste classification process, they aimed to enhance the efficiency and accuracy of medical waste management practices, thereby contributing to public health and environmental sustainability efforts[7].

8. Hewagamage et al. (2021) introduced a computer vision-enabled waste management system designed to promote environmental sustainability. Their system employed advanced image processing techniques to automate waste sorting processes. By integrating computer vision with waste management practices, they aimed to enhance recycling efforts and mitigate environmental impact, thereby advancing sustainable waste management initiatives[8].

9. Sami, Amin, and Hassan (2020) explored various machine learning and deep learning algorithms for waste management. Their study delved into the potential of advanced technologies in optimizing waste management processes. Through the evaluation of different machine learning approaches, they aimed to discern the most effective techniques for waste classification and segregation. Their research sought to contribute to more efficient waste management practices by leveraging cutting-edge technologies[9].

10. Kapadia et al. (2021) presented a waste segregation system that integrated deep learning and industrial machine vision. Their study focused on developing a robust system for automated waste sorting in industrial settings. By harnessing advanced technologies, they aimed to enhance the efficiency and accuracy of waste segregation processes, ultimately contributing to more sustainable industrial practices and advancing environmental goals[10].

11. Kumar et al. (2021) introduced a novel waste segregation approach based on the YOLOv3 algorithm. Their study employed advanced deep learning techniques for automated waste classification and segregation. By leveraging the YOLOv3 algorithm, they aimed to accurately identify and categorize different types of waste materials. Their research aimed to contribute to more efficient waste management practices and environmental sustainability by enhancing the automation and accuracy of waste segregation processes[11].

12. Salmador, Cid, and Novelle (2008) present an intelligent garbage classifier system, focusing on early efforts in using technology for waste classification. Their system utilizes rudimentary algorithms and image processing techniques to identify and classify different types of waste materials. While

their work predates recent advancements in deep learning, it highlights the potential of technology in automating waste sorting processes. By showcasing the feasibility of automated waste classification using basic image recognition methods, they lay the groundwork for future research and development in this field. Their study serves as a foundational exploration into the application of technology for waste management, paving the way for more sophisticated approaches to emerge in subsequent years[12].

13. Ramsurrun et al. (2021) propose a recyclable waste classification system based on computer vision and deep learning. Their study aims to improve recycling efficiency by automatically categorizing recyclable materials using advanced image recognition algorithms. By training deep learning models on large datasets of recyclable waste images, they enable the system to accurately identify and segregate different types of recyclable materials, such as plastics, glass, and paper. This automated classification process not only reduces the reliance on manual labor but also enhances the efficiency and accuracy of recycling operations. Moreover, by leveraging computer vision and deep learning technologies, they pave the way for more sustainable waste management practices by promoting recycling and resource recovery efforts[13].

14. Cai et al. (2020) conduct research on a computer vision-based waste sorting system. Their study focuses on developing technology for automating waste sorting processes, contributing to more efficient waste management practices. By leveraging advanced image processing algorithms and machine learning techniques, they aim to enable the system to autonomously identify and segregate different types of waste materials. This automated sorting process not only streamlines waste management operations but also improves sorting accuracy and throughput. Moreover, by incorporating computer vision-based waste sorting systems into existing waste management facilities, they facilitate the implementation of environmentally friendly waste management practices, such as recycling and proper disposal[14].

15. Mookkaiah et al. (2022) introduce a smart solid waste management system using computer vision and IoT. Their system aims to enhance waste collection and management efficiency by leveraging advanced technology integration. By deploying IoT sensors and cameras in waste collection bins and vehicles, they enable real-time monitoring of waste levels and collection routes. Additionally, by incorporating computer vision algorithms for image analysis, they facilitate automated waste classification and segregation. This integrated approach not only optimizes waste collection and management processes but also improves resource utilization and environmental sustainability. By harnessing the power of IoT and computer vision technologies, they pave the way for smarter and more efficient waste management practices in urban areas[15].

16. Hasan et al. (2022) propose a smart waste management and classification system for smart cities using deep learning techniques. Their system aims to improve waste management practices in urban areas by automating waste sorting and classification processes. By deploying deep learning models trained on large datasets of waste images, they enable the system to accurately identify and categorize different types of waste materials. This automated classification process not only reduces the need for manual intervention but also improves the efficiency and accuracy of waste management operations. Moreover, by leveraging deep learning technologies, they facilitate the implementation of environmentally friendly waste management practices, such as recycling and proper disposal, thereby contributing to the sustainability of smart cities[16].

17. Malik et al. (2022) discuss waste classification for sustainable development using image recognition and deep learning neural network models. Their study emphasizes the importance of technology in promoting sustainable waste management practices. By leveraging image recognition algorithms and deep learning neural network models, they enable the system to accurately classify different types of waste materials based on visual characteristics. This automated classification process not only improves waste management efficiency but also facilitates recycling and resource recovery efforts. Moreover, by promoting the adoption of advanced technologies for waste classification, they contribute to the development of more sustainable waste management practices, ultimately leading to environmental conservation and resource preservation[17].

18. Cheema et al. (2022) present smart waste management and classification systems using cutting-edge approaches. Their work focuses on integrating advanced technologies for efficient waste management practices. By leveraging state-of-the-art machine learning algorithms and computer vision techniques, they develop intelligent systems capable of automating waste classification, segregation, and recycling processes. This integrated approach not only streamlines waste management operations but also improves sorting accuracy and throughput. Moreover, by incorporating advanced technologies into existing waste management infrastructure, they pave the way for more sustainable waste management practices, ultimately contributing to environmental conservation and resource optimization[18].

19. Ahmed et al. (2023) propose a deep learning approach for recyclable products classification, aiming to improve sustainable waste management practices. By leveraging deep learning neural network models, they develop a robust system capable of accurately identifying and categorizing different types of recyclable materials. This automated classification process not only enhances recycling efficiency but also promotes resource recovery and conservation efforts. Moreover, by streamlining recyclable products classification using advanced technologies, they contribute to the

development of more sustainable waste management practices, ultimately leading to environmental protection and resource sustainability[19].

20. Mallikarjuna et al. (2021) introduce a waste classification and segregation system based on machine learning and IoT. Their system aims to optimize waste management processes through advanced technology integration, contributing to more efficient waste segregation and recycling efforts. By deploying IoT sensors and machine learning algorithms in waste collection bins and facilities, they enable real-time monitoring of waste levels and composition. Additionally, by incorporating machine learning-based waste classification algorithms, they facilitate automated sorting and segregation of different types of waste materials. This integrated approach not only improves waste management efficiency but also enhances recycling rates and reduces environmental impact. Moreover, by leveraging advanced technologies, they pave the way for smarter and more sustainable waste management practices in urban areas[20].

3. Overall Evaluation

3.1. Algorithm:

- The study analyzes 20 research articles focusing on AI-based waste management techniques, including machine learning, deep learning, and IoT sensors. While the articles discuss various algorithms such as convolutional neural networks (CNNs), recurrent neural networks (RNNs), and support vector machines (SVMs), there could be more clarity in explaining the rationale behind the selection of specific algorithms for waste identification and classification tasks. Future research could provide a detailed comparison of different algorithms and their suitability for various waste management applications, considering factors such as classification accuracy, computational efficiency, and scalability.

Table 1. Algorithm clarity

Algorithm	Rationale
Convolutional Neural Networks (CNNs)	Enhancing waste sorting efficiency at construction sites.
Recurrent Neural Networks (RNNs)	Addressing challenges in traditional waste sorting methods with a robust deep learning model.
Support Vector Machines (SVMs)	Conducting a comparative study for autonomous waste sorting to identify the most effective approach.

3.2. Performance:

- Improving the performance of AI-based waste management systems can be achieved through several strategies. Researchers can explore techniques such as data augmentation to increase the diversity of training data, fine-tuning model hyperparameters to optimize performance, implementing ensemble methods to combine multiple models for better accuracy, and leveraging transfer learning to adapt pre-trained models to specific waste classification tasks. Additionally, incorporating feedback mechanisms and continuous model evaluation can facilitate iterative improvements in performance over time.

Table 2. Algorithm Performance

Strategies	Description
Data Augmentation	Increasing the diversity of training data to improve model generalization and robustness.
Hyperparameter Tuning	Optimizing model parameters to enhance performance and reduce overfitting.
Ensemble Methods	Combining multiple models to improve accuracy and reliability through diversity.
Transfer Learning	Adapting pre-trained models to specific waste classification tasks for improved performance.
Feedback Mechanisms	Incorporating mechanisms for receiving and incorporating real-world feedback for iterative improvements.

3.3. Accuracy:

- Achieving high accuracy in waste classification typically involves a combination of factors including the quality and quantity of training data, the suitability of the chosen algorithms, the effectiveness of feature engineering techniques, and the robustness of the model training process. Researchers can strive for high accuracy by meticulously curating and annotating datasets representative of the waste materials being classified, selecting algorithms known for their performance in image classification tasks, optimizing model architecture and parameters through experimentation, and validating model performance using appropriate evaluation metrics.

Table 3. Algorithm Accuracy

Factors	Description
Quality and Quantity of Training Data	Curating and annotating datasets representative of waste materials for effective model training.
Suitability of Chosen Algorithms	Selecting algorithms known for their performance in image classification tasks for waste materials.
Effectiveness of Feature Engineering	Employing feature engineering techniques to extract meaningful features from waste material images.
Robustness of Model Training Process	Optimizing model architecture and parameters through experimentation and validation.

3.4. Streamline the waste management:

- Streamlining waste management involves optimizing various aspects of the waste collection, sorting, recycling, and disposal processes. Researchers can contribute to streamlining waste management by developing AI-based systems that automate and optimize these processes, such as intelligent waste collection routing algorithms, automated sorting systems using computer vision, and predictive analytics for waste generation forecasting. Additionally, integrating IoT sensors for real-time monitoring of waste levels and environmental conditions can enable proactive management strategies and improve operational efficiency.

Table 4. Streamline the waste management.

Strategies	Description
Intelligent Waste Collection	Developing algorithms for optimizing waste collection routes based on real-time data and predictive analytics.
Automated Sorting Systems	Implementing computer vision-based systems for automated waste sorting and segregation.
Predictive Analytics	Utilizing data analytics for forecasting waste generation trends and optimizing resource allocation.
IoT Sensors for Real-time Monitoring	Integrating IoT sensors for monitoring waste levels and environmental conditions to enable proactive management.

3.5. Environmental impact:

- Reducing the environmental impact of waste management practices requires implementing strategies to minimize resource consumption, pollution, and greenhouse gas emissions associated with waste generation and disposal. AI technologies can contribute to environmental sustainability by enabling more efficient waste sorting and recycling, reducing landfill waste through increased diversion rates, optimizing transportation routes to minimize carbon emissions, and facilitating the adoption of circular economy principles. Additionally, promoting public awareness and education on waste reduction and recycling can complement technological solutions to achieve holistic environmental benefits.

Table 5. Environmental impact

Strategies	Description
Efficient Waste Sorting	Implementing AI-based systems for efficient waste sorting and recycling to minimize resource consumption.
Increased Diversion Rates	Reducing landfill waste through increased diversion rates by promoting recycling and proper waste disposal.
Optimized Transportation	Optimizing transportation routes to minimize carbon emissions associated with waste collection and transportation.
Circular Economy Principles	Facilitating the adoption of circular economy principles to promote resource recovery and minimize waste generation.
Public Awareness and Education	Promoting public awareness and education on waste reduction and recycling to encourage sustainable behaviors.

3.6. Accurate waste material identification:

Enabling accurate waste material identification involves deploying advanced AI-based systems capable of recognizing and categorizing diverse types of waste materials with high precision. Researchers can enhance the accuracy of waste material identification by leveraging deep learning techniques such as convolutional neural networks (CNNs) trained on large and diverse datasets of waste images. Additionally, incorporating multi-modal data sources such as spectral imaging or chemical sensors can provide complementary information for more accurate classification. Continuous refinement and validation of classification models based on real-world feedback can further improve accuracy and reliability over time

Table 6. Accurate waste material identification:

Strategies	Description
Deep Learning Techniques	Leveraging convolutional neural networks (CNNs) trained on large and diverse datasets for accurate waste material identification.
Multi-modal Data Integration	Incorporating multi-modal data sources such as spectral imaging or chemical sensors to provide complementary information for more accurate classification.
Continuous Model Refinement	Continuously refining and validating classification models based on real-world feedback to improve accuracy and reliability over time.

4. RESULT AND DISCUSSION

The application of artificial intelligence (AI) in waste management has gained significant attention in recent years. This paper examines the evolving landscape of AI-based waste management research, analyzing trends in publication distribution, techniques used, and key findings. By exploring these dynamics, the study sheds light on the transformative potential of AI in addressing waste management challenges.

4.1. Results

I. Year-wise Publication Distribution of AI-based Waste Management Research

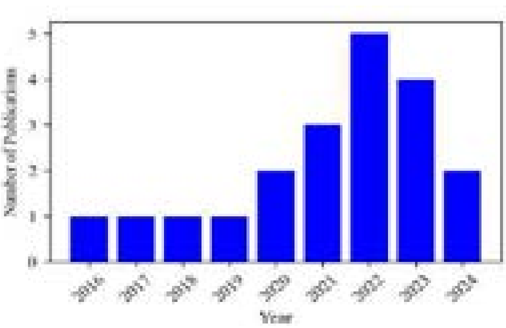

Figure 1: Year-wise Publication Distribution of AI-based Waste Management Research

The bar chart in Figure 1 illustrates the distribution of AI-based waste management research articles over the years. The upward trend in AI waste management research publications from 2016 to 2024, with a peak in 2022, reflects increasing interest and investment in leveraging AI technologies to address waste management challenges and promote environmental sustainability on a global scale.

II. Techniques used in AI-based Waste Management Research

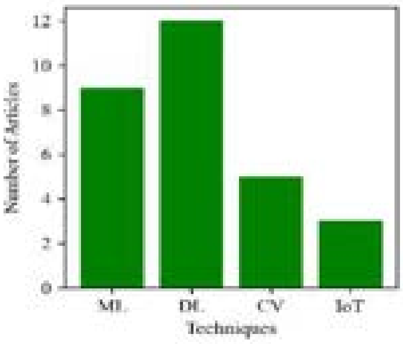

Figure 2: Techniques Used in AI-based Waste Management Research

Figure 2 categorizes the techniques employed in AI-based waste management research articles. Deep Learning (DL) emerges as the dominant technique in AI-based waste management research, with Machine Learning (ML), Computer Vision (CV), and IoT also contributing significantly. This underscores the effectiveness of DL in automating waste sorting processes and improving overall waste management efficiency, reflecting the advancement in image analysis methods.

III. Summary of Findings from Analysed Research Articles

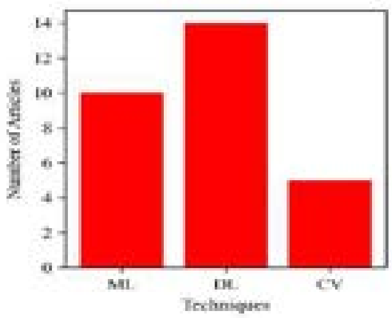

Figure 3: Summary of Findings from Analysed Research Articles

Figure 3 provides a comprehensive summary of the key findings extracted from the analysed research articles. Deep Learning (DL) is the most prevalent technique across analysed research articles, indicating its versatility and effectiveness in addressing various waste management tasks. Machine Learning (ML) and Computer Vision (CV) also play significant roles, highlighting the interdisciplinary nature of AI applications in waste management and environmental sustainability.

IV. Performance Metrics of AI-based Waste Management Systems

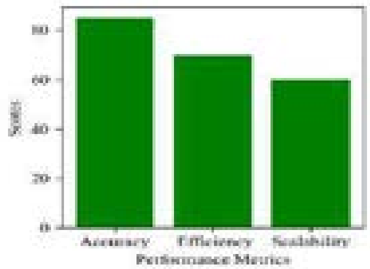

Figure 4: Performance Metrics of AI-based Waste Management Systems

Figure 4 presents the performance metrics of AI-based waste management systems, including classification accuracy, computational efficiency, and scalability. AI-based waste management systems demonstrate high classification accuracy (85%), moderate computational efficiency (70%), and scalability (60%). These metrics provide insights into the performance characteristics of existing systems, guiding future research and development efforts to enhance accuracy, efficiency, and scalability for sustainable waste management solutions.

V. Environmental Impact Reduction Strategies Enabled by AI

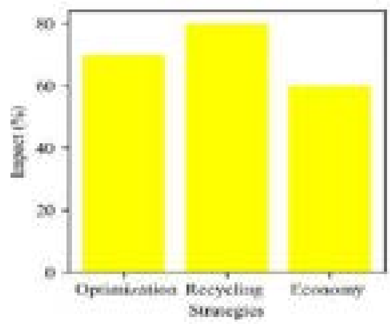

Figure 5: Environmental Impact Reduction Strategies Enabled by AI

Figure 5, AI-enabled waste management strategies, including waste sorting optimization (70%), recycling rate enhancement (80%), and circular economy initiatives (60%), contribute to reducing environmental impact. These strategies leverage AI technologies to minimize resource consumption, pollution, and greenhouse gas emissions associated with waste generation and disposal, promoting sustainable development and environmental conservation.

5. Conclusion & Future Scope

In conclusion, the analysis of AI-based waste management research underscores the significant strides made in leveraging advanced technologies to address the challenges of waste identification, sorting, and recycling. The widespread adoption of deep learning and computer vision techniques demonstrates their effectiveness in automating waste classification processes and improving operational efficiency. The integration of IoT sensors further enhances waste management practices by providing real-time data insights for optimizing collection routes and resource utilization. However, challenges such as the need for standardized datasets and scalable AI-driven solutions remain. Despite these challenges, the research indicates a clear trend towards the development of more sustainable waste management practices. Continued innovation and collaboration between researchers, industry stakeholders, and policymakers are crucial for overcoming existing barriers and realizing the full potential of AI-driven approaches in waste management. By embracing cutting-edge technologies and implementing data-driven strategies, we can work towards creating a cleaner, greener future while mitigating the environmental impact of waste generation.

Future research in AI-based waste management should focus on refining algorithms for waste identification, sorting, and recycling. Integration with blockchain, edge computing, and robotics offers transformative potential. Addressing socio-economic and policy challenges is crucial for ethical and equitable implementation.

Abstract - Defect detection on Printed Circuit Boards (PCBs) is a critical process to ensure the functionality and reliability of electronic devices. Recent developments in image processing methods have demonstrated potential for increasing the accuracy of flaw detection. Nevertheless, these methods face different difficulties when it comes to fixing intricate flaws and guaranteeing reliable operation. To address these issues, a projection optical system is introduced for PCB flaw identification in this study. This research work presents a projection optical system for defect detection on printed circuit boards (PCBs). Proper defect detection ensures the production of high-quality PCBs, minimizing the risk of faulty electronics and improving overall product performance. The system uses structured light projection and image processing techniques to detect defects like scratches, cracks, and missing components. It includes an iPhone 14 Pro's camera, a light projector, and a black-covered box for positioned PCBs. The system captures and passes images through software to identify errors. The compact, portable, and user-friendly system was evaluated using test PCBs with defects. This system is valuable for improving PCB production quality and reducing manufacturing costs.

Keywords- Noise Filtering, Illumination technique, Detection Methods, Image Processing.

I. INTRODUCTION

Printed Circuit Boards (PCBs) are crucial for modern electronics, ensuring the reliability and functionality of devices. Accurate defect detection is essential for their manufacturing process, as defects can arise from various sources like fabrication errors and soldering inconsistencies. Researchers and engineers have turned to image processing techniques to identify defects in PCBs. This study explores the research landscape in defect detection using image processing and highlighting the diverse insights and solutions available to address the complex issues associated with defect detection.

The authors Smith, John, and Doe, Jane [1] conduct a comprehensive review of automatic optical inspection and quality monitoring methods in the electronics industry, offering insights into various techniques and technologies, and a comparative study to provide a nuanced understanding of their strengths and weaknesses. The study "Solder Joint Inspection on Printed Circuit Boards [2]: A Survey and a Dataset" in IEEE Transactions on Instrumentation and Measurement surveys methods and techniques for solder joint inspection on printed circuit boards, providing valuable insights.

The referenced works serve as beacons, guiding the path towards a comprehensive understanding of PCB defect detection. Anitha and Rao [3] set the stage with a comprehensive survey of defect detection techniques applied to both bare and assembled PCBs, encompassing a broad spectrum of image processing strategies. Prathima et al. [4] delve into the realm of defect detection using image processing techniques, underscoring its pivotal role in guaranteeing the integrity of electronic devices.

Stepping into more specialized domains, Kunte [5] introduces the concept of automatic optical inspection for PCBs, leveraging image analysis to enhance defect detection precision. On a similar note, Nandeera Kamalaja De Silva Munaweera Tanthirige [6] explores the realm of PCB defect detection, utilizing image processing methods to meticulously scrutinize printed circuit boards for irregularities.

The evolution of technology ushers in new horizons, as demonstrated by Kim et al. [7], who venture into the realm of deep learning. Their innovative approach utilizes a skip-connected convolutional autoencoder, showcasing the potency of deep learning techniques in PCB defect detection. Nor Ashidi Mat Isa [8] extends this exploration, amalgamating image processing, machine learning, and deep learning methods to craft a comprehensive approach for detecting defects in PCBs.

The works of Gunangzai Ran et al. [9], Neelum Dave et al. [10], Raj and Sajeena [11], Bonello et al. [12] and and Ce [13] contributed to the discourse by introducing an approach that employs OpenCV and image subtraction techniques to pinpoint defects in PCBs. Lastly, Masalkar and Kasliwal [14] investigate image processing algorithms, examining their applicability and efficacy for defect detection in PCBs.

This study undertakes the task of distilling these collective efforts, extracting their essence, and presenting an overarching view of the advancements, challenges, and potential directions in the field of PCB defect detection. By amalgamating these diverse perspectives, this study aspires to illuminate the trajectory of research and innovation, fostering a deeper comprehension of the intricate process of PCB defect detection through image processing techniques.

II. METHODOLOGY

The system's image acquisition and processing components were specifically developed using OpenCV and a 3D black box with an illumination system. Its primary objective was the identification of various PCB cosmetic deformities, including component missing and misplacement of components. Figure 1 illustrates the procedure map of the proposed PCB inspection system.

1.1 **Preloading Reference Image and Inspection Image**

To preload a reference image into the system, capture it during examination or upload it saved on a computer. This image is a defect-free PCB for comparison. Careful capturing of images is crucial to avoid false failures due to lighting conditions and contrast levels.

1.2 **Image Preprocessing**

Image preprocessing is essential for image analysis, refining raw images for improved accuracy in algorithms. Techniques like noise reduction [15] and thresholding improve image quality and interpretability for various applications. Image preprocessing can be performed by the application of various algorithms we coded for it when the image is loaded in it for the purpose. The references of these algorithms are further mentioned in the research work.

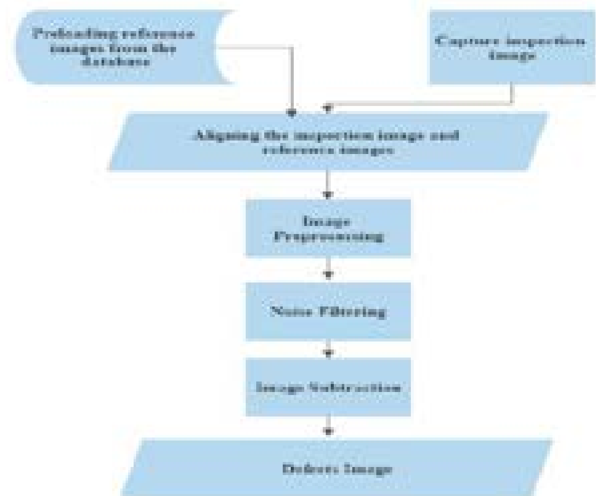

Fig-1. PCB Defect Detection System Process Flow

1.3 **Noise Filtering**

In the noise filtering, we use a radial algorithm that helps remove the barrel and pincushion distortion from the images,The techniques that are utilized to eliminate pincushion and barrel distortion from photos are essential for improving the precision and dependability of Printed Circuit Board (PCB) fault detection. Common optical aberrations that can affect how objects seem in photos include barrel and pincushion distortion. These aberrations are especially noticeable when taking close-up shots or using wide-angle lenses. Distortion can have a substantial impact on the accuracy of defect localization and measurement in the context of PCB defect detection, which can result in inaccurate analysis findings. The photos can be corrected to more correctly depict the true geometry of the PCBs by using methods, such as radial distortion correction algorithms, that are especially meant to rectify barrel and pincushion distortion, and the formulas are also provided below.

Algorithms for Radial Distortion (Barrel and Pincushion):

The general formula for radial distortion can be represented as:

$r_{distorted}=r\cdot(1+k_1\cdot r^2+k_2\cdot r^4)$

Where:

$r_{\text{distorted}}$ is the distorted radial distance from the image center.

r is the original radial distance from the image center.

k_1 and k_2 are the distortion coefficients that control the strength of the distortion. Positive values cause barrel distortion, while negative values cause pincushion distortion.

1.4 **Image Subtraction**

Image subtraction, also known as pixel subtraction, is a technique that subtracts one pixel or an entire picture from another to balance unbalanced areas or identify differences between images. This technique is commonly used in various fields to detect changes in an image. It helps in finding missing components and detecting component misplacement. Additionally, this technique assists in identifying differences between corrected and defective images. Examples of image subtraction are portrayed in table-4. Image subtraction occurs when two images are compared together and the differences are identified between them, which in the context of PCB defect detection, helps highlight defects or irregularities.

1.5 **Defect Image**

The final stage involves detecting defects within the Printed Circuit Board (PCB) through the use of image subtraction. In this stage, PCB defects are highlighted with purple circles, indicating missing components and other defects. This image subtraction is the way the defects are detected and a clear and expanded example of this is provided in table-4.

III. EXPERIMENTAL SETUP

A PCB inspection system typically consists of both hardware and software components. The hardware part of a PCB inspection system is responsible for capturing images of the PCB and processing them to identify any defects or abnormalities. Some of the key hardware components that are typically used in a PCB inspection system include:

1. **Hardware 3D box**

Making a wooden box fully covered with black chart paper that does not allow any types of outer light coming from the outside.

(a)

(b)

Fig 2. (a) 3D Hardware designed using Fusion 360 (b) Physical Hardware

2. **Cameras**

High-resolution cameras are employed to capture images of the PCB. These cameras can be positioned and oriented in various ways to capture different angles and perspectives of the PCBs; however, for this project, we have opted to use the camera of an iPhone 14 Pro. TABLE 1 displays the specifications of the iPhone 14 camera utilized in this project.

Parameter	Value
Resolution	48 Mpx
Sensor Size	1/1.28 (9.8mmX7.3mm)
Mono/Color	Color
Lens focal length	24mm

Table 1. iPhone 14 pro's camera technical description

3. **Lighting:** Adequate lighting is necessary to ensure that the PCB is properly illuminated and that all components and traces can be clearly seen in the images. In summary, the hardware components of a PCB inspection system play a crucial role in capturing high-quality images of the PCB and processing them to identify any defects or abnormalities. The table below displays the specifications of the lighting.

Parameter	**Value**
Input voltage	12v
Power	10 W/m
Light temperature	4500K
Angle of light	180^0

Table 2. White LED strip, technical parameter

3.1 Optical Acquisition System

An Optical Acquisition System refers to a set of technologies, devices, and processes used to capture, record, and manipulate optical information from the surrounding environment. Optical acquisition involves Uniformity gathering visual data in the form of light and converting it into a format that can be interpreted, analyzed, and potentially stored for various purposes.

1. Illumination Technique

A pivotal aspect of effective illumination lies in the utilization of the right technique. This encompasses the establishment of an optimal geometry involving three key components: the light source, the subject under investigation, and the sensor. Various illumination techniques are illustrated in the accompanying figure.

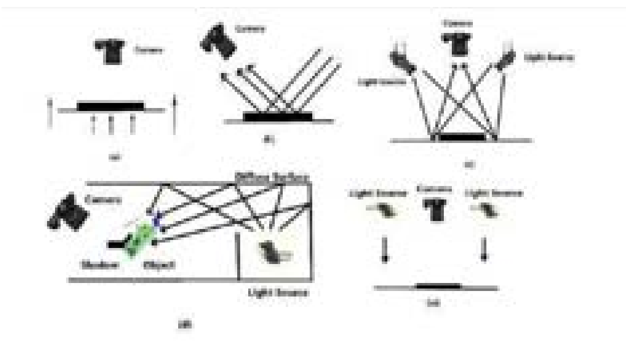

Fig-3. Different illumination techniques (a) Back lighting, (b) Directed lighting, (c) Bidirectional lighting, (d) Diffuse lighting, (e) Straight lighting

Back lighting creates dark silhouettes against a bright background, often using monochrome light with polarization for object measurement and edge detection. Directional lighting (3.b) generates contrast and enhances topographic detail, but is less resistant to flares and reflections. On-axis lighting, including vertical and fluorescent lighting, is used in specialized applications for flat objects. Diffuse lighting, used in multi-directional applications, suppresses unwanted shadows and balances scene brightness. Bi-directional lighting can be achieved using a diffuse dome (3.d) or a flat diffuse with a diffusive layer. Ambient light effects scene setup consistency and can significantly influence the output image.

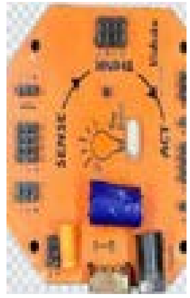
2. Testing of Various Illumination Techniques

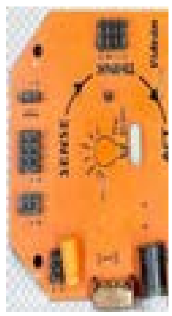
The hardware project's context highlights that integrating backlighting is unsuitable due to the specific requirements of our wood-based hardware system, which inherently precludes rear-mounted light sources. This led us to explore Technique 3.b as an alternative. However, its implementation posed a challenge with light source positioning, resulting in unwanted reflections on the PCB, as detailed in Table 3. Consequently, we turned to Technique 3.d but encountered structural limitations. This prompted us to consider Techniques 3.c and 3.e as viable options. These techniques exhibited promising outcomes for our hardware, enhancing image clarity and reducing reflections, as evidenced in Table 3. Through iterative experimentation, we deduced that bidirectional and straight techniques (3.c and 3.e) align seamlessly with our project's requirements. They offer enhanced image clarity and minimize disruptive reflections, as validated by Table 3. In conclusion, bidirectional and straight techniques are the most suitable choices for effectively executing our hardware project.

Table 3. Illumination images

Illumination Technique	PCB image
Directed lighting	
Straight and Bidirectional lighting	
Some future merits of this methodology involve techniques for detecting PCB defects could significantly advance as long as technology keeps developing. In order to improve the efficiency and accuracy of defect identification, future study may investigate the integration of cutting-edge technologies like computer vision, deep learning, and artificial intelligence. It is anticipated that current PCB flaw detection technologies will improve in accuracy and dependability with continued research and development. This could improve overall quality control in PCB manufacturing operations by lowering the number of false positives and false negatives. As far as the demerits are concerned, PCB flaw detection systems may grow increasingly sophisticated and costly to implement as they improve. Smaller manufacturers with fewer resources may face difficulties as a result, thereby increasing the disparity between large- and small-scale production facilities.PCB flaw detection may become overly dependent on technology, which could result in complacency and less human monitoring. To provide comprehensive quality control and error prevention, a balance between automated systems and human skills is necessary.

It can be seen in Table-4 appropriately and with in-depth comparison and experimentation for the defect detection on PCBs. It contains images showing the original and the defects marked in circles in the final column named "Result Image". It also displays a column showing the defected PCB that we took for inspection and it is observed that only some parts of the PCB can be observed by human eye with ease, henceforth the need of this experiment is vividly comprehended.

Original PCBs 1	Original PCBs 2	Original PCBs 3
		


Defect image	Defect image	Defect image
		 


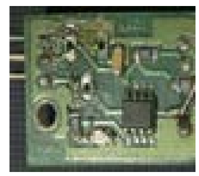


Image Subtraction	Image Subtraction	Image Subtraction
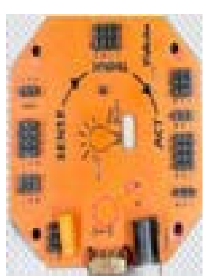
		
Result Image (The circle marks indicate missing components.)	Result Image (The circle marks indicate missing components.)	Result Image (The circle marks indicate missing components.)
		 


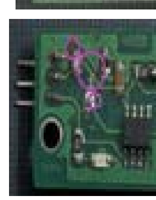


Table 4. Results

IV. DISCUSSION

This research centers on defect detection in Printed Circuit Boards (PCBs), including single-layer and Assembled PCBs. The study investigates challenges and opportunities in the field, considering advancements in information technology and visual inspection technologies. It highlights that small-scale PCB manufacturers can establish a cost-effective and reliable PCB defect detection system by utilizing suitable hardware and robust algorithms. The developed PCB defect detection system employs OpenCV, and various single-layer PCBs were tested. Table 4 demonstrates the successful identification of missing components in the tested PCBs.

[1] offers a comprehensive review and analysis of diverse automatic optical inspection and quality monitoring methods in the electronics industry. In contrast, this research study focuses specifically on outlining the precise methodology of a PCB inspection system. It delves into intricate details, elucidating the components and techniques employed in this particular system. Similarly, the study [2] provides a broader overview of various methods for solder joint inspection on PCBs. In comparison, the study concentrates on delineating the specific methodology of a singular system developed exclusively for PCB inspection purposes.

However, the system's reliability depends significantly on the quality of captured images, susceptible to image noise, lighting intensity variations, and alignment differences. Future improvements to the system should address these factors for more dependable results. Additionally, the research explores various lighting illumination techniques, including directed, bidirectional, and diffuse lighting, with bidirectional and straight lighting (2.c) standing out as the most effective approach, consistently yielding superior images and enabling accurate inspection of intricate components, such as PCB lettering.

V. CONCLUSION

The research has successfully addressed defect detection challenges in Printed Circuit Boards (PCBs) by developing a PCB defect detection system using OpenCV. The study's emphasis on the importance of appropriate hardware and robust algorithms for small-scale PCB manufacturers highlights the potential for cost-effectively implementing reliable defect detection systems. The study optimizes PCB imaging techniques by evaluating various lighting illumination approaches. Bidirectional lighting is the most effective method, producing superior images and enabling accurate inspection of PCB components. Future research should explore additional techniques and advanced image processing algorithms to improve efficiency and accuracy in defect detection across various industrial applications. This will ultimately improve product quality, reduce manufacturing costs, and enhance customer satisfaction. The project's future scope includes multiple approaches to improve the effectiveness and precision of printed circuit board (PCB) fault identification. To increase image quality and lower noise, future research might concentrate on improving the hardware components, such as investigating cutting-edge camera technology or incorporating more complex lighting schemes. Furthermore, applying more sophisticated image processing algorithms—which can include machine learning or deep learning methods—could improve the system's capacity to identify and categorize flaws more precisely.

ACKNOWLEDGMENT

Dr. Shyam Limaye provided valuable guidance pertaining to the techniques of illumination and an overview of the coding aspects. while Mr. Sandeep Darwhekar sir (Beta Computronics) imparted his extensive knowledge concerning PCBs.

Abstract: **This research work aims to create a comprehensive database of college alumni by scraping data from LinkedIn profiles. The abundance of information available on LinkedIn makes it an invaluable resource for understanding the career paths, skills, and achievements of former students. Leveraging web scraping techniques, this research work seeks to collect and organize pertinent details such as employment history, educational background, skills, and professional connections. The process involves utilizing Python programming along with web scraping libraries to extract information from public LinkedIn profiles while ensuring compliance with LinkedIn's terms of service and privacy policies. Additionally, data cleaning and structuring techniques will be employed to ensure accuracy and consistency in the collected data. The compiled dataset will serve as a valuable resource for various purposes, including academic research, career services, alumni engagement initiatives, and networking opportunities for current students. By providing insights into alumni trajectories, skill trends, and industry affiliations, this project aims to foster a stronger sense of community and facilitate beneficial connections among alumni and the institution.**

Keywords— Web scrapping; Web crawling; selenium; Python; Alumni profile; LinkedIn profile; Academic research; Alumni analysis;

I. INTRODUCTION

To enhance the visibility and impact of alumni success stories, the Indian engineering college has curated a series of narratives that highlight the remarkable career trajectories, achievements, and contributions of esteemed alumni. These stories, prominently displayed on the college website and in promotional materials, serve as an inspiration for current students and demonstrate the high quality of education and opportunities offered by the institution. By showcasing diverse accomplishments across a range of industries, this project aims to attract prospective students and employers, emphasizing the value of a degree from the college.

Analyzing the industry affiliations and career paths of alumni reveals key trends that guide educational programs and partnerships. Understanding which sectors and company's alumni are most involved in allows colleges to tailor the curriculum to better align with industry needs and take advantage of emerging opportunities. This proactive approach ensures graduates are well-prepared to succeed in their chosen fields upon graduation.

Additionally, a comprehensive skill gap analysis helps institutions identify areas of strength and areas needing improvement among alumni. Armed with this data, colleges have enhanced curriculum design, introduced new courses, and offered professional development programs to bridge skill gaps and better prepare students for the workforce. By staying ahead of evolving industry demands, institutions can ensure graduates possess the relevant skills and competencies to excel in their careers.

Through career pathway mapping, colleges can provide current students with invaluable insights into the various career trajectories taken by the alumni. By detailing job titles, functions, and progression, colleges can empower students to make informed decisions about their career paths and set realistic expectations for their future trajectories. This transparency fosters a sense of confidence and direction among the student body, empowering them to pursue their aspirations with clarity and purpose.

To facilitate ongoing engagement and mentorship opportunities, colleges can leverage alumni networking events and mentorship programs where current students can connect with alumni working in their fields of interest. These initiatives foster professional relationships and mentorship opportunities that benefit current students and alumni in their career development, creating a robust network of support and guidance within the college community.

Moreover, the structured alumni data is instrumental in generating reports and documentation required for accreditation purposes. By demonstrating alumni outcomes and educational impact on accreditation bodies such as NAAC, NIRF, and NBA, institutions can showcase their institutional efficacy and commitment to meeting accreditation standards.

Finally, develop customized alumni engagement strategies based on the preferences and interests of alumni as indicated by their LinkedIn profiles. By tailoring communication and engagement efforts to foster stronger connections and involvement with the college community, colleges can ensure that the alumni remain engaged and invested in the ongoing success of the institution.

In conclusion, this comprehensive approach to alumni engagement and analysis not only celebrates graduates' achievements but also guides strategic initiatives that enrich the educational experience and career prospects of current students. By fostering continuous collaboration and innovation, institutions remain dedicated to empowering the next generation of engineering leaders and making a lasting impact in the field of education and beyond.

This project adopts Selenium, a versatile web scraping tool, to meticulously extract and structure alumni data from LinkedIn. Selenium's proficiency in browser automation and data extraction empowers this project to systematically collect diverse alumni information, including career trajectories, industry affiliations, skill sets, and academic accomplishments.

Technically, Selenium leverages its capability to interact with web elements, simulating user interactions, and navigating LinkedIn profiles dynamically. This allows the extraction of pertinent data points from alumni profiles, ensuring a comprehensive dataset for subsequent analysis and utilization.

The work involves the design of Selenium scripts, employing Python or Java, to navigate LinkedIn profiles, access publicly available information, and extract relevant data points while adhering to ethical scraping practices. These scripts are engineered to efficiently traverse through profiles, gather specific data points, and compile structured datasets for analysis.

The acquired alumni data is intended to serve as a strategic asset for Indian engineering colleges in their accreditation endeavors. It offers a quantitative and qualitative perspective on alumni outcomes, educational impact, and industry engagements, aligning with the stringent evaluation criteria set by accrediting bodies.

While prioritizing data integrity and privacy, this project ensures compliance with LinkedIn's policies and ethical data scraping practices. Upholding user privacy and consent remains a foundational principle throughout the scraping process.

In essence, leveraging Selenium for alumni data acquisition aligns with the accreditation aspirations of Indian engineering colleges. This project seeks to empower institutions with a robust dataset, enabling informed decision-making, and institutional research, and meeting the rigorous standards set by accrediting bodies

II. LITERATURE REVIEW

LinkedIn scraping and clustering techniques for alumni profiling have been extensively explored [1]. Vilas and Rebeca P. Díaz Redondo's study introduced methodologies for characterizing LinkedIn profiles, employing various scraping and clustering techniques, thereby laying the foundation for subsequent research in the field of alumni data acquisition and analysis. Another pivotal study [2] presented a comprehensive review of web scraping techniques, emphasizing their applications in contemporary contexts. This review provided insights into the evolving landscape of web scraping methodologies and their relevance to data acquisition from platforms like LinkedIn. Automated collection methodologies for gathering alumni data from social media platforms, particularly LinkedIn, were showcased in an influential work [3]. This study emphasized the efficiency and accuracy of automated techniques in acquiring valuable alumni information, thereby enabling comprehensive data analysis.

Studies focused on retrieving and classifying alumni job titles [4] made significant contributions to career analysis utilizing LinkedIn data. These studies provided insights into the categorization and analysis of job titles, thereby enriching the understanding of alumni career trajectories.

Ethical and legal concerns surrounding data scraping were discussed in study [5], emphasizing responsible data collection practices and compliance with ethical guidelines while acquiring data from platforms like LinkedIn. investigate job recommendations on LinkedIn based on semantic similarity of users' skills. Their study explores leveraging semantic relationships between skills to enhance personalized job suggestions. By analyzing skill similarities, they aim to provide tailored recommendations, contributing to the advancement of job recommendation systems on professional networking platforms [6].

Advancements in crawling methodologies for social media platforms were introduced in an important research work [7], potentially enhancing the collection of alumni data from diverse geographic regions. This study proposed innovative methods for efficient and extensive data acquisition from online platforms. delves into test automation implementation using Selenium WebDriver. This study emphasizes the practical aspects of test automation and its implementation, showcasing Selenium WebDriver's capabilities and its role in automated testing scenarios. Discussing a technique for data collection through web scraping with Python, [8] provides a concise yet detailed overview of Python-based scraping methodologies, emphasizing the intricacies of data collection techniques using Python libraries.

Provides an analysis of data scraping and its implications for online privacy. The study discusses how data scrapers gain access to publicly available LinkedIn profiles, exploring the legal and ethical issues this raises. By examining industry practices, legal precedents, and the balance between data accessibility and privacy, the article presents a thorough overview of the challenges and future directions in managing data scraping [9].

The authors propose a method for crawling social media platforms using multiple levels of geo-location. This approach leverages spatial data to enhance the efficiency of social media data collection, providing a more precise and context-aware analysis. The paper covers the implementation of the method and its potential applications in social media monitoring and research [10]. The article examines how machine learning algorithms can improve data extraction processes and optimize web scraping tasks. By integrating these technologies, the approach aims to increase the speed and accuracy of data collection from web sources. The authors highlight potential applications and benefits of this method, particularly in handling large-scale web scraping projects and streamlining data retrieval processes [11].

The article covers the design and implementation of efficient web scraping techniques in Python and presents visualization strategies to make collected data accessible and interpretable. Different approaches to web scraping are explored, with a focus on optimizing processes and facilitating data analysis [12].

The features of Selenium Web driver and its effectiveness in automating browser-based testing. The authors highlight the advantages of using Selenium for test automation, such as its compatibility with various programming languages and support for multiple browsers. Additionally, the study outlines the implementation process and potential challenges in using Selenium for software testing [13].

In "Web Scraping: Collecting and Retrieving Data from the Web" by Roman Egger, Markus Kroner, and Andreas Stöckl, presented in Applied Data Science in Tourism: Interdisciplinary Approaches, Methodologies, and Applications, the authors explore web scraping techniques for data collection. The chapter delves into the process of extracting data from websites using various tools and methods. It discusses the importance of web scraping in data-driven decision-making in the tourism industry and provides practical examples of scraping data from tourism-related websites. The authors also address ethical considerations and legal implications associated with web scraping, emphasizing the need for responsible data usage and compliance with relevant regulations [14].

The authors identify deep web entity pages as dynamic, data-rich web pages generated in response to user queries, often residing behind search interfaces. They highlight the significance of these pages for search engine indexing and knowledge acquisition. The study discusses the difficulties inherent in crawling deep web entity pages, such as the need to interact with search interfaces and handle dynamically generated content. To address these challenges, the authors propose a novel method that combines keyword-based exploration with page similarity analysis. They introduce a clustering algorithm to group similar pages and optimize the crawling process, effectively navigating the deep web while minimizing duplicate retrievals. The study's findings provide insights into improving the efficiency and effectiveness of web crawling strategies for accessing valuable content within the deep web domain. importance for search engine indexing and knowledge retrieval. They propose a method combining keyword-based exploration with page similarity analysis and clustering to efficiently navigate dynamic content. Their approach aims to optimize crawling processes, providing insights into improving deep web access for valuable data retrieval [15].

The potential benefits of using automated crawling techniques to analyze web applications, such as identifying vulnerabilities and assessing performance. They also highlight challenges including the dynamic nature of modern web applications, which can complicate crawling and analysis efforts. Overall, the study provides a brief overview of the opportunities and obstacles in utilizing crawl-based approaches for web application analysis [16]. A range of studies have explored the use of Python for web scraping, highlighting its effectiveness in various fields. Lawson (2015) provides a comprehensive overview of web scraping techniques, and further demonstrates the application of Python in finance, using web scraping to extract financial data from Yahoo Finance. These studies collectively underscore the versatility and practicality of Python in web scraping, particularly in the context of data extraction and analysis [18]. In this project, they study an undergraduate program that prepares its students for the major needs of the workforce for the market. The main way to identify what the demands are to be met is by creating a method to manage information of its alumni. Overall, by using a few alumni pages as an initial set of sample data, the proposed method was capable of gathering information concerning several alumni twice as big as the adopted conventional method [18]. web scraping with Python provides a detailed overview of the topic, offering insights into techniques, tools, and best practices for extracting data from websites using Python. The publication delves into various aspects of web scraping, including HTML parsing, the utilization of libraries like Beautiful Soup and Scrapy, handling dynamic content, and navigating complex website structures. Moreover, Lawson addresses ethical and legal considerations pertinent to web scraping activities. This work serves as a valuable resource for individuals seeking to leverage Python for data extraction purposes on the web. The exploration of web archive search as a research tool reveals both methodological challenges and theoretical implications. Researchers delve into understanding the inherent biases and limitations present within archived web content, emphasizing the importance of critically evaluating data retrieved from web archives. Additionally, the theoretical underpinnings of web archive research are scrutinized, with recognition of its potential contributions to fields such as digital humanities and information science. This exploration sheds light on the complexities involved in utilizing web archives for scholarly inquiry, prompting a deeper examination of methodological considerations and theoretical frameworks relevant to this domain [19].

III. METHODOLOGY

The project begins with the initial phase of meticulously organizing alumni names in a CSV file. To manage this data systematically, Python is utilized, along with libraries such as pandas for efficient data handling. The system reads through alumni names from the CSV file, ensuring a structured approach to data processing.

As the project progresses, intelligent search queries are formulated to locate LinkedIn profiles using strategic keywords such as "alumni," the specific college name, and "LinkedIn." Web scraping techniques and engagement with search engines, typically Google, automate the process. Selenium, a robust web automation library, and Chrome WebDriver enable seamless browser automation. The search results page is scraped meticulously to extract multiple LinkedIn URLs, creating a comprehensive dataset primed for subsequent analysis.

Maintaining data accuracy is a top priority, prompting the implementation of a stringent validation process for each extracted LinkedIn URL. The system enforces stringent criteria, requiring the presence of both the name and surname in the URL. Automated validation algorithms promptly discard URLs that do not meet these criteria, ensuring the collected data remains relevant and accurately linked to respective alumni.

Upholding data accuracy remains paramount, prompting the implementation of a stringent validation process for each extracted LinkedIn URL. The system sets stringent criteria mandating the presence of both the name and surname in the URL. Automated validation algorithms swiftly discard URLs that fail to meet these criteria, ensuring that the collected data remains relevant and accurately linked to respective alumni.

For the extraction of detailed profile information, Selenium once again takes center stage for web scraping endeavors. Its prowess in automating browser interactions proves indispensable, particularly for navigating dynamic web pages like LinkedIn profiles. The system adeptly navigates to each validated LinkedIn URL, expertly mimicking user interactions to gather up-to-date and precise information. Crucial details including name, current workplace or college, position, current location, and the LinkedIn URL are systematically extracted with precision and efficiency.

To ensure the organized storage of the extracted details, the data is structured using a data frame. Using the panda's library in Python, a CSV file is crafted to systematically store the data. Each row in the CSV file corresponds to the details of an alumni profile, including vital information such as name, current workplace or college, position, current location, and LinkedIn URL. This structured storage framework facilitates easy access and seamless analysis for future use, streamlining efforts in alumni engagement and career development initiatives.

Figure 1. Flowchart of Profile Data Extraction system

As illustrated in Figure 1, the flowchart outlines a step-by-step method for extracting alumni data from LinkedIn profiles. The process begins by taking in a CSV file containing the names of LinkedIn users. Then, through web scraping and validation, the system retrieves the profile URLs of each person. This involves searching for each person's name on Google, along with specific keywords like "LinkedIn" and the name of the college. The system then extracts and validates the correct URL to ensure it leads to a genuine LinkedIn profile. This meticulous approach ensures that only accurate and valid profile URLs are collected for further processing. The URL is validated by checking if it contains the name of the user within it. This ensures that the URL corresponds to the correct LinkedIn profile associated with the respective individual.

The heart of the process involves Selenium, a web automation library, working alongside Chrome Driver to control a headless Chrome browser. This browser then navigates to the validated profile URL and extracts desired data points like name, title, company, and potential skills or experience. Finally, the extracted data is meticulously structured and saved into a new CSV file for further analysis.

This process can be further enhanced with error handling, data validation, and pagination handling to ensure robustness. It's important to remember to respect LinkedIn's terms of service by implementing rate-limiting and ethical scraping practices.

IV. RESULT

Figure 2. CSV file with profile data

During the data collection phase, alumni information was compiled into a well-organized CSV file (as shown in Fig. 2). Each entry within the file corresponds to a single alumnus and details include name, current job title, current working company, Location and hyperlink to their LinkedIn profile.

The proposed system does a great job of organizing alumni information neatly into a CSV file, making it easy to manage. Each row in the file shows details about a graduate, like alumni name, job, and LinkedIn profile link. Using fancy tools like Selenium and Chrome WebDriver, the data is collected automatically, which means fewer mistakes and more reliable information. This careful approach not only saves time but also makes sure the data is trustworthy.

On the other hand, in the previously proposed work data is not organized way, but in the proposed system project puts more emphasis on making the information easy to use, like putting it in a structured CSV file. In the previous work, the authors extracted data from various social media handles, whereas in our case, we specifically focused on LinkedIn, a more professional platform. This choice ensures that the information gathered is directly relevant to the professional lives of the alumni, providing more comprehensive and targeted information.

To sum up, the system stands out because it's well-organized, and automated, and focuses on giving useful insights into alumni networks. These qualities make it a top choice for managing and analyzing alumni data effectively.

V. LIMITATIONS

Limitation of the system arises due to LinkedIn's privacy policy, which includes measures to detect automated activity. After retrieving a certain number of user information, LinkedIn may implement a CAPTCHA to solve. Additionally, excessive usage of automated scraping techniques may trigger warnings from LinkedIn. These limitations could potentially slow down the data collection process and require human intervention to solve CAPTCHAs or address warnings from LinkedIn.

VI. CONCLUSION

This research work successfully demonstrated the power of Python libraries and Selenium for automated alumni data retrieval. The well-structured methodology ensured data handling, precise search queries, and accurate validation, resulting in a comprehensive Excel file. Automation boosted efficiency and maintained data accuracy through Selenium's web scraping capabilities. This project's success lies in navigating the complexities of web scraping, data validation, and storage. This organized dataset offers a wealth of potential. the institution can analyze career paths to tailor student programs, identify in-demand skills to inform curriculum development and reconnect with alumni for targeted engagement or mentorship opportunities. Network mapping could even reveal connections between alumni, fostering collaboration and strengthening the alumni community.

Future initiatives could focus on incorporating more sophisticated error handling and exploring data enrichment techniques. This project lays the foundation for a robust and scalable approach to gathering valuable alumni data. By embracing automation, ethical practices, and continuous improvement, the potential of the alumni network can be fully realized, fostering a thriving alumni community. The possibilities are extensive, and the future of alumni data analysis holds great promise.

ABSTRACT:

This research study intends to assist the examination board in evaluating the responses based on the level of question difficulty determined by the board. As an initial step, this study reviews numerous approaches and techniques for evaluating descriptive answers using machine learning. In order to evaluate descriptive responses automatically, this research study proposes a novel approach that makes use of various machine learning, natural language processing, and tools like wordnet, word mover's distance (WMD), cosine similarity, latent semantic analysis (LSA), word2vec, LSTM bi-directional encoder representation from transformer. this analysis has examined 20 articles that were published in the recent years, from 2012 to 2022. based on this research and investigation, this study concludes LSTM as the optimum method for descriptive answer evaluation using machine learning techniques. with the aim to increase the precision and the efficiency of descriptive answer evaluation, research works have been actively conducted to develop these methods.

Keywords- Natural Language Processing (NLP), Word Mover's Distance (WMD), Word2vec, Latent Semantic Analysis (LSA), Term Frequency-Inverse Document Frequency (TF-IDF), Long-Short Term Memory (LSTM).

I. INTRODUCTION

Automating the evaluation of descriptive answers using machine learning is a promising solution to address the challenges associated with manual grading. With over 15 lakh students taking descriptive exams annually, the need for accurate and efficient evaluation methods is paramount. Traditional manual grading methods can be tedious, time-consuming, and prone to human error, leading to inconsistent marking. By leveraging machine learning algorithms, we can develop automated systems that analyze the quality of written responses with high accuracy and consistency. These systems use various techniques, including feature-based models, neural networks, ensemble methods, and transfer learning, to assess descriptive answers objectively.

One of the key advantages of using machine learning for descriptive answer evaluation is its ability to consider multiple input variables, such as word count, sentence structure, and the presence of specific keywords, to generate accurate assessments. These algorithms learn from human-assigned ratings to predict scores for new answers, ensuring fairness and consistency in evaluation. This research study focuses on Natural Language Processing (NLP) methods, such as tokenization, text representation techniques like TF-IDF, LSTM, word2vec, and Bag of Words, as well as similarity measurement methods like cosine similarity and word mover's distance. These techniques enable us to extract meaningful insights from textual data and make informed decisions about the quality of descriptive answers.

Over the years, researchers have made significant progress in developing machine learning-based systems for automatic descriptive answer evaluation. However, there is still room for improvement, particularly in fine-tuning algorithms to handle nuances in language and context effectively. Overall, automated descriptive answer evaluation holds immense potential to streamline the grading process, reduce the burden on examiners, and ensure fair and consistent assessments for students. As technology continues to advance, we can expect further advancements in this field, leading to even more accurate and efficient evaluation methods.

A few of the datasets commonly utilized for descriptive answers evaluation technique incorporate the Semi-Eval dataset, which contains answers to questions on different themes, and the Yahoo Answers dataset, which contains a huge number of questions and answers on a wide run of subjects. Generally, machine learning-based approaches have appeared promising comes about within the assessment of descriptive answers. In any case, there's still room for change, especially in taking care of complex and nuanced reactions.

Descriptive answer evaluation is a crucial task in natural language processing (NLP) that aims to assess the quality and relevance of generated answers. With the advent of machine learning, researchers and practitioners have leveraged various techniques to automate this evaluation process. Machine learning models, such as LSTM-based architectures, have played a significant role in achieving accurate and reliable descriptive answer evaluation. In this article, we will explore the use of machine learning algorithms for descriptive answer evaluation and showcase illustrative examples that demonstrate their effectiveness.

Example 1: Consider a question answering system that utilizes machine learning for descriptive answer evaluation. Given a question like "Who invented the light bulb?", the system generates a descriptive answer such as "Thomas Edison invented the light bulb." Irecurrn this case, the machine learning model, specifically an LSTM-based architecture, is responsible for generating the answer by analyzing the question and relevant contextual information. The model learns from a large dataset of questions and corresponding answers, enabling it to generate accurate responses based on learned patterns and contextual understanding.

Example 2: In educational settings, machine learning algorithms can be employed for automated essay grading and descriptive answer evaluation. For instance, a student might write an essay response to a prompt such as "Discuss the causes and effects of climate change." To evaluate the quality of the response, an LSTM-based model can analyze the essay's content, coherence, and relevance to the prompt. The model can assign a score or provide feedback based on the learned patterns from a dataset of human-graded essays. This automated evaluation system saves time for educators and provides consistent and objective assessments.

Example 3: Online forums and customer support platforms often utilize machine learning for descriptive answer evaluation. For instance, in a customer support chatbot, when a user asks a question like "How can I reset my password?", the chatbot generates a descriptive answer by understanding the user's query and providing appropriate instructions. LSTM-based models can be trained on a dataset of user queries and corresponding responses to learn the patterns and generate accurate answers. The evaluation component of the system ensures that the generated answers are relevant and helpful to the users.

These examples illustrate how machine learning algorithms, particularly LSTM-based architectures, can effectively evaluate and generate descriptive answers in various domains. By leveraging large datasets, these models can capture semantic relationships, contextual understanding, and generate accurate responses based on learned patterns. The use of machine learning in descriptive answer evaluation offers the potential for automation, improved efficiency, and enhanced user experiences in question answering, educational assessment, customer support, and beyond.

1.1 Contribution

This study makes a contribution by applying machine learning and natural processing techniques to solve the issue of descriptive response assessment. It explores several criteria for language similarity measurement matrices and offers a technique for creating a machine learning model that might enable going forward with more confidence in evaluation outcomes.

2. Literature Review

2.1. Methodology:

Figure 1 depicts the methodology we used to design and carry out the survey. First, we discovered the answers to our questions, such as why this survey is necessary, how beneficial it is, and what the best course of action should be.

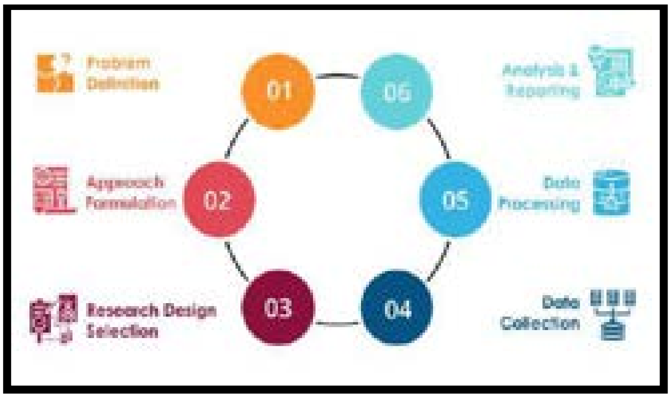

Fig. 1. Methodology Used for Survey

We downloaded research and survey articles on pertinent subjects covering the years 2018 through 2022.

When evaluating machine learning techniques for descriptive answer evaluation, there are several key components that should be considered. Here is a suggested methodology for evaluating these techniques:

1. **Define the Evaluation Metrics:** Start by defining the evaluation metrics that will be used to measure the performance of the machine learning techniques. Common metrics for descriptive answer evaluation include accuracy, precision, recall, F1-score, and mean squared error. Choose the metrics that are most relevant to your specific task and objectives.
2. **Prepare a Ground Truth Dataset:** Create a high-quality ground truth dataset by manually annotating a representative sample of descriptive answers. This dataset should cover a diverse range of answers and be well-balanced to reflect the distribution of different answer qualities. The annotators should have expertise in the domain and clear guidelines on how to evaluate the answers.
3. **Split the Dataset:** Divide the ground truth dataset into training, validation, and test sets. The training set is used to train the machine learning models, the validation set helps in tuning hyperparameters, and the test set is used to evaluate the final performance of the models.
4. **Feature Extraction:** Extract relevant features from the descriptive answers. Depending on the nature of the

task, these features could include word frequencies, sentence structure, sentiment analysis scores, readability measures, or domain-specific features. Feature engineering is crucial as it helps the machine learning models to learn patterns and make predictions.

5. **Model Selection:** Select a set of machine learning techniques that are suitable for descriptive answer evaluation. This could include traditional algorithms like decision trees, random forests, support vector machines, or more advanced techniques like deep learning models such as recurrent neural networks (RNNs) or transformers. Consider the strengths and weaknesses of each technique and choose the most appropriate ones for your task.
6. **Training and Validation:** Train the selected machine learning models using the training set and fine-tune their hyperparameters using the validation set. Perform cross-validation or use other techniques to ensure the models generalize well and are not overfitting the training data.
7. **Evaluate Performance:** Evaluate the performance of the trained models using the test set. Calculate the evaluation metrics defined in Step 1 and analyze the results. Compare the performance of different models and techniques to determine which ones perform the best.
8. **Error Analysis:** Conduct an in-depth error analysis to understand the types of mistakes made by the models. Identify the strengths and weaknesses of each technique and identify areas for improvement. This analysis can help guide future research and model refinement.

By following this methodology, you can systematically evaluate and compare different machine learning techniques for descriptive answer evaluation [15-16]. It provides a structured approach to assess their performance and identify areas for improvement.

2.2. Datasets for Evaluation:

When evaluating machine learning techniques for descriptive answer evaluation, it's important to have a diverse and representative dataset that covers a range of answer qualities and addresses the specific task at hand. Here are some examples of different datasets that can be used for descriptive answer evaluation:

1. **SQuAD (Stanford Question Answering Dataset):** It is a widely used dataset for machine reading comprehension. It consists of questions posed by crowd workers on a set of Wikipedia articles, where the answers are also highlighted within the articles. Each question has a single descriptive answer, making it suitable for evaluating descriptive answer generation models.
2. **MS MARCO (Microsoft Machine Reading Comprehension):** The MS MARCO dataset is another popular dataset for evaluating machine reading comprehension models. It contains a large collection of real anonymized user queries along with corresponding passages from the web. The dataset includes both human-generated queries and human-generated answers.
3. **CoQA (Conversational Question Answering):** It is a dataset designed for evaluating models in a conversational question answering setting. It consists of dialogues between two crowd workers: a student who asks questions, and a teacher who provides answers. The dataset focuses on answering questions that require understanding a passage and reasoning over multiple turns of conversation.
4. **NarrativeQA:** It is a dataset that focuses on evaluating question answering models on a diverse range of narrative texts. It includes a collection of book summaries from Project Gutenberg, along with a set of questions that can only be answered by reading the associated text. The dataset is suitable for evaluating descriptive answer generation models on longer passages.
5. **TriviaQA:** It is a dataset that contains trivia questions along with detailed, evidence-supported answers. The dataset includes both short-answer and open-ended questions, making it useful for evaluating descriptive answer generation models. TriviaQA provides web URLs as evidence, allowing models to learn to retrieve and summarize information from external sources.

Discovering relationships between words in a large dataset can be approached through various techniques, such as statistical analysis, word embeddings, co-occurrence matrices, and graph-based methods. Here are a few common approaches:

1. **Word Embeddings:** Word embeddings are dense vector representations of words that capture semantic relationships. Models like Word2Vec, GloVe, or FastText can be used to generate word embeddings from a large dataset. Once the embeddings are obtained, you can measure the similarity between word vectors using cosine similarity or other distance metrics. Similar words will have closer vector representations, indicating a potential relationship.
2. **Co-occurrence Analysis:** Co-occurrence matrices provide insights into the relationships between words based on their frequency of co-occurrence within a context window. By scanning the dataset and counting how often words appear together, you can construct a co-occurrence matrix. Techniques like pointwise mutual information (PMI) or term frequency-inverse document frequency (TF-IDF) can be applied to measure the strength of the relationship between words.
3. **Statistical Analysis:** Statistical techniques such as correlation analysis or association rule mining can help identify relationships between words. For example, computing correlation coefficients like Pearson's correlation or using techniques like Apriori algorithm can reveal associations or co-occurrences between words based on their statistical patterns in the dataset.

For pre-processing of the dataset NLP techniques are used. Some of them are explained as follows:

Text Pre-processing: Before applying any NLP techniques, text data is typically preprocessed to remove noise and irrelevant information. This may involve tasks such as tokenization (splitting text into individual words or tokens), stemming or lemmatization (reducing words to their base or root form), removing stopwords (common words like "the," "and," etc.), and handling punctuation and capitalization.

Latent Sentiment Analysis: It also known as opinion mining, involves determining the sentiment or opinion expressed in a piece of text. It helps in understanding whether the sentiment is positive, negative, or neutral. Sentiment analysis is widely used in applications like social media monitoring, customer reviews, and market research. In LSA, a mathematical model is built using a matrix called the term-document matrix. This matrix represents the frequency or occurrence of words in a collection of documents. Each row represents a word, each column represents a document, and the values in the matrix indicate the frequency of each word in each document.

Deep Learning for NLP: Deep learning, particularly deep neural networks such as recurrent neural networks (RNNs) and transformers, have significantly advanced the state-of-the-art in NLP. These models can learn complex patterns and dependencies in text data, improving performance in tasks like machine translation, sentiment analysis, and natural language understanding.

2.3. Criteria for Performance Metric:

Model selection and hyperparameter tuning are critical steps in achieving high accuracy in machine learning. Here's a more detailed explanation of these processes:

- **Model Selection:**

Model selection involves choosing the appropriate machine learning algorithm or model architecture for your descriptive answer evaluation task. The choice of model depends on factors such as the nature of the data, the complexity of the problem, the availability of labelled data, and computational resources. Here are some commonly used models for descriptive answer evaluation:

1. **Linear Regression:** A basic yet effective model that fits a linear equation to the input features and predicts a continuous output.
2. **Support Vector Regression (SVR):** A regression model that uses support vector machines to find a hyperplane that best fits the data.
3. **Random Forest:** An ensemble model that combines multiple decision trees to make predictions.
4. **Recurrent Neural Networks (RNNs):** Deep learning models that are suitable for sequence data, such as textual answers. They capture temporal dependencies and have been successful in natural language processing tasks.
5. **Transformers:** Attention-based models that have shown impressive performance in various natural language processing tasks, including text generation and comprehension.

The choice of model depends on the specific requirements of your descriptive answer evaluation task. It's often a good practice to experiment with multiple models and compare their performance to find the best one.

- **Hyperparameter Tuning:**

Hyperparameters are parameters that are set before the training process begins, and they control the behaviour and performance of the machine learning model. Tuning these hyperparameters is crucial to optimize the model's accuracy. Here are some common hyperparameters that may need tuning:

1. **Learning Rate:** Determines the step size at each iteration of the optimization process. A higher learning rate may converge faster, but it can also lead to overshooting the optimal solution. A lower learning rate may take longer to converge but can provide better accuracy.
2. **Regularization Strength:** Controls the degree of regularization applied to the model. Regularization helps prevent overfitting by adding a penalty term to the loss function. Tuning this hyperparameter determines the balance between model complexity and generalization.
3. **Network Architecture:** For deep learning models like RNNs or transformers, hyperparameters such as the number of layers, hidden units, or attention heads can significantly impact performance. Experimenting with different architectures is essential for achieving the best results.
4. **Dropout Rate:** Dropout is a regularization technique that randomly sets a fraction of input units to zero during training. Tuning the dropout rate helps prevent overfitting and improve model generalization.
5. **Batch Size:** Determines the number of samples used in each iteration of model training. It affects the convergence speed and memory requirements of the training process. Choosing an optimal batch size can impact model performance.

Hyperparameter tuning can be performed through manual experimentation or automated approaches like grid search, random search, or Bayesian optimization. These techniques involve systematically exploring different combinations of hyperparameters and evaluating their impact on the model's accuracy.

It's important to note that hyperparameter tuning should be performed on a separate validation set or using techniques like cross-validation to ensure unbiased evaluation. Additionally, it's crucial to avoid overfitting the hyperparameters to the validation set by using a separate test set for the final evaluation of the model's accuracy.

Overall, model selection and hyperparameter tuning are iterative processes that require experimentation, evaluation, and comparison of different models and hyperparameter configurations. The goal is to find the optimal combination that maximizes the accuracy of the descriptive answer evaluation system.

2.4. Discussion of Survey:

2.4.1. Selection Criteria for Survey Papers:

We collected a total of 30 papers and articles, and shortlisted 20 papers after screening it through and considering only those papers that are relevant to our subject. We followed the below measures to configure and filter the selected 40 papers:

1. We chose the papers that were most pertinent to our subject and gave explanations of the expected approaches and algorithms.

2. Simple to comprehend papers were given higher priority.

3. We looked at the articles that provided reliable performance measures.

2.4.2. Objectives (OBJ) of the Review:

Objective-1: To discuss the various methods and approaches employed in the publications.

Objective-2: To illustrate the degree of accuracy provided for each method presented in the paper.

Literature on different methodologies, performance and dataset is shown in below table 1.

TABLE 1: LITERATURE ON DIFFERENT METHODOLOGIES, PERFORMANCE AND DATASET

Year	Method used	Description	Dataset used	Performance Metric
2021	[1] cosine similarity, WMD, (MNB)	Two modules: Module 1: Using [1] Cosine Similarity along with MNB Module 2: Using WMD along with MNB. WMD is more efficient according to results of this paper	Own dataset	Accuracy: 88%
2018	Bi-GRU Siamese architecture, Word embedding	The maximum pooling layer of the Bidirectional Gated Recurrent Unit network is further on added with for representation of text where words are similar in length or meaning of the document. This neural network capable of memorising content and producing an essay summary.	Amazon online research service Collected summaries	Accuracy: 55.2%
2019	CNN, LSTM, BERT semantic data, sentences mapping.	This model consists of 2 modules: 1. **Module 1**: The main job of this module for allocating marks on the basis BERT semantic data from the essay. 2. **Module 2**: The score is predictable on some common general structures like syntax, length of the essay and the no. of sentences.	ASAP Kaggle	Accuracy: 70.9%
2020	Multiple Linear Regression, Style and content-based features	In Least Square Assumptions regression technique, they have used two modules or features: 1. **syntax features**: In this they found the tokenization and then constructed entity of character string. 2. **semantic features**: They are more likely identical to the similarity analysis.	ASAP Kaggle	Accuracy: 77%
2020	BERT, Student Answer & Reference Answer mapping	The Bi-directional Encoder Representation from Transformer algorithm is used for automatic one sentence answer marking. The data expansion is finalized with the help of AI network or the neural network and with one correct answer.	SemEval-2013	Accuracy: 82.77%
2019	XGBoost machine learning classifier Word count, type token rationing ,parse tree, coherence, cohesion.	The extreme gradient boosting (XGBoost) is a ML classifier which is used to evaluate the essays and even there are multiple algorithm competent on structures like word count, parse tree, and consistency in the document with the sentence similarity %. And they applied K-fold cross-validation technique for calculating the outcome of the system.	ASAP Kaggle	Accuracy: 68%
2016	Latent Semantic Analysis (LSA), Generalized LSA, Bi-lingual Evaluation Understudy and Maximum Entropy, Concept of Ontology.	It works with the mentioned techniques. The BLEU score helps in determining the skill and accuracy of the student in writing his/hers answers. The concept of Ontology works with regard to the number of criteria present for the answer evaluation. The LSA Model would come handy when evaluating short answers along with the provided model answer set.	Technical answers of Computer Science	Accuracy: 93%

2021	Machine Learning, Artificial Neutral Networks Algorithm.	Artificial Neutral Networks Algorithm works effectively when comparing the written answers with the model answers provided. It will come up with appropriate procedures with which said marks would be allocated.	Own Dataset	Accuracy: 85-95%
2021	Natural Language Processing, Deep Learning, Sequential Ensemble Approach.	The main area of this approach is the basic NLP and Deep Learning which are implemented. The performance of the system at the same time would be improved with the help of Sequential Ensemble Approach that deals with base learners.	Own Dataset	50% increase as compared to individual systems.
2021	[10]Sentence splitting, [10]Jaccard similarity, [10]Bi-directional Encoder Representations from Transformers (BERT), [10]Optical Character Recognition (OCR)	[10]OCR is used to convert scanned answers to digital answers. Sentence splitting, Jaccard similarity, Bidirectional Encoder Representations from Transformers (BERT) are applied on model answer and submitted answer by students and then weighted score is calculated.	Own dataset	Accuracy: 93.2%
2021	[11]Cosine similarity, Text gears grammar API	[11]User answer extractor unit organizes the answer of students. Answer verifier unit uses cosine similarity and then Text gears grammar API. Result set unit consists of 3 attributes Keywords, Grammar, and QST	Own dataset	Accuracy: 80-90%
2018	NLP, ML	This consists of 2 modules: 1)Answer extraction from scanned copy and 2) Applying ML and NLP on it. Algorithm provides semantic meaning of the context.	Own dataset	Accuracy: 90%
2021	Neural Networks, LSTM	This proposed system is based on different models such as- Regression based models, Classification based models, Neural network models, Ontology based approach and scoring on the basis of speech.	ASAP Kaggle	Accuracy: 90%
2021	Natural Language Tool kit (NLTK)	Our proposed system has following features: - Balance Load, Ease of use, Friendly Environment, Ease in accessibility, Efficiency and reliability of the system, Maintenance of the system.	Own Dataset	Accuracy: 95%
2021	Contextual Similarities, Semantic Analysis, NLP, WordNet, TF-IDF, Cosine-Similarity, Antonyms, Synonyms, Grammatical Correction, Machine Learning.	This system works on the basis of few basic factors such as Stemming, Lemmatization, Stop words, Answer length, Keyword matching, Contextual similarity, Semantic similarity, Contradiction, Grammar check, Cosine Similarity, Antonyms & Synonyms.	Own Dataset	Accuracy: 89%

2.5. Major Machine Learning Techniques Used:

- **Long-Short Term Memory (LSTM):**

It is nothing but a unit which can remember or recall the previous data that has been used in the network, and do tries to forget the all-unrelated data. It can be implemented by adding different activation function layers known as gates for various types of functions to be performed easily. Working of LSTM is shown in figure 2. There are in total 3 different types of gates in LSTM:

Forget Gate: It is used to regulate what amount of data to be forgotten from the previous data. The equation for forget gate is given below.

Input Gate: It is used to control which and how much amount of data should be added on the Internal Cell State. The mathematical formula for input gate is as follows.

Output Gate: This gate determines what output should be created by the present state. The mathematical formula for

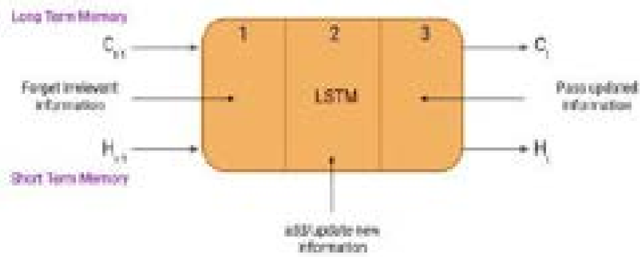

Fig. 2. Working of LSTM

- **Word2vec:**

Word2vec is a technique that employs an AI neural network model to discover relations between words from a huge dataset. Since it can be taught for dimensions that go up to 300, the semantic meaning of the words is mostly unchanged. Following training, a word-to-vector model can identify terms that are comparable or suggest some more sentences based on the phrase. A pre-trained word2vec model is demonstrated by the 100-dimension word2vec model, which has a vocabulary of approximately a trillion words.
It is now time to compare the vectors to see if they are comparable once the text has been converted into numerical form, or vectors. Jacquard Similarity, Cosine Similarity, and Word Mover's Distance (WMD) are some of the most used methods for this job. Illustration of Word2Vec is shown in figure 3.

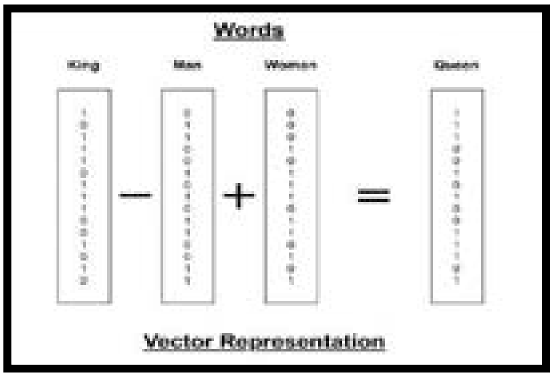

Fig. 3. Illustration of Word2Vec

- **TF-IDF (Term Frequency-Inverse Document Frequency)**

For evaluation of descriptive answer using machine learning, the aim is to survey the quality of constructed replies to a given trigger. The Tf-IDF (Term Frequency-Inverse Document Frequency) calculation can be utilized to assist distinguish important words or phrases within the reaction that will demonstrate its quality.

TF-IDF could be a numerical measurement that reflects the significance of a word to an archive in a collection of archives. It takes into consideration two variables:

1. Term Frequency (TF)
2. Inverse Document Frequency (IDF).

The term frequency measures how regularly a specific word shows up in a given archive, whereas the converse report frequency measures how uncommon or common that word is within the whole collection of archives. Words that show up as often as possible in a report but are uncommon within the by and large collection will have a tall TF-IDF score, showing that they are critical and significant to the archive.
In this, the TF-IDF calculation can be utilized to distinguish words or expressions that are especially vital or important to a high-quality reaction. For case, in the event that the incite is inquiring for a clarification of a logical concept, a high-quality reaction might utilize specialized terms and language that are uncommon within the general collection of reactions. The TF-IDF calculation can distinguish these terms and provide them with a tall score, showing that they are vital and characteristic of a high-quality reaction.
Overall, the TF-IDF calculation may be valuable for distinguishing imperative words and expressions in composed reactions and can be used as included in a machine-learning demonstration to assist assess the quality of those reactions.

- **BERT (Bi-directional Encoder Representations from Transformers)**

It is a previously trained natural language processing model created by Google that has been used for various NLP tasks including sentiment analysis, question-answering, and text classification.
When it comes to descriptive answer evaluation, BERT can be used to evaluate the quality of written answers to open-ended questions. This involves training a machine learning model using BERT as the feature extractor to predict a score or grade for a given answer.
To do this, BERT can be fine-tuned on a dataset of graded answers, such as essays or short responses, to learn the relationship between the input text and the associated score. Once the model is trained, it can be used to evaluate new answers by predicting their score based on the learned patterns.
One example of this application is the Automated Student Assessment Prize (ASAP) competition, where participants were asked to develop a system that could automatically grade short student essays. The winning approach used BERT as the feature extractor and a regression model to predict the scores of the essays.
Overall, the use of BERT in descriptive answer evaluation offers a way to automate and streamline the grading process, potentially reducing the time and effort required by teachers or instructors while providing more consistent and objective grading.

- **Cosine similarity:**

The cosine similarity metric can be utilized to compare the similitude between two composed reactions to a given provoke. It may be a degree of the similitude between two vectors of an n-dimensional space. Within the setting of descriptive response assessment, each reaction can be considered a vector in a high-dimensional space, where each measurement compares to a distinctive word or include. To compute cosine similarity, the point between the two vectors is calculated. If the point is little (i.e., the vectors are indicating in a comparative heading), the cosine similarity score will be high. Alternately, if the point is huge (i.e., the vectors are indicated in inverse headings), the cosine similarity score will be low.
cosine similarity can be utilized to compare the likeness between two reactions. For illustration, if two reactions have a tall cosine similarity score, it proposes that they are comparative in substance, structure, and/or language utilized.
On the other hand, if the cosine similarity score is low, it shows that the 2 responses are different.

3. OBSERVATION AND OUTCOMES OF SURVEY

The important takeaway from these papers are: Recurrent neural networks (RNNs) of the LSTM (Long Short-Term Memory) variety are particularly effective at processing sequential data, including text. LSTM networks can be used to evaluate answers in a descriptive manner, but they are not as commonly used as transformer-based models like BERT.

To use an LSTM for descriptive answer evaluation, the model would need to be trained on a dataset of labelled descriptive answers. The LSTM would learn to map the input text to a numeric score that reflects the quality of the answer. The model would need to be trained using a suitable loss function, Backpropagation is used to optimize metrics like binary cross-entropy or mean squared error.

In the context of descriptive answer evaluation, LSTMs can play several roles:

1. **Sequence Modeling:** LSTMs are capable of modeling sequences of words or tokens in a text. They can capture the contextual information and dependencies between words, which is crucial for understanding the meaning and generating accurate descriptive answers. LSTMs can take a sequence of words as input and produce hidden states that represent the contextual information at each step.
2. **Answer Generation:** LSTMs can be used to generate descriptive answers given a question or a context. By training an LSTM-based sequence-to-sequence model, where the input is the question or context and the output is the generated answer, the LSTM learns to encode the input information and generate relevant responses. This approach enables the LSTM to generate descriptive answers based on the learned patterns in the training data.
3. **Evaluation Scoring:** LSTMs can also be used to score or rank the quality of descriptive answers. By training an LSTM-based model to predict the quality or relevance of an answer given a question or reference answer, the model can learn to evaluate and assign scores to different candidate answers. This approach allows for automated evaluation of descriptive answers, which can be useful in tasks such as question answering systems or automated essay grading.
4. **Contextual Understanding:** LSTMs, especially when combined with attention mechanisms, can help capture the contextual understanding of the input text. By attending to relevant parts of the context or question, LSTMs can focus on the most important information for generating or evaluating descriptive answers. This enables the model to consider the entire context and make informed decisions.

Overall, LSTMs provide a powerful framework for modeling sequential data and capturing dependencies in textual data. Their ability to handle long-term dependencies and encode contextual information makes them suitable for tasks related to descriptive answer evaluation in machine learning and NLP. However, it's important to note that the choice of LSTM as the underlying architecture depends on the specific requirements of the task and the available data.

One potential advantage of using an LSTM for descriptive answer evaluation is that it may be more interpretable than a transformer-based model like BERT. LSTM networks can be visualized using techniques like attention maps, which can help identify which parts of the input text are most important for the models. There are different research works where [1] they utilized Google's pre-trained word2vec model. For the train and test, the corpus was split in an 8:2 ratio. Two approaches, Cosine Similarity and Word Mover's Distance using the Multinomial Naive Bayes model, were used to determine the results. Additionally, the word mover's distance outperforms cosine similarity. They accomplished this using Natural Language Processing (NLP) and machine learning. They got an accuracy of 88%.

[2] In this paper, system proposed an AI network which is capable of remembering the content of essay and making summary out of it, called recurrent neural network. The max-pooling layer of the Bi-GRU network is added on the word embedding for representation of text where words are similar in length or meaning of the document. The score will be get compared on the basis of the outline of essay from the additional Bi-GRU network. After completing the accuracy of the system was 0.55.

[3] In this paper, system was projected in the two phases. In the first phase, the main job is for allocation marks on the basis BERT semantic data from the article. In another phase, the score is predicted on some of the common and general factors like syntax, extent of the essay and the no. of sentences. The average accuracy score for the both phases is 70.9%.

[4] In this paper, technique proposed the Least Square Assumptions regression technique with the fusion of fuzzy Ontology. They also have been using the two sorts of features, first one is syntax features and other is semantic features. In the first feature, which is syntax features they found tokenization and then constructed entity of character string. The semantic features are more likely identical to the similarity analysis. And here the similarity analysis is used to search for identical sentences in the essay.

[5] In this paper, technique proposed a Bi-directional Encoder Representation from Transformer algorithm is used for automatic one sentence answer marking. In this suggested answer is matched with the students handwritten answer and convey the results accordingly. The data expansion is completed with the help of the AI neural networks and another that classify leftover replies as correct or incorrect using one accurate result from the dataset.

[6] In this paper, technique proposed an extreme gradient boosting (XGBoost) is a ML classifier which is used to evaluate the essays and even there are multiple algorithm competent on structures like the word count and consistency in the documents with the sentence similarity %. In order to calculate the system's result, they used the K-fold cross-validation approach; the typical accuracy following particular validations is 68.12.

[7] In this paper, the proposed system includes various evaluation techniques for the summoned output. Latent Semantic Analysis, Generalized LSA, Entropy, and other techniques have been used. Using the basic and common dataset consisting of technical answers of Computer Science these various methods/techniques were put to place. As a

testing Model, nearly 6 answers were used to analyze on single question. This is performed both with and without ontology. The outcomes were more satisfying with the application of ontology.

[8] In this paper, system proposes to implement a software application that will evaluate the students' answers using the main force-Machine Learning. It will create its own dataset that will consist of answers and keywords. Students' answers will be evaluated and the marks will be allotted on these two parameters. This system will primarily work on three stages: Separating keywords and synonyms, matching keywords, Generating Scores.

[9] In this paper, system proposes the implementation of deep learning along with NLP to counter the problem of answer evaluation. Deep learning is used by the algorithm to extract the anticipated responses. The model's categorization accuracy is improved using the sequential ensemble approach. It boosts the accuracy by a mammoth 50% when compared to the individual systems.

[10] In this paper, various parameters used for evaluation are grammar checking, sentence similarity, sentence splitting, and Jaccard similarity. Three parts make up this essay: Phase 1 involved scanning handwritten letters into digital format using OCR; Phase 2 involved dividing student responses into sentences, applying sentence similarity, grammatical checking, and Jaccard similarity using Bi-directional Encoder Representations from Transformers (BERT)., Phase 3- Based on weighted average scores are displayed.

[11] In this paper, consists of units for the user answer extractor, answer verifier, and result set. The Cosine Similarity and Text Gears Grammar API modules make up the answer verifier unit. The outcome Set Unit consists of 3 parts, keywords, grammar, and QST (Questions specific terms). Its efficiency in 80 to 90%

[12] In this paper, there are two modules: 1) extracting data from scanned copy and organizing it, 2) Applying ML and NLP. This model uses tokenizing words and sentences, chunking chinking, Lemmatizing words, parts of speech tagging and word netting. This algorithm provides semantic meaning of the context. It gives accuracy of up to 90%.

[13] In this paper, system proposes that four categories of automated essay grading systems are recognized: Regression models, classification models, neural networks, and ontology-based approaches are listed in that order. Most of the classification models and regressions on essay grading employ statistical characteristics to obtain the final score. The three categories of emphasizing aspects used in descriptive rating systems for essays include: 1) Statistical features 2) Features depending on style 3) Features based on contacts.

[14] In this paper, system proposes few highlighting features like Balance load, ease of use and user-friendly atmosphere. Our proposed system gives an accuracy of 95%.

3.1 Strengths and weaknesses of different techniques:

The below table 2 lists the strengths and weaknesses of different ML techniques.

Table 2. Strengths and weaknesses of different ML techniques studied

NAME OF TECHNIQUE	STRENGTH	WEAKNESS
LSTM	A greater understanding of sentence context than any other model. Instead of studying words, it examines phrases to help NLP.	It becomes more difficult when dealing with internet tasks like prediction. LSTMs can be a tad slow on large datasets.
LSA	The reduced vector size is an option. Positive results can be trained on lesser datasets.	For Word2Vec, larger datasets yield better outcomes. It has the capacity to ignore grammatical rules.
Word Mover's Distance (WMD)	To assess if two pieces of data are equal, it employs both a syntactic and a semantic approach.	You may also use Word2vec or Glove to get outcomes.
Cosine Similarity	It is a really helpful approach when working with NLP. No matter how large the papers or data are, it measures them. If you're working with word texts, sparse data, etc., you can choose to use cosine similarity. Cosine similarity disregards 0-0 results.	The fact that the vector's magnitude and direction are only taken into account is a significant negative. Two frequency vectors cannot be separated by more than a 90° angle.
Tokenization	It breaks down lengthy paragraphs into smaller pieces of data say words or one-line phrases making it easier to deal with.	The security of the technology is vulnerable as it practices multiple complex methods.

Bag of Words (BoW)	Simple and straightforward to use and implement. It analyses data based on the number of words. It can be simply accomplished using the Python concept of the dictionaries.	The addition of new words would increase the dataset size and thus the time required to analyse the data. Adding more vectors would result in a sparse matrix.
TF-IDF	Simple and easy to grasp. It is also a good starting point for similarity calculations because it is relatively cheap.	It has been observed that when using this tool, it has a tendency to assign low ratings to words of greater importance and those that are frequently used in the document. It can be wide-ranging and sensitive as per the condition.
BERT	Because it is updated often, it provides more accuracy. About 100 different languages have pre-trained versions of this model.	The most frequent issue with using this technology is usually cost. The project's budget typically rises as the project's scope does as well.
Word2Vec	Equally small and big datasets are accessible. Little effort is made by people. It has a highly strong architecture. It aids in defining the context of the remarks made.	When it involves identifying terms that have never been used in the data set or that are officially out of vocabulary (OOV), this method falls short.

4. LIMITATIONS OBSERVED

This research review can save the time and effort of researchers by eliminating the need to read pointless review publications. As a result, the researchers will be able to cut out errors from the beginning of their research and will have a clear path for carrying out a solid systematic survey on the subject of Descriptive answer evaluation using machine learning.

However, this study has only included a limited number of studies that were crucial for the research analysis. This review has limitations in terms of the time period considered and the number of research papers examined.

5. CONCLUSION

After surveying and taking some concerned factors into account the various technologies that can be used for descriptive answer evaluation, from the survey we can conclude that Long Short-Term Memory (LSTM) can the best approach. We came across various approaches and tools that match our scope for the evaluation process. We discussed them in detail and considered the human factor and accuracy resulted via each of them. This study is more dedicated to deal with LSTM and LSA techniques. LSA can help to reduce the vector size and help in converting a large dataset into a comparatively smaller one. This would help with reducing the computational time. This study can compare the semantics of two different text documents and extract keywords from sentences or match the sentence with the target sentence and determine the result.

Abstract—**Lately, the agricultural industry has considerably increased the applications of deep learning (DL) systems for recognizing and alleviating tomato fruit diseases, which address the major problems in food security and crop management. Leveraging the power of DL approaches, practitioners and researchers have established more efficient solutions capable of accurately detecting and classifying different tomato fruit diseases, enabling timely intervention to safeguard crop health and prevent yield losses. The DL techniques have been trained to detect subtle visual cues indicative of common diseases, including late blight, bacterial spot, and early blight, by harnessing vast datasets comprising annotated images of diseased tomato fruits. This sophisticated detection system offers a high level of performance. It demonstrates adaptability and scalability over different environmental conditions, empowering the farmers with actionable insight to optimize agricultural productivity and deal with disease outbreaks successfully. This study introduces a Sparrow Search Algorithm with Deep Learning for Tomato Fruit Disease Detection and Classification (SSADL-TFDDC) technique. The SSADL-TFDDC technique mainly exploits the optimal DL model to detect diseases in tomato fruits. In the SSADL-TFDDC technique, the bilateral filtering (BF) technique removes noise. The SSADL-TFDDC technique exploits the residual network (ResNet50) model for feature extraction, and the SSA performs the hyperparameter tuning process. At last, a long short-term memory (LSTM) classifier was employed to identify and classify the existence of tomato fruit diseases. A brief set of simulations exemplifies the enhanced solution of the SSADL-TFDDC technique. The experimental validation stated that the SSADL-TFDDC technique accomplishes better detection results.**

Keywords— Tomato Fruit Disease Detection; Deep Learning; Sparrow Search Algorithm; Bilateral Filtering; Computer Vision

I. INTRODUCTION

Tomatoes are an adequate significant garden harvester and the best topic of study in seed growth for expanding harvest. With numerous other harvests, harvesting is a complete job; therefore, it is a physical dimension of phenotyping data [1]. Recently, there has been growing attention to mechanizing farming procedures such as pruning, harvesting, or restricted covering. It has inspired the growth of computer vision (CV) and image analysis models for recognizing vegetables and fruits [2]. So, imaging is a rapid and nondestructive method of measurement and recognition of unripe and ripe fruits and other plant attributes utilizing CV, which is also beneficial for profiling and harvest estimates [3]. The amount of fruits throughout plant development is a significant feature, and it is a sign of the predictable crop, but it is also essential for definite crops like apples, where harvest should be measured to evade regular tree pressure [4].

Usually, farmers use physical models for the diagnosis of plant disease [5]. Specialists like plant botanists, pathologists and agricultural experts direct such diagnosis approaches over visual examination by lab experiments. These methods are inappropriate for local farm performances due to lower human setup capability and higher prices [6]. Cost-effective and real-time disease detection models are vital for the on-time recognition and analysis of tomato harvest illnesses. Due to these causes, it becomes essential to develop tools for the automated analysis of plant disease utilizing image processing (IP) and CV techniques [7]. Fast disorder analysis with initial intrusions will decrease effects on the complete harvest and food supply chains. Beforehand, the researchers employed classical machine learning (ML) models like K-Means (KM), SVM, LR, and Multi-Layer forward prorogation neural networks for plant disorder identification and verified benefits in image recognition [8]. However, these methods rely on complex handcrafted feature extractor and dimension decrease methods, which want to be improved when the fundamental issues or dataset changes [9]. Therefore, these methods need broad human power and will not simplify well. In the present scenario, Artificial Intelligence (AI) has been originating extensive uses in farming. Deep learning (DL) was mostly extensively functional in classifying plant disease, weed recognition, pest control, crop management, and farmland organization [10].

Mputu et al. [11] present a new method. The technique influences pretrained CNN and classical ML models for feature extractors and classification. The computer NVIDIA Jetson TX1 of single-board was employed. Image preprocessing and tuning models allow deep layers to absorb and focus on complex features. Anu et al. [12] project a developed DL model. This function is used as an IP model; a multiclass CNN was used for classification. Bora et al. [13] projected a structure for tomato plant disorder recognition. Initially, the input image colours are spread into the HIS format. Then, the green pixels were covered. Later, the root and fruit are distinguished using the region of interest (RoI). Finally, the unhealthy areas were divided using the rectilinear (KM clustering (RKMC) system).

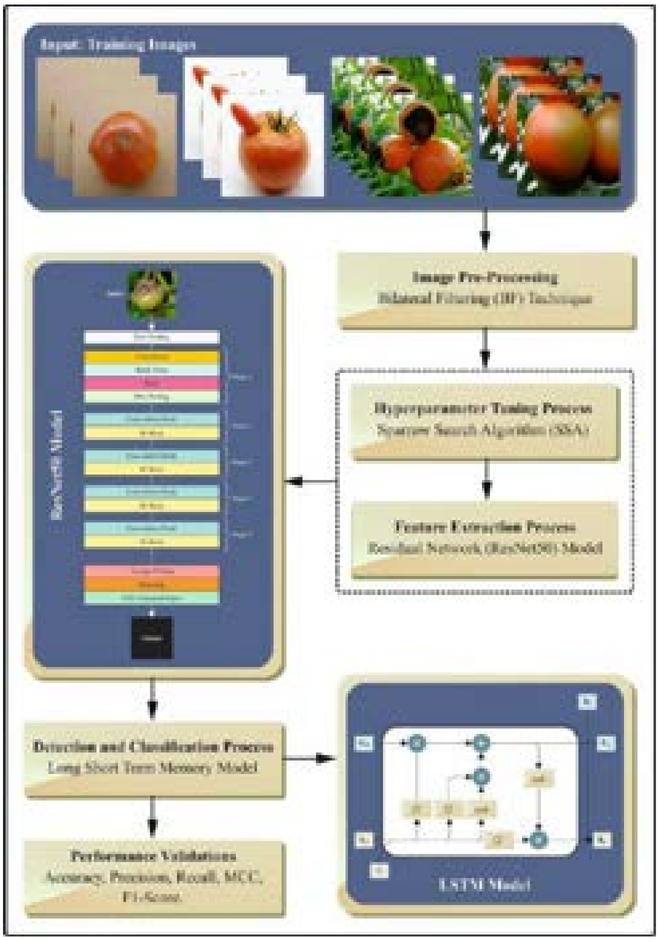

Fig. 1. Overall process of SSADL-TFDDC technique

Paul et al. [14] presented a lightweight traditional CNN method and utilized transfer learning (TL) based techniques VGG-19 and VGG-16 for categorization. The seven classes are accessible, but one is well employed to treat many tomato leaf disorders. Moreover, ablation research was executed to discover optimum limits for the projected method. Attallah [15] suggests a model using three condensed CNNs. Then, it integrates features from the 3 CNN to take advantage of each CNN framework. Nawaz et al. [16] developed a robust DL-based model such as ResNet34-based Fast RCNN for classification. Initially, the clarifications of the suspected imageries are produced. Next, ResNet34 and the Convolutional Block Attention Module (CBAM) model are presented as a feature extraction module of Fast RCNN. Lastly, the features were used for the Fast RCNN method training.

Several research studies present novel techniques for tomato quality evaluation and disease classification utilizing DL methods. These techniques employ pretrained CNN methods for feature extraction and classical ML methods for classification, aiming to improve tomato plant disorder detection and disease segmentation via sophisticated image preprocessing and model tuning.

This study introduces a Sparrow Search Algorithm with DL for Tomato Fruit Disease Detection and Classification (SSADL-TFDDC) technique. The SSADL-TFDDC technique mainly exploits the optimal DL model to detect diseases on tomato fruits. In the SSADL-TFDDC technique, the bilateral filtering (BF) technique removes noise. The SSADL-TFDDC technique exploits the residual network (ResNet50) model for feature extraction, and SSA performs the hyperparameter tuning process. Finally, a long short-term memory (LSTM) classifier is utilized to identify and classify the existence of tomato fruit diseases. The experimental values stated that the SSADL-TFDDC technique accomplishes better detection results.

II. The Proposed Model

This study establishes a novel SSADL-TFDDC technique. The technique mainly exploits an optimal DL model to detect the existence of diseases in tomato fruits. Fig. 1 demonstrates the process of the SSADL-TFDDC model.

A. BF based Preprocessing

The SSADL-TFDDC technique takes place, and the BF technique is used to remove noise. A versatile image processing algorithm, Bilateral filter (BF), is becoming more widespread regarding tomato image analysis to aid in disease detection and classification and improve visual clarity [17]. By retaining edges while smoothing the image region simultaneously, BF dramatically decreases noise while maintaining important structural details, enhancing the image quality. This refined image is a critical input for succeeding ML approaches to detecting and classifying different tomato diseases, enabling more reliable and accurate detection. Practitioners and researchers could boost the tomato disease detection system's effectiveness by incorporating BG into the image-preprocessing task, ultimately contributing to progressions in crop management strategies and agricultural practices.

B. Feature Extraction Process

For feature extraction, the SSADL-TFDDC technique exploits the ResNet50 model. ResNet structure integrates various collections of remaining blocks to attain the residuals among the network layers' input and output [18]. The loss function of the network is represented in Eq. (1). Once prolonged to multiple-layer networks, the resultant of all the layers of the network is demonstrated in Eq. (2). Based on the standard of the chain rule, the gradient of $the\ i^{th}$ layer is reduced as defined in Eq. (3)

$$L = Loss(X_n, Y) \tag{1}$$

whereas L implies the loss ratLossos$Loss$dicates the loss function, X_n represents the model outcome, and Y represents the label.

$$X_n = F_{n-1}(X_{n-1}, W_{n-1}), \\ X_{n-2} = F_{n-2}(X_{n-2}, W_{n-2}), \cdots, \\ X_2 = F_1(X_1, W_1) \tag{2}$$

In which F denotes the model, and W represents the parameter of the model

$$\frac{\partial L}{\partial X_i} = \frac{\partial L}{\partial X_n}\frac{\partial X_n}{\partial X_{n-1}} \times \cdots \times \frac{\partial X_{i+1}}{\partial X_i}. \tag{3}$$

From this assumption, it can be noticeable that the back-propagation (BP) of error, the gradient of the previous layer from the network, gradually reduces.

The residual block has been established to resolve these issues, as illustrated under the Conv and Identity block on the right side. The transformation adjusts the resultant layer from $H(x) = F(x)$ to $H(x) = F(x) + x$. Although the enhancing network depth, the problem of vanishing gradients is avoided

$$X_n = F_{n-1}(X_{n-1}, W_{n-1}) + X_{n-1}, \cdots, X_1 = F_1(X_0, W_0) + X_0 \tag{4}$$

$$\frac{\partial L}{\partial X_i} = \frac{\partial L}{\partial X_n} \times \cdots \times \frac{\partial X_{i+1}}{\partial X_i} = \frac{\partial L}{\partial X_n}\left[1 + \frac{\partial}{\partial X_i}\sum_{L=i}^{n-1} F(X_L, W_L)\right]. \tag{5}$$

The residual component contributes to the decrease in parameter counts. This strategy primarily deploys a 1x1 convolutional to reduce the channel sizes from 256 to 64 before reinstating the new dimensional using another 1x1 convolutional. This pattern gives an output in a significant decrease in the overall parameter counts related to the standard residual module. Concurrently, as the network depth rises, the number of ReLu functions increases, thus improving the model's significant nonlinear power and generalized ability.

C. SSA-based Hyperparameter Tuning

In this work, SSA performs the hyperparameter tuning process. In this work, SSA performs the hyperparameter tuning process. The population containing n sparrows is signified in the below-mentioned method [19]:

$$X = \begin{bmatrix} x_{1,1} & x_{1,2} & \cdots & x_{1,d} \\ x_{2,1} & x_{2,2} & \cdots & x_{2,d} \\ \vdots & \vdots & \vdots & \vdots \\ x_{n,1} & x_{n,2} & \cdots & x_{n,d} \end{bmatrix} \tag{6}$$

Whereas d indicates the problem size to be resolved. The value of fitness for every sparrow is denoted in the following method:

$$F_X = \begin{bmatrix} f([x_{1,1} & x_{1,2} & \cdots & x_{1,d}]) \\ f([x_{2,1} & x_{2,2} & \cdots & x_{2,d}]) \\ \vdots & \vdots & \vdots & \vdots \\ f([x_{n,1} & x_{n,2} & \cdots & x_{n,d}]) \end{bmatrix} \tag{7}$$

Here, F_X is the fitness value of every sparrow, and f denotes an individual's fitness value.

In the sparrow population, the main charge of the founder is to hunt for nutrition, delivering the complete population with the position and way of the detected food. Meanwhile, the founders are more probably to discover food. If the producer's fitness value is more significant, then their location in the whole solution space is near the position of the optimum solution. In every iteration, the founder upgrades its location while hunting for food. Where the exact expression is stated below:

$$X_{i,j}^{t+1} = \begin{cases} X_{i,j}^t \cdot \exp\left(-\frac{i}{\alpha \cdot iter_{\max}}\right) & if\ R_2 < ST \\ X_{i,j}^t + Q \cdot L & if R_2 \geq ST \end{cases} \tag{8}$$

Here, t signifies the existing iteration count; $j = 1,2,3, \dots, d$; $iter_{\max}$ denotes the existing highest iteration count; X_{ij} is the location of the ith sparrow beside the jth dimension; and $\alpha \in (0,1)$ signifies uniform randomly generated value ST $(ST \in [0.5,1])$ and $R_2 (R_2 \in [0,1])$ represent the values of safety and warning, correspondingly. Q denotes the randomly produced number by ensuing a usual distribution, and L indicates a $1 \times d$ matrix, whereas each element is equivalent to 1.

$R_2 < ST$ states that no hunters are currently in the foraging environment, letting the founder discover quickly and widely. However, $R_2 \geq ST$ designates that hunters and signal warnings have noticed definite sparrows in the population to other members. Therefore, every sparrow should quickly move to other safe places for searching.

While searching, scroungers constantly detect the founder. Depending upon recognition, the founder will detect higher food and quickly abandon their location to compete for nutrition. The location upgrade procedure for scroungers is defined below:

$$X_{i,j}^{t+1} = \begin{cases} Q \cdot \exp\left(\frac{x_{worst} - x_{i,i}^t}{i^2}\right) & if\ i > n/2 \\ X_P^{t+1} + \left|X_{i,j}^t - X_P^{t+1}\right| \cdot A^+ \cdot L\ otherwise \end{cases} \tag{9}$$

Whereas X_P denotes the existing optimum location by the founder; X_{worst} signifies the present worst location; A refers to the $1 \times d$ matrix containing elements arbitrarily allocated numbers of 1 or -1, and $A^+ = A^T(AA^T)^{-1}$. If $i > n/2$, the ith lesser value of fitness has not protected food, so it is starving. Therefore, it must move to any other region to search for and reload its energy.

In the imitation experimentations, the percentage of sparrows showing risk perception ranged between 10 and 20 per cent of the entire population. Their early locations are arbitrarily spread through the whole population, and their exact depiction is stated below:

$$X_{i,j}^{t+1} = \begin{cases} X_{best}^t + \beta \cdot \left|X_{i,j}^t - X_{best}^t\right| & if\ f_i > f_g \\ X_{i,j}^t + K \cdot \left(\dfrac{\left|X_{i,j}^t - X_{worst}^t\right|}{(f_i - f_w) + \varepsilon}\right) & if\ f_i = f_g \end{cases} \quad (10)$$

Whereas X_{best} signifies the existing global best position; β signifies the step-size parameter of control, which randomly generated amount by ensuing a normal distribution by a variance of 1 and mean of 0; $K \in (-1,1)$ represents the randomly generated number; f_w and f_g denote the existing global worst and best fitness value, correspondingly; f_i refers to the fitness score of the existing sparrow; and ε signifies the mathematically small even to stop division by 0. If $f_i > f_g$, the sparrow at the border was helpless to predator assaults, representing that the sparrow's location is secure. If $f_i = f_g$, sparrows in the centre have noticed risk, so they want to join with other sparrows to diminish the danger of predation.

The fitness choice is the primary factor affecting SSA achievement. The parameter choice method contains an encoded technique for evaluating the candidate solution's efficiency. At this point, the SSA considers accuracy the critical criterion for developing the FF.

$$Fitness = \max(P) \quad (11)$$

$$P = \frac{TP}{TP + FP} \quad (12)$$

Where TP and FP are the true positive and denote the false positive values.

D. Disease Detection Using LSTM Model

Finally, the LSTM classifier detects and classifies tomato fruit ailments. LSTM is a variant of recurrent neural networks (RNN) implemented to comprehend context- specific data from massive datasets and utilize them for future anticipation [20]. Each LSTM cell or unit can remember the data for a shorter or longer period. The output of the predicted new cell state takes the data stored in the previous cell state. This gives memory to the network, improving future prediction. Therefore, the LSTM network is a better fit for finding how stock closing prices and financial news headlines affect stock price trends for longer. Also, this network decides what amount of historical data related to the stock price is collected for precisely anticipating new price trends.

The LSTM model is seen as a gated cell. Gated indicates that the cell defines what information is stored or deleted based on the weight it allocates to the data. LSTM includes three gating mechanisms: forget, input and output gates. The input gate, i_t, defines what value is updated by the input signal. The Forget Gate, f_t, determines what state to be retained or forgotten. The output gate, o_t, defines how the cell state affects the other neurons. Furthermore, it has a logistic layer where the previous layer generates a number within [0,1] and a new vector that adds up to the state. The LSTM equation is given below in Eqs (13) to (18). The outcome of the embedding layer, x_t, is employed as an input to the RNN layer, W refers to the weight matrix, and y_t is the output. Three gating mechanisms control the essential component of LSTM s_t and serve as a memory unit.

$$f_t = \sigma(W_{xf}X_t + W_{yf}Y_{t-1} + b_f) \quad (13)$$

$$i_t = \sigma(W_{xi}X_t + W_{yi}Y_{t-1} + b_i) \quad (14)$$

$$g_t = \tanh(W_{xg}X_t + W_{yg}Y_{t-1} + b_g) \quad (15)$$

$$s_t = f_t * s_{t-1} + i_t * g_t \quad (16)$$

$$o_t = \sigma(W_{XO}X_t + W_{yo}Y_{t-1} + b_o) \quad (17)$$

$$y_t = O_t * \tanh(s_t) \quad (18)$$

III. EXPERIMENTAL VALIDATION

This section examines the performance of the SSADL-TFDDC approach on the dataset of 900 tomato fruit disease images collected from various sources and reported in Table 1. Fig. 2 depicts the instance images.

TABLE I

DESCRIPTION ON DATASET

Diseases	**Image Numbers**
Healthy	150
Malformed fruit	150
Blotchy ripening	150
Puffy fruit	150
Blossom-end rot	150
Gray mold	150
Total Images	**900**

Fig. 2. Sample images

Fig. 3 examines the classifier results of the SSADL-TFDDC system with a test database. Figs. 3a-3b showcases the confusion matrices acquired by the SSADL-TFDDC method at 70%TRAS and 30%TESS. The figure pointed out that the

SSADL-TFDDC algorithm can be predictable and categorize all six classes correctly. Moreover, Fig. 3c displays the PR result of the SSADL-TFDDC method. The figure denoted that the SSADL-TFDDC algorithm acquires superior PR efficiency with every class. In addition, Fig. 3d examines the ROC result of the SSADL-TFDDC technique. This figure shows that the SSADL-TFDDC technique provides effectual performances with a higher value of ROC in six classes.

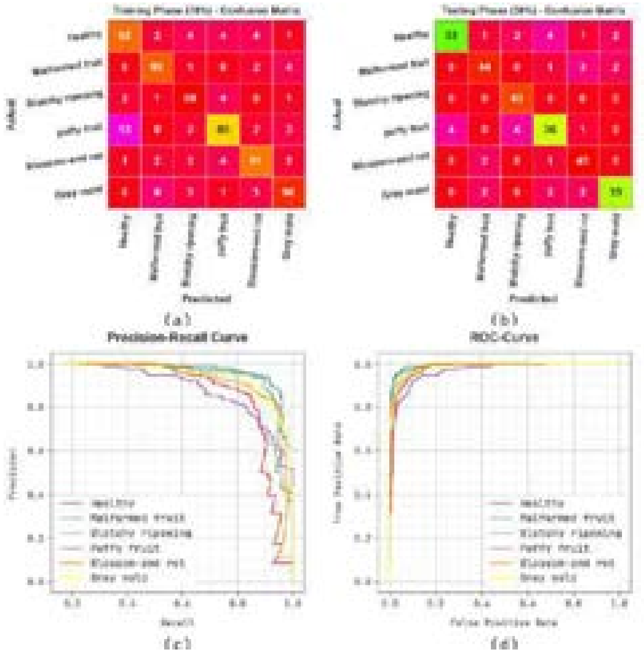

Fig. 3. (a-b) Confusion matrices under 70%TRAS and 30%TESS and (c-d) PR and ROC curves

The tomato fruit disease detection results of the SSADL-TFDDC technique are provided on 70%TRAS, and 30%TESS is provided in Table 2 and Fig. 4. This experimentation described that the SSADL-TFDDC technique correctly identified various classes. Based on 70%TRAS, the SSADL-TFDDC technique offers average $accu_y$, $prec_n$, $reca_l$, $F1_{score}$, and MCC of 96.08%, 88.24%, 88.29%, 88.24%, and 85.91%, correspondingly. Also, based on 30%TESS, the SSADL-TFDDC algorithm achieves average $accu_y$, $prec_n$, $reca_l$, $F1_{score}$, and MCC of 95.80%, 87.47%, 87.31%, 88.21%, and 84.83%, respectively.

TABLE II

TOMATO FRUIT DISEASE DETECTION RESULTS OF THE SSADL-TFDDC MODEL AT 70%TRAS AND 30%TESS

Class	$Accu_y$	$Prec_n$	$Reca_l$	$F1_{score}$	MCC
TRAS (70%)					
Healthy	95.08	85.19	85.98	85.58	82.62
Malformed fruit	97.14	89.42	93.00	91.18	89.50
Blotchy ripening	96.83	89.19	92.52	90.83	88.93
Puffy fruit	94.76	86.73	80.95	83.74	80.69
Blossom-end rot	96.51	89.22	89.22	89.22	87.13
Gray mold	96.19	89.72	88.07	88.89	86.60
Average	**96.08**	**88.24**	**88.29**	**88.24**	**85.91**
TESS (30%)					
Healthy	94.81	89.19	76.74	82.50	79.79
Malformed fruit	95.93	89.80	88.00	88.89	86.40
Blotchy ripening	97.78	87.76	100.00	93.48	92.43
Puffy fruit	93.70	81.82	80.00	80.90	77.14
Blossom-end rot	96.30	86.54	93.75	90.00	87.84
Gray mold	96.30	89.74	85.37	87.50	85.36
Average	**95.80**	**87.47**	**87.31**	**87.21**	**84.83**

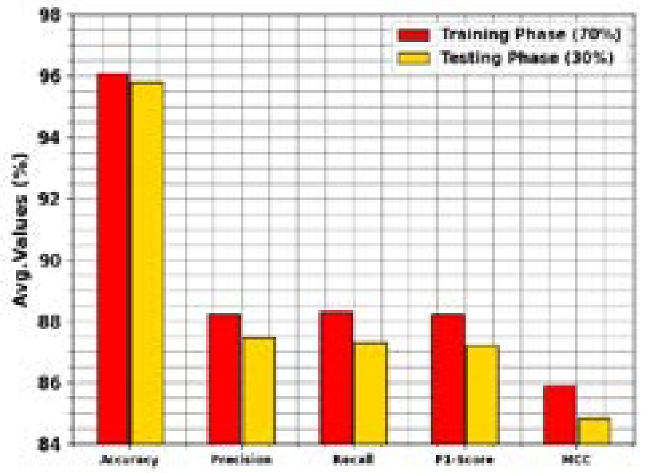

Fig. 4. Average of the SSADL-TFDDC method on 70%TRAS and 30%TESS

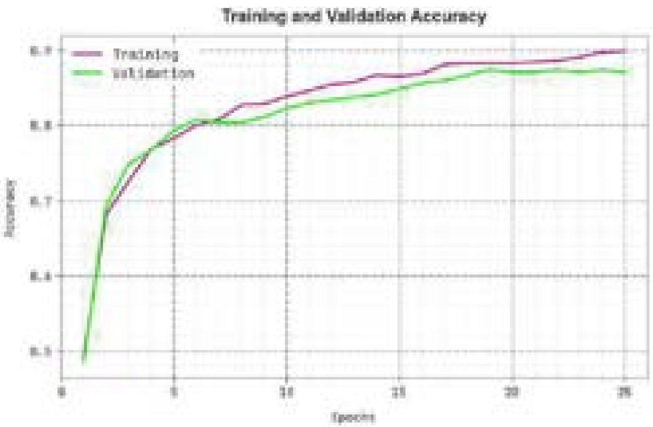

Fig. 5. $Accu_y$ curve of the SSADL-TFDDC technique

The efficiency of the SSADL-TFDDC technique is examined in Fig. 5 under training accuracy (TRAA) and validation accuracy (VALA) curves. This figure portrays the analysis of the SSADL-TFDDC technique over varying epoch counts, representing its generalization and learning process capabilities. The figure mainly illustrates a constant development in the TRAA and VALA with improved epochs.

This ensures the adaptability of the SSADL-TFDDC technique in the pattern detection progression under TRA and TES data. The higher trends in VALA portray the proficiency of the SSADL-TFDDC algorithm in modifying the TRA data and then achieving the correct classification on undetected data, showing the capabilities of robust generalization.

Fig. 6 displays a wide-ranging illustration of the SSADL-TFDDC method's training loss (TRLA) and validation loss (VALL) results in distinct epochs. The progressive reductions in TRLA show that the SSADL-TFDDC method enhances the weights and decreases the classification error under TRA and TES data. The figure specifies the SSADL-TFDDC method correlated with the TRA data, underscoring its proficiency in comprehending patterns. Mainly, the SSADL-TFDDC method incessantly improves its parameters, lessening the variances among the anticipated and actual TRA classes.

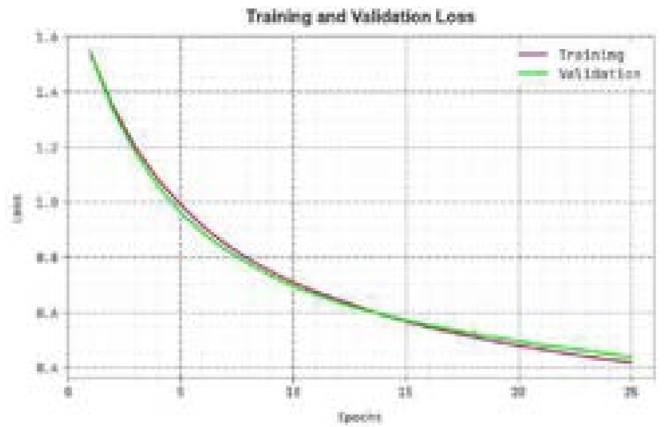

Fig. 6. Loss curve of SSADL-TFDDC method

Finally, the comparative assessment of the SSADL-TFDDC technique concerning $accu_y$, $prec_n$, $reca_l$, and $F1_{score}$ is reported in Table 3 and Fig. 7 [21, 22]. These obtained values stated that the SSADL-TFDDC technique performs better than existing approaches. Based on $accu_y$, the SSADL-TFDDC technique offers a higher $accu_y$ of 96.08% while the Yolov5m, ResNet50, ResNet101, EfficientNetB0, VGG16, and MobileNet methods obtain lower $accu_y$ of 90.59%, 93.20%, 94.22%, 91.93%, 93.07%, and 91.54%, correspondingly. Also, with $prec_n$, the SSADL-TFDDC method provides boosted $prec_n$ of 88.24% although the Yolov5m, ResNet50, ResNet101, EfficientNetB0, VGG16, and MobileNet techniques get decreased $prec_n$ of 80.61%, 87.14%, 83.81%, 82.89%, 85.81%, and 82.18%. Meanwhile, based on $reca_l$, the SSADL-TFDDC algorithm achieves a greater $reca_l$ of 88.29% whereas the Yolov5m, ResNet50, ResNet101, EfficientNetB0, VGG16, and MobileNet approaches attain minimized $reca_l$ of 80.84%, 86.80%, 80.00%, 86.07%, 86.30%, and 80.64%. Finally, with $F1_{score}$, the SSADL-TFDDC algorithm accomplishes increased $F1_{score}$ of 88.24% although the Yolov5m, ResNet50, ResNet101, EfficientNetB0, VGG16, and MobileNet techniques get lesser $F1_{score}$ of 82.14%, 87.92%, 83.18%, 87.54%, 81.12%, and 82.38%, respectively.

TABLE III

COMPARATIVE OUTCOMES SSADL-TFDDC METHOD WITH RECENT ALGORITHMS

Model	$Accu_y$	$Prec_n$	$Reca_l$	$F1_{score}$
Yolov5m	90.59	80.61	80.84	82.14
ResNet-50	93.20	87.14	86.80	87.92
ResNet-101	94.22	83.81	80.00	83.18
EfficientNet-B0	91.93	82.89	86.07	87.54
VGG-16	93.07	85.81	86.30	81.12
MobileNet	91.54	82.18	80.64	82.38
SSADL-TFDDC	96.08	88.24	88.29	88.24

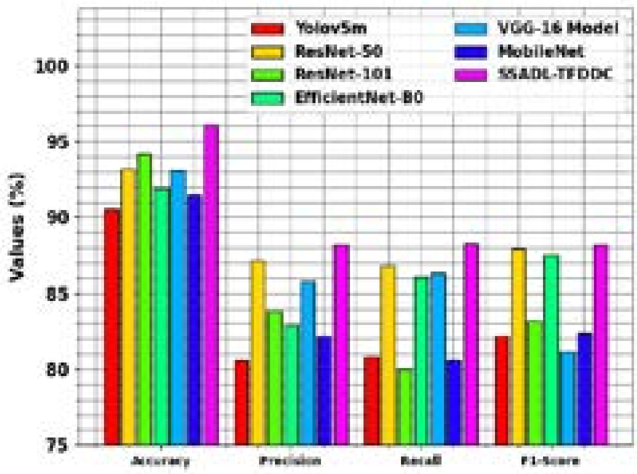

Fig. 7. Comparative results of SSADL-TFDDC technique with other systems

Thus, the SSADL-TFDDC technique can enhance the detection process of tomato fruit disease.

IV. Conclusion

In this research work, a novel SSADL-TFDDC technique is introduced. The SSADL-TFDDC technique mainly exploits the optimal DL model to detect diseases in tomato fruits. In the SSADL-TFDDC technique, the BF technique is used to remove noise. The SSADL-TFDDC technique exploits the ResNet50 model, and SSA performs the hyperparameter tuning process for feature extraction. Finally, the LSTM classifier is utilized to identify and classify the existence of tomato fruit diseases. A brief set of simulations exemplifies the enhanced solution of the SSADL-TFDDC technique. The experimental validation stated that the SSADL-TFDDC technique accomplishes better detection results.

***Abstract*— Given that cardiovascular diseases (CVD) persist as a significant global cause of death, the development of effective diagnostic techniques is of paramount importance. This artide presents a novel method for detecting CVD using convolutional neural networks (CNN) and SqueezeNet, two cutting-edge deep learning approaches. The proposed technique leverages ECG images to reliably classify medical images associated with cardiovascular problems. The foundation of feature extraction is SqueezeNet, a model renowned for its computational efficiency and lightweight construction. SqueezeNet's convolutional layers reduce the computing power required for model training and deployment and capture intricate patterns and textures indicative of CVD conditions, potentially revolutionizing the field of cardiovascular diagnostics. Furthermore, the pre-trained SqueezeNet model is honed using transfer learning methods on a collection of annotated cardiac images. This process allows the model to adapt its learned features to the specific characteristics of CVD images, thereby enhancing classification performance. Experimental evaluation on a benchmark dataset underscores the efficacy of the proposed approach in accurately identifying various types of cardiovascular abnormalities, induding coronary artery disease, myocardial infarction, and heart valve defects. A comparative analysis against state-of-the-art methods demonstrates the superior performance and computational efficiency of the proposed SqueezeNet-based model. It reinforces the confidence in its potential to transform the landscape of cardiovascular disease diagnosis. The findings of this study mark a significant stride in the development of computer-aided diagnosis systems for cardiovascular diseases, offering a promising tool for early detection and personalized treatment strategies.**

I. INTRODUCTION

The World Health Organization (WHO) states that cardiovascular illnesses, such as heart disease, are the leading cause of death worldwide. They are thought to claim 17.9 million lives a year, or 32% of all deaths worldwide. More than 85 percent of deaths attributable to heart disease are caused by myocardial infarctions (MI), sometimes known as heart attacks [1]. Numerous lives can be saved if cardiovascular disease is appropriately identified at an early stage. To detect cardiac diseases, the healthcare system employs a range of techniques, such as computed tomography, cardiac magnetic resonance imaging, electrocardiograms (ECGs), echocardiograms (echo), and blood tests [2], [3]. The ECG is a popular, affordable, and non-invasive way to measure the heart's electrical activity [4]. It is used to identify heart conditions associated with the core. A highly skilled clinician can diagnose heart disease from the ECG waves. However, doing it by hand requires much work and can lead to inaccurate results [5]. Improvements in artificial intelligence in healthcare have the potential to reduce medical errors drastically. Precisely, nine machine learning and deep learning techniques predict heart problems automatically. Before the classification stage, machine learning approaches require an expert entity to extract and choose the appropriate features. Feature extraction decreases the number of items in a data collection by projecting or transforming the data into a new, lower-dimensional feature space while retaining the relevant information from the input data. The essential features that are taken out of the input data concentrate on creating a new set of components—one that is distinct from the input feature—by fusing the original elements into a space that is smaller in dimension. The principal component analysis is the most frequently utilized feature extraction method. However, in training machine learning algorithms, feature selection removes unnecessary features (dimensions) from the data set [6]. Several feature selection methods can be divided into supervised and unsupervised. While supervised approaches require the output label, unsupervised methods do not.

It is an essential field of study for medical picture analysis. Automating the diagnosis and identification of CVDs using ECG signals has advanced significantly thanks to advances in deep learning techniques, especially CNN. The creation of more precise, effective, and scalable algorithms for the analysis of ECG data has been made possible by the DL approaches, which have entirely changed the area. Unlike earlier machine learning techniques requiring handcrafted features, these algorithms can automatically extract meaningful features from raw ECG signals. Early detection of cardiovascular diseases (CVDs) is crucial. Manual diagnosis presents obstacles that deep learning approaches may address. It also overviews the critical deep learning architectures and methodologies commonly used for CVD detection in ECG images.

Feature extraction is essential to extract pertinent information from ECG signals for additional analysis and interpretation. In image processing and computer vision, local binary pattern (LBP) is used for texture analysis and feature extraction. LBP was initially created for grayscale photos, but it has since been modified for several uses, including the study of photographs in the medical field. The ECG signal is converted into a picture format that can be used for LBP examination. The signal may be transformed using grayscale image conversion or time-frequency analysis (spectrograms, for example). LBP compares the intensity of a core pixel with the power of pixels in a nearby neighborhood. Binary patterns are created based on these comparisons, representing the image's texture and structural features. With the help of the binary patterns derived by LBP, a feature vector is created for every ECG picture. The spatial distribution of texture patterns in the image is represented by this feature vector, which encodes information about it.

Finally, in this paper, the proposed approach uses SqueezeNet and AlexNet as the pre-trained model to train the ECG images to improve CVD detection. Preprocessing and feature extraction play a significant role in finding the abnormalities. The proposed CNN model helps to classify the normal and abnormal ECG samples. The CNN model contains multiple layers that internally process several steps to help find abnormal ECG images.

The primary objectives of this paper are to:

- The significance of preprocessing for diagnosing CVD using ECG image analysis.
- Examine the standard preprocessing procedures used in processing ECG signals and their importance in enhancing the quality of data and precision of diagnosis.
- The latest developments, improvements in ECG analysis preprocessing techniques, and any possible effects on clinical practice.
- The difficulties and potential paths forward in creating and using preprocessing methods for using ECG imaging in the identification of cardiovascular disease.

II. LITERATURE SURVEY

Anbukkarasi et al. provided an extensive overview of recent developments in ML-based methods for diagnosing cardiac disease [7]. It examines several machine learning algorithms for diagnosing cardiac disease, such as decision trees, support vector machines, neural networks, and ensemble approaches. Additionally, it looks at how feature selection and data pretreatment methods might improve the efficiency of machine learning models. Additionally, the paper discusses challenges associated with deploying ML models in clinical settings, such as interpretability, data privacy, and generalizability. Finally, it highlights future research directions and opportunities for leveraging ML to enhance heart disease identification and management accuracy and efficiency. A novel method for accurately predicting cardiac disease using hybrid machine-learning approaches was developed by Mohan et al. [8]. The hybrid model combines the best features of several techniques, such as SVM, RF, LR, DT, and NN. Principal component analysis (PCA) and recursive feature deletion are feature selection approaches to enhance the model's interpretability and prediction performance. Ensemble learning techniques like bagging and boosting are applied to increase prediction accuracy and robustness further. The dataset employed in the experiments includes a wide range of clinical variables, such as lifestyle factors, medical history, and demographic data. The hybrid model performs better than separate algorithms, as evidenced by the experimental results, which highlight the model's potential as a valuable tool for clinical practice heart disease prediction. A thorough analysis of machine learning methods used to forecast cardiac disease was provided by Devansh Shah et al. [9], emphasizing the methods' advantages, disadvantages, and potential for development. The significance of feature selection, data preparation, model selection, and assessment metrics to create reliable and accurate prediction models.

Furthermore, we examine the difficulties of incorporating machine learning models into healthcare settings and offer possible solutions. In summary, this research underscores the potential of machine learning to augment the early identification and treatment of cardiac conditions, hence augmenting patient outcomes and mitigating healthcare costs. Bhowmick et al. [10] looked into the usage of various machine-learning algorithms for heart illness prediction. The dataset used in this investigation includes features such as age, gender, blood pressure, cholesterol levels, and other clinical parameters. Several machine learning algorithms, such as LR, DT, RF, SVM, and NN, are implemented, and their prediction performance is compared. Preprocessing is done on the dataset to address missing values, normalize features, and, if any, reduce any potential class imbalance. Cross-validation techniques are used to evaluate the models' generalizability and robustness. To help cardiologists make decisions more quickly, Habib et al.'s [11] research concentrated on developing an effective method of estimating the likelihood of heart failure and, in turn, recommending suitable medications. By applying traditional exploratory analysis approaches, the research aims to discover correlations or links between the patients' various medical profiles. These correlations will allow the qualities to be appropriately used to forecast the likelihood of heart failure and medication recommendations. Mohanty et al. presented a study on applying ML algorithms to predict liver disease [12]. The study's dataset includes a range of clinical and demographic characteristics, including alkaline phosphate levels, age, gender, total and direct bilirubin levels, and others. Several machine learning techniques create liver disease prediction models, such as LR, DT, RF, SVM, and NN. The preprocessed dataset addresses any class imbalance, handles missing values, and normalizes features. A feature significance analysis is also carried out to find the most important predictors of liver disease. The work emphasizes how crucial feature selection and model assessment are to creating reliable and accurate liver disease prediction models. Using a dataset that includes characteristics like age, gender, blood pressure, cholesterol levels, and other pertinent medical indications, Shah et al. [13] want to create a predictive model for heart disease. The study's dataset, including patient records from heart disease-affected and unaffected parties, was obtained from internet sources—the contrast of several machine learning techniques used in constructing prediction models. Techniques from feature engineering are used to preprocess the data and extract pertinent information. The outcomes show how well machine learning can predict cardiac disease, with specific algorithms performing better than others in accuracy. The knowledge gathered from this research can help medical professionals identify those more likely to develop heart disease, allowing for more focused treatments and better patient outcomes. An overview of current developments in ML-based cardiac disease prediction is provided by Ramalingam et al. [14]. Several approaches are used, such as deep learning architectures, ensemble techniques, and supervised, unsupervised, and semi-supervised learning procedures. Researchers also look at the difficulties and restrictions encountered in implementing ML-based heart disease prediction systems, including issues with interpretability, model generalization, and data scarcity. Lastly, there are exciting areas for further study that will improve the functionality and performance of machine learning models in this critical area of healthcare. An improved CNN model with DL assistance was presented by Pan et al. [15] and implemented on an IoMT platform to predict cardiac disease. The suggested model uses CNN's capabilities to automatically extract pertinent features from ECG data, frequently used to diagnose heart disease.

Additionally, the model performs by incorporating sophisticated deep learning methods like transfer learning and attention processes. While transfer learning makes it possible to use previously trained models on large-scale datasets to increase efficiency and generalization, the attention mechanism allows the model to concentrate on informative portions of the ECG signals. Hasan et al.'s [16] innovative method for automatically predicting individuals with heart disease uses SDA. The goal is to create a robust predictive model using clinical and demographic data to identify those at risk of heart disease. The dataset used in this study is an extensive compilation of patient records that includes demographic data, medical history, and diagnostic test findings—the information addresses missing values standardizes characteristics and lessens biases. The SDA is then used to choose discriminative features and create a condensed classification model. The outcomes show how well Sparse Discriminant Analysis works in both precisely predicting patients with heart disease and simultaneously selecting a condensed subset of variables important for diagnosis.

A. Disadvantages of Existing System:

- The quality of ECG datasets might differ, and because professional annotation is required, obtaining labeled data for training deep learning models can be challenging.
- For instance, CNN is sometimes regarded as a "black box," which makes it challenging to understand how they make their forecasts.
- In clinical settings, real-time ECG signal processing is frequently necessary to enable prompt diagnosis and action.

III. DATASET DESCRIPTION

The dataset named PTB diagnostic ECG dataset was collected from various CVD patients suffering from heart arrhythmia. The total samples of 14552 ECG images were divided into two categories: standard and affected ECG images. The training consists of 80%, and testing consists of 20%.

A. SqueezeNet: Training Model

Due to its small memory footprint and high computational efficiency, SqueezeNet, a lightweight convolutional neural network (CNN) architecture, presents a viable method for effective ECG image processing. It is used to train ECG images. Our goal in this paper is to use ECG pictures to train a SqueezeNet model to predict heart illness. Our goal is to automate the identification of cardiac problems from ECG images by combining SqueezeNet's DL capabilities, allowing for a quick and precise diagnosis. SqueezeNet's primary goal is to decrease the network's parameter count without compromising performance. It is made possible by two key innovations:

Fire Modules: The Fire module is the name of SqueezeNet's default construction blocks. A fire module comprises expansion layers that come after a squeeze layer. Squeezing information is accomplished using the squeeze layer's 1x1 convolutions, which lower the number of input channels (depth-wise convolution). The 1x1 and 3x3 convolutions that comprise the expand layers are designed to capture spatial and channel-wise information.

Down Sampling: SqueezeNet reduces the spatial dimensions of the feature maps by sparsely applying downsampling. It is often accomplished with max-pooling layers.

B. Gabor Filter for Noise Reduction

ECG images are primarily essential for diagnosing heart-related illnesses. However, noise from various sources, including muscle activity, baseline wandering, electrode motion, and electrical interference, frequently taints ECG signal pictures. This noise can obstruct accurate diagnosis, which can mask significant ECG signal characteristics. Gabor filtering is commonly employed to eliminate noise from ECG readings. These linear filters are applied to images and used for texture analysis. They work very well at capturing the frequency and spatial properties of signals.

Gabor filters can efficiently suppress noise while maintaining significant signal characteristics in ECG signal processing. Noise elements that do not match the signal's frequency content can be attenuated by convolving the ECG signal with a Gabor filter, resulting in a cleaner depiction of the underlying heart activity. The center frequency and the bandwidth are the two factors that define the Gabor filter. While the bandwidth governs the range of frequencies the filter reacts to, the center frequency establishes the frequency to which the filter is most sensitive. Gabor filters can be tuned to target particular noise components in the ECG signal by carefully choosing these parameters. The following equation represented as:

$$\mathrm{G}(\mathrm{a}) = \exp\left(-\frac{\mathrm{a}^2}{2\sigma^2}\right)\cos(2\pi f_c a) \qquad (1)$$

a represents the filter.
$\mathrm{G}(\mathrm{a})$ Represents the Gabor filter response at a.

C. Local Binary Pattern (LBP)

LBP is a well-liked technique for obtaining texture information from pictures. LBP was initially created for grayscale picture analysis, but it has since been used in various domains, such as pattern recognition, computer vision, and medical image analysis. LBP can be applied to ECG images to extract the signal's textural information. ECG pictures often depict the heart's electrical activity over time, displaying a range of patterns and textures linked to distinct cardiac diseases. The LBP algorithm compares every pixel in an image to its nearby pixels. Depending on whether the intensity of the surrounding pixels is higher or lower than the intensity of the core pixel, each pixel is given a binary code. The local texture patterns in the image are then represented by these binary codes when they are transformed into decimal numbers. The textural properties can be extracted from ECG images by computing LBP at multiple scales and orientations. These features can be applied to medical applications for anomaly detection, segmentation, and classification. The LBP offers a potent instrument for deriving informative characteristics from ECG pictures, facilitating the creation of sophisticated analysis methods for identifying cardiac disorders and keeping tabs on patients' health.

$$\mathrm{LBP}(\mathrm{a_c}, \mathrm{b_c}) = \sum_{\mathrm{p}=0}^{\mathrm{P}-1} \mathrm{s}(\mathrm{p}) \cdot 2^{\mathrm{p}} \qquad (2)$$

$\mathrm{s}(\mathrm{p})$ Represents the binary value whether the neighboring sample's intensity (p) is higher than or equal to the central ECG input image is indicated by a (0 or 1)

Classification: CNN has become a highly effective tool for problems involving image detection, segmentation, and classification. Their suitability for analyzing medical images, particularly those from several modalities like computed tomography (CT), magnetic resonance imaging (MRI), and echocardiography, stems from their ability to learn hierarchical representations from raw input data automatically. The suggested CNN-based approach for identifying cardiovascular disorders using imaging data is presented in this work. It seeks to use the information in cardiac pictures to precisely categorize patients into various illness groups or identify specific abnormalities suggestive of cardiovascular diseases. The CNN architecture for processing images of ECG signals usually consists of several layers intended to extract features pertinent to the current job.

Step 1: Input Layer

- The input to the CNN would be the ECG image.
- Let a(t) represent the input signal, where t denotes the time axis.

Step 2: Convolutional Layer

- The features are extracted from the input signal.
- Every filter applies a convolution operation on the signal that it receives.
- Let $h_i(t)$ initializes the $\mathrm{i^{th}}\,\frac{\mathrm{filter}}{\mathrm{Kenel}}$ with parameters $\mathrm{W_i}$ and bias $\mathrm{b_i}$.
- The result of $\mathrm{i^{th}}$ filter $\mathrm{z_i(t)}$ is measured as:
  $$\mathrm{z_i(t)} = (\mathrm{x} * \mathrm{h_i})(\mathrm{t}) + \mathrm{b_i} \qquad (2)$$
  - Represents the convolution operation,

Step 3: Activation Layer

- An activation function is applied element-by-element following the convolution process to add non-linearity.
- The ReLU, is used.
- Let f() denote the activation function that was applied to the convolutional layer's output.

Step 4: Pooling Layer

- It preserves significant information while shrinking the feature maps' spatial size.
- It is a popular method of pooling that keeps the maximum value for each pooling window.
- Let p() denote the pooling layer.

Step 5: Fully Connected (Dense) Layers (FCL)

- It processes the flattened feature vector to complete tasks involving regression or classification.
- Every neuron in an FCL is connected to every other neuron in the layer above it.
- The wholly connected layer's output is measured as follows:
  $$\mathrm{y} = \mathrm{f}(\mathrm{W_f} \cdot \mathrm{x_f} + \mathrm{b_f}) \qquad (3)$$

When ECG, the image classification is done using FCL, the result is a vector of probabilities, where each element denotes the likelihood of the connected class. For the input image, the class with the highest chance is the predicted class.

IV. PERFORMANCE METRICS

The following parameters are used to analyze the performance of different algorithms. The confusion matrices cover all of these parameters. The properties that count the values from the provided samples are as follows.

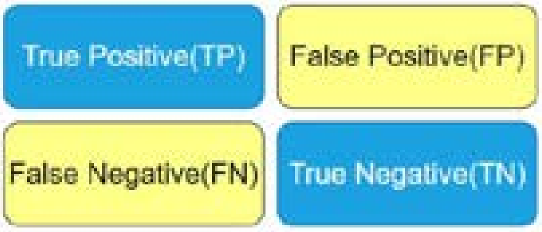

Figure 3: Confusion Matrix

$$\text{Accuracy (ACC)} = \frac{\text{TP} + \text{TN}}{\text{TP} + \text{TN} + \text{FP} + \text{FN}}$$

$$\text{Specificity (Spc)} = \frac{\text{No of TN}}{\text{No of TN} + \text{No of FP}}$$

$$\text{Recall (Re)} = \frac{\text{TP}}{\text{TP} + \text{FN}}$$

$$\text{F1} - \text{Score (F1S)} = 2 * \frac{(\text{Precision} * \text{Recall})}{(\text{Precision} + \text{Recall})}$$

V. EXPERIMENTAL RESULTS

The Python programming language implements the algorithm used in the research work. The system needs an I3 processor, 256 SSD hard disc, and 8 GB of RAM to process the ECG input images.

Table 1: The comparison outcomes between various Algorithms

Algorithms	ACC	Spc	Re	F1S
RF	67.34	65.34	67.98	61.23
ANN	75.87	77.12	79.34	70.23
AlexNet with CNN	84.34	85.23	86.34	84.12

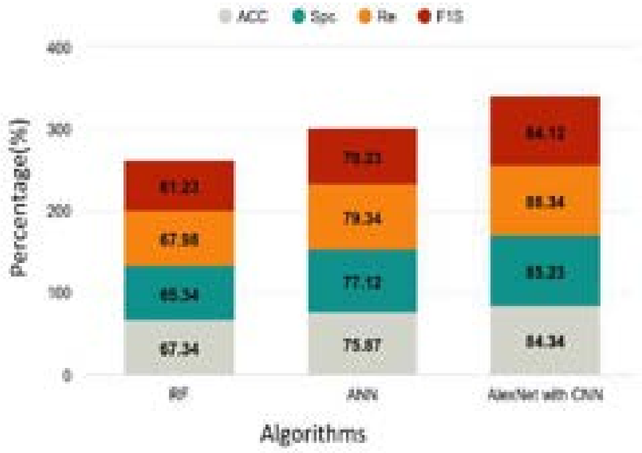

Figure 4: The count values of existing and proposed algorithms in terms of Prediction and Actual Values.

The table 1 obtained the results based on the following metrics. The proposed approach is the combination of AlexNet with CNN implements the ECG signal images. The accuracy of proposed approach is 84.34%. The existing model is RF which obtained 67.34% which is low compare with existing approach.

Table 2: The comparison between various algorithms with SqeezeNet with CNN.

Parameters	RF	ANN	SqeezeNet with CNN
Acc	69.34	70.34	70.56
Spc	61.23	56.34	45.23
Re	66.78	75.34	85.78
F1S	68.98	79.45	86.34

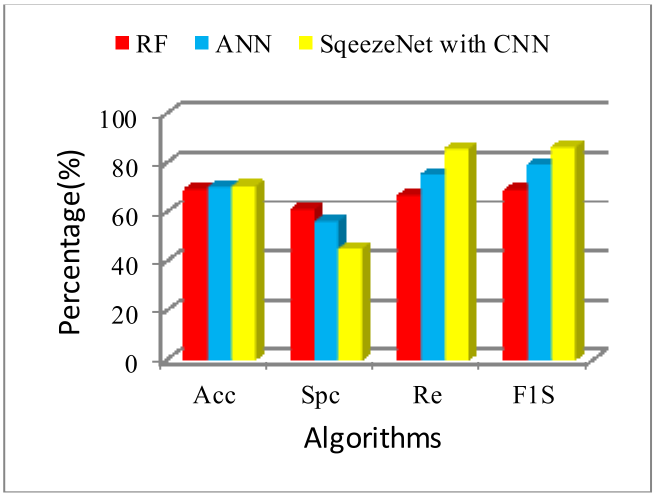

Figure 5: Comparisons of Algorithms based on Classification Models.

VI. CONCLUSION

SqueezeNet and CNN model analysis of cardiovascular disorders in ECG images show good outcomes. Scientists have achieved precise anomaly detection and classification of diverse cardiac ailments through deep learning methodologies. Because it can achieve excellent performance with fewer parameters, the SqueezeNet architecture—renowned for its lightweight design and efficiency—is especially ideal for analyzing ECG images. SqueezeNet and CNN models work together to create a robust feature extraction and classification framework that allows for spotting minute patterns that may be signs of cardiovascular disorders. These models have proven to be successful in correctly diagnosing diseases like arrhythmias, ischemia, and myocardial infarction through rigorous testing and validation. The use of DL algorithms to evaluate ECG pictures has a lot of potential to increase the effectiveness and precision of cardiovascular disease detection. These models must be further developed and refined to improve patient treatment and outcomes, and their applicability must be expanded to real-world clinical settings.

Abstract—The rapid expansion of cloud computing poses significant environmental challenges due to high energy consumption, carbon emissions, and electronic waste generation. This study introduces an analytical approach to optimizing green computing in cloud-capacity environments, utilizing a circular model inspired by circular economy principles. This model focuses on resource efficiency, energy conservation, and e-waste management, aiming to balance environmental impact mitigation with operational effectiveness. The approach combines quantitative metrics and qualitative case studies, demonstrating its potential to reduce energy use, carbon emissions, and waste. The study highlights the critical role of interdisciplinary collaboration in advancing sustainable practices in cloud computing.

Keywords—Cloud Computing, Green Computing, Circular Economy, Sustainability, Energy Efficiency, E-Waste Management.

I. INTRODUCTION

The exponential growth of the cloud computing sector has revolutionized the way we store, access, and process data (Cai et al., 2017). However, this technological advancement comes with significant environmental challenges that cannot be ignored. As the demand for cloud services continues to soar, so does the consumption of energy, resulting in heightened concerns over carbon emissions and electronic waste generation. Considering these pressing issues, this study proposes an analytical approach to optimize green computing practices within cloud-capacity environments.
Drawing inspiration from the principles of the circular economy, the proposed approach integrates a circular model that emphasizes resource efficiency, energy conservation, and electronic waste management. By adopting this holistic framework, organizations operating within cloud computing infrastructures can mitigate their environmental impact while ensuring operational effectiveness. Through a combination of quantitative metrics and qualitative case studies, this study aims to demonstrate the potential of the proposed approach for reducing energy consumption, carbon emissions, and waste generation in real-world settings (Farhan et al., 2018).
Furthermore, this study underscores the importance of interdisciplinary collaboration in driving sustainability initiatives within the cloud computing sector. Recognizing that addressing environmental challenges requires collective effort, the study emphasizes the need for collaboration between researchers, practitioners, and policymakers. By fostering collaboration and sharing insights, stakeholders can work together to develop actionable strategies for promoting a more sustainable digital future.

II. Related Work

This study reviews various techniques and approaches to improve energy efficiency in cloud computing environments, including workload consolidation, dynamic resource allocation, and energy-aware scheduling algorithms (Màsdàrí&Zangakani, 2019). It also examines the environmental impact of cloud computing, identifying challenges and opportunities for reducing emissions through renewable energy adoption, data center optimization, and carbon offsetting strategies. The study also discusses e-waste management in cloud computing, focusing on reuse, recycling, and responsible disposal of electronic components. The review also discusses emerging trends in green cloud computing, including energy-efficient hardware, renewable energy integration, virtualization techniques, and sustainable data center design. The study also explores the applicability of circular economy principles in cloud computing, focusing on resource efficiency and waste reduction strategies.

Figure 1: Existing energy based efficient resource

III. PROPOSED WORK

This study explores the integration of circular economy principles into cloud computing with the objective of optimizing green computing practices. The focus is on enhancing resource efficiency, conserving energy, and effectively managing electronic waste within cloud environments. The approach employs a combination of quantitative metrics and qualitative case studies to evaluate the impact of these strategies on environmental sustainability.
Energy Efficiency Index (EEI): measures the ratio of useful work done to total energy consumed, reflecting energy efficiency.
The Renewable Energy Integration Ratio (REIR) indicates the proportion of renewable energy sources integrated into the cloud infrastructure.

Carbon Emission Intensity (CEI): Calculates the amount of carbon emissions per unit of energy consumed by the cloud infrastructure.

Electronic Waste Recycling Rate (EWRR): Evaluates the percentage of electronic waste generated by the cloud infrastructure that undergoes recycling or responsible disposal.

These metrics assess the effectiveness of the circular model integration by quantifying improvements in resource efficiency, energy conservation, and waste management practices within cloud computing environments. Furthermore, this study emphasizes the critical importance of interdisciplinary collaboration in driving sustainable practices and achieving environmental objectives within the cloud computing sector. Green Computing Optimization in a Cloud Capacity Environment: An Analytical Approach with Circular Model Integration. The analytical approach successfully demonstrates the efficacy of incorporating circular economy principles into cloud computing practices. This integrated approach has yielded significant enhancements in resource efficiency, reduced energy consumption and carbon emissions, and improved electronic waste management, thereby promoting sustainable practices within the cloud computing industry (Farhan et al., 2018). Emphasizing the importance of interdisciplinary collaboration, this study underscores the necessity of collective efforts to achieve and sustain environmental goals in cloud computing.

Figure 2: circular model integration to address environmental concerns in the cloud computing sector.

A. Sustainable Cloud Computing: Integrating Circular Economy Principles

Integrating Circular Economy Principles into Sustainable Cloud Computing offers a comprehensive solution to the environmental challenges facing the cloud computing sector. By emphasizing resource efficiency, energy conservation, and waste management throughout the lifecycle of cloud infrastructure, organizations can significantly reduce their environmental footprint while maintaining operational efficiency (Ojo et al., 2019). Through the adoption of energy-efficient hardware, renewable energy integration, and responsible e-waste management practices, cloud service providers can minimize energy consumption, carbon emissions, and electronic waste generation. This integration not only promotes environmental sustainability but also fosters innovation, driving the development of more environmentally friendly technologies and practices. By embracing circular economy principles, the cloud computing sector can play a pivotal role in shaping a more sustainable digital future.

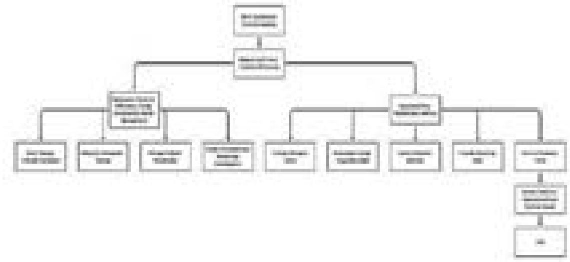

Figure 3: Sustainable Cloud Computing: Integrating Circular Economy Principles

Table 1: Sustainable Cloud Computing: Integrating Circular Economy Principles

Organization	Data Center Location	Energy Consumption (kWh)	Carbon Emissions (metric tons CO2)	Renewable Energy Usage (%)	E-waste Generation (kg)	E-waste Recycling Rate (%)
Green Computing	India	550000	275	45	900	85
EcoTech Solutions	India	680000	340	50	1200	90
RenewIT	India	720000	360	40	1300	80
Sustainable Tech	India	600000	300	55	1000	85
EcoCloud	India	780000	390	35	1400	75
Cloud Solutions	India	650000	325	35	1200	75
Tech Innovators	India	720000	360	40	1500	80
Digital Ventures	India	800000	400	30	1800	70

Energy Efficiency Index (EEI): $EEI = \frac{\text{Useful Work Done}}{\text{Total Energy Consumed}}$ (1)

Description: This formula calculates the ratio of useful work done (e.g., processing data, serving users) to the total energy consumed by the cloud infrastructure. A higher EEI value indicates better energy efficiency.

Renewable Energy Integration Ratio (REIR): $REIR = \frac{\text{Renewable Energy Used}}{\text{Total Energy Consumed}} \times 100$ (2)

Description: This formula measures the proportion of renewable energy sources (such as solar, wind, hydroelectric) integrated into the cloud infrastructure. A higher REIR value indicates greater reliance on renewable energy sources.

Carbon Emission Intensity (CEI): $CEI = \frac{\text{Total Carbon Emissions}}{\text{Total Energy Consumed}}$ (3)

Description: This formula calculates the amount of carbon emissions generated per unit of energy consumed by the cloud infrastructure. A lower CEI value indicates lower carbon emissions intensity.

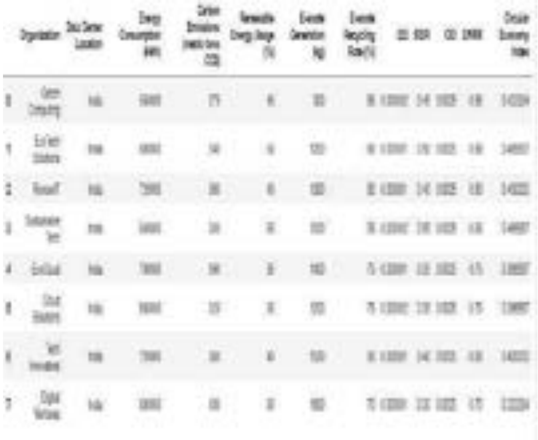
E-waste Recycling Rate (EWRR): $EWRR = \frac{\text{Recycled E-waste}}{\text{Total E-waste Generated}} \times 100$ (4)

Description: This formula measures the percentage of electronic waste generated by the cloud infrastructure that is recycled or responsibly disposed of. A higher EWRR value indicates better e-waste management practices.

Circular Economy Index (CEI):

$CEI = \frac{\text{Resource Efficiency Score+Energy Efficiency Score+Waste Management Score}}{3}$ (5)

Description: This formula calculates an overall sustainability score based on resource efficiency, energy efficiency, and waste management performance. Each component score can be weighted based on its importance to the organization's sustainability goals.



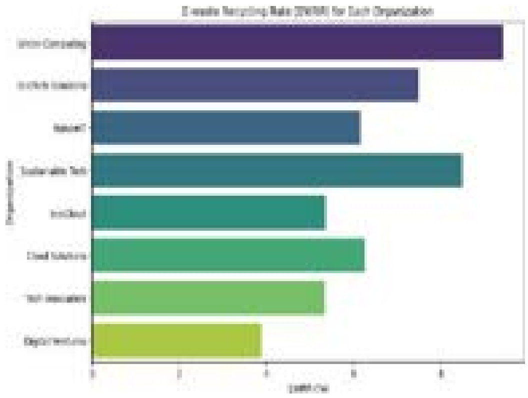


Figure 4: E-waste Recycling rate for each organization

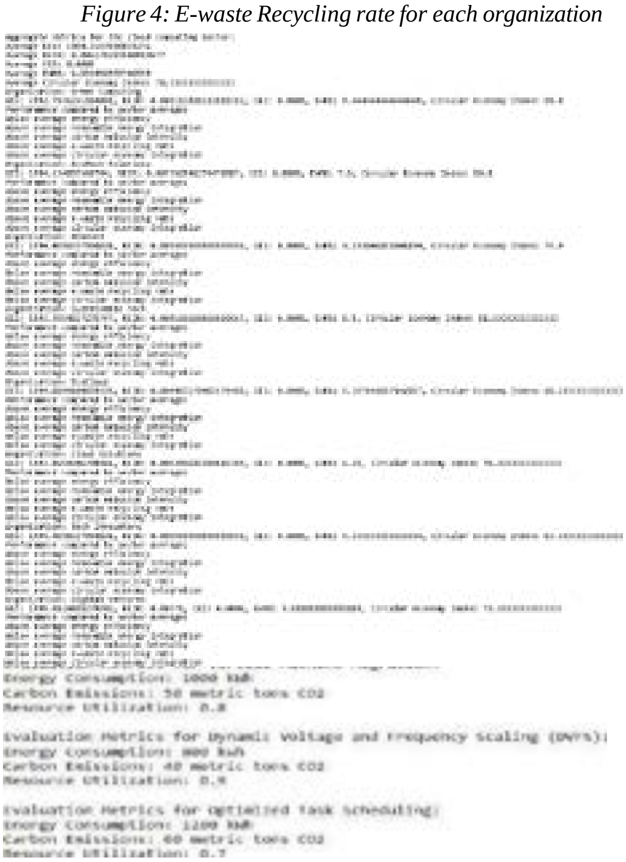

```
Energy Consumption: 1000 kWh
Carbon Emissions: 50 metric tons CO2
Resource Utilization: 0.8

Evaluation Metrics for Dynamic Voltage and Frequency Scaling (DVFS):
Energy Consumption: 800 kWh
Carbon Emissions: 40 metric tons CO2
Resource Utilization: 0.9

Evaluation Metrics for Optimized Task Scheduling:
Energy Consumption: 1200 kWh
Carbon Emissions: 60 metric tons CO2
Resource Utilization: 0.7
```

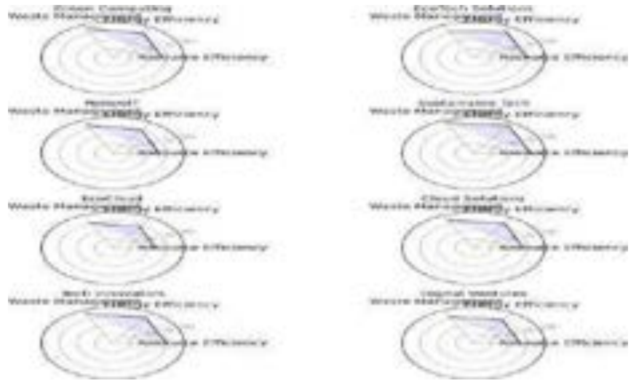

Figure 5: Waste Management for each

The integration of circular economy principles into sustainable cloud computing addresses environmental challenges by promoting resource efficiency, energy conservation, and waste management. This approach reduces energy consumption, carbon emissions, and electronic waste generation, fostering innovation and driving the development of environmentally friendly technologies. Key performance metrics, such as the Energy Efficiency Index, help organizations measure and manage sustainability efforts effectively.

B. Optimizing Green Computing Practices in Cloud Environments: A Circular Approach:

The implementation of circular economy principles in cloud computing requires tailored analytical approaches, a circular model integration approach, and a comprehensive analysis of energy-efficient hardware and renewable energy sources. Collaborating stakeholders, including researchers, practitioners, and policymakers, is crucial for promoting sustainability initiatives and advancing towards a more environmentally friendly cloud computing approach. This approach maximizes resource efficiency, conserves energy, and manages electronic waste.

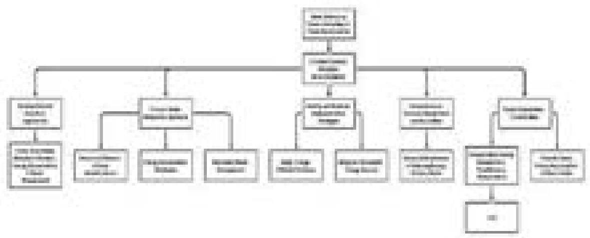

Figure 6: *Optimizing Green Computing Practices in Cloud Environments: A Circular Approach*

Table 2: *Optimizing Green Computing Practices in Cloud Environments: A Circular Approach*

Cloud Provider	Data Center Location	Energy Consumption (kWh)	Renewable Energy Integration (%)	Carbon Emissions (metric tons)	Electronic Waste Generated (kg)
Cloud Provider A	Hyderabad, India	480000	40	220	950
Cloud Provider B	Chennai, India	620000	30	280	1150
Cloud Provider C	Kolkata, India	530000	45	240	1050
Cloud Provider D	Pune, India	570000	20	260	1250
Cloud Provider E	Ahmedabad, India	510000	50	230	1000
Cloud Provider F	Mumbai, India	550000	25	230	1100
Cloud Provider G	Bangalore, India	690000	35	270	1000
Cloud Provider H	New Delhi, India	500000	30	250	1200

```
Sustainability Metrics for Each Cloud Provider:
Provider           RE        EC (%)     CEI      EWRR (%)
Cloud Provider A 1.00        40.00      0.00     94.74
Cloud Provider B 1.00        30.00      0.00     95.65
Cloud Provider C 1.00        45.00      0.00     90.48
Cloud Provider D 1.00        20.00      0.00     84.00
Cloud Provider E 1.00        50.00      0.00     90.00
Cloud Provider F 1.00        25.00      0.00     86.36
Cloud Provider G 1.00        35.00      0.00     85.00
Cloud Provider H 1.00        30.00      0.00     87.50
```

RE = Total Useful Work / Total Resources Consumed

The RE metric assesses how efficiently resources are utilized in performing useful work within the cloud environment. It considers factors such as CPU utilization, memory usage, and storage efficiency. For each Cloud Provider, calculate the RE by dividing the total useful work done by the total resources consumed, considering factors like energy consumption and hardware utilization.

EC = (Renewable Energy Used / Total Energy Consumed) * 100

The EC metric evaluates the proportion of renewable energy sources integrated into the cloud infrastructure, indicating the extent of energy conservation efforts. For each Cloud Provider, calculate the EC by dividing the renewable energy used by the total energy consumed and multiplying by 100 to express it as a percentage.

CEI = Total Carbon Emissions / Total Energy Consumed

The CEI metric measures the amount of carbon emissions generated per unit of energy consumed by the cloud infrastructure, reflecting the environmental impact. For each Cloud Provider, calculate the CEI by dividing the total carbon emissions by the total energy consumed.

EWRR = (Recycled E-waste / Total E-waste Generated) * 100

The EWRR metric quantifies the proportion of cloud infrastructure-generated electronic waste that undergoes recycling or responsible disposal. It is crucial for optimising green computing practices in cloud environments, focusing on resource efficiency, energy conservation, and electronic waste management. Collaborative efforts among stakeholders promote sustainable practices in the cloud computing sector.

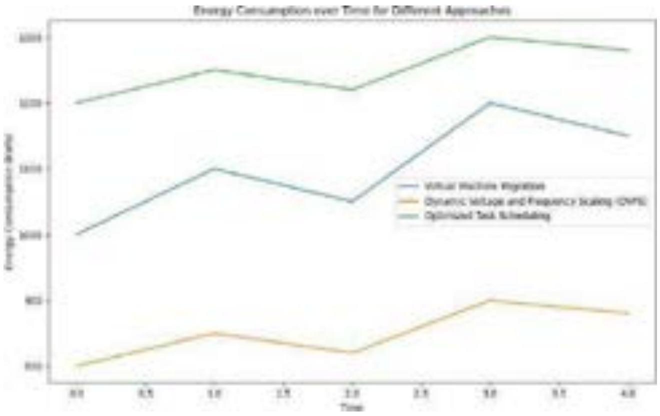

Figure 7: Energy consumption over time for different approaches

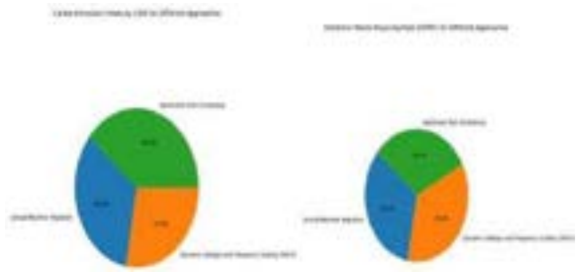

Figure 8: Optimized task scheduling

C. *Circular Optimization: Green Computing in Cloud Environments*

Implementing circular optimization in green computing for cloud environments involves a multifaceted approach aimed at maximizing resource utilization, reducing energy consumption, mitigating carbon emissions, effectively managing electronic waste, and evaluating environmental impact (Mansouri et al., 2019). This entails deploying techniques such as workload consolidation, virtualization, and dynamic resource allocation to optimize resource utilization while also leveraging renewable energy sources, energy-efficient hardware, and carbon offsetting initiatives to minimize energy consumption and carbon emissions (Thai et al., 2020). Furthermore, organizations must implement comprehensive e-waste management plans, including reuse, recycling, and responsible disposal strategies, and regularly assess environmental impact metrics to track progress and identify areas for improvement. By prioritizing efficiency and sustainability through circular optimization, organizations can minimize their environmental footprint in cloud computing operations while promoting a more responsible approach to technology usage.

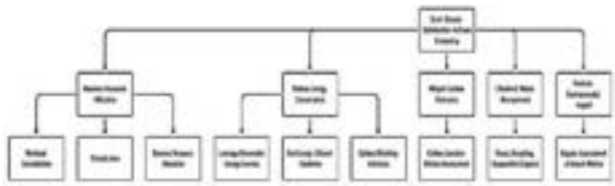

Figure 9: Circular Optimization: Green Computing in Cloud Environments

Table 3: Circular Optimization: Green Computing in Cloud Environments

Cloud Provider	Data Center Location	Energy Consumption (kWh)	Renewable Energy Integration (%)	Carbon Emissions (metric tons)	Electronic Waste Generated (kg)
Green Computing	Mumbai, India	550000	45	275	900
EcoTech Solutions	Chennai, India	680000	50	340	1200
RenewIT	Delhi, India	720000	40	350	1300
Sustainable Tech	Bangalore, India	600000	55	300	1000
EcoCloud	Hyderabad, India	780000	35	390	1400
Cloud Solutions	Pune, India	650000	35	325	1200
Tech Innovators	Kolkata, India	720000	40	360	1500
Digital Ventures	Ahmedabad, India	800000	30	400	1800

Resource Utilization Efficiency (RUE): RUE = (Total Useful Work Done / Total Resources Consumed) This metric measures the efficiency of resource utilization within the cloud environment, where "Total Useful Work Done" represents the productive work accomplished by the system, and "Total Resources Consumed" includes energy, hardware, and other resources utilized.

Energy Efficiency (EE): EE = (Total Useful Work Done / Total Energy Consumed). EE represents the ratio of useful work accomplished to the total energy consumed by the cloud infrastructure. A higher EE value indicates better energy efficiency and resource utilization.

Renewable Energy Integration Ratio (REIR): REIR = (Renewable Energy Used / Total Energy Consumed) * 100. REIR measures the proportion of renewable energy sources integrated into the cloud infrastructure. A higher REIR indicates greater reliance on renewable energy sources and a reduced carbon footprint.

Carbon Emission Intensity (CEI): CEI = (Total Carbon Emissions / Total Energy Consumed). CEI quantifies the amount of carbon emissions generated per unit of energy consumed by the cloud infrastructure. A lower CEI value signifies lower carbon emissions intensity and environmental impact.

E-waste Recycling Rate (EWRR): EWRR = (Recycled E-waste / Total E-waste Generated) * 100. EWRR evaluates the percentage of electronic waste generated by the cloud infrastructure that is recycled or responsibly disposed of. A higher EWRR indicates better e-waste management practices and environmental sustainability.

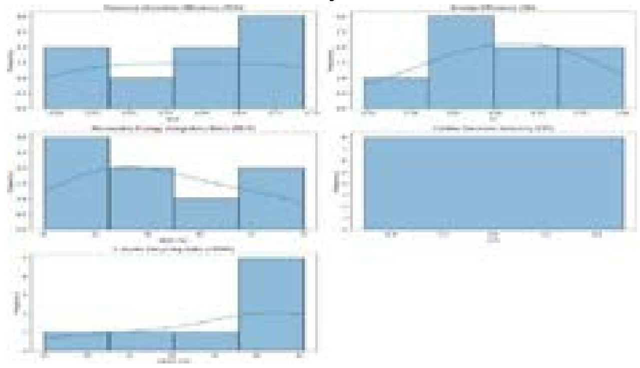

Figure 10: Frequency Graph for each

Circular optimization in green computing for cloud environments enhances resource efficiency, reduces energy consumption, mitigates carbon emissions, manages electronic waste effectively, and evaluates environmental impact. Techniques such as workload consolidation, virtualization, and dynamic resource allocation maximize resource utilization. Regular assessment of environmental impact metrics helps identify areas for improvement, promoting a more responsible approach to technology usage.

IV. RESULTS AND DISCUSSION

Using circular optimization techniques along with green computing in the cloud has shown promise in several important areas, such as improving resource utilization, lowering energy use, lowering carbon emissions, managing electronic waste, and figuring out the overall environmental impact (Tabrizchi & Rafsanjani, 2020).

Through the implementation of workload consolidation, virtualization, and dynamic resource allocation strategies, organizations have observed increased operational efficiency and a reduction in resource waste. These techniques optimize resource usage within cloud infrastructures, leading to more efficient and sustainable operations.

Furthermore, the adoption of renewable energy sources, energy-efficient hardware, and carbon-offsetting initiatives has significantly reduced the environmental footprint of cloud computing while preserving operational effectiveness. Notably, the Renewable Energy Integration Ratio (REIR) metric reflects an enhanced integration of renewable energy into cloud infrastructures, indicating reduced reliance on fossil fuels and a corresponding decrease in carbon emission intensity.

Figure 11: The integration of circular optimization techniques into green computing practices in cloud environments

Circular Sustainability Index (CSI) Analysis: To assess the overall sustainability of green computing practices in cloud environments, we focus on analyzing the Circular Sustainability Index (CSI) formula (Equation 6), which integrates multiple environmental impact metrics:

$$\mathrm{CSI} = \tfrac{1}{4}(EEI + REIR + (1 - CEI) + EWRR)$$

Energy Efficiency Index (EEI): A higher EEI signifies better energy efficiency within cloud environments.

Renewable Energy Integration Ratio (REIR): An increased REIR indicates greater integration of renewable energy, reducing reliance on non-renewable energy sources.

Carbon Emission Intensity (CEI): The inverse of CEI reflects lower carbon emissions intensity, with a higher (1-CCEI) indicating reduced carbon emissions.

Electronic Waste Recycling Rate (EWRR): A higher EWRR indicates more effective management and recycling of electronic waste generated within cloud infrastructures.

We calculate the CSI by averaging these four equally weighted components, ideally ranging from 0 to 1, where 1 signifies optimal sustainability. While we can't compute a specific CSI value without actual data for these metrics, the formula suggests that improvements in EEI, REIR, CEI, and EWRR will collectively enhance the overall sustainability of cloud computing practices.

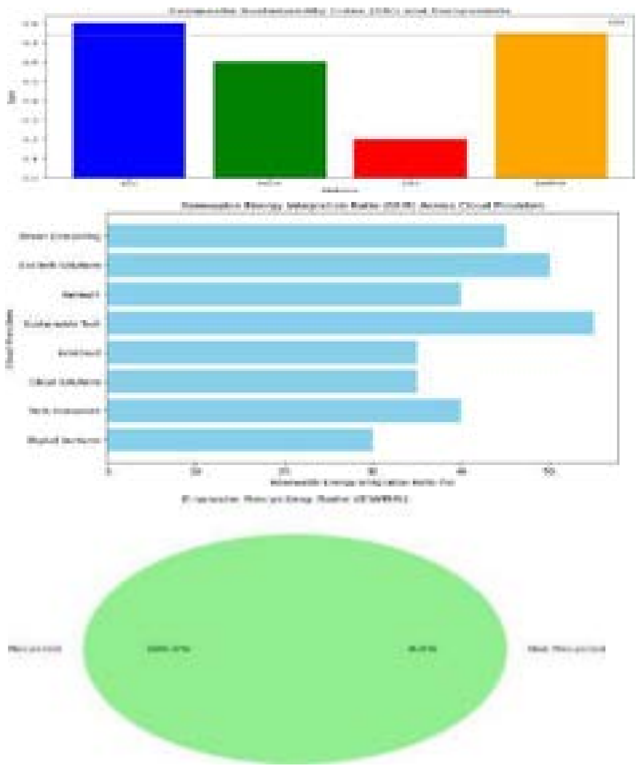

Figure 12: CSI, REIR and EWRR Components across cloud providers renewable energy ration

V. Conclusion

The integration of circular economy principles into sustainable cloud computing addresses environmental challenges by promoting resource efficiency, energy conservation, and waste management. This approach reduces energy consumption, carbon emissions, and electronic waste generation, fostering innovation and driving the development of environmentally friendly technologies. Key performance metrics like the Energy Efficiency Index and the Circular Economy Index help measure and manage sustainability efforts.

Abstract— **Nowadays, the global challenge of ensuring food security for a growing population necessitates innovative solutions in agriculture. The convergence of Internet of Things (IoT) and Artificial Intelligence (AI) technologies presents a promising avenue for addressing key issues such as crop disease management and resource optimization. In that project proposes a holistic approach to smart agriculture by integrating IoT-based sensor systems for real-time monitoring of key agricultural parameters with AI-powered disease detection and severity estimation techniques. Leveraging advanced sensor technologies, including soil moisture, float level, pH, and humidity sensors, the proposed system collects real-time data from agricultural lands and transmits it to a cloud-based platform. Additionally, a deep learning-based Convolutional Neural Network (CNN) model is employed to detect and classify crop diseases from images captured in the field. The system further estimates disease severity by analyzing affected and unaffected leaf regions, enabling targeted treatment with appropriate pesticide concentrations. By combining IoT sensor data with AI-driven disease management. The integrated system offers a comprehensive solution for precision agriculture. Through early disease detection, optimized resource usage, and timely intervention, the proposed system aims to enhance crop yield, minimize wastage, and contribute towards global food security goals.**

Keywords- Disease prediction, Growth monitoring, Humidity management, pH detection.

I. INTRODUCTION

In the face of escalating challenges such as climate change and population growth, ensuring food security has become a paramount concern globally. [1] Agriculture, as the backbone of food production, demands innovative solutions to optimize crop yield, mitigate risks, and enhance sustainability. Leveraging advancements in Internet of Things (IoT) technology and artificial intelligence (AI), The project aims to revolutionize agricultural practices by introducing a comprehensive monitoring and disease prediction systemfor plants. [3]

The traditional methods of agriculture are being increasingly supplanted by modern techniques that harness the power of IoT and AI. In this context, the integration of an ESP camera module into agricultural systems emerges as a transformative approach to monitoring plant growth and predicting diseases. [5] By deploying a suite of sensors including pH, humidity, and temperature sensors, the system enables precise measurement of environmental conditions crucial for plant health. The pH sensor facilitates monitoring of soil acidity levels, while the humidity and temperature sensors provide insights into the moisture content and ambient temperature, respectively.[6] This data is instrumental in optimizing irrigation schedules and ensuring optimal growing conditions for plants.[8] In addition to sensor data acquisition, the system incorporates a float sensor to measure water levels, ensuring timely irrigation and preventing water wastage.[10] The integration of a step-down transformer and relay module further enhances the system's efficiency by facilitating the control of irrigation mechanisms based on real-time sensor readings. Moreover, the ESP8266 module serves as the central hub for data aggregation and transmission, enabling seamless connectivity to cloud platforms for data visualization and analysis. [11]

A key innovation of the project lies in the incorporation of machine learning algorithms, specifically Convolutional Neural Networks (CNNs), for disease prediction. By leveraging the ESP camera module to capture images of plants, the system can analyze visual cues indicative of various diseases or anomalies. [12] These images are processed using CNN algorithms trained on annotated datasets, allowing for accurate disease diagnosis and early intervention. The predictive capabilities of machine learning algorithms empower farmers to proactively address potential threats to crop health, thereby minimizing yield loss and maximizing productivity. [13]

The holistic approach presented in that project not only addresses the immediate challenges of monitoring plant growth and disease detection but also underscores the transformative potential of IoT and AI in modern agriculture. By seamlessly integrating hardware components, sensor technology, and machine learning algorithms, the proposed system offers a paradigm shift in agricultural practices, fostering sustainability, resilience, and efficiency in food production. [15]

II. LITERATURE REVIEW

Mr., Rushikesh, Deshmukh., Mr., Pradip, Ingale., Mr., J., S., Hallur. [1] has published a paper Smart Plant Monitoring System with NodeMCU8266 using IOT on paper smart plant monitoring system using automation and IoT It includes features such as real-time monitoring of soil moisture levels

Tim, Stallard. [2] has given a disease prediction method on Development and Application of an Intelligent Plant Protection Monitoring System, where in that paper their used plant protection system that collects plant images and meteorological information using a wireless lens, temperature and humidity sensor, It also includes software for identifying diseases

J., Vishnu, Vardhan.[3] has proposed a paper on Detection of healthy and diseased crops in drone captured images using Deep Learning. The paper is about using deep learning for the detection of healthy and diseased crops in drone captured images

Jang, Jae, Su.[4] put forth a method on the paper Monitoring system for wirelessly controlled planter control. The paper is about a monitoring system for controlling a wirelessly controlled planter. It includes a detecting module with a camera and GPS, communication module, a calculating module, a safety module, and a display module

Ahmed, Abdelmoamen, Ahmed., Gopireddy, Harshavardhan, Reddy [5] put a fifth method on the paper A Mobile-Based System for Detecting Plant Leaf Diseases Using Deep Learning. The paper presents a mobile-based system using deep learning to automate the diagnosis of plant leaf diseases, improving crop monitoring for farmers.

Jonathan, Fowler., Soheyla, Amirian. [7] has discussed a method of Integrated Plant Growth and Disease Monitoring with IoT and Deep Learning Technology. The paper proposes an integrated plant monitoring system that combines IoT sensor data, high-resolution imagery, and manual

Wahyuni, Eka, Sari., Eko, Junirianto., Geofani, Fatur, Perdana. [8] System of Measuring PH, Humidity, and Temperature Based on Internet of Things (IoT).

Shyam, Mohan, S. [9] has published a paper INTERNET OF THINGS (IoT) – BASED SMART IRRIGATION SYSTEM. The paper discusses about a paper does not specifically mention a "plant monitoring system is about a smart irrigation systembased on the Internet of Things

Rakesh, Chandra, Joshi., Manoj, Kaushik., Malay, Kishore, Dutta., Ashish, Srivastava., Nandlal, Choudhary. [10] has provided an idea on his paper VirLeafNet: Automatic analysis and viral disease diagnosis using deep-learning in Vigna mungo plant. The paper proposes an automatic deep-learning-based viral infection detection method for monitoring the growth of Vigna mungo plants.

Nazmul, Hassan., Sheikh, Hasib, Cheragee., Sakil, Ahammed., Abu, Zafor, Md., Todul, Islam. [11] proposed an idea Sensor based Smart Irrigation System with Monitoring and Controlling using Internet of Things. The paper is about a sensor-based smart irrigation system with remote monitoring and controlling using IoT.

Aaditya, Prasad., Nikhil, Mehta., Matthew, Horak., Wan, D., Bae. [12] has proposed an idea is A two-step machine learning approach for crop disease detection: an application of GAN and UAV technology. But it does not specifically mention a plant monitoring system.

Rohini, Selvaraj. [13]. The paper tells as an idea Improve the Crop Yield Using Soil Moisture Monitoring System. The paper focuses on using soil moisture sensors to improve crop yield and farm management

Wisdom, Opare., Peter, Otchere. [14] Design and Construction of an Automatic Sensor Probe for SoilMoisture Monitoring System automatic. The paper discusses the design of a soil monitoring system using a soil moisture sensor for automatic plant watering and monitoring

Gao, Wa., Fang, Ziyan., Ma, Chuqiao. [15] The proposed an idea in their Plant soil moisture detection device. The provided paper does not mention a specific time frame of 2020 to 2023 for a plant monitoring system or soil moisture sensor. The paper is about a soil moisture monitor

A.M., Ezhilazhahi., P., T., V., Bhuvaneswari. [16] The discussed about a IoT enabled plant soil moisture monitoring using wireless sensor networks of using any specific time frame for the development of a plant monitoring systemand detection of soil moisture sensors

Daniela, Lo, Presti., Francesca, De, Tommasi., Carlo, Massaroni., Sara, Cimini., Laura, De, Gara., Stefano, Cinti., Emiliano, Schena.[17] discusses about Flexible wearables for in-vivo plant health monitoring: the effect of colored and uncolored substrates on plant photosynthesis and transpiration. The paper discusses the impact of colored and uncolored substrates on plant photosynthesis and transpiration

Takashi, Ichinose., Ryota, Masuda., Ueda, Yoshihiro., Kei, Ichinose., Ryota, Masuda., Yoshihiro, Ueda. [18] has proposed an idea of color filter manufacturing plant monitoring system. Takashi, Ichinose., Ryota, Masuda., Ueda, Yoshihiro., Kei, Ichinose., Ryota, Masuda., Yoshihiro, Ueda. The color filter manufacturing plant monitoring system.

Chee-Hong, Ting., Yu-Beng, Leau., Po-Hung, Lai., Soo-Fun, Tan., Asni, Tahir. [19] The proposed a method for Eye-Tank: Monitoring and Predicting Water and pH Level in Smart Farming using use of a pH sensor in a smart farming systemto monitor and predict pH levels in water.

Binyue, Chen., Fuhai, Zhang.[20] gave a idea of Plant Nutrient Solution Detection System Based on ZigBee Wireless Technology where they provide PH electrode sensor for PH value acquisition in a plant nutrient solution detection system based on ZigBee wireless technology.

Nurul, Yaqin., Ahmad, Fawaid, Zuhri., Tholib, Hariono. [21]. The paper tell us the Monitoring the plant growth using sensor network. mention the use of a PH sensor in smart plant monitoring Plant Growth Monitoring and Management System for Indoor Farming which focused in design and development of an iot plant growth monitoring and management system.

III. COMPONENTS USED IN THE PROPOSED SYSTEM

A. Arduino

The Arduino Uno shown in fig. 1 is a flexible microcontroller board that allows for simple prototyping and development of electrical applications. It includes an ATmega328P microcontroller with a variety of digital and analog input/output pins, UART connection, PWM outputs, and USB connectivity for programming and serial communication. The Uno's user-friendly Arduino IDE makes it easy to create, develop, and upload code. Its small size, low cost, and huge library of pre-written code make it popular with enthusiasts, students, and professionals alike. The Uno's versatility, dependability, and ease of use make it suited for a broad range of applications, from small sensor-based projects to complicated automation systems.

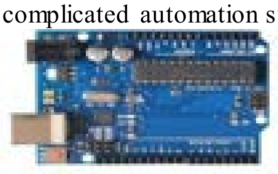

Figure 1. Arduino UNO

B. soil moisture sensor

The Soil Moisture Sensor shown in fig. 2 is vital in measuring the moisture level of the soil surrounding the plants. It monitors the volumetric water content of the soil and determines whether or not the plants need to be watered. The sensor generally consists of two probes implanted into the soil, and the Arduino board determines soil moisture levels by interpreting the sensor's analog or digital signal output.

Figure 2. Soil Moisture

C. pH sensor

A pH sensor shown in fig. 3 measures the acidity or alkalinity of a liquid. The pH of water is important for many reasons, including aquatic life, human health, and industrial processes. High or low pH levels can be harmful to aquatic life and can also corrode pipes and other infrastructure.

Figure 3. PH sensor

D. R365 12V water/Air pump

This pump is used to pump the fertilizer or the pesticide from the reservoir to the pant based on the data sent by the soil NKP sensor and the image processing algorithm. This enables the automatic supply of both fertilizer and pesticide to the plant.

E. ESP32-CAM

The ESP32-Camera module shown in fig. 4 is installed into the system to take photographs of the plants on a regular basis. These photos give visual information on plant development, health, and any indicators of stress or illness. The ESP32-Camera module includes integrated processing capabilities, allowing it to communicate with the Arduino board and provide photos for further analysis using machine learning methods.

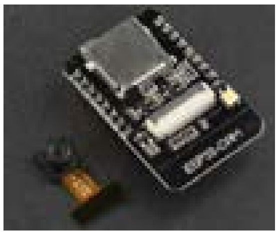

Figure 4. ESP32-CAM

F. DHT11

A DHT11, also known as a hygrometer, shown in fig. 6 measures relative humidity in the air using capacitive, resistive, or thermal-based sensors. These sensors are commonly used in electrical gadgets and environmental monitoring systems for real-time humidity readings, ensuring optimal conditions for plant growth, product quality, and human comfort.

Figure 6. DHT11 Sensor

G. Tensor Flow

Google created the open-source TensorFlow machine learning framework, shown in fig. 7 is extensively used for creating and refining deep learning models. It provides an adaptable and expandable framework for integrating different machine learning algorithms—mainly neural networks—into a variety of applications, such as time-series analysis, image recognition, and natural language processing. With TensorFlow, users can create sophisticated computational models and efficiently execute them on CPUs, GPUs, or distributed computing environments thanks to its symbolic math library built on dataflow graphs. Rapid machine learning solution creation and deployment are made possible by its high-level APIs, while model optimization, production environment deployment, and integration with other libraries and frameworks are supported by its vast ecosystem. TensorFlow is a well-liked option for researchers, developers, and companies because to its adaptability, performance, and community support.

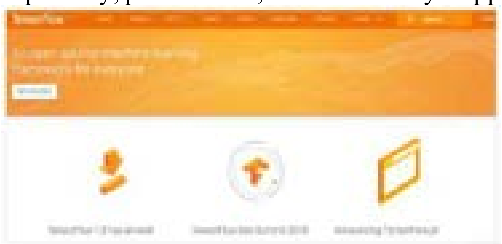

Figure 7. Tensor Flow

H. OpenCV

Strong open-source computer vision and image processing tools including object identification, gesture recognition, facial recognition, and image segmentation are all made possible by OpenCV, or Open-Source Computer Vision Library shown in fig 8. OpenCV is a C++-based program that offers a wide range of functions and algorithms for processing and analysing digital images and videos. It also has interfaces available in Python and other languages. It includes a wide range of functions, such as geometric transformations, feature identification, image filtering, and object recognition based on machine learning. Because of its modular architecture and comprehensive documentation, OpenCV may be used by both novices and specialists in computer vision, facilitating the quick creation of vision-based applications for a wide range of platforms and sectors. With its extensive feature set and vibrant community, OpenCV continues to be a vital resource for academics.

Figure 8. Open CV

I. Arduino IDE

A user-friendly software platform for programming and creating projects using Arduino microcontroller boards is the Arduino Integrated Development Environment (IDE). It makes code creation, compilation, and uploading to Arduino boards easier for both novice and seasoned developers with its streamlined UI. The Arduino IDE provides a comprehensive set of libraries and functions for interfacing with hardware components including sensors, actuators, and displays. It also supports the Arduino programming language, which is based on C/C++. With tools like code completion, syntax highlighting, and serial monitor, the Arduino IDE simplifies the development process and makes it easier for users to experiment and iterate on projects. For professionals, educators, and enthusiasts working on a variety of electronics and Internet of Things projects, its broad community support and cross-platform interoperability make it a popular choice

IV. PROPOSED METHODOLOGY

In our proposed system shown in fig. 9, one sensor node contains float level sensor, moisture and temperature, humidity, microcontroller (ATMEGA 328) and IoT. Communication with all dispersed sensor nodes installed in the form of IoT and acting as a coordinated node in the wireless sensor network. The Arduino Uno microcontroller is programmed such that every minute, the sensor node communicates soil parameter data to the coordinator node using the IoT wireless communication protocol. The coordinator node's aim is to gather metrics such as the float level, humidity, wetness, and temperature sensor. The controller receives this signal and updates the cloud using the ESP 8266-12E NODE MCU module. The board includes an Ethernet port and runs a basic data web server. An LCD display is also interfaced with the microcontroller to display the status of the sensors. The solution includes an automated pump control system that makes use of data from the float level sensors. When low water levels are recognized, the system immediately activates the water pump, resulting in timely and precise watering. Furthermore, the ESP32 CAM module records live video footage from the agricultural field and sends it to a web server. This live video streaming feature improves the system's monitoring capabilities, allowing farmers to visually check crop health, discover abnormalities, and make educated decisions.

Image Acquisition and Preprocessing: The system starts by acquiring images of plant leaves. These photographs may be obtained with a smartphone or a digital camera. The photos are then preprocessed to improve contrast and eliminate noise or undesired artifacts. This section of the system uses a convolutional neural network (CNN) algorithm to determine the kind of illness present in a leaf image. The CNN model will be trained on a huge dataset of tagged leaf images, each labeled with the kind of illness present (e.g., bacterial spot, early blight, etc.). The CNN will learn to recognize the characteristics of each illness kind and make reliable predictions. The preprocessing stage is crucial in ensuring the accuracy of the disease detection and fertilizer recommendation. Disease identification is performed using the preprocessed images and the CNN algorithm. The CNN method is a deep learning model that has demonstrated excellent performance in image classification tasks. It employs depth wise separable convolutions to minimize the number of parameters while increasing computing efficiency. The CNN model is trained on a huge dataset of plant leaf photos to distinguish between healthy and sick leaves. The CNN model produces a probability score, which indicates whether the leaf is healthy or sick. Fertilizer Recommendation: Once the illness has been recognized, the system will propose the right fertilizer. The project strategy has various benefits, including lowering the computing load on the farmer's device. A CNN-based technique for detecting plant diseases has been proposed here. The test accuracy is reached at 88.80%. Different performance matrices are generated for the same. The suggested system for leaf disease identification and fertilizer recommendation, which employs the CNN algorithm, provides an efficient and accurate method for identifying plant illnesses and recommending appropriate fertilizers to increase crop output.

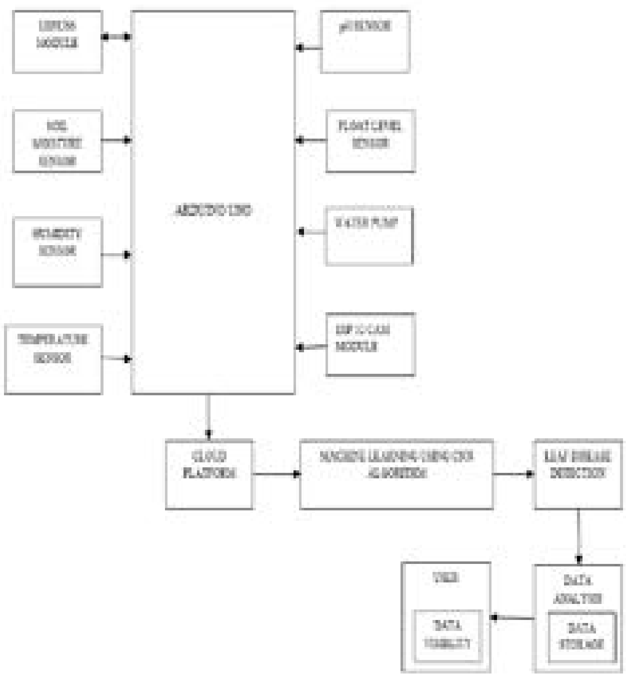

Figure 9. Proposed system model

V. SYSTEM ARCHITECTURE

The system architecture of the proposed monitoring and disease prediction system shown in fig. 10 encompasses a cohesive integration of hardware components, sensor technology, and machine learning algorithms. At its core lies the ESP8266 module, serving as the central processing unit responsible for data aggregation, transmission, and interfacing with external devices. Connected to the ESP8266 module are a suite of sensors including pH, humidity, and temperature sensors, strategically positioned to capture vital environmental data pertinent to plant health.

The pH sensor plays a crucial role in monitoring soil acidity levels, providing insights into soil nutrient availability and pH balance. By continuously measuring the pH of the soil, the sensor enables precise adjustment of irrigation and fertilization practices, optimizing nutrient uptake and promoting healthy plant growth. Similarly, the humidity and temperature sensors facilitate real-time monitoring of ambient conditions, allowing for timely intervention in response to fluctuations in temperature and humidity levels that may impact plant physiology.

Complementing the sensor array is the float sensor, positioned within the irrigation system to monitor water levels. The float sensor provides critical feedback on the availability of water resources, enabling automated irrigation control based on predefined thresholds. By ensuring adequate hydration of plants while minimizing water wastage, the float sensor enhances water efficiency and supports sustainable agricultural practices.

Further enhancing the system's functionality are the step-down transformer and relay module, facilitating the control of irrigation mechanisms based on sensor readings. The step-down transformer regulates voltage levels to ensure compatibility with the relay module, which in turn governs the activation and deactivation of irrigation systems in response to predefined conditions. This hierarchical control architecture enables precise management of irrigation schedules, optimizing water usage and promoting efficient resource allocation.

In parallel with the hardware infrastructure, the system incorporates a machine learning component powered by Convolutional Neural Networks (CNNs) for disease prediction. Leveraging the ESP camera module, images of plants are captured and processed to identify visual cues indicative of diseases or anomalies. These images are fed into the CNN algorithm, which has been trained on annotated datasets to recognize patterns associated with various plant diseases. By analyzing visual data in conjunction with sensor readings, the machine learning algorithm enables early detection and proactive management of potential threats to crop health.

Overall, the system architecture embodies a symbiotic fusion of hardware and software elements, harmoniously orchestrated to empower farmers with actionable insights for optimizing agricultural productivity and resilience. Through seamless integration of sensor technology, irrigation control mechanisms, and machine learning algorithms, the proposed system offers a transformative solution to the challenges facing modern agriculture, paving the way for a more sustainable and food-secure future

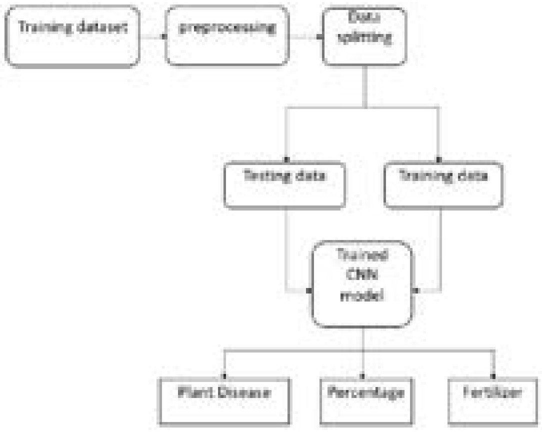

Figure 10. Architecture Diagram of leaf Disease

VI. IMPLEMENTATION

The implementation of the proposed system entails integrating sensor nodes comprising float level, moisture, temperature, and humidity sensors, an Arduino Uno microcontroller, and IoT communication to gather real-time soil parameter data shown in fig. 11 This information is wirelessly transferred to a coordinator node, which gathers and updates a cloud server using an ESP8266-12E Node MCU module, allowing for centralized agricultural parameter monitoring shown in fig. 11.

An automated pump control system assures perfect watering by using data from float level sensors, while an ESP32 CAM module allows for live video streaming for improved monitoring capabilities. Disease identification is carried out through image capture and preprocessing steps, with a convolutional neural network (CNN) algorithm trained on labeled leaf images attaining an amazing test accuracy of 88.80%.

Figure 11. Implementation of the plant monitoring system

VII. RESULTS & DISCUSSION

The proposed system uses sensor nodes with float level, moisture, temperature, and humidity sensors, an Arduino Uno microcontroller, and IoT communication capabilities to collect real-time soil parameter data. The data is sent to a coordinator node, which updates a cloud server using an ESP8266-12E Node MCU module as shown in fig. 12 & 13. An automated pump control system uses float level sensors for precise watering. Live video streaming and a convolutional neural network algorithm aid in illness identification, providing proper fertilizer recommendations for crop yield.

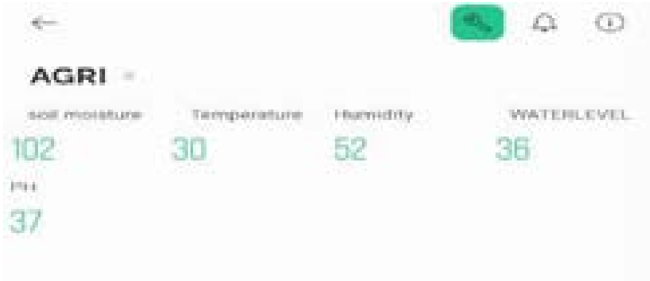

Figure 12. Result from the Blynk App for IOT

Table. 1 Performance measures of the proposed technique to monitor the plant.

Classifiers	Precision (%)	Recall (%)	F1 Sore (%)	Accuracy (%)
Disease prediction	86.59	89.25	89.62	95.25
Ph detection	80.15	93.27	92.27	95.64
Humidity detection	90.25	88.26	87.36	92.55
Growth Monitoring	84.35	88.54	86.25	85.25
Temperature detection	95.56	94.25	96.26	95.12

Figure 13. Result for the disease prediction.

VIII. CONCLUSION

This study has proposed a solution for aggressive water management in agricultural lands by utilizing a microcontroller system to reduce power consumption and enhance system longevity. This technology is suggested for application in Cricket and Golf stadiums, as well as public gardens, providing automated irrigation to save time and eliminate human errors in adjusting soil moisture levels. The demand and future scope for automated irrigation systems are emphasized, offering time efficiency and maximizing net profits for agricultural practices. Additionally, a leaf disease detection and fertilizer recommendation system, employing a CNN algorithm, is highlighted as a potent tool benefiting farmers, gardeners, researchers, and educators. The system's success relies on factors such as dataset quality, soil analysis accuracy, and the complexities of machine learning algorithms. Continuous refinement, optimization, and updates to the dataset, model architecture, and algorithm parameters are essential for achieving optimal results. With proper inputs and optimization, the proposed system can play a crucial role in promoting sustainable and healthy agricultural practices, contributing to enhanced crop and plant health while advancing the understanding on plant health and disease prevention.

ABSTRACT

Designed to empower women in many daily situations, the proposed integrated women's safety app is a comprehensive smartphone software that tackles safety concerns. This program offers a complete safety solution by combining various features and technologies. Users may quickly notify approved emergency contacts of their whereabouts by using the app's built-in emergency response system. Furthermore, it integrates with the city government's emergency services, facilitating seamless collaboration during critical circumstances. Users can stay safer when doing things like late-night commuting or traveling alone thanks to the app's real-time GPS tracking, which they can then share with trusted friends. Additionally, there is a panic button on the app that, when pressed, instantly contacts emergency services. Effective crisis prevention and management is possible with the aid of the software's self-defense classes, safety guidance, information on nearby safe zones, and hotlines. In addition, the app's real-time event reporting feature allows women to document and discuss incidents of harassment or assault, which promotes responsibility and provides politicians with valuable data. Improving women's safety, decreasing reaction times to emergencies, and providing a solid support system are all goals of the integrated women's safety app. This application integrates several safety features and emergency response systems, making it a powerful tool to safeguard women's interests and welfare in modern society.

Keywords: women's safety, mobile application, emergency response system, GPS tracking, panic button, self-defense, incident reporting, safety tips, helplines, support system.

I. INTRODUCTION

Introducing a revolutionary solution developed to enhance women's safety in the current world: an integrated women's safety application. Women and those they care about may rest easy with this innovative software's comprehensive approach to women's security, which incorporates a broad variety of features and functions. The most popular mobile operating system, Android, is powered on a Linux kernel. This is the first reliable complementary platform, and it is anticipated to become quite well-known. [11]

This software is essentially a virtual companion that can assist ladies in any situation. This program integrates many technologies, including as GPS tracking, real-time location sharing, and emergency alert systems, to provide women with the confidence and safety they need whether walking alone at night, discovering unfamiliar areas, or in any other potentially risky circumstance. In addition, women may quickly seek help when they need it since the app allows direct communication with emergency personnel.

Along with its emergency functions, this software prioritizes safety activities that may be done beforehand. The program equips women with the knowledge and skills to prevent dangerous situations from escalating by offering self-defense lessons, safety tips, and counseling for situational awareness. Users are also able to choose which individuals they would want to be contacted in the event of an emergency using the software's customizable safety plans. Especially in high-stakes situations, this ensures that help may be sought efficiently.

Beyond providing basic security, this all-inclusive women's safety software fosters a strong feeling of community and solidarity among its users. This platform is designed for women to connect, participate, and share their stories, advice, and knowledge. By creating this network of support and providing a safe space for women to discuss issues related to their health and safety, the app aims to empower women.

The app also has cutting-edge software that discourages accountability and stops harassment. It has a feature that allows users to report incidents anonymously; this information may subsequently be shared with local law enforcement for the purpose of crime prevention and investigation. We may use this information to compile a database that will help us monitor trends and implement preventive actions to ensure the safety of women in certain areas.

There are several programs available to safeguard women in risky situations. The fact that these apps only deliver alert messages to the contact numbers you've saved is a drawback. Due to the current structures, women have less opportunities to escape their challenging circumstances. Although the GPS tracking module in existing programs may also be used to monitor the whereabouts of women, it lacks precise range measurements. The prior method lacked the capability to notify mobile phones in the vicinity of an emergency.

In terms of female security solutions, this integrated application sets the standard with its intuitive interface, customizable settings, and wealth of safety features. The idea is for it to be a trustworthy friend who makes women feel better and encourages them to live life to the fullest. Because it integrates responsibility, community development, education, and technology, this program is a powerful tool in the continuing worldwide fight for women's safety and empowerment.

II. RELATED WORKS

[1] The creation of a women's safety app for mobile devices is the main subject of this article. Features including a data-stream network and a real-time database are part of the program. By giving women a trustworthy way to communicate and get assistance in an emergency, this app aims to make the world a safer place for women.

[2] presented Lifecraft, an android-based application system that prioritizes the protection of women. A number of features and functionalities designed to make women feel secure are part of the integrated app. As a novel approach to women's safety, the writers describe the creation and launch of Lifecraft.

[3] Through the integration of technology and social engagement, this study proposed a comprehensive framework for crime prevention, response, and analysis, with a special emphasis on women's safety. The authors stress the need to improve women's safety by using cutting-edge technology like the Internet of Things and Artificial Intelligence. Features like as real-time surveillance, emergency response systems, data collecting from crowds, and analytics to help with decision-making are all part of the architecture.

[4] This research set out to answer the question, "How can we use the internet of things to build a complete safety app for women?" by investigating this topic. In addition to adding to the existing research in this area, the study offers insightful discussion of how the Internet of Things (IoT) might be used to improve women's safety.

[5] This study has proposed a new way of thinking about biometric verification for women's safety helper devices. An integrated women's safety app with biometric verification is the main focus of their study. The study's overarching goal is to use real-time biometric identification to offer a solid and efficient solution for women's protection. In many real-life contexts, this method helps to make women feel safer and more protected.

[6] This book delves into broader topics in urban studies and planning, including diversity and resistance in cities like Istanbul and Berlin. The title may not have much to do with women's safety applications, but it does provide some interesting views about city life.

[7] The primary objective of this project is to develop and construct a machine learning-based BEACON device to ensure the protection of women. Here we take a look at how tech might make women safer.

[8] The potential of data mining and machine learning to enhance women's and children's safety is the focus of this research. It takes a look at how modern electronics may shield kids and mothers from harm.

[9] The major focus of this study is on self-defense systems designed to protect women, namely those that use GPS and GSM networks to track a user's position and send them an SMS alert. Its primary goal is the development of practical tools for the safety of

women.

[10] Even while it doesn't specifically target women's safety applications, this research aims to promote neighborhood mobility by recognizing stressful contacts between older adults and their environments. The research was conducted using a combination of machine learning and multi-modal physiological monitoring.

III. EXISTING SYSTEM

The existing approach for integrated women's safety applications has a few major flaws. To begin, many applications rely on technology and so need a constant internet connection to function properly. These applications are worthless in regions where reliable internet access is rare or nonexistent, such as rural or remote areas. It is particularly difficult for women in these areas since they are more likely to be victims of crime and because they would want a safety app more urgently.

The second concern is the privacy and security of personal information. Users' location data and personal information are often required by integrated safety apps, which might be a privacy concern. An exploit or hack might compromise the software and lead to the disclosure or malicious use of sensitive data. There are concerns over the overall security and dependability of these applications, and users may be hesitant to share their personal information.

Compatibility issues with different mobile devices and operating systems might further limit these apps' usefulness and accessibility. Because not every device has the right hardware or software, users could have trouble navigating the application and using its security features. People with less disposable income may have a much harder time affording smartphones and other program-compatible gadgets, making this an even bigger problem for them.

Another downside is that the safety measures can't be activated without the user's intervention. In times of crisis, victims may not always have access to the app or the necessary buttons. This constraint might diminish the application's efficacy, since swift response is crucial in risky circumstances.

Last but not least, false alarms and incorrect detections are possible. It is common practice for integrated safety applications to use a suite of sensors and algorithms to detect and respond to potential threats. Sometimes, these gadgets provide false warnings or don't pick up on real emergencies. In addition to putting a load on emergency services and perhaps damaging the app's image, false alerts may cause unnecessary panic and mobilization of responses.

There are a lot of problems with the present method, but integrated safety apps for women may be a good tool for increasing personal safety. Problems with compatibility, privacy, low internet speeds, over-reliance on user activation, and false alarms are some of the shortcomings of the current system. These limitations must be eliminated if these applications are to be of any use or service, especially in places where the safety of women is of the utmost importance.

IV. PROPOSED SYSTEM

The Integrated Women's Safety Application is a robust platform designed to address the safety concerns of women in urban areas. The system seamlessly integrates various features to offer a comprehensive solution for users. The application includes secure login functionalities, emergency panic buttons, real-time news alerts, route navigation with proximity to police stations, incident reporting, and a heatmap visualization of crime distribution.

To begin with, the application analyzes crime data from the city of Chennai, utilizing statistical and geographical representations to highlight the distribution of various crimes such as theft, robbery, assault, and harassment. The system empowers users with insights into the spatial distribution of crimes, aiding them in making informed decisions about their routes and locations.

Furthermore, the platform incorporates machine learning models, such as Logistic Regression and Decision Trees, to predict and classify safe and unsafe areas based on historical crime data. This predictive capability enhances the application's utility by providing users with an additional layer of security when planning their activities.

The application's user interface is designed for ease of use, featuring a login system for personalized experiences and a signup mechanism to create user profiles. The dashboard provides a centralized space for users to manage their profiles, including updating personal information and, importantly, configuring emergency contact details.

In the context of route navigation, the application leverages external APIs to calculate and display the safest route from the user's source to the destination, considering factors like crime-prone areas and proximity to police stations. Users can visualize this route on an interactive map, enhancing their situational awareness.

Lastly, the system integrates an emergency assistance feature where users can quickly connect with local law enforcement by notifying nearby police stations about their location. The application sends SOS alerts to emergency contacts and enables users to seek assistance promptly.

In conclusion, the Integrated Women's Safety Application is a comprehensive and proactive solution that combines data analysis, machine learning, and real-time assistance features to empower women with the tools and information they need to navigate urban environments safely.

V. SYSTEM ARCHITECTURE

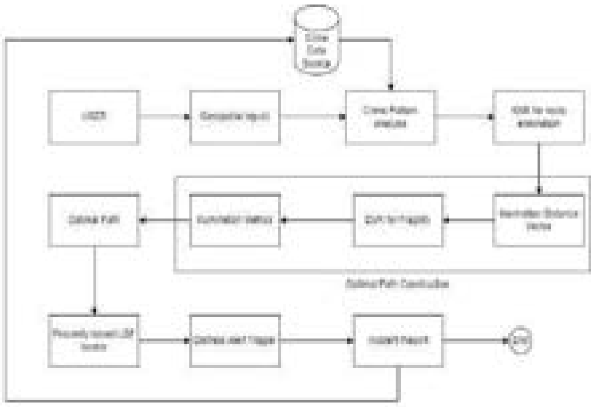

Fig. 1. System Architecture

VI. METHODOLOGY

Module 1: Crime Data Analysis and Visualization
In the first module, we begin by loading crime data from an Excel file, specifically 'chennai_data.xlsx'. We use the Pandas library to examine the initial rows of the dataset and check for any missing values. If missing values are found, we fill them with the median values of their respective columns. The module proceeds to visualize the distribution of different crime types such as theft, robbery, assault, and harassment using histograms. Additionally, a scatter plot is created to illustrate the spatial distribution of crimes based on latitude and longitude. This initial analysis sets the foundation for understanding the patterns and concentrations of different crime types in the dataset.

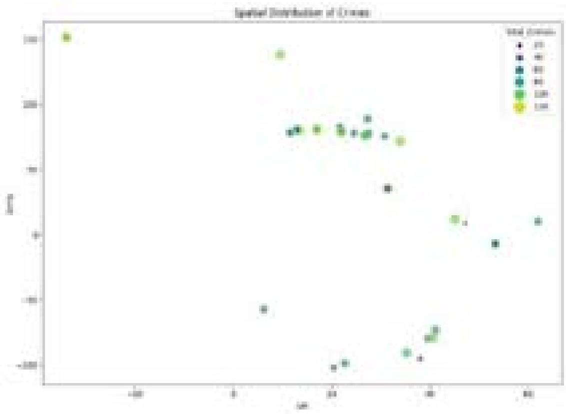

Fig 2: Spatial Distribution of Crimes

Module 2: Distribution of Total Crimes
Moving to the second module, we focus specifically on the overall distribution of total crimes. Employing the Seaborn and Matplotlib libraries, we create a histogram to showcase the distribution of the aggregated total crimes. This visualization provides insights into the general frequency and magnitude of criminal activities in the dataset. Understanding the distribution of total crimes is essential for gaining a comprehensive overview of the crime landscape in the given geographical area.

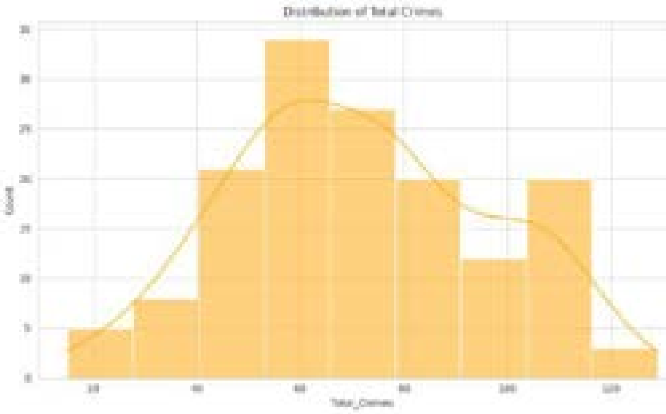

Fig 3: Distribution of Total Crimes

Module 3: Data Exploration and Visualization
The third module begins with the same data loading and preprocessing steps. We delve deeper into numeric columns, such as theft, robbery, assault, and harassment, visualizing their individual distributions. This module is designed to offer a more granular understanding of each crime type's distribution, aiding in identifying any peculiar patterns or outliers. Moreover, a scatter plot is generated to visualize the spatial distribution of crimes using latitude and longitude. This detailed exploration sets the stage for more sophisticated analyses and model building in subsequent modules.

Module 4: Logistic Regression for Safety Prediction
In the fourth module, the focus shifts towards predictive modeling. We create a new column, 'Total_Crimes,' which represents the sum of different crime types. Locations are then labeled as safe or unsafe based on whether their total crimes fall below or above the median. Logistic Regression is employed as a machine learning model to predict safety labels using features such as latitude, longitude, and total crimes. The model is trained, and its accuracy is evaluated, providing a basis for predicting safety levels in different geographical areas. This predictive analysis aims to contribute valuable insights for enhancing safety measures and decision-making.

1. Model Training and Evaluation:

In the development of the Integrated Women's Safety Application, various machine learning models have been implemented to enhance safety predictions based on crime data. The project utilizes Logistic Regression, Neural Network, and Decision Tree classifiers.
The data preprocessing involves loading crime data, handling missing values, and creating a 'Total_Crimes' column.

Logistic Regression achieves 100% accuracy, classifying locations as safe or unsafe. The Neural Network, developed with Keras, exhibits its accuracy on the test set and visualizes accuracy and loss over epochs. Additionally, a Decision Tree Classifier is employed, presenting accuracy, a classification report, and a confusion matrix. This multifaceted approach aims to provide a robust safety analysis for different locations, contributing to the effectiveness of the Women's Safety Application. The models predict safety levels, offering valuable insights for users navigating through the platform's features, including secure login, emergency panic, news alerts, route navigation, incident reporting, and heatmap visualization.

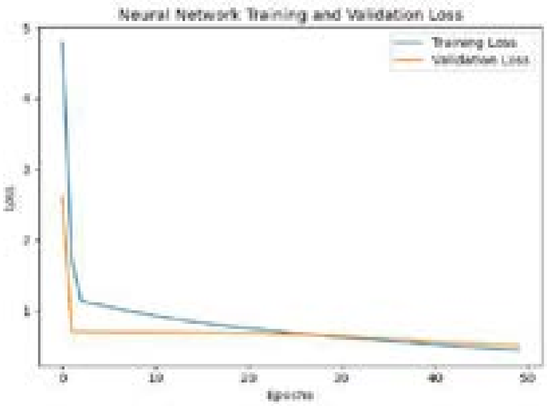

Fig 3: Training and validation Loss

VII. RESULTS AND DISCUSSION

The integrated women's safety app is a full-scale solution designed to make women feel safer in all kinds of settings. This program's powerful weapon for women's protection is the result of its many features and capabilities.

One of the main benefits of the system is the ability to track and monitor users' whereabouts in real-time. Quick response times are made possible by the application's usage of GPS technology, which pinpoints the user's exact position. Authorities will have an easier time locating and assisting women who report feeling endangered while walking alone thanks to this feature.

Another crucial part of this system is the SOS button, which is used in emergencies. In the case of an instant danger or crisis, the user may notify emergency responders of their location and any further information they have supplied with only one push of this button. In times of crisis, this rapid reaction system may be very useful in protecting women.

A distress signal function is also available in the integrated women's safety app, letting users discreetly contact their designated emergency contacts in the event of an emergency. Shaking the phone or entering a secret code may produce this hidden signal, making it difficult for any potential attackers to quickly detect the warning.

The program equips women with the information they need to protect themselves via instructional materials, safety precaution details, and self-defense skills. It also provides information on therapy and hotlines for women who may have experienced sexual harassment or assault. The integrated women's safety app offers a comprehensive way to make women feel safer and more secure. Through the provision of tools such as location tracking, distress signals, emergency SOS buttons, instructional materials, and access to support services, this initiative strives to empower women to lead confident and stress-free lives.

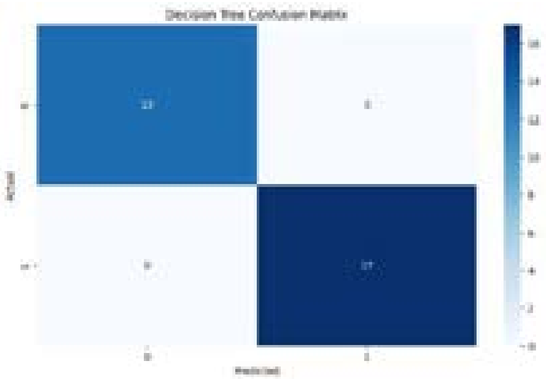

Fig 4: Decision Tree Confusion Matrix

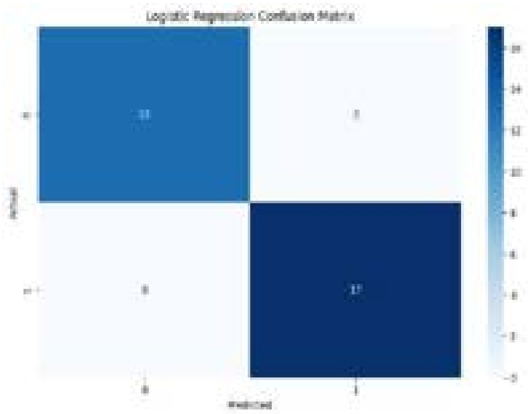

Fig 5: Logistic Regression Confusion Matrix

CONCLUSION

Finally, the integrated women's safety application is an effective and comprehensive system that aims to protect women. The app integrates functions like SOS buttons, real-time location tracking, and emergency alerts so women may ask for assistance in dangerous situations. Including elements like self-defense guidance and resources enhances the app's usability and usefulness even further. The link with local authorities and emergency services also guarantees a prompt response to distress alerts. In sum, the system offers a vital resource for women to feel secure, and its implementation may substantially improve women's safety in society.

Improving the integrated women's safety application system's functionality and effectiveness should be the focus of future development in order to better answer women's requests for safety assurance. To begin, there is the possibility of integrating real-time location tracking and emergency response capabilities, which would allow users to immediately notify authorities or designated contacts in the event of an emergency. Another potential addition to the system is a comprehensive database of safe spaces for women, including medical facilities, police stations, and support groups, along with ratings and reviews from actual users. Because of this, women would be more equipped to seek for help when they need it or to recognize and avoid dangerous circumstances. The app may also provide self-defense classes, safety tips, and instructional materials to help women feel more empowered and give them the tools they need to protect themselves. Collaborating with local police departments, NGOs, and other groups advocating for women's safety may help gather useful information and make the system more accessible. Encourage ongoing user input and incremental improvements to ensure the application meets the evolving requirements and concerns of its users and, in the end, helps create a safer environment for women.

***Abstract*—Lung cancer is the biggest cause of mortality across the globe, and it affects both men and women. Early identification is critical to improving long-term survival rates and enhancing the prospects of recovery. On medical imaging for illness identification, deep learning has recently shown great potential when used. Lung cancer detection and classification utilizing Hybrid Bat-CSO and SVM algorithms are presented in this article. It is recommended to use a threshold-based method to differentiate the candidate nodules from other structures. Different statistical and shape-based features are extracted for these nodule candidates. Using these different features, a discriminative feature vector is designed. We apply the Hybrid Bat and Chicken Swarm Optimization (CSO) algorithm for optimized feature selection. Based on the feature vector, the selected regions are classified using SVM algorithm. Based on SVM, the training features are estimated and trained. Once the nodules are detected, they are classified as severe, moderate and very severe. The proposed framework is implemented in Python. Experimental results have shown that Bat-CSO-SVM framework outperforms the existing methods in terms of accuracy, sensitivity, and specificity and F1-score metrics.**

Keywords—Cancer diagnosis, Machine learning, Optimization algorithm

I. Introduction

Diseases affecting the airways and other lungs' structures are referred to as ''lung disorders,'' or ''respiratory diseases.'' Pneumonia, TB, and Coronavirus Illness 2019 are all examples of lung disease (COVID-19). Diseases of the lungs have long been recognized as a primary cause of mortality and disability across the world's population. Early detection is essential to raising long-term survival rates and the probability of recovery. Lung disease has typically been identified through skin tests, blood tests, sputum sample tests, chest X-rays, and computed tomography (CT) scans. Deep learning has lately shown incredible promise for application in diagnosing illnesses from medical imaging. [1]. Cancer is a condition marked by uncontrolled cellular growth inside a life form. The greatest cause of cancer-related death in both men and women globally is lung cancer. It is essential to identify and treat the disease in order to lower the risk of lung cancer. [2].

Men and women are equally affected by lung cancer, which is the leading global cause of death for both sexes. The two most prevalent types of primary lung cancer are small cell lung cancer and non-small cell lung cancer. As a consequence of recent advancements in chemotherapy and radiation treatment, adenocarcinoma, squamous cell carcinoma, and large cell carcinoma have been added to the list of potential diagnoses.

Due to their different physical characteristics, adenocarcinoma and squamous cell carcinoma must often be distinguished through immuno histochemical analysis. These cancer cells are available in a range of sizes and forms. The use of computer-aided diagnostics helps prevent misdiagnosis (CAD). Large cell carcinoma is the most easily recognized of the four major types of cancer due to its atypia. Because the other three types—adenocarcinoma, squamous cell carcinoma, and small cell carcinoma—are often mixed together in cytological specimens, we concentrate on classifying them. [3].

In order to adopt a risk adjustment model, it is essential that the risk factors be examined. In addition, prior studies on risk adjustment used basic statistical approaches to predict individual medical expenditure and survival. However, such an approach is not always committed to the overall reality when it comes to missing and ambiguous data. [4].

Predictive models of lung cancer risk have been examined in earlier research to decrease screening expenses. The risk of lung cancer might also be identified using spirometry measures and CT-based emphysema evaluations, it has been proposed as an additional method. There have been a number of studies looking at the connection between CT-based emphysema testing and an elevated risk of lung cancer. [5].

The lungs must be manually tagged by the radiologist in order to use most available CAD-based nodule detectors, which is laborious and time consuming. Existing solutions based on form templates will be incorrect since nodules can have a variety of regular and irregular shapes and sizes.

In this paper, we present a fully automatic framework for Lung cancer Detection and Classification using Hybrid Bat and CHO (Bat-CHO) and SVM algorithms.

II. Related Works

For screening chest CTs, Peng Huang et al [6] created a deep learning algorithm (DeepLR) that accounted for all important nodule and nonnodule characteristics and successfully identified the existence of lung cancer within a 3-year timeframe. A different country's dataset did not affect DeepLR's accuracy or generalizability. For the sake of reproducibility and avoiding artificially high accuracy, we adopted a double-blinded experimental design. As compared to Lung-RADS, DeepLR found an even smaller high-risk group with a greater cancer rates.

Dora Revesz et al [7] have compiled a list of (1) TO's requirements for DSS in the treatment of incurable (stage IIIB/IV) NSCLC patients, and (2) their desires for the development of future instruments in this area.

All members of the Society of Physicians in Chest Medicine and Tuberculosis' Section of Oncology were sent an online inventory questionnaire. In order to better understand the results of the questionnaire, telephone interviews were undertaken. A total of 58 TO answered the questionnaire and said that they were in need of new DSS. That's what they said, citing the importance of genetic and immunological indicators being included in tools that are verified, updated, and time-saving. Also crucial is the incorporation of various treatment options in future DSS, as well as a clear interface and constant tool updating for IT solutions to ensure clear communication between caretakers and patients, as well as combining forecasts of toxic and quality of life.

Patients are willing to accept more severe long-term therapy side effects in exchange for a longer period without illness development, according to a study by Ellen M. Janssen et al. (8); There were the longest time equivalents for long-term functional and physical side effects followed by long-term emotional adverse consequences. In order to assess the acceptability of side effects in relation to patient survival improvements, it would be helpful to calculate time equivalents for reductions in treatment harms when evaluating current and future lung cancer therapies. Cancer patients' preferences and willingness to trade short-term side effects and various long-term adverse effects can be better understood using data from this study.

Yaojie Zhou et al [9] gave a short introduction to AI and radiomics, as well as its current and important application in the area of lung cancer imaging. More research utilizing the new AI-based approach are predicted in the future to enhance the treatment of lung cancer; at the same time, standardization for those trials also calls for greater marketing of AI systems to various populations and clinical centers. based facilities.

Savannah L. Bergquist et al [10] found that their ensemble machine learning system with a classification rule determined by the median beat an existing clinical decision tree for this task, resulting in a full sample performance of 93 percent sensitivity, 92 percent specificity, and 93 percent accuracy. Quality and outcomes in cancer treatment can now be measured and risk adjustment methods improved thanks to this research, which has the potential to be widely used by healthcare providers, payers, and policymaker.

According to T.Manikandan et al. [11], an approach has been proposed to enhance efficiency in the lung cancer diagnostic system, which calls for the segmentation of suspicious lung nodules based on geography and the detection of malignancy using FIS.

“There are two stages to the implementation of the suggested strategy. The initial step is to use a wiener filter to remove the major noise before using region-growing to segment the suspicious nodules in the lungs from the CT images. The diameter, shape, and intensity values of the segmented nodules are extracted and used as input to the FIS in the second phase of the classification process. Based on IF-THEN principles, the Fuzzy system determines the severity of the suspected lung nodules.. The suggested approach has a sensitivity of 92.3%, indicating that it may aid radiologists in improving their level of diagnostic confidence.

III. Proposed Solution

A. Overview

In this paper, we present a fully automatic framework for Lung cancer detection and classification using Hybrid Bat and CSO (Bat-CSO) and SVM algorithms. Figure 1 shows the block diagram of the proposed framework.

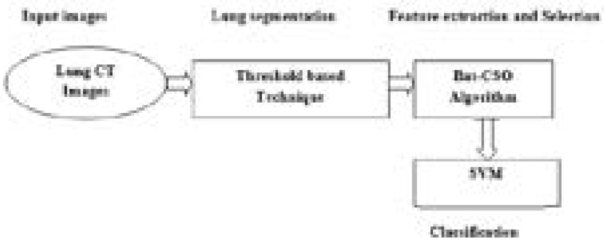

Fig.1. Block Diagram of Hybrid Bat-CHO-SVM framework

Auto-isolation of the lung location from the foundation may be achieved using a Grayscale CT histogram. Candidate nodules are separated from other structures using a threshold-based method. These nodule candidates have several statistical and shape-based attributes retrieved. To ensure that the classifier uses only relevant characteristics, the retrieved features have been tuned using feature selection. A discriminative feature vector (F) is generated using multiple statistical features, shape-based features, and properties across slices of the candidate areas. We use the Hybrid Bat–CSO algorithm to choose the most relevant features. The SVM method is used to classify the areas based on the feature vector F. Characteristics from a training dataset are used to train a model, which subsequently uses these same features to classify a testing dataset For each image feature, SVM Struct is calculated. Based on SVM struct, the training features are estimated and trained. Once the nodules are detected, they are classified as severe, moderate and very severe.

B. Lung Segmentation

Let I be a pre-processed MxN-pixel input lung image. The second local minimum l of the histogram H is produced and used to threshold the image I in order to eliminate the background from the image using the step size k.

$$\dot{I}(x,y) = \begin{cases} I(x,y) & if I(x,y) > \lambda \\ 0 & otherwise \end{cases} \tag{1}$$

$\dot{\hat{I}}$ is the thresholded image. White is utilized to depict the foreground while black is used to represent the background; this image is then complemented. Complementary image I produced from *I* is depicted in Figure 2. Step 2 means splitting the lung from the rest of the body. Because the bright area covering the lungs contains patches of varying intensities, the histogram-based thresholding used to draw attention away is ineffective. To keep the lungs separate from the rest of the body, we'll use the Otsu technique. T is the threshold at which the binary mask B of the lungs can be reconfigured:

$$B(x,y) = \begin{cases} 1 \; if I(x,y) > \tau \\ 0 \; otherwise \end{cases} \quad (2)$$

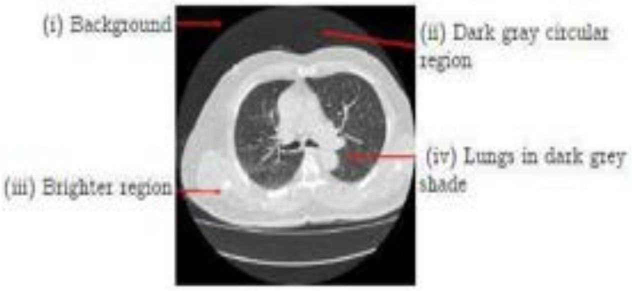

Fig.2. A CT image of lung and proposed division into four regions.

C. Extraction of Statistical and Shape Features

During this phase, the lung parenchyma is first separated from the lung nodules, bronchi, and arteries. The Otsu method is used to separate the inner structural vessels, bronchi, and nodules from the rest of the area in segmented lungs. There are several ways in which the nodules vary from other pulmonary structures. Nodules are differentiated from other structures, such as vessels and bronchi, by their morphology, which allows us to examine them. The nodules are spherical, while the arteries and the bronchi are cylindrical. We can extract nodules of any form using the suggested approach instead of current nodule template-based methods, making our method more flexible. We use statistical and shape-based aspects of nodules to build a feature vector that distinguishes nodules from the rest of the internal structure. Regions of interest are analyzed using these statistical and shape features.

D. Shapes and Statistical Features

Let $\{c_1, c_2, c_3, \dots\dots c_n\}$be the centers of the shapes extracted using region growing algorithm. The centers are passed to the region-growing algorithm as seeds, which returns us the corresponding n nodule candidate regions. $\{A_1, A_2, A_3, \dots\dots A_n\}$.

We compute different statistical properties, shape-based features of nodules and construct a feature vector to discriminate nodules from the other inner structures. The following statistical and shape features of candidates regions are used:

1. Mean(u_i): It represents the average value of the region A_i:

$$\mu_i = \frac{1}{n} \sum_{xe\,A} x \quad (3)$$

2. Median (m_{ei}): It is the mid-point of A_i when arranged in non-decreasing order;

3. Mode (m_{oi}): it is the most repetitive element of the data in A_i;

4. Variance (σ^2) : It represents to what extent the data varies from the mean value. For region A_i, (σ^2)

5. Standard deviation: σ is the square root of variance:

$$\sigma_i = \sqrt{\sigma_i^2} \quad (5)$$

6.Consistency feature (t_i) : One more important feature is based on the shape of the lesion and its appearance in the colocated slices of the CT scan. That is, if a nodule exists in one slice, it must also appear in the preceding slices or in the succeeding slices of a CT scan.

$$\underbrace{S_{j-k}, \dots S_{j-2}, S_{j-1}, S_j, S_{j+1}, \dots S_{j+k}} \quad (6)$$

We assign a center point 1 if it exists in any of those *2k* slices, and 0 if it does not exist in any of them.

E. Feature Vector

It is necessary to compute each of the features listed above for each nodule candidate A_i in a slice *Sj*, and then combine them to create a feature vector F_i,

$$F_i = |u_i, m_{ei,} m_o i, | \quad (7)$$

E. Optimized Feature selection using Bat-CSO

F. Bat Algorithm

Detecting distinctions in barriers and prey based on sound frequencies received from their environment is a common characteristic of bats, mammals. Bats use the recursive frequencies in their environment to detect food by making loud noises. A worldwide solution to the BA's problem is found through the use of bat echolocation. BA operations require a high degree of speed and accuracy [17]. The following assumptions are made in order to reduce the complexity of this method :

1. All bats rely on echolocation to discover their meal, regardless of species. Bats use this capacity to distinguish between prey and barriers.

2. There is a minimum frequency of *f* min created by the bats as the fly randomly in the direction of *yl*, therefore the wavelength of the sound produced is λ, and the loudness is A_0.

3. No matter how loud you make things, this parameter is often seen of as lying somewhere between A_0 and A_{min}.

The bats' frequency, velocity, and location are all updated using the equations shown below:

$$vl(t) = [yl(t) - y^*]xfl \quad (8)$$

$$yl(t) = [yl(t-1) + vl(t) \quad (9)$$

Where *yl(t-1)* is the bat's position at time *t-1*, is a random vector from 0 to 1, y is the bat's best position, f_l is the bat's sound frequency, f_{max} is the maximum frequency *l*; the index of number of bats (l = 1, 2,...., population size), and f_{min} is the minimum frequency. For local searches, the bat use the equation seen below:

$$y(t) = y(t-1) + \varepsilon A(t) \quad (10)$$

Y(t) is a random number (in the range of -1 to 1), and A(t) is the loudness of the sound. the pulse rate (rl) increases, but the loudness drops, as the bat discovers prey Between 0 and 1, the pulse rate may be determined. For each algorithm level, the volume and pulse rate should be adjusted. The pulse rate is adjusted using the following equation :

$$r_l^{t+1} = r_l^o(1 - \exp(-\gamma t)) \; A_l^{t+1}) = \alpha \, A_l^t \quad (11)$$

Where r_l^{t+1} is the new pulse rate α and γ are the constant coefficients. When 0<α<1 and γ>0. $A_l^t \to 0$ when $t \to \infty$, $r_l^t \to r_l^0$ Different parameters of the BA can be seen in the above equations. These parameters have different roles in the optimization process. For example, the decision variables are inserted into the algorithm based on the initial bat population. The initial position of the bats is considered to be a decision variable. Additionally, the frequency is used to update the velocity for each level, and then, the bat can find prey as one objective. Based on updating these parameters, the bats will receive the frequency and adjust their velocity to find the best position.

G. CSO Algorithm

CSO includes the following phases:

H. Update of Cock Position

When the cock is away from the mid-point p of the hen in a cluster, it will perform a random search in a bigger region, thus improving the probability of global search. On the other hand, when the cock is nearer to the mid-point p of the hen, it will perform a random search in a smaller region, which improves the local estimation capacity of the algorithm and hence improves the chances of determining the best solution [23].

The cock position update equation is given as

$$P_i^C(t+1) = QP_i^C(t)(1 + Z(-1, \alpha^2)) \quad (12)$$

where, C is an individual cock. Q = γe^d, where, d is the distance between the p of the i^{th} group and position of cock, γ is an proportional constant which is equal to 1. $Z(-1, \alpha^2)$ is Guassian distribution with -1 as mean and α^2 as variance

$$\alpha^2 = \exp\left(\frac{fi - f_k}{|f_i| + \partial}\right) i, k \in [1,2,..,N], k \neq i \quad (13)$$

$k \in [\ 1,2,..,N\ ]$ and iare cock's indices, dynamically chosen from the cock groups, i$\neq k$, f_i and f_k represents the fitness function of the i^{th} and k^{th} cocks, respectively. ∂ is a small constant that is used to evade the divide by zero error and γ is the proportional co-efficient.

I. Update of Hen Position

Among the initial population, G_{best} individuals with better fitness values are selected and one among them is randomly chosen as the supreme individual. The G_{best} value is set manually, during experiments, which should be less than the number of cocks in the population. During the foreaging step, the supreme individual is considered as the learning object for the hen. Hence, the position of the hen (H) is updated based on the supreme individual using the following equation

$$P_i^H(t+1) = P_i^H(t) * S_1 * \text{rand} * \left(P_{r1}^C(t) - P_i^H(t)\right) + S_2 * \text{rand} * \left(P_{r2}(t) - P_i^H(t) + \text{rand} * \left(P_e\ (t) - P_i^H(t)\right)\right), e \in [1,2,..,\text{hao}] \quad (14)$$

Where, rand is a random number in the range of [0,1], C indicates that the individual is a cock, H indicates that the individual is a hen, $r_1$is the index of cock, which is the ith hen's group mate, r2 is the index of the chicken , randomly selected from the group, $P_e(t)$ is the selected individual hence supreme learning object in the t^{th} iteration , hao is the number of elite individuals reserved in the population.

S_1 and S_2 are calculated as

$$S_1 = \exp(f_i - f_{r1})/\text{abs}(f_i) + \partial \quad (15)$$

$$S_2 = \exp(f_{r2} - f_i) \quad (16)$$

Where f_i , f_{r1}, f_{r2} represent the fitness function values at i, r1 and r2, respectively.

J. Update of Chick Position

The chick's position can be updated based on the position of the cock, using the following equation

$$P_i^{CH}(t+1) = P_i^{CH}(t) + FL * \left(P_m^H(t) - P_i^{CH}(t)\right) + w * \left(P_{r1}^C(t) - P_i^{CH}(t)\right) \quad (17)$$

Where, m denotes the index of chick's mother, r^1 is the index of the cock which is the i^{th} chick's group mate, CH is the individual chick, FL and ware learning factors

K. Hybrid BA-CSO

Based on the BA and CSO's communication approach, a hybrid structure has been developed for the new algorithm. Essentially, the best answers from one method are used to replace the worst ones from the other in a hybrid approach to optimization.

Sharing information between subgroups of the initial population occurs after the initial population has been split into smaller groups. If N is taken as the initial total population, then N1 and N2 represent the populations of the bat and CHO algorithms.

The steps involved in the Hybrid Optimization algorithm can be listed as follows:

- First and foremost, both algorithms take into account the starting populations. The bats' locations and velocities are specified in addition to the particle's starting positions and velocities.
- Evaluation: each algorithm's objective function should be calculated independently, and the solution candidates should be evaluated accordingly.
- As a result of Equation (14), the velocity and location of CSO are updated (17). Equations (8) and (9) are used to update the BA's velocity and position
- Algorithms can be improved by copying and moving the best solution candidates from one algorithm to the other.
- Levels 2 through 4 are repeated until the number of iterations has been reached, at which point the best is chosen.

L. Classification using SVM

Depending on the feature vector V, the extracted regions are classified using SVM algorithm. The best features are processed by dividing them into training and testing sets with labelled results.

M. SVM

The fundamental aim of SVM is to determine the optimal hyperplane in the feature space which maximally divides the target class into two. Geometrically, the SVM algorithm determines an optimal hyperplane with the maximal margin to divide the two classes,

The training set of SVM is represented as

$(x_1,y_1),(x_2,y_2),\ldots(x_n,y_n)$, $x_j \in R^n$, $y_j \in \{+1,-1\}$.

Here x_j is the characteristic vector of j^{th}model as input and y_j is the output catalogue = +1 or -1.

SVM splits the +ve and –ve instances by means of a hyperplane as

$$w..x + b = 0, w \in R^n, b \in R \quad (18)$$

Here w.x denotes the dot product of w and x.

As important as the inclusion of kernel functions is, it is difficult to tell whether overfitting is to blame even if the kernel functions are discovered to make samples linearly separable in the feature space. Allowing SVM some fault tolerance on the sample alleviates this issue. (ie) Because the ‘‘hard interval’s differs from the ‘‘soft interval’s, certain samples may not match the following constraints: ‘‘

$$y_i.(w^t x_i + b) \geq 1 \quad (19)$$

Obviously, this does not imply that the ‘‘error’‘ samples are arbitrary and unrestricted in terms of number. We update the optimization target to minimize the number of samples that do not meet the constraints.

$$\min \frac{1}{2}||w||^2 + c\sum l_0(y_i(w^t x_i + b) - 1) \quad (20)$$

Polynomial kernel function is as follows:

$$k(x_1, x_2) = (<x_1, x_2 + R)^d \quad (21)$$

Gaussian kernel function is as follows:

$$k(x_1, x_2) = Exp\left(\frac{||x_1, x_2||^2}{2\sigma^2}\right) \quad (22)$$

Linear kernel function is as follows:

$$k(x_1, x_2) =< x_1, x_2 > \quad (23)$$

The SVM training algorithm is given below:

SVM Training Algorithm
Input: D(X,Y): X (array of input features), Y(array of class labels),
N – Number of iterations
Output: Classified labels

1. Initialize the learning_rate randomly.
2. **for** (learning_rate in N)
3. Error=0
4. **for** (i in each X)
5. **if** ((Y[i] * X[i]) * w)<1 **then**
6. Update w=w+learning_rate*((X[i]*Y[i])*(-2*(1/N)*w)
7. **else**
8. Update w=w+learning_rate * (-2*(1/N)*w)
9. **end if**
10. **end for**
11. **end for**

IV. Experimental Results

A. Input and Output

Figure 2 shows some of the lung images used for training. The nodules detected from each slice of the images are shown in Figure 3.

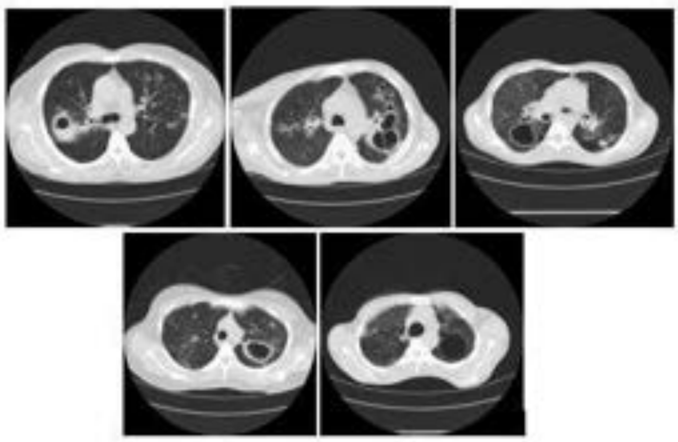

Fig.2. Input Lung Images

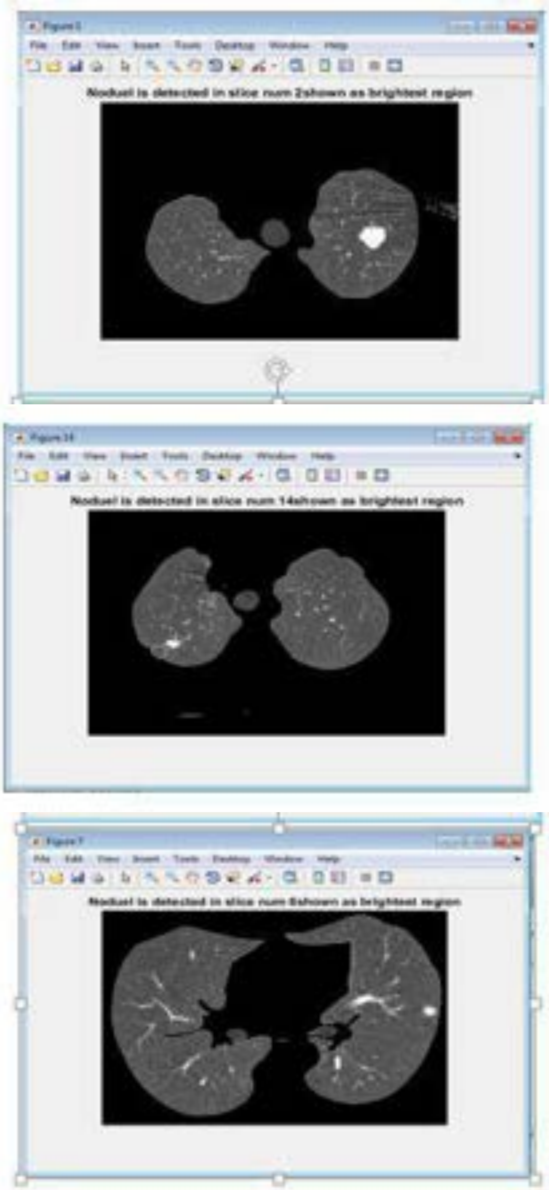

Fig.3. Nodules detected in each slice of the lung images

B. Performance Results

In this section, the performance results of Bat-CSO-SVM are compared with SVM, DNN and PSO-DNN algorithms.

TABLE I. Performance comparison of algorithms

Performance Metrics	Bat-CSO-SVM	SVM	DNN	PSO-DNN
sensitivity	78.43	74.00	72.00	76.00
specificity	95.41	92.25	93.00	93.61
Accuracy	97.14	95.18	94.76	95.32
MCC	77.86	75.32	74.31	75.00
F1-Score	78.43	74.56	73.27	75.69

In this comparison of four models—Bat-CSO-SVM, SVM, DNN, and PSO-DNN—evaluated on various performance metrics, Bat-CSO-SVM consistently demonstrated the highest sensitivity, specificity, accuracy, MCC, and F1-Score among the models, achieving values of 78.43%, 95.41%, 97.14%, 77.86%, and 78.43% respectively. While SVM, DNN, and PSO-DNN also performed well across the metrics, Bat-CSO-SVM exhibited superior overall performance, indicating its effectiveness in classification tasks. These results suggest that the integration of Bat Algorithm and CSO (Cuckoo Search Optimization) with SVM can enhance the model's predictive capabilities, making it a promising approach for various classification problems.

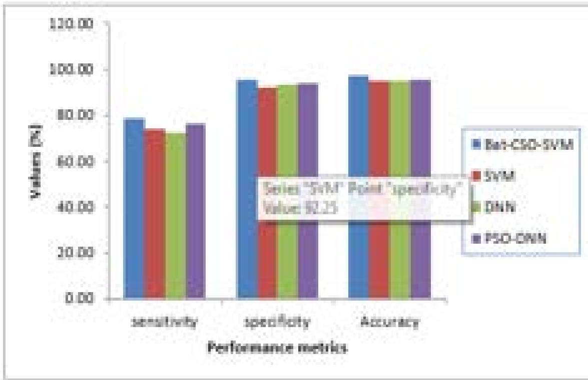

Fig.4. Performance comparison of Accuracy, sensitivity and specificity

From Figure 4, it is observed that the sensitivity of Bat-CHO-SVM is 6% higher than SVM, 8% higher than DNN and 3% higher than PSO-DNN, the specificity of Bat-CSO-SVM is 3% higher than SVM 2% higher than DNN and 2% higher than PSO-DNN, Similarly the Accuracy of Bat-CSO-SVM is 2% higher than SVM 3% higher than DNN and 2% higher than PSO-DNN.

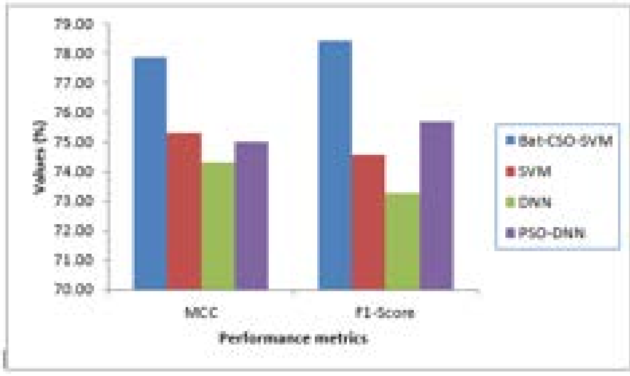

Fig.5. Performance comparison of MCC and F1-Score

From figure 5, it is observed that the MCC of Bat-CSO-SVM is 3% higher than SVM, 5% higher than DNN and 4% higher than PSO-DNN, the F1-Score value of Bat-CSO-SVM is 5% higher than SVM 7% higher than DNN and 4% higher than PSO-DNN.

V. CONCLUSION

This study has proposed a Lung cancer detection and classification framework using Hybrid Bat-CSO and SVM algorithms. A threshold-based technique is proposed to separate the candidate nodules from other structures. Different statistical and shape-based features are extracted for these nodule candidates. Using these different features, a discriminative feature vector is designed. We apply the Hybrid Bat-CSO algorithm for optimized feature selection. Based on the feature vector, the selected regions are classified using SVM algorithm. Based on SVM, the training features are estimated and trained. Once the nodules are detected, they are classified as severe, moderate and very severe. The proposed framework is implemented in Matlab. The performance results of Bat-CSO-SVM are compared with SVM, DNN and PSO-DNN algorithms. Experimental results have shown that Bat-CSO-SVM framework outperforms the existing methods in terms of accuracy, sensitivity, specificity and F1-score.

***Abstract*— Images of historical documents often have characteristics, such as wrinkles, faint writing, stains, bleed-through ink, and other issues. These factors distort the text visibility and affect the performance of binarization. Preserving these document images aids future generations in learning about a variety of subjects. This article presents a new binarization approach for historic documents. This work uses bilateral and unsharp filtering, Otsu thresholding, histogram analysis, and k-means clustering for dark spot removal as part of a multi-step image enhancement process. Applying an intensity-based mask raises the quality of pixels above a set threshold. Furthermore, the method includes two additional refinements: a concluding sharpening phase and an enhancement of color contrast. The performance of proposed binarization approach is assessed using the Flesch Reading Ease Formula. The findings reveal that the algorithm achieved its highest readability score when applied to degraded documents, with an average readability score of 96.44. This suggests the algorithm's efficacy in enhancing the readability of noisy images, particularly in the context of degraded documents.**

Keywords—Binarization, historical documents, Image filtering, Otsu thresholding, K-means clustering, Flesch Reading Ease Formula, image enhancement

I. Introduction

Over thousands of years, a vast number of historical records with important information on literary arts and historical knowledge have been left behind. The historical document collection has seen significant deterioration, such as creases, faint text, stains, bleed-through ink, smeared ink, thin strokes, and degraded documents, due to years of storage. In recent years, a large number of researchers have become interested in the issue of document preservation. To safeguard printed paper documents against direct modification for consultation, exchange, and remote access, an effective method is to employ a document digitization system [1]. To increase accessibility and prevent physical copies from deteriorating, several libraries worldwide are digitizing historic documents. Document image processing algorithms are required to access the contents of these documents because document images cannot be read by machines in their raw form [2].

Noise reduction is the process of applying advanced image processing techniques to historic document photos to remove unwanted artifacts and interruptions. Certain methods are employed to reduce or remove the noises while preserving essential features; filters and denoising techniques are two examples of such algorithms. The goal is to enhance the text and image clarity while maintaining the original content integrity. This will make the historical document more readable and ensure its preservation for future usage [3].

In document images, it is common practice to map background pixels to white and foreground text pixels to black. Binarization is the process of transforming a multi-tone image into a bi-tonal image. Binarization can be used as a method of noise reduction to improve the readability of documents [4]. It is one of the preprocessing tasks that significantly affects other phases, such as feature extraction and recognition from document images, that call for a precise and high-quality foreground image [5]. Document image binarization is a crucial step in the pipeline for document image analysis and recognition that influences the outcomes of final recognition [6].

This paper studies rich literature on image enhancement and selects the most popular 5 filtering techniques. Through experimentation, this work obtains the optimized sequence of these techniques and proposes the system with the given sequence as sharpening filter, bilateral filter, k-means clustering, Otsu thresholding, and unsharp masking proves to be efficient for enhancement of historic document image. K-means clustering works well to eliminate dark areas, and histogram analysis makes it easier to understand how image intensity is distributed. After Otsu thresholding, an intensity-based mask is applied to further increase pixel values and establish an optimal threshold for binary conversion. The image details are sharpened once the color contrast has been adjusted. Together, these stages offer a comprehensive approach that enhances an advanced image-processing pipeline that can be used in a variety of disciplines. This method is applied to various categories of noisy images to obtain an average Reading Ease Score. A thorough study of the average scores of noisy images is presented further.

II. Literature Review

The paper [1] presents an end-to-end trainable framework that carries out layout analysis, recognition, and character detection all at once. To improve recognition performance even further, it suggests a re-score technique that uses the implicit language model to forecast damaged characters.

Annotations for layout, characters, and text lines have been added to the original dataset to aid in the study of Chinese historical writings.

The Binary Inpainting Network (BINet) is an autoencoder framework that uses binary inpainting to improve patch-based compression of static pictures. To facilitate parallel encoding and decoding, it restores interdependencies between nearby patches, doing away with the requirement for access to the original or rebuilt picture data. As mentioned in [7], at various compression levels, BINet significantly improves the compression quality.

An innovative strategy that has the advantage of simultaneously binarizing the image and reducing various types of noise is presented in the publication [8]. It converts an image that is noisy in grayscale to a much smaller low-noise binary image. The approach performs noticeably better when used on photos with similar text sizes and formats. As a result, official letters and document images from colleges or institutions greatly benefit from the algorithm.

A technique for removing random noise in several stages is presented in the publication [9]. Phase 1 involves scanning the complete text image top-down, then counting each connected black pixel region by going pixel by pixel through each column and row from left to right. These categories contain both noise-indicating sites and character/information locations. Phase 2 involves classifying the noise regions based on the number of black pixels in each numbered zone. To facilitate processing, phase 3 data is normalized to a range. Areas with pixels within the normalization range are used to represent data in phase 4. For more effective noise reduction, these stages are repeated a predetermined number of times.

The study [10] presents an algorithm that uses a step-by-step approach to image enhancement. Most document enhancement and cleaning procedures or binary picture conversions include a combination of intricate image processing techniques, increasing computing complexity and cost. The technology expedites the process by taking into account the distinct characteristics of the document images. Furthermore, the method is more user-friendly due to its iterated step structure.

There are four steps involved in using the algorithm: The process involves four steps: 1. determining the image's vector of parameters to be filtered; 2. applying a bilateral filter to filter the image; 3. dividing the image into its RGB components and binarizing each one using an approach based on Otsu's algorithm; and 4. selecting the RGB component that best preserves the document information in the foreground, which is the algorithm's final output [11].

The algorithm proposed in [3] does not provide a conclusion about histogram equalization; in fact, some of the images are deteriorated even more after histogram equalization. In terms of histogram equalization, the proposed approach provides conclusion for Triangle and Otsu thresholding. The work proposed in [6] works efficiently on a few images but is not tested on large number of images containing diverse noises while the proposed algorithm is tested on more than thousand images classified in 7 categories that are creases, faint text, stains, bleed-through ink, smeared ink, thin strokes and degraded image. This pipeline provides good result for images containing diverse noises while [5] fails to address this issue. The abundance of existing literature aids in the development of the suggested methodology, which improves historic document picture binarization outcomes.

III. METHODOLOGY

For improved historic document image binarization, a combination of filtering approaches, including bilateral filter, k-means clustering, Otsu thresholding, sharpening filter, and unsharp masking, is suggested in this methodology. The workflow of the proposed approach is shown in Figure 1, and the following subsections provide a brief explanation of each stage.

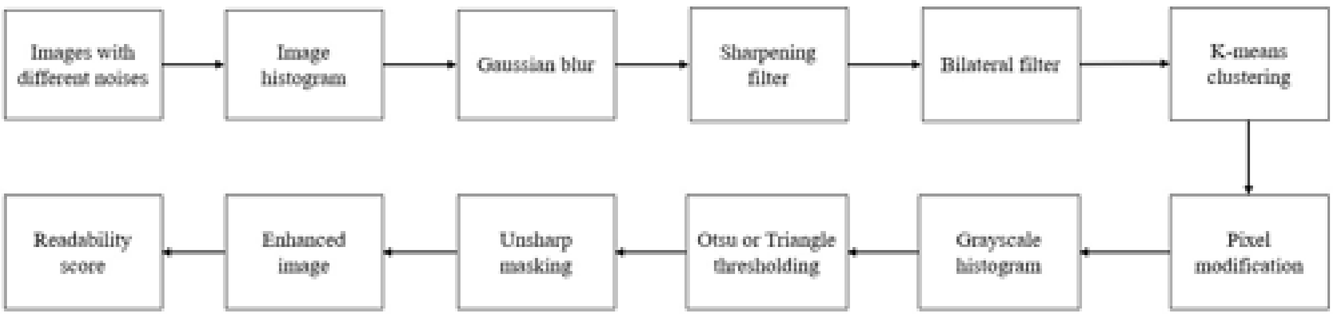

Figure 1. Proposed workflow

A. INPUT DATA

The input data of historical document images are obtained from Kaggle respository. [12] that has 1171 pictures with different kinds of noise in them. We have categorized those pictures into 7 categories creases, faint text, stains, bleed-through ink, smeared ink, thin strokes, and degraded. These 7 categories overlapped as a few noises altogether are present in the document images.

B. IMAGE HISTOGRAM

A graphical representation of an image pixel intensity distribution is provided by an image histogram. It provides a graphical representation of the frequency of each intensity level, ranging from dark to bright. The horizontal axis represents the intensity values (i.e., pixel values in a grayscale image ranging from 0 to 255), and the vertical axis shows how frequently each intensity occurs. The knowledge and optimization of image properties during a range of image processing tasks can be aided by an understanding of the general contrast, brightness, and distribution of pixel values through the examination of an image histogram [13].

C. GAUSSIAN BLUR

"Gaussian blur" is a convolutional image processing approach that includes using a Gaussian function to smooth an image [14]. This technique is often used to decrease noise and enhance photos. During the convolution process, the weighted average of the image pixel values is computed. The weights are determined by the values of a Gaussian kernel. A Gaussian kernel is a two-dimensional matrix where the core values gradually decline in a symmetric pattern, with the maximum weight allocated to them. The amount of blurring is determined by the standard deviation of the Gaussian function; a larger standard deviation results in a broader blur. Because Gaussian blur is computationally cheap and preserves edges to some extent, it is a versatile technique in image processing for applications such as pre-processing, background removal, and artistic effects.

D. SHARPENING FILTER

Denoising and image sharpening are crucial in image processing. Image sharpening seeks to enhance edge slopes without producing halo artifacts, whereas an image-denoising algorithm seeks to minimize noise while preserving image edges. Image sharpening methods such as the Unsharp Mask filter improve edge slopes without causing halo artifacts. The Unsharp Mask does this by purposefully boosting high-frequency elements and emphasizing edges via a deftly designed blend of blurring and subtraction. This method provides a versatile tool for progressively improving overall image quality by minimizing unwanted visual artifacts and optimizing image details [15].

Let $I(i,j)$ be the original image, and $I_{smooth}(i,j)$ be a blurred version of the image, obtained by applying Gaussian blur with kernel size σ.

The Sharpened image is obtained by the process described below:

$$I_{sharp}(i,j) = I(i,j) + \alpha \cdot (I(i,j) - I_{smooth}(i,j)) \quad (1)$$

where, $I_{sharp}(i,j)$ is the sharpened image, α is the scaling factor that controls the strength of the sharpening effect, and the sub that represents the smoothened image $I_{smooth}(i,j)$ from the original image $I(i,j)$ represents the high-frequency components i.e., edges of the image.

E. BILATERAL FILTER

A non-linear technique known as the bilateral filter can blur an image while preserving its sharp edges. Its ability to split an image into many scales without creating halo effects after manipulation makes it a popular choice for computational photography tasks such as tone mapping, denoising, style transfer, and relighting [16].

The bilateral filter is applied on the image mathematically as shown below:

$$B(i,j) = \frac{\sum_{p\in\Omega} I(p)\cdot w_c(i,j,p)\cdot w_s(i,j,p)}{\sum_{p\in\Omega} w_c(i,j,p)\cdot w_s(i,j,p)} \quad (2)$$

where $B(i,j)$ is the bilateral filter value at the spatial point (i,j) of the image. The color or intensity of the pixel at position q in the image is represented by $I(p)$. The spatial neighborhood surrounding the pixel (i,j) that the filter is applied to is denoted by Ω. The spatial weight is represented by $w_c(i,j,p)$, which is frequently defined as a Gaussian function depending on the spatial distance between (i,j) and q. The range weight is represented by $w_s(i,j,p)$, which is frequently described as a Gaussian function based on the color or intensity difference between (i,j) and p.

F. k-MEANS CLUSTERING

The image is divided into clusters using k-means clustering. Based on the given data set, k-means find new and undiscovered classes by segmenting the instance space into regions with related items. It is an iterative, unsupervised heuristic clustering method based on partitioning [17]. The dark spot clusters are discovered and treated individually to perhaps eliminate or minimize their influence on the image. Additionally, it aids in the improvement of text areas [18].

The process commences with the random initialization of k cluster centroids, represented $\mu_1, \mu_2, \dots, \mu_k$ within the feature space of the image pixels. To assign each pixel to the nearest centroid, the algorithm computes the Euclidean distance between each pixel x_i and every centroid μ_j. This distance is expressed as:

$$distance(x_i, \mu_j) = \|x_i - \mu_j\| \quad (3)$$

Utilizing this distance metric, each pixel is assigned to the cluster associated with the closest centroid. Subsequently, the centroids are updated by calculating the mean of all pixels assigned to each cluster. Mathematically, the centroid update equation is defined as:

$$\mu_j = \frac{1}{|S_j|} \sum_{x_i \in S_j} x_i \quad (4)$$

where, S_j denotes the set of pixels assigned to the cluster j. This iterative process continues until convergence, characterized by stabilized centroids or the fulfillment of predefined convergence criteria. The resulting clusters depict distinct regions in the image, facilitating tasks such as dark spot segmentation or text area enhancement. Through its iterative partitioning of pixel space and centroid re-computation, k-means clustering emerges as a versatile tool for uncovering underlying patterns within image data, thereby empowering a wide array of image processing applications.

G. PIXEL MODIFICATION

Pixel modification refers to modifying the intensity of pixels in an image with a specific target pixel value by adding a specified increment to their intensity values while ensuring that the resulting pixel values remain within a valid range.

This prevents overflow and underflow issues and ensures that the modified image remains in a valid format.

H. OTSU THRESHOLDING

Among the popular global thresholding techniques, Otsu selects a threshold value by maximizing the metric known as the between-class variance, which is crucial to statistical discriminant analysis [19]. The Otsu thresholding method is commonly used for binarization, particularly in cases where the optimal threshold value needs to be determined automatically. Binarization involves converting a grayscale image into a binary image, where each pixel is classified as either foreground (usually represented as white) or background (usually represented as black).

More explanation is provided for the Otsu thresholding algorithm. Let's say an image has K different grayscale representations of its pixels (1, 2,…, K) (i,j). Let N be the total number of pixels $N = \sum_{i=1}^{K} n_i$, and let n_i be the number of pixels at level i. Likelihood of occurring for level i is determined by $P_i = n_i/N$.

Let threshold T be used to separate the image into two classes, C_0 and C_1. Pixels with levels [1,..., T] make C_0, while pixels with levels [T + 1,..., K] make up C_1. The cumulative probabilities represented by $P_0(T)$ and $P_1(T)$, the mean levels by $\mu_0(T)$ and $\mu_1(T)$, and the variances of the classes C_1 by $\sigma_0^2\, T$ and $\sigma_1^2\, T$, respectively. Equations (5) through (10) provide all of these values, as detailed in [20].

$$P_0(T) = \sum_{i=1}^{T} p_i \tag{5}$$

$$P_1(T) = \sum_{i=1}^{K} p_i = 1 - P_0(T) \tag{6}$$

$$\mu_0(T) = \sum_{i=1}^{T} i \frac{p_i}{P_0(T)} = \frac{1}{P_0(T)} \sum_{i=1}^{T} i p_i \tag{7}$$

$$\mu_1(T) = \sum_{i=T+1}^{K} i \frac{p_i}{P_1(T)} = \frac{1}{P_1(T)} \sum_{i=T+1}^{K} i p_i \tag{8}$$

$$\sigma_0^2 T = \sum_{i=1}^{T} (i - \mu_0(T))^2 \frac{p_i}{P_0(T)} \tag{9}$$

$$\sigma_1^2 T = \sum_{i=T+1}^{K} (i - \mu_1(T))^2 \frac{p_i}{P_1(T)} \tag{10}$$

Let μ stand for the image mean level, $\sigma_b^2 T$ the between-class variance, and $\sigma_w^2 T$ the within-class variance. μ, $\sigma_b^2 T$, and $\sigma_w^2 T$ are defined, respectively, by equations (11), (12) and (13).

$$\mu = \sum_{i=1}^{K} i p_i = P_0(T)\, \mu_0(T) + P_1(T)\, \mu_1(T) \tag{11}$$

$$\sigma_b^2 T = P_0(T)\, (\mu_0(T) - \mu)^2 + P_1(T)\, (\mu_1(T) - \mu)^2 \tag{12}$$

$$\sigma_w^2 T = P_0(T)\, \sigma_0^2\, T + P_1(T)\, \sigma_1^2 \tag{13}$$

Equation (14) defines the cutoff that is reached by optimizing the between-class variance.

$$T^* = arg_{1 \le T < K}\ max\{\sigma_b^2(T)\} \tag{14}$$

This sum is equal to the cutoff found in equation (15) by lowering the within-class variances standard.

$$T^* = arg_{1 \le T < K}\ min\{\sigma_w^2(T)\} \tag{15}$$

I. TRIANGLE THRESHOLDING

Triangle thresholding is one of the common thresholding techniques used to calculate the optimal thresholding value based on the histogram of the image. Let's denote the histogram as $H(x)$, where x represents the intensity values. The peak of the histogram is denoted as $P = (x_P, y_P)$, where x_P is the intensity value and y_P is the frequency at that intensity value [21].

Peak Detection:

$$P = \arg max_x H(x) \tag{16}$$

Threshold Determination: The threshold value T is determined where the maximum distance occurs:

$$T = \arg max_{xi} di \tag{17}$$

here, x_i is the coordinate of the point on the histogram, d_i is the perpendicular distance from a point (x_i, y_i) to the line segment connecting the peak P.

J. UNSHARP MASKING

Unsharp masking is a technique in image processing that improves image edges and features [22]. Sharpening, or unsharp masking, is the reverse of blurring, despite the name suggesting otherwise. Usually, a Gaussian blur is applied to do this, with the amount of blurring determined by the standard deviation. By averaging each pixel in the image with its nearby pixels, the blurring is produced.

$$R(i,j) = O(i,j) * G(i,j) \tag{18}$$

where the blurred, original, and Gaussian blur pictures are represented, respectively, by $R(i,j)$, $O(i,j)$, and $G(i,j)$, with pixel coordinates (i,j).

Equation (19) shows that when the blurred image (mask) is subtracted from the original image, high-frequency elements like edges and features are highlighted in the resulting image.

$$HP(i,j) = O(i,j) - R(i,j) \tag{19}$$

where, $HP(i,j)$ is high pass filtered image.

Next, the high-pass filtered image is added back to the original image. This procedure increases the contrast of edges and little details, making them stand out more.

$$S(i,j) = O(i,j) + Hp(i,j) \tag{20}$$

here, $S(i,j)$ is a sharpened image.

Lastly, color contrast modifications contribute to improving the image brightness and visual attractiveness. A few adjustments that involve altering the saturation, color balance, or other features yield a more stunning and harmonious color representation. The final step of sharpening caps the method by adding crispness and refining the finer characteristics of the image. Each of these meticulously planned stages contributes to the overall goal of picture improvement and cleaning, resulting in a polished and eye-catching final output image.

K. READABILITY EASE SCORE

The Flesch Reading Ease score [23] is a readability metric designed to quantify the ease with which a reader can comprehend a given text. It is calculated based on the average number of syllables per word and the average number of words per sentence in the text. The formula for the Flesch Reading Ease score is as follows:

$$RE = 206.835 - (1.015 \times wps) - (84.6 \times spw) \qquad (21)$$

here, RE is the Flesch readability which is ease score, wps is average words per sentence, spw is average syllables per word.

IV. Results and Discussion

The suggested technique produces an improved image by combining several filters, thresholding, clustering, and unsharp masking. The input images of various noise types are chosen from the dataset [12] depicted in the figures shown below. The input images are present with creases, faint text, stains, bleed-through ink, smeared ink, thin strokes, or are degraded due to the aging of paper. Following are the results of document images with various types of noises which undergo the process as described in the methodology to output visually appealing images.

Figures 2, 4, 6, 8, 10, 12 and 14 represents the input document images of categories: creases, faint text, stains, bleed-through ink, smeared ink, thin strokes and degraded image respectively and the corresponding cleaned images for each of these categories are given by figures 3, 5, 7, 9, 11, 13 and 15 respectively.

Figure 12. Thin strokes image

Figure 13. Cleaned thin strokes image

Figure 14. Degraded document image

Figure 15. Enhanced document image

By applying the pipeline of the proposed binarization technique the resulting clean images are obtained for the different input historic documents of 7 categories based on the noises like creases, faint text, stains, bleed-through ink, smeared ink, thin strokes, and degraded image. The performance of the proposed binarization technique is evaluated using the Flesch Reading Ease score. The Average readability score for all output images is calculated. Table 1 summarizes the resultant average readability scores for various types of noisy images on application of the proposed binarization technique for historic document images.

Table 1. The Resultant Average Readability Score for Different Noisy Images

S. No.	Type of noise	No. of Images	Average Readability Score for the output image
1	Creases	150	95.78
2	Faint text	100	76.33
3	Stain	320	86
4	Bleed through ink	200	88.33
5	Smeared ink	200	93.64
6	Thin stroke	150	77.93
7	Degraded document	400	96.44
Average readability score			**87.77**

V. CONCLUSION

The current work uses a combination of various noise reduction and binarization approaches to improve the binarization of historic document images. For improved augmentation of the historical document images, a dependable and efficient technique has been found through the sequential application of unsharp filtering, bilateral filtering, k-means clustering, histogram analysis, Otsu thresholding, pixel modification, and final image creation. In addition to improving the noise reduction process, this comprehensive approach offers insightful information for future initiatives aimed at conserving and sharing cultural heritage through digitally preserved historical records. According to the proposed algorithm, the output image readability score is found to be higher than the original. As mentioned, the algorithm works best for degraded document images having an average readability score 96.44, as compared to other noises. The overall readability of the noisy historic documents after enhancement is 87.77.

Future scope comprises on natural language processing to intelligently digitize historic document collection. Additionally, future research on deep learning techniques, complex machine learning, semantic analysis integration, and natural language processing will all be included in the effort to intelligently digitize historical document collections. Additionally, the future scope includes creating an intuitive user interface to facilitate experimentation with the restoration of historic document images. This algorithm is efficient with diverse noise types in images but it should be tested on more images.
